**Abstract:** Do pictorial illustrations distract from learning and, thus, decrease learning outcomes, as suggested by Cognitive Load Theory and Cognitive Theory of Multimedia Learning? Or can pictorial illustrations trigger interest and thereby enhance the willingness to learn as suggested by interest theories? Although these approaches seem to contradict each other, we assume that they are compatible: Pictorial illustrations may hamper short-term learning but raise interest and engagement so that in the medium run learning may be enhanced. In order to test our "integrative" hypothesis, we explored the potential of different types of pictorial illustrations to trigger situational interest in the context of geometry learning. Results showed an effect of pictorial illustrations on the interestingness of geometry problems. In addition, interest in further learning with the computer-based learning environment was higher with pictorial illustrations than without. On the other hand, interest in deepening geometry knowledge was reduced when illustrations were added.

## Introduction

Most (German) mathematical textbooks are full of pictorial illustrations. Does this make sense given that such pictorial illustrations may be "*seductive details*" that impede learning (Harp & Mayer, 1997, 1998)? Or do they actually enhance interest and, thereby, the willingness to engage in learning? Weidenmann (1991) suggests that pictorial illustrations have different supporting functions such as activation, construction, or focusing special aspects of the learning materials. In addition, Anglin, Towers, and Levie (1996) suggest in their review that pictorial illustrations–beside their compensatory, cognitive, and attentional functions–also have an affective function in learning.

Contrary to these assumptions on the beneficial functions of pictorial illustrations, *Cognitive Load Theory* (Sweller, 2005)–which assumes that many difficulties in learning are due to unnecessary (i.e., extraneous) working memory load–postulates a number of potential negative effects of pictorial illustrations (Sweller, van Merrienboër & Paas, 1998): Redundancy effect (i.e., when different sources such as pictures and text provide the same information and, thus, induce unnecessary processing demands), split-attention effect (i.e., extraneous load due to difficulties in mapping text and pictures), and extraneous load due to irrelevant illustrations that do not contain essential information. Similarly, *Cognitive Theory of Multimedia Learning* (Mayer, 2005) predicts that words, illustrations, or sounds which are not relevant to the central learning goals should be omitted (e.g., Harp & Mayer, 1997, 1998). In addition to the redundancy effect (Mayer, Heiser & Lonn, 2001; Moreno & Mayer, 2002) and split-attention effect (Mayer & Moreno, 1998; Moreno & Mayer, 1999; Moreno, Mayer, Spires, & Lester, 2001) Mayer and Moreno (2003) refer to the coherence effect (e.g., unnecessary load through interesting but extraneous material). In conclusion, learning materials should be as concise as possible (Mayer & Moreno, 2003). Both theories suggest eliminating any redundant or decorative elements. Accordingly, computer-based multimedia environments should not contain redundant or decorative pictorial illustrations.

In the last years, however, even cognitive load researchers increasingly call for the consideration of motivational and emotional aspects (e.g., Zander, Brünken, 2009; Paas, Tuovinen, van Merrienboër & Darabi, 2005; van Merrienboër & Ayres, 2005). Against this background, the construct of *interest* seems especially relevant (Tulis, 2009; Krapp, 1999, 2000; Krapp, Hidi & Renninger, 1992). It comprises a value-related and emotion-related component (Schiefele, Krapp, Wild & Winteler, 1992). Hidi (2000) distinguishes between two different, but linked types of interest, *individual* and *situational interest*. Individual interest is defined as a relatively stable predisposition, whereas situational interest arises as a reaction to environmental input, for example, visual and auditory (Krapp, 1999). Research has shown that (situational) interest eases comprehension (Hidi, 2001) and learning (Ainley, Hidi & Berndorff, 2002; Hidi, 2001; Schiefele, 1998). Explanations for such effects include deeper processing, and a higher degree of cognitive organization (Ryan, Connell & Plant, 1990). Interest is also positively related to persistence (Ainley, Hidi, 2002; Ainley, et. al., 2002), activation (Schiefele, 1990), and elaboration (Krapp, 1999; Schiefele, 1996, Ryan et al., 1990). Furthermore, it is essential for engagement in learning (Anderman, Noar, Zimmerman, & Donohew, 2004). Examples of factors that trigger and maintain situational interest are novelty, concreteness, and visual imagery (Hidi, 2001). Most results on situational and individual interest were found in the context of learning from text. *Concreteness, a personally relevant context, ease of comprehension*, and *unexpected information* (see Anderson, Shirey, Wilson & Fielding, 1987; Hidi & Baird, 1986, 1988) are, for example, factors that trigger and maintain situational interest in text learning. One way to adapt these aspects to computer-based multimedia environment is the use of concrete, meaningful and relevant context oriented pictorial illustrations.

Although the different theoretical perspectives on potential effects of pictorial illustrations seem to contradict each other, we assumed that they are compatible: Pictorial illustration may hinder short-term learning outcomes but can raise interest and engagement so that in the medium term learning is enhanced. As a first step in testing our "integrative" hypothesis, we conducted a study to explore the following aspects: First, we were interested whether pictorial illustrations can actually increase situational interest. Second, we wanted to identify sets of pictorial illustrations that do or that do not enhance situational interest in the domain of geometry. These pictorial illustrations will subsequently be used to test the integrative hypothesis in the context of learning with intelligent tutoring environments (here: Cognitive Tutors; Koedinger & Corbett, 2006). Up to now, most of the interest research has been conducted in the context of learning from text (Anderson, Shirey, Wilson & Fielding, 1987; Hidi & Baird, 1986, 1988). Our third goal was to test whether and how the four factors mentioned above would affect situational interest for the case of pictorial illustrations in the context of tutoring environments. A last goal was to identify potential relationships between picture-induced interest and the willingness to work with a picture-enriched computer-based learning environment as well as the willingness to deepen geometry knowledge.

## Method

### Participants and Design

Participants were 87 students (52 female, 35 male) from grade 8 of a German secondary school (age: $M = 13.9$ years; $SD = 0.6$). In a within-subjects design, students evaluated screenshots showing geometry problems with and without pictorial illustrations. In order to be able to evaluate a larger number of pictorial illustrations, we used a multi-matrix-design with eight questionnaires. Within each questionnaire one half of the screenshots corresponded to another half of the screenshots of another questionnaire.

More specifically, the main part of the questionnaire consisted of fifteen screenshots of a computer-based learning environment on the topic intersecting lines (mathematical principles: angle addition, vertical angles, linear pair, and complementary angle). Each screenshot showed a word problem and a corresponding line drawing. The problems varied in the number of sub-problems (one to three). Eleven of the fifteen drawings included pictorial illustrations that–from an instructional designer's point of view–were mainly decorative (i.e., without explicit instructional functions such as providing information or activating relevant schemas). The remaining four drawings did not include a pictorial illustration. However, each of these four drawings corresponded to one of the drawings that included a pictorial illustration.

### Materials

The screenshots were taken from a Cognitive Tutor Geometry (Koedinger & Corbett, 2006). The Cognitive Tutor is an Intelligent Tutoring System based on cognitive theory (Anderson, Corbett, Koedinger & Pelletier, 1995). Cognitive Tutors promote learning by tutored problem solving. They provide step-by-step feedback adapted to the actual knowledge level of students. Cognitive Tutors are successfully applied in a diverse set of domains such as mathematics, genetics, and computer programming (for an overview, see Anderson et. al., 1995; Koedinger & Corbett, 2006).

All pictorial illustrations were drawn from a pool of 44 illustrations. They showed real-life situations (e.g., sitting in front of computer, gables, and compasses). In the first part of the questionnaire, each page contained a screenshot of a geometry problem from the Cognitive Tutor lesson either with or without pictorial illustration (see Figures 1 and 2). Students had to rate the interestingness (adapted from Schiefele, 1990) of the screenshots on two different subscales (nine point Likert scales). The first subscale referred to the emotion-related component of interestingness, the second subscale to the value-related component (see Figures 1 and 2). The emotion-related component was assessed by the three items *Excitement*, *Entertainment*, and *Boredom,* the value-related component by the items *Usefulness*, *Worthless,* and *Unimportance* (similar items were used by Schiefele, 1990). Furthermore, for each screenshot the students rated (on nine point Likert scales) the previously mentioned four potential factors for interest (*concreteness, ease of comprehension*, *unexpected information*, and *personally relevant context*; see bottom part of figure 1 and 2).

Further questions (to be rated on five point Likert scales) referred to willingness for further learning with the computer-based learning environment (enriched with pictorial illustrations), willingness to deepen geometry knowledge, individual topic interest related to the content of the pictorial illustrations, to computer knowledge and mathematics knowledge and demographic characteristics.

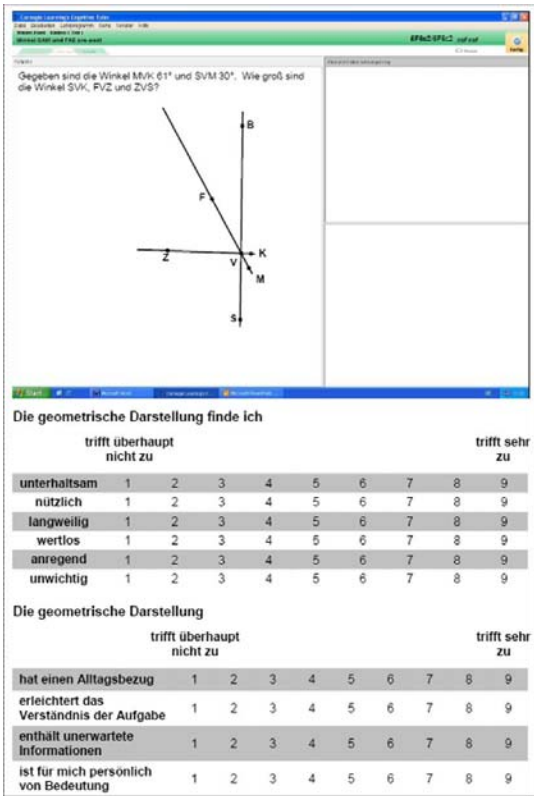

Figure 1. Page without pictorial illustration.

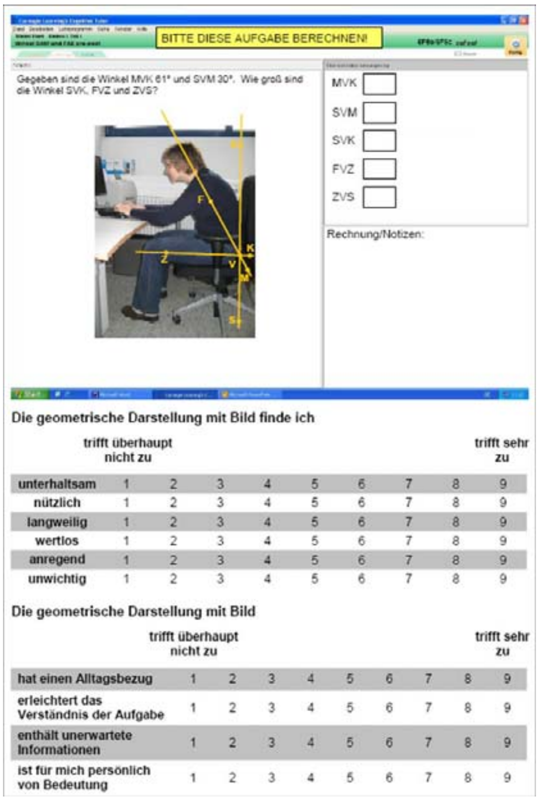

Figure 2. Page with pictorial illustration.

## Procedure

The study was performed in group sessions. The sessions lasted about 28 minutes (Range: 16 - 46 minutes). First, all students were introduced to the topic of intersecting lines by the experimenter. Then, they received an example of how to evaluate the screenshots. In order to provide a context as much similar as possible to actually working with the computer-based learning environment, the students then worked on four geometry problems (two with line drawings, two with line drawings enriched with pictorial illustrations). Afterwards the students rated the interestingness of the screenshots and they were asked to rate different potential reasons for their interest. Finally, all participants answered a set of additional questions (e.g., demographic characteristics).

## Results

Our first research question referred to a potential effect of pictorial illustrations on situational interest. A paired *t*-test (two-tailed) revealed a significant difference between screenshots (i.e., geometry problems) with and without pictorial illustrations, $t(85) = 4.02$, $p < .001$, $d = .55$. Figure 3 shows that this effect can largely be attributed to the emotion-related component of interest, $t(85) = 6.68$, $p < .001$, $d = .88$, as there were no differences in the value-related component, $t(85) = 0.85$, *n.s*, $d = .11$. Therefore, in all further analyses we concentrated on the emotion-related component (if not stated otherwise).

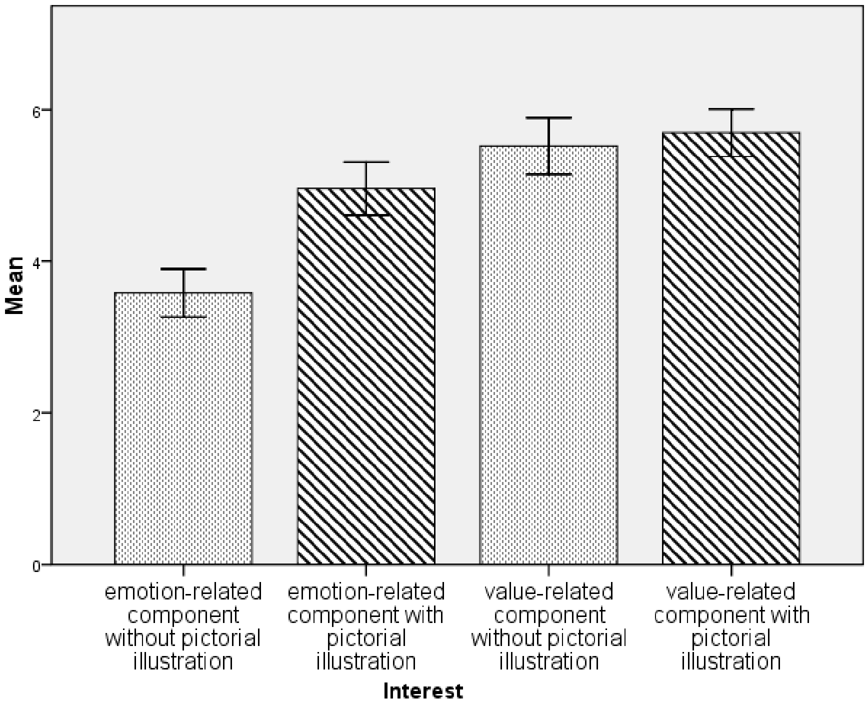

Figure 3. Effect of pictorial illustrations on interest (emotion-related and value-related)

Our second goal was to distinguish between the most interesting and the least interesting pictorial illustrations. We compared the effect sizes between the most interesting pictorial illustrations (upper quarter) and the least interesting pictorial illustrations (lower quarter). This comparison yielded an effect size of $d$ = .56 for the ninth most interesting pictorial illustration compared to the ninth least interesting one. Pictorial illustrations rated as "interesting" could be characterized as *dynamic* (e.g., showing activities such as sailing, volleyball, or riding). The most interesting picture, for example, showed a sailboat sailing close to the wind. Pictorial illustrations rated as "non-interesting" could be characterized as *static* (e.g., showing artifacts such as compasses, maps, or traffic signs). One of the least interesting pictures, for example, was a canvas. Therefore, it can be speculated that dynamic attributes are perceived as more entertaining, less boring and more exciting.

Our third goal was to assess whether and how factors that were found to increase interest in texts (i.e., concreteness, personally relevant context, ease of comprehension, and unexpected information) could be related to interest in tutoring environments that are enriched with pictorial illustrations. Table 1 shows that in the present study each of these four factors correlated significantly with both the emotion-related component and the value-related component of interest. This result supports the notion that these factors that are related to interest as induced by texts also have a psychological validity for interest as induced by pictorial illustrations (in tutoring environments).

Table 1: Correlations between reasons for interest and interest in drawings with and without pictorial illustrations ($N$ = 87)

| | Perceived concreteness | Perceived personally relevant context | Perceived ease of comprehension | Perceived unexpected information |
|---|---|---|---|---|
| *Emotion-related* | .46*** | .53*** | .55*** | .42*** |
| *Value-related* | .44*** | .45*** | .63*** | .29*** |
| | | | | |

***$p$ < .001.

Against the background of this strong pattern of correlations, we were interested whether and how these reasons would differ in situations (i.e., geometry problems) in which pictorial illustrations were available or not. Paired $t$-tests (two-tailed) showed that concreteness was rated higher in situations with pictorial illustrations than in situations without, $t(85) = 12.24$, $p < .001$, $d = -1.76$. Similarly, the perceived personally relevant context was rated higher in situations with pictorial illustrations $t(85) = -2.28$, $p < .05$, $d$= -0.21. There were, however, no significant differences for ratings of the ease of comprehension ($t(85) = 0.91$, *n.s.*, $d = .00$) or unexpected information, $t(85) = -1.98$, *n.s.*, $d = -0.20$.

In summary, this pattern of results indicates that decorative pictorial illustrations increased the perceived personal relevance and perceived concreteness of the learning material, but they did not increase the perceived ease of comprehension. This latter finding further indicates that the pictorial illustrations might not have activated relevant schemas as suggested, for example, by Schwartz and Collins (2008).

Finally, we were interested in whether pictorial illustrations can enhance further learning and engagement. For this purpose, we investigated the relationships between interest in situations with and without pictorial illustration and both the willingness to deepen geometry knowledge as well as in further learning with the illustration-enriched computer based learning environment. As can be seen in Table 2, the willingness to deepen geometry knowledge and the willingness for further learning with the computer-based environment were positively related to interest ratings (irrespective of the availability of pictorial illustration).

Table 2: Correlations between interest (with/without pictorial illustrations) and the willingness to learn with the computer-based learning environment and to deepen geometry knowledge (in Parentheses: partial correlations controlling for individual interest in geometry).

| | Willingness to learn with the computer-based learning environment | Willingness to deepen geometry knowledge |
|---|---|---|
| Interest (*n* = 84) | | |
| Without pictorial illustration | .24* (.15) | .45*** (.36)** |
| With pict illustration | .54*** (.47)*** | .22* (.04) |

*$p < .05$. **$p < .01$. ***$p < .001$

Comparisons of the correlation coefficients between mathematical problems with and without pictorial illustrations, however, showed that the correlations between interest and the willingness to learn with the computer-based learning environment was rated significantly higher when a pictorial illustration was available than when it was not, $t(84) = 2.58$, $p < .05$. This was not the case for the correlations of interest and the willingness to deepen geometry knowledge, $t(84) = 1.89$, *n.s*.

As it can be assumed that students who are generally interested in geometry might not need pictorial illustration to further increase their interest, we controlled the individual interest in learning geometry. The difference of the partial correlations (see Table 2, in parentheses) between interest and the willingness for further learning with the environment remained significant, $t(84) = 2.35$, $p < .05$. In addition, the partial correlation between interest and the willingness to deepen geometry knowledge became significant, $t(84) = 2.24$, $p < .05$.

Thus, interest as induced by pictorial illustrations seemed to be strongly positively related to students' perceptions of the learning environment more than to their willingness to deepen geometry knowledge. On the other hand, interest as induced by the mathematical problems per se (i.e., when no pictorial illustration was available) was strongly related to the willingness to deepen geometry knowledge; there was no such relationship for interest when a pictorial illustration was available. In other words, students who like pictorial illustrations might prefer to work with a computer-based learning environment but they are not necessarily interested in deepening geometry knowledge.

## Discussion

The main purpose of the present study was to identify pictorial illustrations with the potential to enhance interest. A secondary purpose was to test whether factors that were found to increase interest as suggested by text research (e.g., text attributes such as concreteness) might also enhance interest in the context of illustrated tutoring environments. A final purpose was to explore the relationships between interest and the students' willingness to engage in further learning.

The results showed that pictorial illustration increased the emotion-related component of interest, but not the value-related component. This suggests that the illustrations were mainly perceived as decorative but not as informative. Furthermore, our findings also suggest that interest-evoking attributes as identified in text research can be transferred to interest research with pictorial illustrations (in the context of tutoring environments), at least in part: The pictorial illustrations did not–according to the learners' perception–enhance comprehension or provide unexpected information. However, they were perceived as making the geometry problems more concrete and to provide a personally relevant context. These results are first indications that pictorial illustrations do not give a semantic context and, therefore, activate certain schemas which support learning (Schwartz & Collins, 2008). Further steps to investigate not only the perceived ease of comprehension, but real comprehension (in terms of conceptual and procedural knowledge) will be taken in a subsequent study.

Interestingly, the more the students perceived the pictorial illustrations as interesting the higher was their willingness to learn with a picture-enriched computer-based learning environment. Contrary, interest in pictorial illustrations was unrelated to the willingness to deepen geometry knowledge (especially when the individual geometry interest was held constant). The willingness to deepen geometry knowledge was rather related to interest in mathematical problems without pictorial illustrations. It can be speculated that students might have realized the "decorative" aspect of the pictorial illustrations, and thus, perceived them as irrelevant for further engagement in learning geometry. In conclusion, interesting pictures might primarily influence how much students engage in further working in a learning environment, but not necessarily how much they engage in concentrating on the learning content. In these respects, the present findings quite well reflect the contradictive positions between interest research and cognitive research. As suggested by interest research, pictorial illustrations can enhance interest and the willingness to learn. At the same time, however, students can perceive pictorial illustrations as irrelevant for deepening geometry knowledge, as suggested by the cognitive research.

A restriction of this study was that we did not measure learning outcomes. Moreover, the students did not work in a real computer-based learning environment (e.g., a Cognitive Tutor). Therefore, our conclusions are based on self-assessed measurements. An interesting question with respect to learning outcomes arises from the finding that interest elicited by decorative pictures seemed to foster the willingness for further working with a picture-enriched computer program but not to deepen geometry knowledge. If the learners would actually show certain persistence in working with an illustrated computer program, but without intentions to deepen the geometry knowledge, would this nevertheless deepen their understanding? A follow-up experiment (in preparation) will address this question. In addition, it will explicitly test our integrative hypothesis stating that pictorial illustration may hinder short-term learning but may raise interest and engagement so that in the medium term learning is enhanced. In order to test this assumption, we will compare three experimental groups (students from the 8th grade) working in a Cognitive Tutor Geometry (topic of intersecting lines): one group with interesting pictorial illustration, one with non-interesting pictorial illustrations (control of picture effects), and one group without any pictorial illustrations. While working with the computer-based learning environment the students will rate the interestingness of the pictorial illustrations after each geometry problem. Before and after the learning phase a geometry knowledge test (conceptual and procedural knowledge) will be administered. In addition, data on interest and mood experiences will be collected. During the two weeks between the immediate posttest and a delayed posttest the students will have the opportunity to deepen their geometry knowledge by studying a small geometry booklet (at home). The delayed posttest will be very similar to the first posttest but will additionally include problems from the booklet. We assume that in the immediate posttest learners will be best off without pictorial illustrations. For the delayed posttest, we expect, however, that interesting pictorial illustrations will lead to superior learning.

**Abstract:** This paper presents a framework model that defines learning and knowledge building as a co-evolution of cognitive and social systems. This model brings together Scardamalia and Bereiter's theory of knowledge building and Nonaka's knowledge creation theory. We demonstrate how learning and knowledge building may occur when people interact with each other, using shared digital artifacts such as tag clouds (that result from social-tagging activities) or wikis. For both technologies, we provide illustrating data from two pilot studies. As an example, we refer to the learning processes that take place while searching for information in tag clouds. In addition, we illustrate processes of knowledge building by referring to users working on a wiki. In conclusion, the differences and similarities between these technologies are assessed, regarding their potential for knowledge building.

## Introduction

Recent developments of software technology have made new tools available, which are of great importance for computer-supported collaborative learning and knowledge building. They provide new opportunities for learning and knowledge building, because they are capable of facilitating the interplay between individual and collective processes. These technologies are associated with social-software systems. *Social software* is a term for software systems that support human communication, collaboration, and interaction in large communities (Kolbitsch & Maurer, 2006). They facilitate the establishment and maintenance of self-organizing communities and social networks (Köhler & Fuchs-Kittowski, 2005; Wasko & Faraj, 2005). Social software is mainly associated with Internet communities, but may also be applied in educational contexts (Notari, 2006; Wang & Turner, 2005). We believe that social software has a great potential in the field of learning and knowledge building.

For a long time, psychological and educational research have examined individual learning and collaborative knowledge building as two separate things (for an early systematic model of collaborative knowledge building cf. Stahl, 2000). We propose that software tools are now able to support "interdigitation" and, so to speak, a "merger" of individual and collective knowledge processes. This new development of software technology also calls for a new theoretical framework, in order to focus on the tight conjunction between individual learning and collective knowledge building, in the sense that the knowledge of individuals and of a community may cross-fertilize and mutually support the development of each other. The aim of this paper is to provide such a theoretical framework. For this purpose, we will present and bring together two theoretical approaches.

The first approach is Scardamalia and Bereiter's (1991) theory of knowledge building. It deals with the mechanism through which a community of learners will manage to develop knowledge jointly. This approach was already based on the use of computer technology, and it emphasized the impact of epistemic artifacts on knowledge building. So it appears to be quite a suitable theory to explain how social software can support the development of collective knowledge. The second approach is Nonaka and Takeuchi's (1995) knowledge creation theory. Its focus is on the building and transfer of tacit knowledge. This approach is very popular in literature on knowledge management, but has hardly received attention in educational research and the learning sciences. Although Nonaka's model does not explicitly mention computer support and the creation of artifacts, we believe that the major underlying ideas of this model are very useful to explain some details of knowledge building with social software.

We will finally present our own co-evolution model of cognitive and social systems. The model takes into account social processes that are facilitated by a collaboratively developed technical artifact and, at the same time, cognitive processes of the individual users. Our model demonstrates how these social and cognitive processes will mutually influence each other. It is a theoretical framework which integrates many of the processes that have been described by the theory of knowledge building and the theory of knowledge creation. After a more general description of what we mean by "co-evolution" of cognitive and social systems, we will provide two examples of social-software technologies, and present some empirical data to demonstrate how these technologies can support this process of co-evolution. For this purpose, we will describe the use of social-tagging systems and the application of wikis. Each of these technologies creates a unique kind of artifact, which supports, in its own specific way, those processes of knowledge building which we have described. In conclusion, we will assess the differences and similarities between these technologies, regarding their potential for knowledge building.

## Theories of Knowledge Building and Knowledge Creation

Scardamalia and Bereiter have proposed a theory of knowledge building (Bereiter & Scardamalia, 1996; Scardamalia & Bereiter, 1996, 1999, 2003). Knowledge building is defined as a socio-cultural process, which takes place in a community and aims "at producing something of value to the community – theories, explanations, problem formulations, interpretations, and so on, which become public property that is helpful in understanding the world" (Scardamalia & Bereiter, 1999, p. 276). Scardamalia and Bereiter consider knowledge building as a collective creation of public knowledge. They compare learning in classrooms to learning in knowledge-building communities, such as research laboratories (Bereiter, 2002), and conclude that knowledge building should be rendered possible in all communities. Educational software, such as CSILE (Computer-Supported Intentional Learning Environments) or Knowledge Forum, can support knowledge building. These environments provide shared databases as collaborative design spaces. Here, all participants may contribute their own theories, models, examples, visualizations, notes, and other epistemic artifacts. The design space supports mutual citing and referencing, in order to initiate a dynamic and self-organized process in which ideas are formulated, discussed, revised, or rejected. The design space visualizes this collective improvement of ideas. Accordingly, there is a set of requirements that have to be fulfilled to make successful knowledge building possible (Hewitt & Scardamalia, 1998; Scardamalia, 2002). All members of a community should contribute to the advancement of knowledge, and learners in a community should be concerned with authentic real-life problems. Advancing knowledge should be regarded as an improvement of ideas, not a search for a perfect or true solution. Learning is regarded as a discourse-oriented process, in the sense of common problem solving.

Nonaka's knowledge-creating theory (Nonaka, 1991, 1994; Nonaka & Takeuchi, 1995) is also concerned with innovation. This theory emerged from research on knowledge management, and it regards knowledge dissemination as one of the aims of any knowledge organization. But the authors assume that within an organization only little knowledge is available in the form of explicit knowledge. Most knowledge is contained in the experience of individuals, and as such it is *tacit knowledge* (Polanyi, 1966). Tacit knowledge can hardly be expressed verbally, so this type of knowledge is difficult to transfer to others. But effective knowledge creation requires such a transfer. In order to describe how a transfer of tacit knowledge takes place, the authors refer to four processes, which build on each other in a dynamic way: socialization, externalization, combination, and internalization. *Socialization* is a process in which the experience of an individual is shared. Tacit knowledge can only be communicated from one person to the other through direct experience. Experience may be transferred by observation and imitation, and, as a result of this transfer, the observer acquires new knowledge, but this remains tacit. So a process of *externalization* is necessary. It consists of the articulation of tacit knowledge and the transfer from tacit to explicit knowledge. At this stage, new concepts are formulated using tacit knowledge. When knowledge has been made explicit, then it can be combined, in order to develop new knowledge within an organization. So, *combination* refers to connecting and giving a new structure to explicit knowledge. Such combination is supported by interpersonal sharing of knowledge. Explicit knowledge will then, once more, become tacit knowledge through a process of *internalization*. This conversion is an individual process, in which explicit knowledge becomes part of that person's personal knowledge. Internalization will occur through learning by doing. Nonaka has formulated the idea of a *knowledge spiral* in which socialization, externalization, combination, and internalization succeed each other. The spiral allows the inter-individual transfer of knowledge and, at the same time, the creation of new knowledge, through a combination of externalized knowledge which was previously tacit.

## Co-Evolution Model of Cognitive and Social Systems

The authors of this paper have introduced a theoretical model of individual learning and collaborative knowledge building (Cress & Kimmerle, 2007, 2008; Kimmerle, Moskaliuk, & Cress, 2009; Moskaliuk, Kimmerle, & Cress, 2008). In this model, collaborative knowledge building is described as an interplay between cognitive systems and a social system. Just like Scardamalia and Bereiter, we think that knowledge building is a central issue in modern knowledge societies. Consequently, our model is basically predicated on the ideas of Scardamalia and Bereiter. But our considerations go beyond those of these authors, as we focus equally on individual learning processes and on the collective development of knowledge. And as far as social software is concerned, epistemic artifacts are not only considered as a means to an end, but also as an end in itself, because we are convinced that collective knowledge manifests itself in shared digital artifacts. The model borrows, so to speak, from systemic and from cognitive approaches. Its main assumption is that knowledge building can only be understood if the interplay between individuals and the collective is taken into account. From a systems-theoretical point of view – in the sense of Luhmann (1995) – the cognitive systems of individuals are different from a social system, which is (in our theory) represented by a shared digital artifact (Cress & Kimmerle, 2008).

Cognitive systems and social systems have different kinds of operations. Due to their different modes of operation, both systems cannot simply merge. But one system can affect the other one in its development by irritating it. Each system can provide its own complexity for the development of the other.

The co-evolution model of cognitive and social systems (Cress & Kimmerle, 2008) is based on this systemic view, and it describes learning processes and knowledge-building processes as reactions of a system to irritations. Irritations are interpreted, in the sense of Piaget (1977), as cognitive conflicts, and the assumption is that cognitive systems will develop when people solve such cognitive conflicts. A cognitive conflict exists when people's prior knowledge and information which they receive from their environment are somewhat incongruent. Cognitive conflicts can be solved by processes of equilibration. There are two types of such equilibration processes: people will either assimilate information, i.e. they simply add new information to their prior knowledge; or they will accommodate their prior knowledge to new information. In either case, people will somehow have to internalize information from their environment. In this way, their cognitive system becomes more complex. This development of a cognitive system refers to what is traditionally called *learning*. These two processes represent two types of internalization from the social system, i.e. both *assimilation* and *accommodation* support the development of cognitive systems. The model states that processes which take place in a cognitive system by means of internalization will take place analogously in a social system by means of externalization. Through externalization, a cognitive system can bring that person's own individual knowledge into the shared artifact. People do not only internalize information from their environment into their cognitive systems, but also externalize their knowledge. This means, just as individuals can learn by internalizing new information, social systems can also learn by incorporating information, and social systems can develop new knowledge by assimilation or accommodation respectively. They can develop by just adding new content (assimilation) or by changing their own structure (accommodation). We propose that emergent effects usually occur through such accommodations of artifacts. This external accommodation leads to a higher complexity of the shared digital artifact and, accordingly, to new equilibration processes in other people's cognitive systems. Thus, the users' knowledge supplies the artifact's content, and the artifact itself provides its users with new information and releases new cognitive conflicts. What is important here is that the processes of internalization and externalization, or of individual learning and knowledge building respectively, are not independent from each other. It is always a matter of internalization *and* externalization, i.e. of continuous exchange processes between cognitive systems and the social system. In this way, there exists a mutual development of cognitive and social systems, and this is what we refer to as co-evolution (cf. Figure 1).

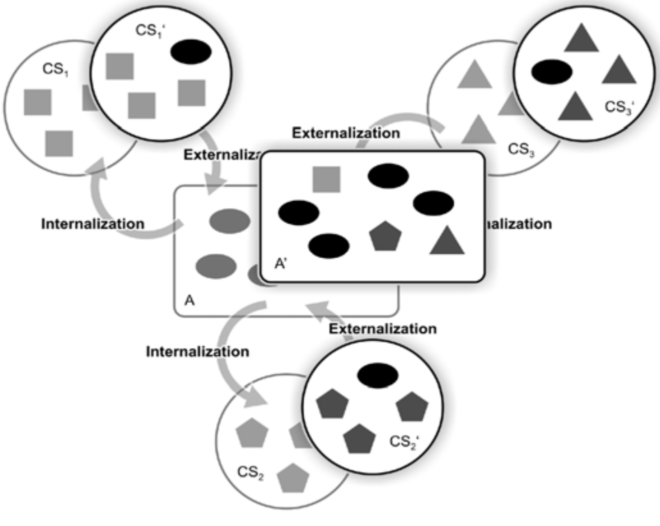

Figure 1. Co-evolution of cognitive systems ('CS') and a social system, i.e. an artifact ('A').

We can now apply the four processes, as they were described by Nonaka, to this model of knowledge building with shared artifacts. For this purpose, we translate the processes of making tacit knowledge explicit, and vice versa, into processes of externalization and internalization. This will help us to understand exchange processes between cognitive systems and the social system in more detail. Externalization can then be described by those processes which Nonaka has labeled *externalization* and *combination*. When people introduce their own knowledge into a shared digital artifact, they will have to articulate their knowledge, i.e. they need to couch their cognitive concepts in words. For this purpose, they have to translate their knowledge into a form that is generally understandable and intelligible to all. People have to consider the information which is already available in an artifact in order to integrate their own thoughts adequately. Internalization combines the two processes which Nonaka calls *internalization* and *socialization*. When people incorporate information from a shared digital artifact, they "dig around" for information by browsing the artifact. In this way, they gather and collect relevant information, which they have to transfer into their own cognitive structures. In the following we will explicate these processes by referring to two concrete examples of shared digital artifacts. The first example – social tagging – considers the process of internalization, the second example – wikis – will take a closer look at externalization.

## Examples of Social-Software Supported Knowledge Building

We present our notions by providing two examples that use new software technology. The first one will illustrate the interplay between individual and collaborative processes by analyzing *social-tagging activities* and the processes which may be supported by social tagging. Then, we will describe how *wikis* can contribute to knowledge building. For both technologies we point out their potential as learning environments, and demonstrate the processes of internalization and externalization. For this purpose, we provide some empirical data from two pilot studies: processes of internalization (individual learning) will be illustrated by a reference to searching for information in tag clouds; processes of externalization (knowledge building) will be demonstrated by quoting contributions of people who worked on a wiki.

### Social Tagging

Social tagging has become a standard feature of many social-software tools, and it has potential to play a role in learning scenarios (Marlow, Naaman, Boyd, & Davis, 2006). The term tagging describes the annotation of digital resources with keywords (Golder & Huberman, 2006). These resources are primarily objects in virtual environments, like the Internet or intranets, and they may include web sites, photos, videos, research papers, or other pieces of digital information. The keywords (or tags) may be chosen by its users, and they represent the users' associations concerning the objects. Tagging is used on platforms which offer file sharing within a community, or which support users in organizing their own stored resources. The labeling of items with tags may facilitate search processes and the retrieval of information on these platforms, not only for individual users, but also for the benefit of others. The term *social* tagging refers to this social context in which tags are used, and in which all members of a community may benefit from them. Most of the social-tagging systems allow each user to tag all available resources individually and independently. In this way, all tags in a community that concern a particular object may be aggregated, and a large set of metadata for that resource may come together. This accumulated collection of tags (or metadata) represents the users' connections, concepts, or categorizations for items, and builds a jointly created artifact of keywords that refer to a specific resource. The World Wide Web provides loads of information and many opportunities for acquiring knowledge. This can take place as an individual and independent learning process, beyond formal educational settings. Users may browse through the information space of the Internet, and access information on virtually any topic of interest. Limitations lie mainly in the overwhelming amount and inconsistent quality of that information. Social-tagging systems can help to overcome these problems and provide a tool for structuring and filtering information.

When dealing with social-tagging systems, individuals have the opportunity to externalize their own knowledge and, at the same time, they also may internalize information. In the process of externalization, users add tags to specific resources and describe the object with their own set of keywords. For this activity of creating tags, users have to articulate their own cognitive concepts of an item, and transform them into keywords. When people add tags, they externalize their knowledge about a resource. They focus on the essential concepts of an item, and may, consequently, elaborate on the resource more thoroughly. The additional cognitive effort which is involved here will induce processing of information in such a way that individual learning takes place. The creation of tags and externalization of cognitive concepts can lead to knowledge building (Budiu, Pirolli, & Hong, 2009): the artifact of metadata develops in a step-by-step incremental process of individual tagging. All individual tags of a community are summed up in one accumulated artifact of keywords. A single user has only a marginal influence on the whole product. The artifact depends on the tagging activities of numerous people, and tag clouds will only emerge from a large quantity of added keywords. As the artifact grows, it represents the most important related concepts and connections that concern a resource or a keyword.

In the process of internalization, people integrate new information into their cognitive systems. In a social-tagging environment, users will browse a web site in order to explore relevant resources. For this purpose they may use tags as an orientation and searching device. The jointly created artifacts of metadata, typically visualized as tag clouds, help them to navigate through the information space and find relevant information related to the tags. In this process of browsing, the users of the system will become aware of the keywords that were annotated by other users. In this way, the users incorporate information about the concepts and categorizations of an object, and learn how other users have classified that resource. Moreover, the artifact of tags may show interconnections between resources and concepts that may previously have been unknown to the individual user. The information which is represented in the metadata of tags can lead to knowledge acquisition and a change in the cognitive structures of individuals. People can be made aware of new information and incorporate the community's concepts and categories (Fu, 2008). These concepts and connections may differ from individual cognitive structures, and if they do, individual knowledge may increase and new understanding may develop. This process of learning may be defined as assimilation or accommodation of knowledge. Assimilation describes the process of merely adding new pieces of information to previously existing knowledge. This happens when people acquire additional facts about a subject, but do not significantly change the underlying structure of the cognitive concepts involved. For instance, when users learn new tags and related concepts which are in accordance with their prior knowledge about a certain resource, this will extend their factual knowledge, but they will not form a new concept of this subject. The following example will illustrate this process. The data are taken from a pilot study with university students. Participants had to find out what "EMDR (eye movement desensitization and reprocessing)" means, by searching and browsing for information only with the help of tag clouds and, at the same time, they had to think aloud. The following transcript from the thinking-aloud audio protocols (translated from German) is an example of assimilation:

> *"Yes, this is a form of psychotherapy, I know that, that's why I click on 'therapy' […] yes, exactly, and there is 'treatment', there I will get it in more detail […] okay, now, here is 'trauma', it has something to do with that […] and with 'anxiety' […] and it could also be about 'stress' […]".*

This participant expanded his knowledge, but he relied very much on his prior knowledge (that EMDR is a form of psychotherapy). So he specified his knowledge: later, he knew what this therapy is used for (the treatment of post-traumatic stress disorder). Previously existing knowledge was supplemented, but the knowledge structure did not have to be changed. In contrast to this process of assimilation, accommodation takes place when a qualitatively new understanding of a subject develops and prior knowledge is transformed. If other people use very different tags from those that this particular user would have applied, then it is obvious that specific resources or tags are related to very different concepts. So users may learn that their associations on a subject or topic were incorrect, and may change their cognitive concepts accordingly. Another sample from the thinking-aloud protocols of the pilot study will illustrate the accommodation process:

> *"I think it is about an eye movement disorder […] okay, here is 'movement', I click on that […] now there is 'desensitization' […] now 'reprocessing' remains as the biggest tag […] and, yes, 'treatment' […] and now it's about 'behavior' and eh? Hm, 'trauma'? Now I'm confused, somehow I can't see any connection. But I would click on that, on 'trauma', yes. It somehow stands out from the crowd […]".*

Even though this participant did not find out (in the given time) that EMDR is a form of psychotherapy, she did understand that her prior knowledge was not adequate, which is an important prerequisite for accommodation. Another participant had a similar experience, but her gain of knowledge went even further:

> *"[…] 'anxiety'? I'm irritated now […] I don't understand […] I just see that it has something to do with 'psychiatry' and with 'clinical' […] I see, it seems it is about psychology and psychotherapy, and, although I first thought it was an eye disease […]".*

The process of co-evolution of cognitive and social systems takes place when individuals use tags for browsing and navigating the Internet, and stumble across relevant information and resources. These cognitive processes of internalization and the retrieval of new information may prompt users to tag the discovered new resources themselves. In this way, the individuals' concepts and categorizations are externalized and incorporated into the artifact of metadata, and the whole system evolves (Fu, 2008). All members in a social-tagging community offer and obtain knowledge, and a continuous process of advancing knowledge takes place. The community constantly adds new resources and new tags to the artifact, in this way developing new information, new interconnections, and new ideas. Anyone can contribute and participate in this process of improvement, which takes up the viewpoints of many different people; the collective as a whole is responsible for the advancement of knowledge.

## Wikis

A wiki is a web page that allows users to change its content online (Leuf & Cunningham, 2001). It is easily accessible and can simply be used by everyone (Désilets, Paquet, & Vinson, 2005). In a wiki, people may easily revise all parts of the text, add, change, or delete anything at their discretion (Raitman, Augar, & Zhou, 2005). In that way, people can form communities that work collaboratively on a certain topic and create new content (Köhler & Fuchs-Kittowski, 2005; Moskaliuk & Kimmerle, 2009). Wikis may be used in educational contexts (Notari, 2006; Wang & Turner, 2005) – schools, universities, but also informal learning settings. A wiki lends itself, for example, to collective work on a scientific topic in school or a university class, particularly if people tend to have controversial opinions on that topic. In a wiki, those involved can introduce their own points of view on equal terms. Participants may express opposing opinions, addressing each other, and they incorporate their own perspective into a coherent text. But such processes of knowledge acquisition and knowledge exchange will not only take place in formal settings but also in informal contexts, for example, when people try to deal with and develop a topic through the Internet. This is a way for them to increase their own understanding, and they are able to acquire new knowledge. In addition to their individual learning, they also develop some collective knowledge.

Individuals may acquire new knowledge when they internalize information from the wiki. In order to incorporate information from the artifact, they will have to start off by browsing for information in a more or less target-oriented manner. When they have found some relevant information, they will have to transfer it into their own cognitive system. They will have to treat this information in some way or other to fit it into their own existing knowledge. So this internalization process allows people to increase their individual knowledge and gain new insights. This type of individual learning may, again, either take place in the form of assimilation or accommodation. When people assimilate information, they simply acquire knowledge without developing a different quality of understanding. Accommodation will occur when they incorporate new information in such a way that it modifies their prior knowledge. In an accommodation process, people transform knowledge with the aim of better understanding new information. In addition to this individual learning, as a result of internalization, there is also a supplementary form of knowledge generation: people will not only internalize information as it is, but also develop knowledge that is completely new, knowledge that was originally neither part of the digital artifact nor a component of their individual knowledge. This supplementary knowledge may develop when people have internalized new information, which will then, in turn, interact with their prior knowledge. This is the way in which a process of emergence is enabled. In such a situation, collaboration is a prerequisite for emergent knowledge. People on their own will not be able to develop this kind of knowledge; they need stimulation by other people. So knowledge processes enabled by a wiki are not simple knowledge-sharing processes, but collaborative processes of knowledge development.

When people want to contribute to a wiki, they will have to externalize certain aspects of their own knowledge. People who introduce their own knowledge to a shared digital artifact will have to put some effort into articulating that knowledge. That means they have to transform cognitive concepts into written language. Ideally, people will express their thoughts in a way that can easily be understood by others. They need to consider pre-existing information in the artifact to make sure that they integrate their own thoughts adequately. When people contribute to a wiki article, this will not only support the development of the wiki itself, but also its contributors' individual learning: people who externalize their knowledge will have to elaborate on it. This cognitive effort helps people to process their own knowledge more deeply, and this, in turn, will broaden their understanding (cf. the *self-explanation effect*; Chi, Bassok, Lewis, Reimann, & Glaser, 1989). When individuals have externalized their own knowledge, the resulting information continues to exist independently from its contributors. This information may, in turn, be picked up by other users, who may develop it further.

When people introduce knowledge into a wiki, there are two options for incorporating this information into the artifact. The information is either assimilated or accommodated. It is a matter of assimilation when information is simply attached to a text that already exists. In this case, new information is not connected to earlier information. Assimilation means that the previous arrangement of the artifact remains unchanged. An example will illustrate this process. The data are derived from another pilot study in which participants had to deal with a wiki text about causes of schizophrenia. The original wiki text was rather one-sided – only presenting biological causes, such as inheritance – and some participants only added information to the text that argued along the same lines, even though they had access to a variety of information sources; for example, the original text stated that an inherited disposition caused schizophrenia, and a participant wrote:

> *"This is supported by a study of the University of Göttingen about the genetic influence on suffering from schizophrenia. The results show that the probability of being afflicted with schizophrenia is increased when someone is consanguineous with a schizophrenic person. The probability of being afflicted with schizophrenia is 9.35 % for children. Another study with monozygotic twins shows that…".*

This contribution may be considered an essential addition, because it is important to provide empirical data for claims and statements. But it contains only supplementary information; it does not provide an alternative point of view. In a well-organized wiki, however, the process goes beyond such a simple assimilation of information. An efficient wiki community will endeavor to interpolate new information evenly. A wiki reflects accommodation if newly-introduced information is not just added to some existing text, but this text is also re-arranged in a new way. Accommodation has taken place if the article has been re-organized or new aspects have been integrated into existing information. A further example (by another participant) from the same study illustrates this accommodation process:

> *"Beyond biological causes, another potentially interesting reason is the interrelation of schizophrenia and the social environment. A study collected data about people's social class, their profession, education, income, and social situation (period of 2 years) as well as stress and personal living conditions that have negative psycho-social effects. The results were unambiguous: schizophrenic persons come from a low social class, have experienced inferior*

> *education, earn less money and are under considerable psycho-social strain. As a consequence, it may be concluded that a negative social environment contributes fundamentally to the onset of schizophrenia."*

People working on a wiki will not only improve their individual knowledge, but may also contribute to the development of collective knowledge at the same time. Thus, wikis support individual learning, and they may be an attractive tool for knowledge-building purposes, as described by Scardamalia and Bereiter. Collaboration with a wiki has the primary goal of advancing knowledge. Processes of externalization and internalization are going on all the time. In this way, both individual and collective knowledge are being developed constantly. The cognitive systems of individuals as well as the social system are continuously being enhanced and advanced, due to these processes of equilibration. All the people involved here can introduce information, and this information may be treated by each member of the community on an equal footing. A wiki community gets together when there is a need for jointly developing solutions to some problem which its members have in common. An idea that is introduced to the artifact will stimulate and inspire another community member to incorporate, develop, and improve this idea. In this way, concepts and ideas are developed, and the community and all the individuals involved can expand their knowledge.

## Conclusion

In this paper, we have elaborated on a framework in which knowledge building is defined as a co-evolution of cognitive and social systems. New knowledge may develop when people interact with each other via shared digital artifacts. It is assumed that collective knowledge becomes manifest in these shared artifacts. In order to illustrate these processes, we have demonstrated how they work, referring to two examples of social-software technologies: social-tagging systems and wikis. These allow different degrees of influencing and manipulating artifacts. Social tagging gives individuals only little scope for manipulating the whole artifact and its content. They can only add some new keywords or add a tag which has already been used. If many users have participated, resulting in a tag cloud which is already rather large, one individual contribution will probably not change this tag cloud very much. In such systems, it is not each individual's tagging behavior that will directly define the artifact. Instead, the artifact represents the accumulation of all the tags, giving each user equal impact. Regarding wikis, there are many opportunities for individual users to influence the artifact's content. They may, at their discretion, revise, change, or delete any part of a wiki article. If a user deletes some content, it will not be part of the shared artifact any more. The current state of a wiki does not represent the sum total of all these activities, as is the case with tagging systems. Instead, a modified wiki represents only the most recent interventions. This means that one person who modifies content in a wiki has the opportunity to make the whole text coherent. So in a wiki, a user can directly deal with incongruities.

To what extent a certain tool is conducive to knowledge building, depends very much on the potential of that technology to induce cognitive conflicts. In social tagging, productive conflicts are primarily caused by differences between a person's internal conceptual structure and that provided by the artifact. Individuals may solve this conflict mainly by changing their own individual knowledge structure. Wikis provide a high potential both for the development of cognitive conflicts and for solving them. The content of a wiki may differ fundamentally from its users' previous knowledge and understanding. If they want to improve the wiki text, they need to connect new content by re-organizing and re-conceptualizing it in order to adapt it to the content that already exists. This course of action will necessarily lead to the development of the shared artifact and to knowledge building.

To sum it up, this paper shows the potential of social software for learning and knowledge building. Social-software tools open up specific opportunities to combine individual and collective learning processes. Such tools are particularly relevant for knowledge-building purposes when they provide opportunities to influence and manipulate shared digital artifacts and when they have the potential to induce cognitive conflicts. Future developments of such technologies may benefit from taking these considerations into account.

# The Influence of Presentation Format and Subject Complexity on Learning from Illustrated Texts in Biology

Mareike Florax, Rolf Ploetzner, University of Education, Freiburg, Germany
mareike.florax@ph-freiburg.de, rolf.ploetzner@ph-freiburg.de

**Abstract:** In an experimental study, we investigated how learning from illustrated texts is influenced by presentation format (separated format, integrated format, and active integration) and subject complexity (low, medium and high complexity). Subject matter were biochemical processes of signal transmission in the human nervous system. A total of 180 students participated in the study. Results show that the active integration of texts and illustrations can improve the comprehension of highly complex material, whereas it can have inhibiting effects for less complex material. The results are discussed with respect to the process requirements associated with the different presentation formats.

## Introduction

Learning material often consists of different representations. A very common combination of representations is made up of expository texts and illustrations. The beneficial effects of combining texts and illustrations may be attributed to the fact that they complement each other with regard to their content (e.g., Ainsworth, Bibby & Wood, 2002), differ with regard to their computational efficiency (e.g., Larkin & Simon, 1987), or constrain each other's interpretations (Ainsworth, 2006). Although beneficial effects of learning from combinations of texts and illustrations have been frequently observed (e.g., Levie & Lentz, 1982), research has also identified certain difficulties that learners may encounter when processing such combinations. While some of these difficulties seem to be related to the design of the learning material, others seem to be intrinsic to the learners such as their prior knowledge and learning preferences. For instance, it is assumed that the design of learning material may pose unnecessary high processing demands on the learners which, in turn, can lead to an overburdening of their cognitive capacities (e.g., Sweller, van Merriënboer & Paas, 1998). With regard to difficulties intrinsic to the learners, research indicates that particularly those learners with only little prior knowledge may experience difficulties in relating different representations to each other. This seems to be especially true if the learning material is of high complexity (e.g., Bodemer & Faust, 2006; Kozma, 2003). Research also indicates that many learners engage in rather shallow information processing when learning from texts and illustrations (e.g., Peek, 1993).

In all the cases mentioned, learners do not take advantage of the synergetic effects that texts and illustrations may provide them and, as a consequence, fail to construct a coherent mental model of the information presented (cf. Ainsworth et al., 2002). In order to be able to fully exploit the potential of combined texts and illustrations, learners seem to need instructional support (cf. Ainsworth et al., 2002; Bodemer et al., 2004; Hegarty, Carpenter & Just, 1991). At least two approaches aiming at such support can be distinguished. One approach, the *design-oriented approach*, focuses on improving the design of learning material. A second approach, the *engagement-oriented approach*, aims at inducing appropriate mental processes in the learners. In three studies, Bodemer et al. (2004, 2005) demonstrated that learning can be improved by encouraging learners to spatially integrate texts and illustrations by themselves. Because these studies revealed that higher learning gains were associated with higher subject complexity, Bodemer et al. (2004, 2005) assumed that the higher the subject complexity, the more advantageous is learning by integrating texts and illustrations. However, since each study investigated learning in a different domain, the results of the three studies were difficult to compare.

In this paper, we present an experimental study in which we varied the presentation format as well as the subject complexity within the same domain of biology. We begin by outlining the theoretical assumptions and empirical findings within the design-oriented and engagement-oriented approaches. The role of complexity in learning from combined texts and illustrations is then explored. Thereafter, the experimental study and its results are described and discussed.

### The Design-Oriented Approach

Research on how to design combinations of texts and illustrations has been highly influenced by two theories: Richard Mayer's *Cognitive Theory of Multimedia Learning* (CTML; Mayer, 2001, 2005) and John Sweller's *Cognitive Load Theory* (CLT; Ayres & Sweller, 2005). CTML takes a process-oriented perspective on learning from combined texts and illustrations. Based on Paivio´s (1986) dual coding theory, and the assumption that human working memory is limited in its capacity (Baddeley, 2003), CTML postulates the following cognitive processes required for successful learning from multimedia: a) selecting relevant information in each presentation, b) organizing the selected information in either a verbal or a pictorial mental model, and c) integrating the verbal and pictorial models as well as prior knowledge by means of mapping processes between corresponding information (Mayer, 2005). Like other conceptualizations of learning from multimedia, CTML considers the integration of verbal and pictorial information to be pivotal for constructing a mental model, which in turn is considered to be important for deep understanding. On the basis of his theory, Mayer (2001) advises that texts and illustrations should be presented in spatial proximity rather than spatially separated. Essentially, it is assumed that spatial proximity facilitates the mental integration of textual and pictorial information. In numerous studies, Mayer and colleagues (e.g., Mayer, 1989; Moreno & Mayer, 1999) were able to demonstrate that a spatially contiguous presentation format leads to more successful learning than does a spatially separated presentation format. This empirical finding has been termed the *spatial contiguity effect*.

As in Mayer's (2001) CTML, it is also assumed in the resource-oriented CLT that human working memory is of limited capacity (e.g., Ayres & Sweller, 2005). According to CLT, three different types of cognitive load may burden working memory during learning: (1) extraneous cognitive load, which results from unnecessary cognitive processes induced by the inappropriate design of learning material; (2) intrinsic cognitive load, which is imposed by subject complexity which, in turn, is determined by the interactivity of elements in the learning material as well as the learners´ prior knowledge; and (3) germane cognitive load, which is related to learning processes such as the construction of concepts and schemata (cf. Ayres & Sweller, 2005).

For a long time, research on CLT has focused on reducing extraneous cognitive load by improving the design of learning material (van Merriënboer & Sweller, 2005). For instance, it is assumed that texts and illustrations which are spatially split induce unnecessary processes such as visual search processes. These processes contribute to extraneous cognitive load and may therefore impede learning. In contrast to Mayer's (2001) CTML, CLT recommends not only to present texts and illustrations together in spatial proximity, but to spatially integrate segments of the texts into the illustrations, resulting in a so-called integrated format. Envision, a text directly positioned above an illustration. From the perspective of CTML, this would correspond to a spatially proximate presentation format because both the text and illustration are presented close to each other. From the perspective of Sweller's CLT, however, this would still correspond to a spatially separated presentation format because the text is not integrated into the illustration. Sweller and colleagues have demonstrated that an integrated format leads to more successful learning than a spatially separated format (e.g., Cerpa, Chandler & Sweller, 1996). They termed this empirical finding the *split-attention effect*. Research also revealed that an integrated format is especially beneficial when the subject complexity is high (e.g., Pollock, Chandler & Sweller, 2002; Ginns, 2006).

A further design principle aimed to reduce extraneous cognitive load and to support the mental integration of verbal and pictorial information is to make the corresponding information in each presentation explicit. This can be achieved by visual indicators such as colour-codes (e.g., Bodemer et al., 2004; Tabbers, Martens & van Merriënboer, 2004), highlighting (e.g., Jamet, Gavota & Quaireau, 2008), or dynamic linking. For example, van der Meij and de Jong (2006) found that learning from dynamically linked presentations is especially beneficial when the subject complexity is high.

Whether corresponding information is made explicit by spatial proximity or by visual indicators, in both cases it is completely up to the learners as to whether or not they engage in the desired selection, organization, and integration processes. Although well-designed learning material may free the learners from unnecessary cognitive processes, thereby making more cognitive capacity available for learning, it is unknown to which degree learners actually take advantage of this capacity. Perhaps learning could be further improved by systematically encouraging the learners to engage in the desired learning processes. Furthermore, various studies indicate that providing learners with well-designed learning material may even act to inhibit learning, since some learners undervalue the complexity and difficulty of the learning material, and therefore exhibit only shallow information processing (e.g., McNamara, Kintsch, Songer & Kintsch, 1996; Schnotz & Rasch, 2005).

## The Engagement-Oriented Approach

In contrast to the design-oriented approach, the engagement-oriented approach encourages learners to more actively process the information presented. Various theories of learning, especially constructivist theories, emphasize that the learners' engagement is crucial to successful learning. For example, in Wittrock´s (1992) theory of generative learning, it is assumed that learners do not passively take up and store information, rather they actively search for and process information in order to construct knowledge. Learning thus takes place by actively establishing relations between different pieces of information that are presented to the learners, as well as by establishing relations between new information and prior knowledge. Accordingly, Wittrock's (1992) theory implies that understanding depends on the mental processes actively carried out by the learners.

Various methods have been developed in order to induce and support the learners' engagement in active information processing. Two examples which have been proven to facilitate learning are the production of self-explanations (e.g., Chi et al., 1989; Renkl, 2002) and the visualisation of information present in texts (e.g., van Meter, Aleksic, Schwartz & Garner, 2006). Peek (1993) also recommends instructional interventions which lead to an external and observable product. For instance, various instructions aim at inducing the relevant learning processes by asking the learners to organize textual and pictorial components on the computer screen (e.g., Bodemer et al., 2004).

Bodemer et al. (2004, 2005) developed an instructional method which takes all mentioned aspects into account. They termed this method *active integration*. Initially, learners were presented spatially separated texts and illustrations on a computer screen. They were then asked to move segments of the text to their referential areas in the illustration using the drag and drop method. After completing the task, the learners had constructed a spatially integrated presentation format by themselves. In three experimental studies, Bodemer and colleagues were able to demonstrate that learners who integrated texts and illustrations themselves outperformed learners who were provided with a spatially integrated or a spatially separated presentation format (Bodemer et al., 2004; 2005; Bodemer & Faust, 2006).

Because higher learning gains were attained with higher subject complexity in the studies of Bodemer et al. (2004, 2005), the authors assumed that learning by integrating texts and illustrations may be more successful as the subject complexity increases. This assumption is in line with findings concerning the split-attention effect (cf. Ginns, 2006): while learning from an integrated format is most beneficial if the subject complexity is high, it leads to only small improvements if the subject complexity is low. However, because learning encompassed a different subject domain (physics, statistics and mechanics) in each study of Bodemer et al. (2004, 2005), the results of their studies were difficult to compare.

In the following, we present an experimental study which investigates how presentation format and subject complexity influence learning from combined texts and illustrations. In this study, subject complexity is varied systematically within the same subject domain. According to Sweller and Chandler (1994), subject complexity denotes the number of interacting elements that have to be processed simultaneously by the learners. Increases in complexity were achieved by successively adding interacting elements to the learning material.

## Experiment

### Design

Two factors, each with three variations, were considered: (1) *presentation format* of combined texts and illustrations (separated format, integrated format, active integration) and (2) *subject complexity* (low, medium, high). Dependent variables were retention and comprehension of the learning material. The learners´ working memory capacity was assessed and taken into account as a covariate. Furthermore, the learners´ spatial abilities were also assessed and taken into account as a covariate. Because learning time was not fixed, it was recorded as a further covariate.

### Hypotheses

In accord with Bodemer et al. (2004, 2005), we expected that active integration facilitates learning from combined texts and illustrations more than learning from an integrated format. This hypothesis relies on the assumption that active integration induces and supports the learners' engagement. Because such engagement processes are more important with respect to comprehension than to retention, more substantial effects were expected concerning comprehension. In accord with Ayres and Sweller (2005), as well as Mayer (2001), we expected learning from an integrated format to be more beneficial than learning from a separated format; i.e., we expected the split-attention effect. With regard to subject complexity, we expected active integration to be more beneficial, the higher the subject complexity. More substantial effects of subject complexity were expected with respect to comprehension than with respect to retention. These hypotheses rely on the assumption that during learning from complex material learners need more encouragement and support to systematically and comprehensively process the material.

### Material

The subject domain was information processes of the human nervous system. Various biochemical processes related to the transmission of signals between neurons were verbally described and graphically illustrated in such a way that the texts and illustrations complemented each other. For each group, the computer-based learning material consisted of an explanatory text and an accompanying illustration which were presented together on a single computer screen. In order to systematically increase the subject complexity, interacting textual and pictorial information was successively added to the material. Learning material of low complexity addressed the development of resting potentials within the human nervous system (cf. Figure 1). Learning material of medium complexity additionally described the development of action potentials. Processes involved in resting potentials and those involved in action potentials influence each other. Therefore, the processes described in the material of medium complexity did not only complement the processes described in the material of low complexity but the former interacted with the latter. Learning material of high complexity additionally described processes of inhibiting action potentials (cf. Figure 2) which, again, interacted with processes described in the material of low and medium complexity.

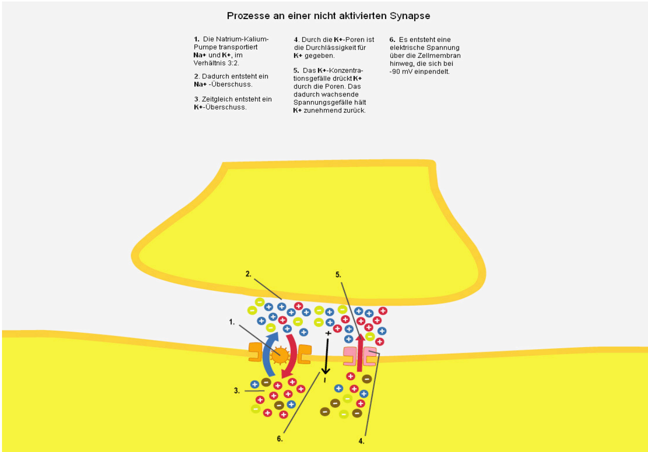

Figure 1. Learning material of low complexity in a separated format.

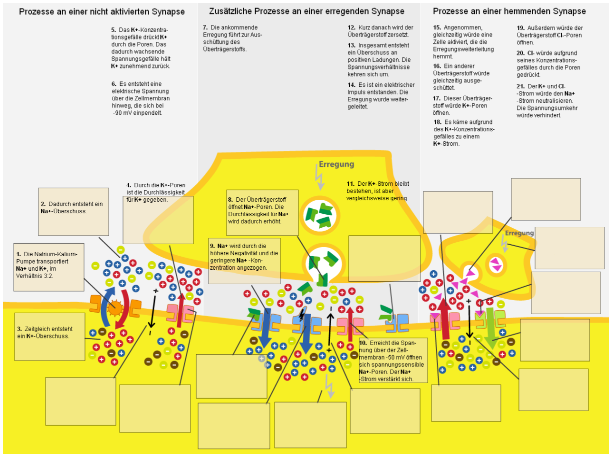

Figure 2. Learning material of high complexity with active integration.

Figure 1 also shows an example of the separated format (SF). Each text segment and corresponding part of the illustration were numbered according to the reading sequence. In the integrated format (IF), the text segments were placed next to the corresponding parts of the illustration. Active integration (AI) began with a separated format (cf. Figure 2); participants were then required to drag and drop the given text segments onto the appropriate part of the illustration. After having arranged all text segments, participants received feedback. If segments were placed incorrectly, the participants were given two opportunities to revise their integration. In the end, the participants were presented with the correct integrated format.

All participants received a short introductory text about the general structures and processes within the human nervous system. On the basis of four multiple-choice questions, participants who did not properly process the introductory text were excluded from the study; at least two of the the four questions had to be answered correctly. To familiarize participants in the active integration group with dragging and dropping text segments, they received an introduction to this functionality.

A pre-test of the participants´ prior knowledge was made up of eight multiple-choice questions which addressed the learning material. Three overlapping post-tests were constructed addressing respectively the low, medium and high complex learning material. All post-tests were comprised of questions relating to retention and comprehension. Both types of questions were constructed in such a way that the correct answers required the mental combination of verbally and pictorially presented information. Whereas questions on retention asked for the recall of information explicitly presented in the learning material, questions on comprehension demanded the participants to draw inferences from the information presented. The post-test for low complex material consisted of eight questions on retention and five questions on comprehension. The questions on retention were identical to the questions used in the pre-test. The post-test for medium complex material was comprised of eleven questions on retention and seven questions on comprehension. In the case of retention, five questions were identical to questions of the post-test for low complex material and six questions were new. In the case of comprehension, three questions were identical to questions on the post-test for low complex material and four questions were new. The post-test for high complex material was also comprised of eleven questions on retention and seven questions on comprehension. In the case of retention, seven questions were identical to questions found on the post-test for medium complex material and four questions were new. In the case of comprehension, five questions were identical to questions on the post-test for medium complex material and two questions were new. Pre- and post-tests were administered on the computer. Each item answered correctly was scored with one point.

With respect to the covariates, working memory capacity was assessed by means of the subtest "memorizing digits" from the Wilde Intelligence Test (Jäger & Althoff, 1983). Spatial abilities were assessed by means of three subtests of the System for the Assessment of Performance (Horn, 1983).

## Procedure

Participants were investigated in groups of no more than three; they worked, however, individually on the different material. Sessions were structured into five phases. During the first phase, participants took the memory capacity test and the spatial ability test. During the second phase, participants read the introductory text and answered the pertaining questions. They were allowed to keep the text until the post-test started. During the third phase, learners took the pre-test. The learning material was processed in the fourth phase. The amount of learning time could be chosen individually and was recorded by the computer. Finally, during the fifth phase, participants worked on the post-test.

## Participants

Overall, 180 students from two different universities in Freiburg, Germany, were randomly assigned to the nine experimental groups. Students of medicine, psychology and the natural sciences did not participate in the study. Two participants were excluded from the study due to insufficient processing of the introductory text. Five participants were excluded due to high prior knowledge: they answered more than 25% of the pre-test questions correctly. Four participants were excluded due to technical problems. Overall, 169 participants remained (age: $M = 22.3$, $SD = 2.4$; gender: 58 males, 111 females).

## Results

### Prior Knowledge

On average, the participants' prior knowledge was low ($M = .34$ (4.3%), $SD = .62$) and there were no significant differences between groups with respect to prior knowledge ($F(8,160) = 1.18$, *n.s.*). There was also no significant correlation between performance on the pre- and post-test ($r = .03$, *n.s.*). Therefore, prior knowledge was not further considered in the analysis.

### Covariates

An analysis of variance with the factors presentation format and subject complexity on learning time revealed a statistically significant effect for subject complexity ($F(2,160) = 130.30$, $p < .01$, $\eta^2_{part} = .62$). There was no statistically significant effect for presentation format ($F(2,160) = 1.13$, *n.s.*). The interaction between the two factors was also not statistically significant ($F(4,160) = 1.55$, *n.s.*). Post-hoc tests indicated that learning from low complex material took significantly less time than learning from medium complex material (Games-Howell, $MD = -5.01$, $SE = .44$, $p < .001$), which, in turn, took significantly less time than learning from highly complex material (Games-Howell, $MD = -3.87$, $SE = .63$, $p < .001$). On average, participants exhibited high spatial abilities ($M = 6.8$ (75.5%), $SD = 1.1$) and medium working memory capacity ($M = 100.9$ (52.3%), $SD = 10.1$). Analyses of variance showed no significant differences between groups, neither for spatial abilities ($F(8,160) = 1.27$, *n.s.*) nor for working memory capacity ($F(8,160) = 1.01$, *n.s.*).

### Learning Performance

With respect to highly complex material, descriptive data shows that active integration led to more successful learning than learning from an integrated format, which in turn was superior to learning from a separated format (cf. Table 1). The differences between these conditions were larger for comprehension than for retention. While the descriptive trends for medium complex material were similar to those of highly complex material, the descriptive trends for low complex material reversed.

A multivariate analysis of covariance (MANCOVA) on the dependent variables retention and comprehension was computed; it included the factors presentation format and subject complexity, as well as the covariates spatial ability, working memory capacity and learning time. Overall, it revealed no significant influence of learning time ($F(2,156) = 2.26$, *n.s.*) on post-test results, but significant influences of spatial ability ($F(2,156) = 3.24$, $p < .05$) and working memory capacity ($F(2,156) = 5.90$, $p < .01$). Furthermore, a statistically significant effect was found for subject complexity ($F(4,312) = 3.78$, $p < .01$). The analysis revealed no statistically significant effect for presentation format and no statistically significant interaction effect between subject complexity and presentation format. The main multivariate effect of subject complexity can be attributed to statistically significant differences with respect to retention ($F(2,157) = 3.43$, $p < .05$).

Table 1: The means and standard deviations of the relative solution frequencies in the post test.

| | | Low complexity | Medium complexity | High complexity |
|---|---|---|---|---|
| **Separated format** | Retention | 63.1% (23.5%) | 72.7% (19.9%) | 54.5% (29.1%) |
| | Comprehension | 40.0% (24.3%) | 45.1% (28.3%) | 42.0% (24.5%) |
| | Overall | 54.2% (20.5%) | 62.0% (20.7%) | 49.7% (25.1%) |
| **Integrated format** | Retention | 62.5% (27.0%) | 66.0% (23.2%) | 59.1% (23.3%) |
| | Comprehension | 38.9% (29.4%) | 45.1% (20.4%) | 51.4% (22.0%) |
| | Overall | 53.4% (25.3%) | 57.9% (20.1%) | 56.1% (20.3%) |
| **Active integration** | Retention | 56.3% (31.0%) | 60.5% (27.7%) | 61.5% (28.3%) |
| | Comprehension | 28.9% (24.0%) | 44.3% (21.7%) | 55.5% (23.1%) |
| | Overall | 45.7% (25.8%) | 54.2% (22.5%) | 59.2% (24.1%) |
| **Overall** | Retention | 60.7% (26.9%) | 66.3% (24.0%) | 58.7% (26.5%) |
| | Comprehension | 36.1% (26.0%) | 44.8% (23.4%) | 49.7% (23.3%) |
| | Overall | 51.3% (23.8%) | 58.0% (21.0%) | 55.0% (23.0%) |

In order to further explore the data, we conducted a trimmed means analysis according to Wilcox (1998). Based on the results in the post-test, the lower 10% as well as the upper 10% of the participants were removed from each group. In the analysis of trimmed means, the covariates learning time, spatial ability, and working memory capacity showed less influence on post-test results than in the analysis of untrimmed means. The most important difference between the two analyses was that the interaction between presentation format and subject complexity reached statistical significance with respect to comprehension ($F(4,121) = 2.52$, $p < .05$, cf. Figure 3). According to a post-hoc simple effects analysis, this interaction results from the changing effects of active integration ($F(2,123) = 7.34$, $p < .001$): The active integration of learning material inhibits learning when subject complexity is low, but facilitates learning when subject complexity is high. The simple effects analysis did not reach statistical significance with respect to the seperated and integrated presentation formats.

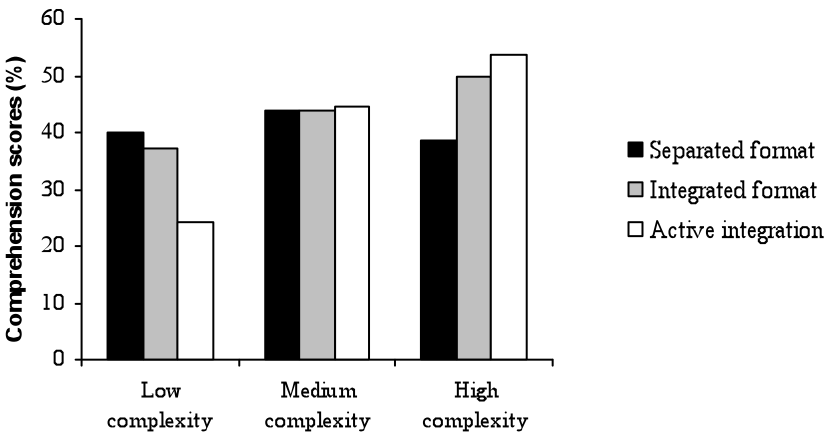

Figure 3. Comprehension scores for the three formats at different levels of complexity.

## Discussion

Whether the active integration of texts and illustrations as proposed by Bodemer et al. (2004, 2005) acts to inhibit or to facilitate learning is dependent upon the subject complexity. However, it was only after reducing the variances within groups, that the expected interaction between presentation format and subject complexity was statistically confirmed with respect to comprehension. When subject complexity was high, actively integrating texts and illustrations was of greater benefit than learning from a separated or an integrated format. The active integration of text and illustrations inhibited learning when subject complexity was low. What could have caused this inhibition? It could be that the participants underestimated the difficulty of learning from the low complex material. In the low complex material, the amount of textual and pictorial information was rather small and both types of information were clearly arranged. Requesting the participants to integrate this information might not have led to the intended effortful engagement leading to a deeper understanding of the material, but rather to a more or less “mindless” execution of the drag-and-drop-task (cf. Salomon, 1983). Overall, our findings support, or to say it more carefully, do not contradict the hypothesis of Bodemer et al. (2004, 2005) that learning by integrating texts and illustrations is most successful when the subject complexity is high.

Like Martin-Michiellot and Mendelsohn (2000), as well as Bodemer et al. (2004), we were not able to replicate the split-attention effect - not even with respect to highly complex material. This finding is in contradiction to many studies, especially those by Sweller and colleagues (e.g., Cerpa, Chandler & Sweller, 1996). A comparison of the learning material used, however, reveals two differences. First, in the spatially separated learning material used in many other studies, a more or less unstructured text was combined with an illustration. In many cases, the relevant areas within the illustration were not clearly distinguished. Thus, it was up to the learners to identify meaningful assertions in the text and relevant parts of the illustration, and to then appropriately relate them to each other. In these studies, the separated and integrated formats differed not only with regard to spatial proximity, but with regard to other factors as well such as text segmentation and picture labelling (e.g., Chandler & Sweller, 1991). In contrast, the text in our learning material was always structured into meaningful segments and the relevant areas within the illustration were indicated. It is therefore plausible that our material imposed smaller extraneous cognitive loads on the learners than the material used in other studies. As a consequence, the chance that a split-attention effect would occur was also smaller. From a theoretical point of view, the finding that an integrated format does not lead to better learning than a well-structured separated format supports an explanation put forward by Erhel and Jamet (2006): the beneficial effects of integrated formats result from the explication of relations between texts and illustrations rather than from spatial proximity. A second difference is the design of the pictorial material employed. While Sweller and colleagues (e.g., Sweller & Chandler, 1994) often made use of simple black-and-white line drawings, we employed coloured schematic illustrations comprised of many visual elements. Both colours, as well as the number of visual elements, increase the visual richness of an illustration (cf. Peek, 1993). This difference also could have contributed to a convergence of the extraneous cognitive load imposed on the learners by the separated and integrated formats.

Overall, the differences addressed above indicate that the roles of segmenting text, pointing out relevant parts of illustrations, and designing visual material are underspecified in the context of the split-attention effect. It appears that the distinction between a separated format and an integrated format might not correspond to a clear-cut dichotomy. Martin-Michiellot and Mendelsohn (2000) assume that texts and illustrations can be designed and arranged in such a way that they do not yield an integrated format, but nevertheless support the learner in relating and mentally integrating both presentations. In a recent study, Florax and Ploetzner (in press) found evidence for this assumption: learning from segmented texts and spatially separated pictures improved learning as much as learning from spatially integrated texts and pictures.

The reported study is a first step to clarify the role of active integration for learning from material of different complexity. According to our observations, active integration should only be employed when the subject complexity is high, otherwise it might hinder learning. For example, in the realm of academia, where learning material is usually of high complexity, active integration has the potential to improve learning.

**Abstract:** A large number of studies in CMC have assessed how social interaction, learning processes and outcomes are intertwined. Although recent research findings indicate that learners differ with respect to the amount and type of discourse contributed in virtual settings, little is known about the underlying causes and its consequences explaining differences between participants' contributions to discourse. The present research investigates how motivational orientation of a learner influences the interaction patterns with other learners in a virtual network.

Our research among 100 participants in six virtual teams indicates that three sub-groups were formed within each virtual network. These subgroups were generated by a K-means cluster analysis of academic motivation measured by AMS. Extrinsically motivated learners prefer to connect to intrinsically motivated learners. Intrinsically motivated learners prefer to discuss mainly among themselves, implying that extrinsically motivated learners will receive less feedback and discourse possibilities from other members within the virtual network.

## Introduction

In recent years, the attention for virtual collaborative learning seems to be fuelled by two separate, yet mutually enforcing developments: First, the availability of increasing possibilities of Information Communication Technologies (ICT) provide enhanced support for collaboration (Bromme, Hesse, & Spada, 2005; Resta & Laferrière, 2007; Schellens & Valcke, 2005). Second, growing amounts of evidence have become available showing that collaboration can enrich student learning through interaction (Jonassen & Kwon, 2001; Lindblom-Ylänne, Pihlajamäki, & Kotkas, 2003; Van den Bossche, Gijselaers, Segers, & Kirschner, 2006). In general, it can be said that virtual collaborative learning is built on the assumption that ICT has the power to provide a rich learning experience by using a variety of learning methods (Beers, Boshuizen, Kirschner, & Gijselaers, 2007; Giesbers, Rienties, Gijselaers, Segers, & Tempelaar, 2009; Jonassen & Kwon, 2001; Resta & Laferrière, 2007).

Despite the learning possibilities created by ICT-tools, recent findings in research on computer-mediated communication (CMC) indicate that interaction and contributions made to interaction depend on a variety of factors. Not every learner contributes equally to others. It has been found that learners who are similar with respect to educational background and prior knowledge nevertheless contribute differently to discourse (Caspi, Chajut, Saporta, & Beyth-Marom, 2006; De Laat, Lally, Lipponen, & Simons, 2007; Martens, Gulikers, & Bastiaens, 2004; Rienties, Tempelaar, Van den Bossche, Gijselaers, & Segers, 2009). An overall finding in research is that the majority of interactions and contributions within online courses can be attributed to a small number of learners. While this research has demonstrated the existence of this phenomenon, the obvious question is how these differential patterns between learners can be explained.

Several studies have examined this phenomenon by using social network analysis to explain interaction patterns in CMC. Social network analysis (SNA) provides powerful tools to analyze how people interact over a given period of time (Hurme, Palonen, & Järvelä, 2007; Martinez, Dimitriadis, Rubia, Gomez, & de la Fuente, 2003; Rienties et al., 2009). It considers whether certain individuals are central in networks or at the peripheries, and how interactions between individuals may change over time. Research findings have indeed revealed that some learners are more central in the social network than other learners (Hurme et al., 2007; Russo & Koesten, 2005). It has been found that learners who were central in a social network received and also contributed more messages than other learners. In addition, Russo and Koesten (2005) found that learners who were central in the social network had better cognitive learning outcomes.

Although recently several researchers have identified that some participants are more likely than others to be in the centre of networks, they could not explain the underlying mechanisms of these social interaction patterns. The present study aims to fill in this gap, by examining the underlying causes that explain differential contributions to social networks. We address the question why some learners receive relatively more replies to their contributions in discourse while others do contribute but get only limited response from others. So the issue is to what extent is it a coincidence that some learners become central contributors? In this article, we will investigate what the "invisible" mechanisms in social interaction are that result in learners of virtual networks being central or learners being on the outer fringe of a social network.

## An invisible hand in social interaction in CMC: motivation

In most virtual networks learners are geographically separated and dispersed over many settings. In collaborative settings, learners have to construct meaning and co-construct knowledge in a virtual setting. However, participation and making contributions to discourse in collaborative settings cannot be taken for granted (Bromme et al., 2005; Kirschner, Beers, Boshuizen, & Gijselaers, 2008). In particular when learners are interacting using lean ICT-tools like discussion forums or WIKIs, establishing a critical mass of interaction whereby participants contribute actively to cognitive discourse is troublesome (Caspi, Gorsky, & Chajut, 2003; Schellens & Valcke, 2005). Some learners are more inclined to start and actively contribute to a discussion than others. Other learners might prefer to wait for a while before contributing to a discussion, in particular when the members of the virtual network are seeking for effective working and learning strategies (Beers et al., 2007; Kirschner et al., 2008).

Within CMC, several researchers have tried to influence the interaction patterns among learners by (re-)scaffolding the learning process by designing scripts (Weinberger & Fischer, 2006), adjusting the degree of social presence of ICT tools (Giesbers et al., 2009; Jonassen & Kwon, 2001; Tu & McIsaac, 2002) or regulating the interaction processes (Kirschner et al., 2008). For example, by increasing the regulation of interaction processes, Beers et al. (2005) found that interaction among participants could be enhanced. By establishing argumentative scripts, learners contributed more argumentative discourse than when other scripts were used (Weinberger & Fischer, 2006). Nonetheless, individual differences to contributions to discourse still persist when redesigning the learning environment. Limited research has been conducted how differences in individual traits influence the interaction patterns of learners in networks.

One of the explanations for these individual differences lies in the motivation of learners to contribute to the virtual network. Recent research highlights indeed that motivation has a strong influence on how learners contribute to discourse in online settings (Järvelä, Järvenoja, & Veermans, 2008; Martens et al., 2004; Rienties et al., 2009; Veermans & Lallimo, 2007; Yang, Tsai, Kim, Cho, & Laffey, 2006). For example, Yang et al. (2006) conducted a survey among 250 respondents of eleven online educational psychology courses and found that goal-oriented motivation positively influences social presence among peers, that is the perception that emotions can be shared using CMC. Veermans and Lallimo (2007) found that messages contributed by motivated students demonstrate a richer variety of topics. Järvelä et al. (2008) found that students in the face-to-face setting reported more (favourable) learning goals and less performance goals relative to students in virtual settings.

The present research builds further on these findings by examining how motivation affects the creation, development and evolution of links between learners in virtual networks. As motivation is a multidimensional and multilevel construct (Boekaerts & Minnaert, 2006), a wide variety of definitions and instruments are discussed and used in educational psychology research. We adopt the concept of motivation developed by Deci and Ryan (1985), where to be motivated means to be moved to do something. The degree of self-determination of learners might explain why some learners contribute more to discourse in CMC than others. As a consequence, it is expected that some learners contribute more to discourse in CMC than others, given their motivation. However, focusing only on the level of motivation ignores the underlying attitudes and goals the learner has in order to pursue an action or goal (Deci & Ryan, 1985).

*Evolution of Social Networks*

The present study considers the way learners interact in virtual networks as social network interactions. According to Newman (2003), "[a] social network is a set of people or groups of people with some pattern of contacts or interactions between them". Within educational psychology, limited research has been conducted to understand dynamic social network interactions. According to network theorists, there are two important conditions that determine how social networks evolve: 1) the stability of the number of nodes (i.e. participants in virtual network); 2) the (in)equality of characteristics of nodes in the network (Barabási & Albert, 1999; Erdős & Rényi, 1960; Newman, 2003). In case the number of participants in a social network grows continuously (e.g. Wikipedia, Facebook), being among the first participants in the social network might imply that one is more likely to be connected to others than when one has recently joined a social network. In contrast, in an online course (as in most classes), the number of learners is mostly pre-determined and relatively stable. Therefore, a straightforward assumption from network theory would be that the social network of an online course will develop and evolve according to random graph theory (Barabási, 2002; Erdős & Rényi, 1960). In random graph theory, learners connect to other learners in a network with a more or less equal probability.
*H1:Learners in a virtual network will have an equal amount of connections to all other learners.*

If hypothesis 1 has to be rejected in our setting, then learners in virtual networks do not connect to other learners in line with the random graph theory. A crucial assumption of random graph theory is that people in the social network are perceived by others as equal (Erdős & Rényi, 1960; Newman, 2003). However, in line with the second condition when nodes (i.e. learners) have a specific preference to connect to some type of nodes, the network will not develop according to random graph theory (Barabási & Albert, 1999; Newman, 2003). Several researchers have indicated that learners in online settings differ with respect to prior knowledge, expertise and motivation when they become member of a virtual network (Järvelä et al., 2008; Martens et al., 2004; Rienties et al., 2009; Yang et al., 2006). When learners in a virtual network become aware that interacting with some learners who have a trait (e.g. intrinsic motivation, large knowledge base, expertise) that is (perceived to be) beneficial, these learners might be more interesting to interact with (Martens et al., 2004).

As intrinsically motivated learners are more inclined to contribute to discourse than extrinsically motivated learners, in particular with regard to higher cognitive discourse (Rienties et al., 2009), they possess crucial characteristics for distance learning. Superior contributions to discourse at a higher cognitive level might bring them a positive (expert) reputation in the virtual network. Other learners might be more willing to contribute to a learner who is perceived to be motivated and has some expert knowledge. In addition, as extrinsically motivated learners will perceive a lack of external regulation in distance learning, they might direct their attention more towards intrinsically motivated learners. In other words, intrinsically motivated learners lead the discourse development within the virtual network, thereby providing the desired external regulation to extrinsically motivated learners. This will imply that most learners will be connected to intrinsically motivated learners, as phrased in our second and third research hypotheses: *H2: Extrinsically motivated learners are more likely to interact with intrinsically motivated learners than with other extrinsically motivated learners; H3: Intrinsically motivated learners are more likely to interact with other intrinsically motivated learners than with extrinsically motivated learners.*

## Method

### Setting

The present study took place in an online summer course for prospective bachelor students of an International Business degree program at an Institute for Higher Education in the Netherlands (Rienties, Tempelaar, Waterval, Rehm, & Gijselaers, 2006). This online course was given over a period of six weeks in which learners were assumed to work for 10-15 hours per week. The participants never met face-to-face before or during the course and had to learn using the virtual learning environment "on-the-fly". In our setting, learners participated in virtual networks within a collaborative learning environment using discussion forums and announcement boards. During six weeks, learners had to collaborate together on solving six tasks through a problem-based learning method. No obligatory meetings were scheduled. The results of three interim-tests and a final summative test combined with graded participation in the discussion forums were used to make a pass-fail decision. Learners who passed the course received a certificate.

### Participants

In total 100 non-Dutch participants were randomly assigned in six networks. Data were analysed for those individuals who actually posted at least once a reaction in the discussion forum. We found that 18 learners, although registered for this course, never posted a contribution to the discussion forums. The 82 participants who posted at least once a reaction in the discussion forum were selected for our analysis. The six networks had an average of 13.66 members (SD = 2.16, range = 11-17) per network. The average age was 19 years and 45% of the learners were female.

### Academic Motivation Scale (AMS)

Vallerand and colleagues have added further theoretical concepts to the model of Deci and Ryan (1985) as well as adjusting the model for different contexts as SDT was primarily developed to measure motivation among children. Individual motivation was measured by the Academic Motivation Scale (AMS), which was developed by Vallerand et al. (1992) for college/university learners and measures the contextual motivation for education. The instrument consists of 28 items, in all of which learners respond to the question stem "Why are you going to college?". There are seven subscales on the AMS, of which three belong to the intrinsic motivation scale, three to the extrinsic motivation scale and one for amotivation. The response-rate on AMS-questionnaire among the summer course participants was 93%. The Cronbach alpha reliability for the seven scales ranged from .760 to .856. The 82 students who participated in our setting were unaware of the scores of the AMS and those of their peers with whom they worked and learned together in their virtual team.

### Statistical analyses

*Cluster analysis*

The 82 students in the experiment are part of the inflow of 765 international freshmen. Motivational profiles were determined of all international students by applying k-means cluster analysis to subscale scores of the AMS-instrument. It was decided to base motivational profiles on the complete sample of international freshmen. First of all, this will lead to a more stable outcome of the cluster analysis. Second, in this way we are able to express the motivational patterns found amongst participants relative to the motivational profiles present amongst all international students. Since participation in the experiment is voluntarily, motivation scores of participating freshmen might be different from motivation scores of all freshmen. In this situation, profiles found amongst all international students were regarded as more relevant benchmarks than profiles found in the restricted group of participants of the experiment. It was found that a three cluster solution provides the best fit for different motivation profiles present in these freshmen. Afterwards, data on cluster membership of all participants of the virtual networks were combined with individual data resulting from the social network analysis. The interrelationships between all measures were assessed through standard T-tests analyses using SPSS 15.0.1.

*Positioning of individuals within social network using SNA*

Two SNA measures were used, namely ego network density, which measures to how many other learners a learner is directly connected, and Freeman's degree of Centrality, which measures whether learners were central in the social network or not (Freeman, 2000; Wassermann & Faust, 1994). Main indicator for this study is the relative position of each learner within the social network, derived by UCINET version 6.158. In order to assess whether learners with different motivational orientations connect equally to each of the clusters, we will use the (absolute/relative) number of send and received messages per learner to members in each of the (send to own/outside) clusters as a measurement for equality of interaction between clusters. An innovative feature of this study is that by combining the results of the SNA and cluster analysis, we were able to distinguish interaction patterns amongst individual learners based upon their motivation profile.

## Results

In order to test hypothesis 1, the average number of connections in the cohort of online summer course participants is compared. On average, a learner has 6.43 (SD = 4.03) connections to other learners and there are substantial differences amongst individual learners with respect to the number of connections as assessed by a Chi-Square test ($\chi 2$ (df = 76) 159.46, $p < .001$). Furthermore, significant differences are found using a Chi-Square test in each of the six virtual networks with the exception of network 3. In other words, in contrast to random graph theory the social networks in our setting do not evolve to a random network with an approximately equal amount of connections per learner, with the exception of network 3. Furthermore, some learners are more central than other learners in the network, as is illustrated by the large standard deviation of the Freeman's degree of centrality (M = 26.60, SD = 24.29), as well as by the Chi-Square test for all participants ($\chi 2$ (df = 80) 1772.74, $p < .001$) and the Chi-Square test for participants within each of the networks. As a result, we need to reject hypothesis 1 that social networks develop and evolve in accordance to the model of the random graph theory for five out of six of our networks.

In order to test hypotheses 2 and 3 and to investigate whether the motivation profile of a learner has an influence on the formation of links to other learners within the social network, a K-means cluster analysis is applied to obtain three different profiles for motivation, which are further labeled according to the final cluster center position (see Table 1). The three motivation profiles are: cluster 1: low intrinsic motivation (Low In), high extrinsic motivation (High Ex); cluster 2: medium intrinsic motivation (Med In), low to medium extrinsic motivation (Med Ex); cluster 3: high intrinsic motivation (High In), high extrinsic motivation (High Ex).

Table 1 Means and standard deviation of classification measures per cluster (K-means)

| | Cluster 1 Low In, High Ex (N=182) | Cluster 2 Med In, Med Ex (N=152) | Cluster 3 High In, High Ex (N=415) |
|---|---|---|---|
| Intrinsic motivation to know (IMTK) | 4.68 (0.94) | 5.38 (1.02) | 6.06 (1.10) |
| Intrinsic motivation to accomplish (IMTA) | 3.95 (0.89) | 4.09 (0.89) | 5.42 (1.06) |
| Intrinsic motivation to experience stimulation (IMES) | 3.17 (0.95) | 3.81 (0.99) | 4.92 (1.18) |
| Identified regulation (EMID) | 6.04 (1.00) | 5.58 (1.20) | 6.48 (1.03) |
| Introjected regulation (EMIN) | 4.61 (1.14) | 3.24 (1.23) | 5.35 (1.22) |
| External regulation (EMIR) | 6.05 (1.03) | 4.52 (1.43) | 6.12 (1.23) |
| Amotivation (AMOT) | 1.44 (0.73) | 1.40 (0.73) | 1.32 (0.62) |

As a third step, the cluster memberships are added as learner attributes to the social networks of each of the six virtual networks. Based upon the division of motivational profiles, network 5 (Figure 2) and network 6 (Figure 3) can be categorised as prototypical networks. Learners for which no motivation attributes are available and teachers are represented by a light-coloured circle, while cluster 1 learners (Low In, High In) are represented by a light-coloured square box, cluster 2 learners (Med In, Med Ex) by a dark triangle, and finally cluster 3 learners (High In, High Ex) by a shaded diamond box[1]. In this way, we are able to visualise the position of each learner

[1] The names of the participants are replaced by fictitious names in order to guarantee privacy of the participants.

in the network as well as to whom each learner is connected to depending on his/her motivational profile. When looking at the three motivation profiles, it appears that learners with high intrinsic motivation are situated closely together. For example, in network 6 most of the connections of Veronica and Jonas (cluster 3) are to learners with the same cluster membership. Learners with low and medium motivation are positioned mostly on the outer fringe of the network and are mainly connected to highly intrinsically motivated learners. Furthermore, learners within cluster 1 (Kathi and Markus of network 5; Paul and Bart of network 6) and learners within cluster 2 (Judith and Laura; Elena, Christina and Bernard) are not well connected to other learners with the same motivation profile. In fact, most cluster 1 and 2 learners are only indirectly linked to each other through cluster 3 learners. For example, in network 6 Bart can only be linked to Paul via Jonas or Caroline. In sum, our learners differ with respect to the number of ties as well as with respect to the position in the network. Furthermore, we find that the position of learners in a social network depends on the type of motivation. Cluster 3 learners form the center core of the network, while the other learners are mostly situated on the outer fringe.

Table 2 Interaction among learners per cluster corrected by relative cluster size

| | Cluster 1 Low In, High Ex (N=15) | Cluster 2 Med In, Med Ex (N=12) | Cluster 3 High In, High Ex (N=50) | t-test difference |
|---|---|---|---|---|
| Sent total | 1.60 (1.50) | 2.30 (2.45) | 2.74 (2.74) | 1.950† |
| Sent to own cluster | 0.62 (0.67) | 1.22 (1.54) | 1.70 (1.71) | 2.790** |
| Sent outside own cluster | 0.97 (0.98) | 1.07 (0.95) | 1.04 (1.18) | 0.518 |
| Sent difference | -0.35 (0.76) | 0.15 (0.75) | 0.66 (1.08) | 3.80*** |
| Received total | 1.67 (1.64) | 2.32 (2.23) | 3.25 (2.57) | 2.824** |
| Received from own cluster | 0.62 (0.72) | 1.17 (1.34) | 1.84 (1.68) | 3.356*** |
| Received from outside own cluster | 1.04 (1.09) | 1.15 (1.07) | 1.41 (1.17) | 1.660 |
| Received difference | -0.42 (0.86) | 0.02 (0.95) | 0.42 (1.10) | 3.033** |

Note: Independent sample T-test (2-sided) (Cluster 1 + 2 vs. Cluster 3)
† Coefficient is significant at the 0.10 level (2-tailed).
* Coefficient is significant at the 0.05 level (2-tailed).
** Coefficient is significant at the 0.01 level (2-tailed).
***Coefficient is significant at the 0.001 level (2-tailed).

In Table 2, the relative interactions within and between clusters are illustrated, whereby we correct for the total number of each of the three profiles of motivation within a virtual network. Both cluster 1 and 2 differ significantly from cluster 3 using an independent sample T-test with the exception of sent outside own cluster and received from outside own cluster. For all cluster 1 learners in the six networks, this implies that on average 0.62 messages are sent to each of the cluster 1 learners. At the same time, on average 0.97 messages are sent by cluster 1 learners to each learner outside their own cluster. That is, cluster 1 learners send on average 56% more messages outside their cluster and this difference is significant at 10% ($T = -1.768$, $p < 0.10$) in a paired-samples T-test. At the same time, cluster 1 learners receive 68% more external messages from outside their cluster than from inside their cluster and this difference is again significant at 10% ($T = -1.883$, $p < 0.10$) in a paired-samples T-test. Therefore, both sent to and received from measures indicate that cluster 1 learners are mainly focussed on communication with learners outside their own cluster, implying that the motivation profile has an influence on whom cluster 1 learners are connected to. In other words, we find support for hypothesis 2 that extrinsically motivated learners are more likely to interact with intrinsically motivated learners than with extrinsically motivated learners.

Cluster 2 learners (medium intrinsic, low to medium extrinsic motivation) send about an equal amount of messages to both within and outside their cluster. At the same time, they receive an equal amount of messages from within as well as outside their cluster. This implies that cluster 2 learners do not distinguish with whom they communicate. Thus, cluster 2 learners are connected to other learners within the social network as predicted by random graph theory (Barabási, 2002; Barabási & Albert, 1999; Erdős & Rényi, 1960).

Finally, cluster 3 learners contribute most actively to discourse in absolute and relative numbers. More messages are contributed to learners within the same cluster, namely 1.70 messages per learner in cluster 3. In contrast, only 1.04 messages are sent to each learner outside their own cluster. In other words, cluster 3 learners are almost 40% more likely to send a message to their own cluster and this difference is statistically significant at 1% ($T = 4.326$, $p < 0.01$) in a paired samples T-test. In addition, the majority of the messages received by learners in cluster 3 originate from their own cluster ($T = 2.748$, $p < 0.05$). If we subtract the average number of contributions sent to external clusters (1.04) from those received from external clusters (1.40), we find that the communication of cluster 1 and 2 members is more strongly directed to cluster 3 members than vice-versa, and this difference is significant ($T = -3.879$, $p < 0.01$) in a paired-samples T-test. Hence, the stronger extrinsically motivated learners, and the learners with a less outspoken motivational profile, are connecting primarily to the intrinsically motivated learners, which supports hypothesis 2. Last but not least, intrinsically motivated learners are the most active contributors to discourse, but, in agreement with hypothesis 3, are contributing mostly with learners having similar motivational profile.

## Discussion

The results of the present study indicate that in our settings learners connect to other learners in their virtual network depending on their motivation profile. We find evidence that learners with high intrinsic motivation receive a relatively large amount of contributions from learners with other motivational profiles. At the same time, intrinsically motivated learners themselves are focussing more on discourse with other intrinsically motivated learners. These findings indicate that in distance learning settings interaction patterns amongst participants and evolutions of social networks of virtual networks do not develop randomly. In fact, we find that highly extrinsically motivated learners are more likely to connect to intrinsically motivated learners than vice versa. A new feature is that we are able to link the position of the learner in the virtual network to his/her motivational profile. Most extrinsically motivated learners seem to be stronger connected to intrinsically motivated learners than vice versa.

These findings might have important consequences for instructional designer and online teachers (Mishra & Koehler, 2006; Wang, 2009) as we find support of the idea that in distance learning settings learners prefer to interact with learners who are highly intrinsically motivated (Martens et al., 2004; Rienties et al., 2009). This implies that learners strong in intrinsic motivation, who due to the nature of distance learning already have an advantage over other learners (Rienties et al., 2009), will in the duration of the course be further stimulated by extrinsically motivated learners as well as other intrinsically motivated learners that are keen to link to them. By receiving more contributions from others to initiated discourse (in particular from intrinsically motivated learners), they can exchange more knowledge and receive more feedback than learners with low intrinsic motivation who receive little contributions from others. In a way, it seems like a self-fulfilling prophesy: active contributors to discourse receive further encouragements from others to continue, while these active contributors at the same time interact mostly with other active contributors rather than learners on the outer fringe of the network. Therefore, intrinsically motivated learners appear “well-suited” for our distance learning setting and continuously receive acknowledgements from other learners (Martens et al., 2004). Given that many educational psychologists have found that learners who are actively co-constructing knowledge eventually have a deeper learning experience (Hmelo-Silver, 2004; Järvelä et al., 2008; Van den Bossche et al., 2006), receiving a lack of reply on contributions might have a negative impact on learning for extrinsically motivated learners. As a result, extrinsically motivated learners receive less feedback and stimuli from others, which might further decrease their integration within the virtual network.

The role of the teacher in designing a challenging and interactive learning environment (Mishra & Koehler, 2006; Wang, 2009) for all types of learners seems to be a prerequisite for interactive learning for all learners. Furthermore, a helpful tool for teachers to understand the complex dynamics of social interaction is to use the insights from motivational science to enhance learning. We suggest that teachers ask their students to fill in a motivation questionnaire before the beginning of the course. This can for example be the Academic Motivation Scale developed by Vallerand and colleagues (1992) or the Quality of Working in Groups Instruments developed by Boekaerts and Minnaert (2006). The results can be used to assess what type of motivated learners teachers have in their course and to actively stimulate students who are less active in discourse.

## Limitations

The results of this study were based on a k-means cluster analysis on learner self-scores for a questionnaire on academic motivation, which was afterwards linked to the social network of each virtual network using Social Network Analysis. This can be viewed as a potential limitation to this study as a self-reported measurement of academic motivation was used with obvious limitations. However, the patterns of interaction among the three identified motivational profiles follow the anticipated direction. In addition, research by Vallerand and colleagues has found that the AMS instrument is a robust predictor of learning outcomes and academic performance. As a second limitation, the long-term consequences on learning outcomes have not been demonstrated. However, our longitudinal analysis of learning outcomes among summer course participants indicate that active summer course participants outperform others in the first year of their bachelor programme (Rienties, Tempelaar, Dijkstra, Rehm, & Gijselaers, 2008). A third limitation of this study is that no measures were taken to prevent self-selection in the summer course programme. In our setting, which matches the practice teachers in online settings are confronted with (i.e. networks with a mix of various types of motivated learners), we did not balance networks based on a pre-determined mix of motivational types. We established that the proportion of cluster 3 learners amongst summer course participants is indeed somewhat higher than the proportion in all freshmen, yet cluster 1 and cluster 2 learners are not statistically significantly underrepresented in our subsample. So selection effects, if present, are of limited size.

### Future Research and Implications for Education

Based on our findings, we will redesign the learning environment to capitalise on the merits of social interaction, peer-support and planning of learning processes. By increasing social presence in our virtual learning environment by using Web 2.0 tools like wiki's and web-videoconference, we hope to increase the relatedness among learners, which has shown to increase the internalisation of motivation regulation (Ryan & Deci, 2000). Socio-emotional support is an important factor in relational development of networks. In particular in CMC environments, socio-emotional communication is not an automatic artefact. These findings are relevant for teachers, managers, admission officers and schedulers as the results imply motivational orientation has a moderately strong influence on the type of discourse and position within the social network. Social Network Analysis tools can be used to assess who is contributing actively to discourse and can be used as a tool for teachers to identify learners on the outer ring of the social network. Appropriate strategies to deal with various types of motivation should be designed to assist each type of learner.

**Abstract:** We described and compared 94 pre-service elementary teachers' epistemologies during three different activities: one semi-structured interview, an asynchronous on-line discussion about a physics problem and their reflection on the discussion of the second activity. Using discourse-based analysis, we analyzed the data in terms of the teachers' underlying epistemologies and findings revealed significant differences across the three activities. This suggests that (a) teachers' epistemologies might be better understood as finer grained cognitive resources whose activation is sensitive to the context, unlike most research which views them as coherent and stable cognitive structures, and that (b) the research community is far from settling the debate as to what particular approaches should be used to assess or study personal epistemologies. Depending on the context and the manner of investigation, students and teachers may "show" different epistemological understanding.

## Introduction

Current science education standards (NRC, 1996; 2007) argue that inquiry should be a central strategy of science instruction, partly because that inquiry can be a dynamic way for helping students to develop sophisticated understanding of the nature of science (NOS) or sophisticated scientific epistemologies. Epistemology is a term used differently by philosophers and psychologists (Sandoval, 2005). For the purposes of this paper we take scientific epistemologies to mean the individual's understanding of or views about the nature and characteristics of scientific knowledge and its construction, including the sources of scientific knowledge, its truth value and what constitutes scientifically appropriate warrants, and science as a way of knowing and its values inherited in the development of the scientific knowledge (Abd-El-Khalick & Lederman, 2000; Abd-El-Khalick et al., 1998; Lederman, 1992). The development of sophisticated epistemologies has been a central component of scientific literacy for some years (AAAS, 1993; NRC, 1996).

However, this agenda has been slow to become established in instructional practice for a number of reasons. First, despite a wide consensus for the importance of developing epistemological awareness in science among learners, the education community has yet to agree on precisely how this awareness is developed, how epistemological knowledge is developed and in what form (Louca et al, 2004). Most research on personal epistemologies has assumed they consist of developmental stages or beliefs and thus can be explicitly taught and developed (van Driel et al., 2001; Olson, 2007). Others have advocated a structure of epistemologies that consists of units of cognitive structure at a finer grain size than stages or beliefs, suggesting that it is not really a matter of developing new knowledge constructs, but a matter of organizing a network of existing epistemological resources (Louca et al, 2004; Hammer & Elby, 2002). Second, there is no consensus regarding the methodological approaches used to study students' epistemologies (Sandoval, 2005). One approach has argued that students' epistemologies can be directly investigated, e.g., via interviews (Van Driel et al., 2001). A second approach has suggested that students' personal epistemologies are manifested through practice, and, thus, practice is the only way of studying them (Sandoval, 2005; Richardson, 1996). These ambiguities have resulted in a rather fragmented picture of students' epistemologies, with often contradicting findings and frequently students' practices of inquiry appear to share much with scientific practice but their expressed epistemologies are naïve (Sandoval, 2005).

Our purpose in this paper was to investigate 94 pre-service elementary teachers' epistemologies while engaged in three different activities. The differences among these activities refer to the context in which we investigated their expressed or enacted epistemologies. Firstly, participants were prompted to talk about their personal epistemologies during an individual interview. Secondly, they were asked to "enact" science, by talking about a physics topic on relative motion through an online discussion (without specifically talking about their personal epistemologies). By enactment, we refer to the participants' efforts to reach a consensus about a problem related to relative motion. In some cases this involved students trying out experiments and reporting them to the group or debating various points of view. Thirdly, they were asked to reflect on their enactment of science during the second activity by debating whether their discussion was scientific or not – thus, prompting them to reflect on the NOS underlying their discussion of relative motion.

## Theoretical framework

### Current views of NOS

Traditionally, science has been presented to students as a rigid body of facts, theories, and rules to be memorized and practiced, rather than a way of knowing about natural phenomena (van Driel et al., 2001). The learning of correct answers, memorizing of information, rote learning, and reading were central components of the exploration of questions, critical thought, understanding in context, argument, and doing science. In this view, teaching science assumed that an already developed body of knowledge, one generally accepted by the scientific community, could be transmitted to students through passive instructional means (Tobin, Tippins, & Gallard, 1994).

To an increasing extent this approach has become the subject of criticism among policy makers, teachers, educators, and researchers (e.g., Tobin et al., 1994). This approach has been related to the decreasing popularity of science among students (van Driel et al., 2001). Furthermore, research on students' scientific epistemologies has demonstrated that students exposed to this approach often end up with a poor understanding of scientific concepts (van Driel et al., 2001). Moreover, science education in its traditional form fails to adequately prepare future citizens to understand science and technology issues in a rapidly evolving society (Millar & Osborne, 1998).

Recently, modern views of NOS suggest that scientific knowledge is (a) tentative (that is, subject to change), (b) empirically based (that is, testable), (c) subjective (and thus, not absolute), (d) creative, (e) socially and culturally embedded, (f) unified, (g) amoral, (h) parsimonious (scientific knowledge attempts to achieve a simplicity of explanation as opposed to complexity), and (i) differentiates between observation and inference (Abd-El-Khalick, Bell, & Lederman, 1998). In this sense, scientific knowledge is based on observations from the natural world and reflects human attempts to impose order on the understanding of nature and explain the mechanism underlying the physical phenomena.

Reform documents (e.g., AAAS, 1990; NRC, 1996) and researchers (e.g., Lederman, 1992; McComas & Olson, 1998) have advocated that there are several elements of NOS that should be communicated to students in order for them to become scientifically literate. Thus, aspects of NOS are crucial to guide the current assessment of individuals' understandings of NOS, because they are not contentious, they are developmentally appropriate for K–12 students, they are learnable by K–12 students as indicated by empirical research, and they are arguably important for all high school graduates to know. Consequently, the objective of helping students (and teachers for that manner) to develop understandings of NOS is one of the most common objectives for science education (Abd-El-Khalick, Bell, & Lederman, 1998).

### Views about the nature of scientific epistemologies

Disagreements about the tenets of NOS exist at a general level among scientists, science educators, historians and philosophers of science. Despite these disagreements, there is a widely shared view which suggests that individuals' epistemologies have a developmental aspect and that these are learnable throughout K-12 (Abd-El-Khalick & Lederman, 2000). This perspective presents the development of epistemologies as developmental stages somewhat resembling cognitive development as conceptualized e.g., by Piaget (1967). For instance, in the seven-stage scheme of King and Kitchener (1994), children initially view knowledge as comparatively certain and gained from authority or direct observation. From there they progress to relativist stages in which they view knowledge as constructed and different viewpoints as valid. Finally, some reach expert stages in which they see knowledge as constructed yet subject to scrutiny, judgment, and synthesis. Invoking more recent developmental theorists such as Fischer's (1980), King and Kitchener (2004) adopt a "complex stage theory" in which a typical subject's epistemology is like a wave spread over two stages.

A second perspective suggests that students' epistemologies are not a unified whole. Following a growing set of studies that suggest that students' epistemological views of science are not stable coherent frameworks, but inconsistent, fragmented and possibly unstable beliefs, this perspective deals separately with each different dimension of NOS, such as, structure, certainty and source of knowledge (Hofer & Pintrich, 1997). It suggests that learners' epistemologies along each dimension are assumed to consist of semi-independent beliefs, implying that a student could hold sophisticated views about the structure of e.g., physics knowledge, seeing it as a hierarchy of concepts rather than a collection of equations, while also holding naïve beliefs about the certainty of that knowledge, viewing new theories as fixed and absolute. In Leach et al.'s (2000) study, students' responses to decontextualized and contextualized open-ended survey items that asked them to reason about the relation between theory and data were found to be inconsistent across the two contexts. Sandoval and Morrison (2003) interviewed a sample of high school students before and after a month-long intervention and found that both individual students' responses to different questions reflected different epistemological levels, and that student responses were not stable across interviews (nor predictable). According to this perspective, views about NOS consist largely of comparatively stable, robust cognitive structures corresponding to articulate, declarative knowledge. These epistemologies are taken to be the units of views about NOS (Schommer-Aikins, 2004). Some researchers view epistemological beliefs as comparatively global (Schommer, 1990), while others have investigated how epistemological beliefs vary by discipline, e.g., in chemistry vs. psychology (Hofer, 2002a). What they all agree upon, however, is that epistemologies consist largely of comparatively stable, robust cognitive structures corresponding to articulate, declarative knowledge.

Hammer and colleagues (Hammer & Elby, 2002; Louca et al, 2004) have proposed a third perspective, suggesting that personal epistemologies are made up units of cognitive structure at a finer grain size than stages or beliefs, which they call resources. Rather than attribute to individuals any general epistemological theories or beliefs, they understand them to have a range of cognitive resources for understanding scientific knowledge and its nature. They suggest that the difference between naïve and expert epistemologies lies not just in the content (views), but also in the form of the relevant cognitive elements. Other studies show that students often hold inconsistent epistemologies which emerge in different contexts (Hammer, 1994; Roth & Roychoudhury, 1994; Solomon, Duveen, & Scott, 1994). There is also some evidence for fragmented epistemologies from those studies that have been unable to assign large portions of students to a single epistemological "type" (Khishfe & Abd-El-Khalick, 2002; Linn & Songer, 1993). In this sense, a teacher's professed epistemology, for example, her stated views about knowledge and learning, may possibly differ substantially from her enacted epistemology, the views about knowledge and learning an observer would infer from her classroom behavior (Hofer, 2002b; Tobin & McRobbie, 1997), suggesting that it could be a matter of different resources being activated in different contexts – that of an interview and of teaching contexts (e.g., Louca et al., 2004; Leach et. al, 2000; Roth & Roychoudhury, 1994; diSessa, Elby, & Hammer, 2002).

## Novice teachers' epistemologies

A large number of studies have indicated that teachers' epistemologies influence their teaching and their students' learning to a great extent (AAAS, 1993; NRC, 1996). As a result, researchers have investigated teachers' epistemologies, in addition to developing programs that seek to improve them (e.g., Abell & Smith, 1994; Palmquist & Finley, 1997; Abell et al., 2001). Many of these studies were consistent in showing that teachers (both in-service and pre-service) possessed naive scientific epistemologies (e.g., Abd-El-Khalick & BouJaoude, 1997).

Moreover a number of these studies has provided insights about how novice teachers (pre-service and early-career teachers) encounter teaching and their ability to reflect on practical experience (Penso, Shoman, & Shiloah, 2001), how science teachers' views about science and science teaching influence their classroom practice (Brickhouse & Bodner, 1992) and how induction programs are essential in addressing the pedagogical and content needs of science teachers (Luft, Roehrig, & Patterson, 2003). Other studies have documented the nature and persistence of pre-service teachers' epistemologies. For instance, many pre-service teachers think of teaching as passing on knowledge, and learning as absorbing and memorizing knowledge (e.g., Calderhead & Robson, 1991). When they imagine themselves teaching, pre-service teachers often picture themselves standing in front of a group of attentive students presenting information, going over problems and giving explanations. A significant proportion of teachers believe that scientific knowledge is not tentative, and hold a positivistic, idealistic view of science (Lederman, 1992).

## The relationship between teachers' views of NOS and classroom practice

Research concerning improving teachers' epistemologies has followed the assumption that teachers' epistemologies directly transfer into their classroom practices (Lederman, 1992). In other words, it is assumed that studying teacher practices can help understand their epistemologies (Sandoval, 2005), and that improving teachers' epistemologies is sufficient for promoting "effective" NOS instruction in science (Lederman, 1992).

However, through a range of studies, it is currently understood that the relationship between teachers' epistemologies and their classroom practice is more complex than originally assumed. Several factors have been identified to mediate and constrain the translation of teachers' epistemologies into practice. These factors include pressure to cover content (Abd-El-Khalick et al., 1988; Hodson 1993), classroom management and organizational principles (Hodson, 1993), concerns for student abilities and motivation (Brickhouse & Bodner 1992; Lederman, 1999), institutional constraints (Brickhouse & Bodner, 1992), teaching experience (Lederman, 1999), discomfort with understandings of NOS, and the lack of resources and experiences for assessing student epistemologies (Abd-El-Khalick et al., 1998).

Research on the translation of teachers' epistemologies into classroom practice indicates that even though these can be thought of as a necessary condition for promoting the development of students' NOS understanding, these epistemologies should not be considered sufficient (Lederman 1992). This may suggest that research efforts should concentrate beyond simply identifying teachers' professed epistemologies, to investigating their translation into enacting (or practical) epistemologies as they appear during everyday teaching. By teachers' practical epistemology we refer to the set of epistemologies about ones' own knowledge production in school science, including what knowledge is, the methods through which knowledge can be produced, and the criteria for evaluating knowledge claims, which are reflected in the epistemic decisions people make during the construction and evaluation of scientific knowledge (Sandoval, 2005).

All these issues raise three questions about teachers' scientific epistemologies and their development. First, the nature of epistemologies remains somewhat unclear; whether epistemologies are organized in coherent frameworks, or are fragmented beliefs or finer-grain resources. Second, the specific epistemologies that guide teachers' practices are largely unknown. Third, the relation of these practical epistemologies and teachers' expressed epistemologies are not well articulated. Given the discrepancy between what teachers seem able to do and the difficulty they have in articulating epistemological aspects of formal science, it seems more likely that epistemological beliefs are contextualized rather than coherent frameworks (Hammer & Elby, 2002).

Our purpose in this paper is to contribute specifically to these needs: to investigate teachers' expressed and practical epistemologies through multiple data sources. The differences among these data sources refer to the context in which we investigated their expressed or enacted epistemologies. Thus, we compare 94 pre-service teachers' expressed epistemologies as revealed through an interview, their practical epistemologies underlying a discussion about relative motion, and their epistemologies underlying a reflective discussion about whether their science enactment in the relative motion discussion was scientific or not.

## Methodology

The present study was interpretive in nature and focused on the epistemologies that participants held, expressed or underlay their actions in the three aforementioned tasks. Ninety-four pre-service elementary teachers participated in this study. All participants were enrolled in a science methods course in the same semester (separated in two groups), taught by the first author. The data collection took place at the very beginning of the course (during the first three weeks), prior to any intervention and discussion about NOS characteristics.

Data sources consisted of three different activities. For the first activity we randomly selected 47 out of the 94 pre-service teachers of the study, whom we interviewed individually about their views concerning NOS. All interviews were conducted by the second author, using a semi-structured protocol which focused on three areas, namely, demographics, views about science and about teaching science. The first part of the interview focused on identifying pre-service teachers' experiences with science from both pre-university and university studies. The second part of the interview aimed at identifying pre-service teachers' epistemologies (for instance, we asked them what is Science for them; under what conditions is something scientific; and what does the term "experiment" mean to them). The third part of the interview focused on investigating pre-service teachers' views about science teaching. For instance, we asked them what they thought the goal of Science education is; about the role of a teacher during a science lesson; and what they thought the components of a "good" science lesson are. Finally, interviewees watched a short video clip from a science lesson and were asked to comment about the ways they might respond to students' ideas and reasoning, had they been the teacher during this lesson.

For the second activity, all 94 teachers had an online, asynchronous threaded discussion about relative motion. We randomly assigned pre-service teachers into groups of 10 or 11 participants and provided them with a question on relative motion: A person is running, holding a set of keys in her hand, which she holds still next to her body. What would happen to the keys, if she let go, while still running? We asked each pre-service teacher to have at least one posting of her own answer to the question, respond to at least three other group-mates' answers, respond to all the comments she received for her own postings, including her answer to the initial question, in an effort to reach consensus about the answer to the question, after discussing this with the rest of the members of her group. The pre-service teachers had a week in which to reach a consensus. A total of 341 posts were made by the 94 teachers which reflected an average of 80 words per post, and all groups of students were close to, or reached consensus. The third activity was also an online, asynchronous threaded discussion, carried out by the same groups of pre-service teachers as above. This occurred immediately after the second activity and also lasted for a week. In this activity, pre-service teachers had to reflect on the discussions they had during the second activity, in an attempt to discover whether that discussion was scientific or not. A total of 359 posts were made by the 94 teachers, which reflected an average of 105 words per post.

All interviews were transcribed and along with all threaded discussions served as the primary sources of data. We analyzed all data using a discourse-based analysis focusing on three particular aspects of NOS: (a) what is science (b) what is the result of science and (c) what is scientific knowledge? Categories for this analysis were drawn from the literature we have described in the theoretical framework of the paper. Some categories identified in the literature were not observed in our data and thus are not part of our coding scheme. The final categories that we used for each aspect of NOS were organized in an ordinal scale based on their sophistication. Each teacher's postings for a particular discussion were analyzed separately and coded in terms of the underlying ideas about the three aspects of NOS. The same was done with each participant's interview. In all cases, each teacher's postings or interview was assigned with only one code for each of the three aspects of the

NOS. All codings were carried out independently by the first and the second author (Cohen's Kappa=0,84), and differences were resolved through discussion.

We used descriptive statistics to compare teachers' views about the result of science, science as a process and the scientific knowledge from the three different contexts. Lastly, the non-parametric Wilcoxon Signed-Rank Test was applied to test for significant differences in teachers' views among the three data sources (contexts). The test was applied only to the 47 pre-service teachers from whom we had data from all three contexts.

## Findings

Findings revealed considerable differences among teachers' epistemologies about NOS in the three contexts (see Table 1). Activity 1 will be referred to as "interview," activity 2 as "enacting science" and activity 3 as "reflection."

Table 1. Differences between teachers' epistemologies about NOS

| Codes | Interviews | Enactment | Reflection |
|---|---|---|---|
| *A. Science* | | | |
| *i. The result of science:* | | | |
| 1. improves life quality | 14.3% | 0.4% | 0% |
| 2. is a number of laws that govern the physical world | 5.7% | 83.9% | 8.6% |
| 3. provides answers to questions about physical phenomena | 20.0% | 0% | 0.8% |
| 4. is an interpretation of everyday physical phenomena | 60.0% | 15.7% | 90.6% |
| *ii. Science (as a process) is:* | | | |
| 1. a process of memorizing scientific facts | 0% | 0% | 0% |
| 2. a process of observations and experimentation | 45.7% | 17.6% | 43.2% |
| 3. a process of investigating, accepting or rejecting theories or hypotheses | 54.3% | 82.4% | 56.8% |
| *B. Scientific knowledge is:* | | | |
| 1. absolutely true (there is only one answer) | 20.0% | 5.3% | 10.5% |
| 2. how each individual understands the truth about the physical world | 5.7% | 77.5% | 33.7% |
| 3. the most commonly accepted answer to questions about the physical world | 5.7% | 9.0% | 47.1% |
| 4. the knowledge we learn from experimentation | 54.3% | 4.1% | 6.2% |
| 5. a truth that might change in the future | 14.3% | 4.1% | 2.5% |

### Pre-service teachers' epistemologies related to what is science

When "enacting science" most of the pre-service teachers (83.9%) felt that the result of science consists of a number of laws that govern the physical world. This idea appeared less often in the interviews (5.7%) and in the reflections (8.6%). During the interviews, pre-service teachers suggested that science improves quality of life (14.3%) and provides answers to questions about physical phenomena (20.0%); these ideas did not appear during the two online discussions. During the interview and the reflection, the majority of the teachers felt that scientific knowledge is an interpretation of everyday physical phenomena (60% and 90.6%, respectively), an idea which did not appear as often when teachers enacted science (15.7%).

### Pre-service teachers' epistemologies related to what is the result of science

During the interviews, pre-service teachers described science as a process of observation and experimentation (45.7%). Similarly, this idea appeared in teachers' reflections (43.2%), while only 17.6% of the pre-service teachers seemed to use this idea while enacting science. When enacting science, most of the pre-service teachers (82.4%) seemed to view science as the process of investigating, accepting or rejecting theories. However, during their reflection and the interview, only about half of the pre-service teachers (56.8% and 54.3%, respectively) seemed to view science as such. The other half (43.2% and 45.7%, respectively) viewed science as a process of observation and experimentation. None of the teachers appeared to see science as a process of memorizing scientific facts during the three activities.

### Pre-service teachers' epistemologies related to what is scientific knowledge

While enacting science 77.5% of the pre-service teachers felt that scientific knowledge reflects how each individual understands the truth about the physical world, whereas, during the reflection fewer teachers (47.1%)

seemed to understand scientific knowledge as the most commonly accepted answers to questions about the physical world. During the interview more than half of the teachers (54.3%) indicated that scientific knowledge is what we learn from doing experiments. This idea appeared less during the rest of the activities. Moreover, during the interview 20,0% of the teachers seemed to understand scientific knowledge as absolutely true, but less seemed to do so during their reflections (10.5%) and even less when they enacted science (5.3%). Similarly, during their interviews 14.3% of the pre-service teachers described scientific knowledge as a "truth" that might change in the future, an idea observed much less during the enactment of science (4.1%) and the reflection (2.5%).

### Comparison of pre-service teachers epistemologies across the three contexts

Overall, the Wilcoxon Signed-Rank Test indicated that the pre-service teachers' epistemologies for each of the three aspects of NOS investigated were statistically significantly different across the three contexts. Specifically, the pre-service teachers' epistemologies about the result of science differed significantly among all three contexts ($p<0,001$ across all comparisons). In terms of what science is, pre-service teachers' epistemologies during the interview and the reflection were not found to differ significantly, but both were found to differ significantly from the enacting science activity ($p<0,001$ across all comparisons). Finally, the findings concerning what scientific knowledge is, revealed that all the contexts were significantly different ($p< 0,001$ across all comparisons).

## Discussion

The aim of this study was to investigate and describe pre-service teachers' epistemologies from three different data sources reflecting three different contexts. Findings revealed statistically significant differences of the pre-service teachers' epistemologies among the three contexts investigated, which raises two issues.

The first issue is related with the nature and/or the development of epistemological understanding. Our findings, along with a number of other studies (Hammer, 1994; Roth & Roychoudhury, 1994; Solomon, Duveen, & Scott, 1994; Hammer & Elby, 2002; Louca et al, 2004) contend that personal epistemologies seem to be better understood as fine-grain cognitive structures that are activated depending on the context in which the activation takes place. Asking teachers about their views of NOS or inferring those views from their enactment in science or their reflections seem to invoke statistically different epistemological resources, which they use to explain, understand or respond to a particular situation.

The fact that the differences among the three contexts are not similar in terms of the three areas of NOS that we have investigated (what is science, what is the result of science and what is scientific knowledge), has another important implication. It suggests that viewing personal epistemologies as semi-independent beliefs (Hofer & Pintrich, 1997; Schommer-Aikins, 2004) cannot explain these differences. The teachers' epistemologies investigated in this study, differ among the three contexts, but the differences in the three areas of NOS investigated are not similar among the three contexts. Teachers' epistemologies are not only different across contexts, but there is also a variation of those differences within the various contexts. For instance, pre-service teachers' views about science as a process are similar between the interview and the reflection. However, the same teachers' views about the nature of scientific knowledge are statistically significantly different in the two contexts. Thus, we suggest that our findings indicate that even within a particular area of NOS, the same pre-service teachers hold multiple epistemological resources, which they activate based on context. Thus, attributing robust epistemologies developed into coherent theories (McComas, 1996; Sandoval & Morrison, 2003) to pre-service elementary teachers is definitely inappropriate.

The second issue is related to the debate that exists in literature about the approaches of studying personal epistemologies (Sandoval, 2005). Assessments of formal science tend to ask students to express their views about the nature of scientific knowledge and activity, including questions about what scientists do, what theories are, how theories and experimentation influence each other and so forth. The general picture from such studies is that students' ideas about formal science follow a developmental trajectory toward increasing sophistication throughout adolescence (e.g., Leach et al., 1997), but tend to remain fairly naïve even during university instruction. Our findings show a similar picture, which we feel suggests that the research community is far from settling the debate as to which particular approaches should be used to assess or study personal epistemologies. Depending on the context and the manner of investigation, students and teachers may "show" different epistemological understanding. One suggestion is that, the research community may choose to follow a multiple-data-source approach when studying personal epistemologies.

Finally, disagreeing with the suggestion that it is an academic issue whether teachers' epistemologies are necessarily reflected in their classroom practice (Lederman, 1999), an implication stemming from our findings is that methodological effects might be possible. The ideas teachers express, explicitly or implicitly, may differ depending on the situation in which they are engaged. For example in the context of an interview, teachers may report views they believe they hold, whereas when they enact science, or reflect back on their enactment they may reveal "alternative" views. In the interview context, the teachers self-report views they think they hold about an issue, which are often influenced by social desirability. While enacting science their conceptions will be interpreted by independent coders and are possibly influenced, not only by what they have been taught about science, but also by their experience with science in formal informal learning contexts. Consequently, we propose that a broader account of personal epistemologies should include investigations with methods that are not limited to questionnaire surveys and interviewing.

# Exploring how novice teachers learn to attend to students' thinking in analyzing case studies of classroom teaching and learning

Daniel M. Levin, American University, 4400 Mass Ave., NW, Washington, DC 20016, levin@american.edu
Jennifer Richards, University of Maryland, College Park, College Park, MD 20742, jrich@umd.edu

**Abstract:** In this paper, we explore how candidates in a science teacher preparation cohort attend to the substance of student thinking while watching classroom videos or reviewing students' written work. Our findings suggest that the teacher candidates are able to attend to specific student ideas and reasoning from the beginning of their pre-service preparation, but their practices of attending become more sophisticated over time. We also consider participation dynamics within the cohort, as participants assume different roles and begin to regulate their discussions.

## Introduction

The National Research Council (NRC) (2007) characterizes students' science learning in terms of knowledge and use of conceptual content, reasoning abilities, epistemological understandings, and participation in scientific practices. In line with the NRC's conceptualization of science education reform, it is suggested that "proximal formative assessment" (Erickson, 2007), as it refers to teachers' ongoing, everyday attention to the substance of students' ideas, plays an important role in shaping teachers' instructional moves and supporting students' science learning across these strands (Atkin & Coffey, 2003). We believe that an important focus for science teacher education is thus to help novice science teachers learn to attend to the substance of student thinking, interpreting the meaning students are trying to convey.

This paper is our effort to document what happens in our science pedagogy program, which takes as a specific aim the development of teacher candidates' practices of attending to the substance of student thinking while examining records of classroom practice. We report results from the first two semesters in the science pedagogy course sequence, focusing our inquiry on three questions:

- What do our teacher candidates attend to when discussing records of classroom practice?
- How do our candidates attend to student thinking?
- How do practices of attending to student thinking develop over time within the cohort?

## What teachers notice in records of classroom practice

We refer to practices of "attending" to student thinking, but our work is similar to a body of literature primarily in mathematics education that uses the term "noticing." The noticing literature is explicitly focused on the substance of student thinking, responding to reform documents in both mathematics and science education (NCTM, 2000; NRC, 2007) that call for teachers to "base their instruction on the lesson as it unfolds in the classroom, paying particular attention to the ideas that their students raise" (van Es & Sherin, 2008, p. 244). Several scholars (Hammer & Schifter, 2001; Jacobs, et al., 2007) argue that professional development and teacher education aimed at focusing teachers' attention on the substance of student thinking is crucial for teacher learning; it is assumed that helping teachers notice students' ideas when exploring records of practice like classroom videos (e.g., van Es & Sherin, 2008) and samples of student work (e.g. Kazemi & Franke, 2004) will amplify teachers' tendencies to do so in their own classrooms. For the purposes of this paper, we are focusing on the teacher education setting, but we take up the issue of connections between teacher education and teachers' classroom practices in our discussion.

Little research has been conducted on pre-service teachers' practices of attending to student thinking, but Carter et al. (1988) suggest that novice teachers' abilities to notice student thinking are poorer than experienced teachers' abilities. Theoretically, lacking any experience in classrooms, new teachers have more difficulty hearing and interpreting student ideas in the classroom than experienced teachers do. However, in a more recent study in a pre-service secondary mathematics teacher education course, Star and Strickland (2008) found that teacher candidates generally did not enter the course with well-developed observation skills, but the course led to significant increases in these skills, particularly novice teachers' abilities to notice features of the classroom, mathematical content, and student thinking. Sherin and van Es (2005) have also shown that pre-service teachers can learn to attend to student thinking fairly quickly. Our current study contributes to the noticing literature and literature on pre-service teacher education by exploring what happens in a pre-service science teacher pedagogy course sequence focused on attending to the substance of student thinking.

## A framework for learning to attend to the substance of student thinking

Drawing on the noticing literature, and based on our iterative coding for this project (see the section on data analysis below), we describe in this section what we take as evidence of attending to the substance of student thinking. We also draw from other genres of literature, including physics education (diSessa, 1993; Hammer, Elby, Scherr, & Redish, 2005), cognitive science (Minsky, 1985), sociolinguistics (Goffman, 1974; Tannen, 1993), and anthropology (Lave & Wenger, 1991) to understand what it means to learn to attend to the substance of student thinking.

### Attending to the substance of student thinking

Three aspects of attending to student thinking are prevalent in the noticing literature; we have identified these aspects in this study as well, and we consider them to provide varying degrees of evidence of attending to student thinking. These three aspects include identifying students' ideas and reasoning, interpreting the meaning students are trying to convey, and evaluating the ideas and reasoning inferred from students.

Goodwin (1994) describes "highlighting" or identifying ideas as an important part of what practitioners in a field do. Identifying important ideas helps to "divide a domain of scrutiny in a figure and ground, so that events relevant to the activity of the moment stand out" (Goodwin, p. 610). We consider identifying important ideas to be a necessary precursor to attending to the substance of those ideas.

Once teachers identify important student ideas, Crespo (2000) distinguishes between teachers' comments that are evaluative and focused on correctness and those that are interpretive and focused on understanding. We believe that van Es and Sherin's (2008) definition of interpreting is closest to the meaning that we ascribe to the term. As van Es and Sherin state, "… we want to emphasize the importance of interpreting classroom events. Thus, how individuals reason about what they notice is as important as the particular events they notice" (p. 247). We speak of attending to the substance of student thinking in this strict sense – interpreting the meaning students are trying to convey, without simply evaluating the ideas. Thus, we take interpretive statements to be the best evidence that a teacher is attending to the substance of student thinking. Furthermore, we believe that interpretive statements are the most productive in professional development contexts or teacher education courses – when teachers identify and interpret specific student ideas in collaboration with others, they have the opportunity to argue about their interpretations of the ideas, which leads to better-warranted evaluations and proposed instructional responses.

It is important to note that we view these aspects of attending to student thinking as analytical tools that help us make sense of how candidates are attending to students' ideas and reasoning. We are not making claims that these are separate cognitive processes within teachers' minds. Our purpose in describing these components is simply to examine those aspects of attending to student thinking that the candidates make explicit.

### Learning to attend to the substance of student thinking

Our perspective for understanding how teachers learn to attend to the substance of student thinking draws from research on learning in physics. Hammer (2000) argues that students do not draw on nascent fully formed theories to reason in physics but rather that students employ small-grained, context-sensitive *resources* to do so. Hammer's framework builds on diSessa's (1993) description of phenomenological primitives or "p-prims," which are conceptual resources, based on learners' experiences with physical phenomena, which can be useful for learning physics. Hammer et al. (2005) have expanded the idea of resources to include fine-grained bits of declarative and procedural knowledge, metacognition, epistemology, and understandings of social norms that are derived from people's past experiences and activated in different situations.

Hammer et al. (2005) also suggest that in any moment, locally coherent sets of resources or *framings* are activated that are mutually consistent and reinforcing. Framing stems from a diverse history in cognitive science and sociolinguistics (Goffman, 1974; Minsky, 1985; Tannen, 1993). Here, we define framing as an individual or collective sense of "What is going on here?" Thus, framing involves an interaction between the contextual cues present in any given situation and the resources that various participants already have.

In any practice, which Wenger (1998) refers to as sustained engagement in a joint enterprise with shared tools, newcomers must learn relevant norms. Lave and Wenger (1991) describe the process by which newcomers learn these norms as "legitimate peripheral participants" (p. 29), which we take to mean that newcomers learn the framing of a particular practice through engaging and participating in that practice. We will argue that our teacher candidates draw on resources that they already have in order to participate in the practice of attending to student thinking. Additionally, by engaging and participating in this practice in various ways, the cohort establishes and reinforces a collective framing of attending to student thinking.

The language of framing has been used to understand how physics students frame what is going on in a particular context and how their framing is associated with their physics learning (Hammer et al., 2005); it has only been recently applied to secondary science pre-service teacher learning. Additionally, there has been little focus on how a framing of attending to student thinking is established and reinforced in a community of preservice teachers. We return to our framework in our conclusion to articulate how pre-service secondary science teaching candidates learn to attend to student thinking while watching video and looking at samples of student work.

## Research context and methods

Our data come from the first two courses of the three-course science pedagogy sequence in a one-year graduate-level initial teaching certification program at the University of Maryland, College Park. The course sequence is explicitly structured to draw teacher candidates' attention to the substance of student thinking, first by having them collectively examine records of classroom practice (videos and samples of student work), and then by having them collect and analyze such records from their own classrooms. During the first course (summer session), the teacher candidates identify frameworks for understanding students' science learning in the literature, interview students about science topics, engage in their own scientific inquiry, examine curricula for opportunities to draw out students' ideas and reasoning, and discuss samples of student thinking in classroom video and student work. The second pedagogy course (fall semester) continues these practices of examining and discussing samples of student thinking but goes beyond the first course in helping candidates develop instructional strategies consistent with science education reform and respond to student ideas as they arise during instruction. Candidates write lesson plans in which they anticipate what students might say or do and how they (as teachers) might respond instructionally. They then teach these lessons, collect student work or recordings of the class, and analyze the student thinking in evidence. The third course involves candidates in collecting data from their own teaching and writing case studies of the student thinking in evidence. Here, we report on data from the first two pedagogy courses – specifically on how the teacher candidates attended to the substance of student thinking in records of classroom practice.

### Subjects

The first course was comprised of eleven pre-service secondary science teacher candidates. Seven of these candidates were in a one-year program to earn a Masters degree and certification. Three were post-doctoral scientists pursuing certification only, and one was a former patent attorney who was pursuing certification only. In the second course, three additional candidates joined who were participants in an integrated bachelors/Masters program for certification. They had taken the initial pedagogy course the previous year as undergraduates. For the purposes of this paper, we primarily consider the candidates as a group. We discuss some differences among candidates in terms of their participation, but an in depth discussion of other differences is beyond the scope of this paper.

### Procedures

We shared eight cases of secondary science classroom work with the teacher candidates. Six cases were videos (20-45 minutes long) of secondary science classrooms with typed transcripts and/or captions. One of the videos was shown twice, as we discuss below. Two cases were collections of samples of student work. We selected all of the cases from a collection developed as part of another project (Levin, 2008); these cases will be included in a book/DVD package of teacher-authored case studies, similar to one produced for elementary teacher education (Hammer & van Zee, 2006).

As the instructor, Levin began the discussion of each case by describing the context in which the work occurred or by having the group read the introduction to the teacher's written case study. We then shared the video or student work with the group, and Levin asked, "What do you notice in the students' ideas and reasoning?" Levin facilitated the discussion to draw specific attention to the substance of students' ideas and reasoning. For example, if candidates made a general statement such as, "It seems like the students get it," Levin would say, "Can you point to something someone said or did that makes you think they get it?" Similarly, if candidates directed attention to the action of the teacher by suggesting what the teacher should do or describing problems with the teacher's approach, Levin would ask what they saw in the students' reasoning that led them to make that claim about the teacher.

### Data collection

We videotaped the candidates' discussions of student thinking in each of the cases. The discussions were each approximately 30-45 minutes in length. Due to the great variability among the cases, it was difficult to compare the cases in order to explore how the cohort's practices of attending to the substance of student thinking changed over time by looking at the progression throughout the cases. Thus, we showed the case we had shown at the beginning of the summer session again at the end of the fall semester in order to look at differences in how the candidates attended to the substance of student thinking at the beginning of the first course and at the end of the second.

### Data analysis

To explore our first question ("What do our teacher candidates attend to when discussing records of classroom practice?"), we drew on a coding scheme to categorize each speech turn, which was developed by inductive coding (Miles & Huberman, 1994) in a similar project with practicing teachers (Levin, 2008). We then developed our codes further through an iterative process of coding a sample of the discussions, discussing our codes, and expanding or collapsing codes as appropriate. In doing so, we developed a scheme that organized what candidates attended to into eight categories: specific student thinking, general student thinking, the actions of the teacher, the nature of the activity, the science content, student attributes, student engagement, and "other." We provide a detailed description of how we defined each of the codes in another paper (Levin & Richards, 2009), but the most important categories for our purposes in this paper are specific student thinking and general student thinking. We identify candidates' comments about specific student ideas or reasoning as attending to specific student thinking; for instance, we would code a statement like, "Maybe he's saying that they are practice for hunting – the snakes are just practice" as attending to specific student thinking. Alternately, we identify candidates' comments about the general understanding or reasoning of students in the class as attending to general student thinking (e.g. "I think most of them get it"). Levin coded all of the transcripts. Richards coded one third of the transcripts, and we compared our coding to arrive at an inter-rater reliability of 83%. We then discussed each disagreement until we reached consensus on the remaining codes.

To explore our second question ("How do our candidates attend to student thinking?"), we conducted another round of iterative coding, focusing only on the comments we had coded as attending to specific student thinking. As we previously described, we saw that candidates made three kinds of comments that we coded as attending to specific student thinking. At times, candidates 1) simply identified students' ideas, which we took as evidence that the candidates noticed the ideas, but we could not tell whether they attended to the meaning that the students were trying to convey. Candidates also 2) made evaluative statements in reference to students' ideas, which again indicated that the candidates were attending to the ideas that were present and perhaps making tacit interpretations of these ideas, but their interpretations (if present) were not made public. Finally, candidates sometimes 3) attempted to interpret what students were saying, which we took as the strongest evidence that they were attending to the substance of students' ideas. We did not take frequency counts of this coding because many utterances included overlapping codes at this level of analysis; instead, we considered how the three kinds of comments seemed to be related in candidates' statements. We explore the occurrences and relationships of these codes qualitatively in our data analysis.

To explore our third question ("How do practices of attending to student thinking develop over time within the cohort?"), we showed candidates the same case twice – once at the beginning of the summer session and again at the end of the fall semester. This case, hereafter referred to as the "Owls and Snakes," showed a teacher and students discussing a strange relationship between a species of owl and a species of blind snake that lives in the owls' nests undisturbed. We compared the initial coding of the first showing with the coding of the second showing. The discussions were slightly different in length, so we normalized the results by converting them to the frequency of codes uttered per 30 minutes of discussion. Both of us scored both transcripts completely, and we had 84% inter-rater agreement. Again, we resolved differences in coding by meeting and agreeing on the disputed codes.

We also looked across all of the case study discussions for patterns in the nature of the conversations and how participation in the norms and practices of attending to student thinking developed over time within the cohort. Specifically, we looked at who participated and how they did so over the course of the two semesters, how candidates drew each other's attention to specific student ideas, and how the role of the facilitator changed.

## Data and analysis

In this section, we present the results of our coding, followed by our analysis of the data and a discussion of the cohort's practices over time.

### Results and analysis of coding

We collected 995 coded passages over the course of nine discussions, including discussions of the eight cases plus the repeat of the first case. We coded 43% of utterances as specific attention to student thinking, 6% as general attention to student thinking, 18% as attention to teacher action, 9% as attention to the activity, 11% as attention to science content, 3% as attention to student attributes, 1% as attention to student engagement, and 6% as "other."

As we discussed above, it was difficult to make any claims about changes in what candidates attended to because of differences in the content of the cases. To look at changes, we led a discussion of the same case study at the end of the second course that we had discussed at the beginning of the first course and compared the changes in the frequencies of our coding. We only saw notable changes in the relative frequencies of attending to "specific" and "general" student thinking – the percentage of specific comments about student thinking (per

30 minutes) increased from 36% to 48%, while the percentage of general comments about student thinking decreased from 7% to 2%.

Thus, we can make two assertions related to our research questions at this point. First, our secondary science teacher candidates were able to attend to the substance of student thinking from the beginning of the pedagogy course sequence. Second, our candidates focused more on specific student ideas relative to general student ideas over time.

We saw that candidates consistently attended to the substance of student thinking from the beginning of the first pedagogy course. We coded almost half of all comments throughout the cases as "attending to specific student thinking," and our coding varied little across the cases in this respect. In terms of how candidates attended to student thinking, we saw that candidates routinely identified, interpreted, and evaluated students' ideas. At times, candidates made comments simply identifying a student's idea, and Levin followed up to ask what the candidates thought the student meant and what the candidates thought of the idea. Frequently, however, candidates specifically interpreted the student's meaning without prompting. These specific interpretations frequently led to sophisticated evaluations of students' conceptual understanding, reasoning, epistemological stances, and participation in scientific practices. Specific interpretations often occurred during long stretches of conversation that were about students' ideas and reasoning. For example, during an early case discussion in which candidates were discussing whether the students understood the relationships among force, mass, and acceleration when considering gravitational motion, Sarah, who was often one of the quieter students, identified an idea on a student's worksheet that she did not understand:

> Sarah: "I was confused by what she meant about inertia canceling out, like for, on page 2, when they talked about how... and not falling at the same time because their inertia's different?"
>
> Jack: "Well again I think that just mass, or heavier mass is less acceleration because they were just going back to that and less mass is higher acceleration."
>
> Alex: "It's interesting because on question 3 she -- at first the student states the right answer, they've got the concept that they land at the same time, and she understands that things that fall land at the same time, but then has trouble explaining why... she has this idea of the inertias canceling each other out, which indicates that she doesn't really have an understanding of what inertia is or how it applies in the case of falling objects."
>
> Jack: "Well again I think that goes back to their thinking the forces are the same, because she's saying 'the higher the mass the lower acceleration' versus 'a lower mass and a faster acceleration,' they are going to equal the same thing, so that's what she means, 'canceling out' -- they're gonna equal the same thing."

Here, Alex offered an interpretation of the student's thinking that she "has this idea of the inertias canceling each other out" and evaluated that she "doesn't really have an understanding of what inertia is or how it applies in the case of falling objects." Jack interpreted the student's idea more specifically, suggesting why the student might be thinking about "canceling out," which had not been obvious to everyone. As the conversation continued, Mark suggested another possible interpretation for what the student was thinking, and Elsa, Sarah, Ryan, and Alex debated Mark's interpretation, all drawing on the student's responses to other problems to debate what she might mean by "canceling out." This conversation about one specific student's thinking was followed by a discussion about how to teach the $F = ma$ formula more generally, including how to help students recognize different situations (e.g. when acceleration is constant versus when force is constant).

However, candidates often made general comments about student thinking early in the first semester. In the first discussion of the "Owls and Snakes" case, for example, we heard many general claims about what students understood or how they were reasoning. Candidates made declarative statements like "They were thinking out loud, and thinking logically;" "They're asking the right questions;" and "They're doing good stuff, they're reasoning, they're connecting their prior knowledge" without including interpretations of students' specific ideas to warrant their statements.

Candidates also made general comments about student thinking after long discussions of particular students' ideas. For example, in the "Owls and Snakes" case, the teacher presents the students with some data, which leads to an interesting argument about whether or not the data fits students' hypothesized relationship between the owls and snakes. During the first viewing of the case, candidates had a long discussion about particular students' ideas during this segment (including a number of comments we coded as "specific" student thinking), at the end of which Ryan made the following general claim:

> "I can see the students are, uh, doing something that I agree with, which is not assuming that just because there's data that indicates something, that that means that [the owls and snakes are] getting something out of it."

Here, we see an example of a general statement about student thinking, which is an evaluation that the students are doing something with which Ryan agrees. It differs from the other general statements above in that, following a conversation about specific student ideas and reasoning, it is grounded in the interpretations that candidates provided during the preceding conversation. Ryan was therefore able to specify what he liked about the students' argument – they did not assume that the data supported a particular answer.

When we looked at candidates' general comments in the second discussion of the "Owls and Snakes" case, we found that there were fewer general comments relative to specific comments. Also, the general comments were all of the kind that followed interpretations of specific student ideas and reasoning; none were the blanket evaluations we had seen in the first discussion. This kind of general claim about student thinking draws on specific interpretations of students' ideas and reasoning and can therefore provide novel and productive warrants for the evaluation of student thinking.

## Developing practices of attending to student thinking

In addition to exploring the content of what candidates attended to, we looked at how their participation in the conversations changed over time. In the earliest discussions, four candidates spoke the most in the discussions: Alex (the patent attorney), Brian and Elsa (post-doctoral scientists), and Ryan (an engineer by training). Alex in particular seemed to understand that the central aspect of the practice of attending to student thinking was to make claims about students' meaning by identifying specific things that students said. As we discussed above, Levin actively modeled this practice by asking candidates for specific examples. In the exchange below from the first "Owls and Snakes" discussion, we see Alex jumping in with an example even before Levin has finished asking for it:

> Ryan: "I thought it was a really impressive class."
>
> Levin (instructor): "Say more about that, why?"
>
> Ryan: "Because, uh, they were thinking out loud, and thinking logically, and the teacher was doing a great job of getting them to use reasoning."
>
> Levin: "So let's see if we can find – " (overlapping with Alex)
>
> Alex: (overlapping) "I like that distinction of that there's the good, the good maid and the bad maid, because the students are told there's a distinction, right, some snakes are eaten and some snakes aren't, there's eighty-nine percent that are alive and eleven percent that are dead, although they're not really told that they're eaten. Only one seems to be half eaten. So they're trying to immediately come up with a reason about why there are these two groups, why some snakes are alive and some snakes are dead and the reason that they come up with, well some are good at burrowing and cleaning up the nest and some are bad at this job and so they're eaten by the owls. At least that's an interesting reaction to being told there's two groups and they immediately come up with some mechanism, some reason, some logical reason to explain why there are two groups, why there are alive and dead snakes."

Throughout the case study discussions, Alex continued to identify examples of student thinking himself and to provide interpretations of others' examples to support evaluations. In some cases, he asked other candidates to support their statements with references to the transcripts or student work, asking several times "Where is that?" or "Where do you see that?" Alex appeared particularly comfortable with practices of interpreting students' meaning. Both in and outside of the pedagogy classes, Alex explained that his work as a lawyer helped him to focus on what people were saying.

Although Alex and some others dominated the conversations at the beginning, others began to participate within the first few case study discussions. By the second viewing of the "Owls and Snakes" case in the second pedagogy course, multiple candidates were participating in long conversations about student thinking without prompting from Levin. For example, Jack brought attention to a situation in the video in which a student, responding to a question from the teacher, said that a particular piece of data could be "used to evaluate" the students' hypotheses about the relationship between the owls and snakes. Jack thought that the student was just choosing one of the options the teacher had given him (can or cannot be used to evaluate the hypotheses) without thinking about it. Other candidates were not so sure. When the teacher asked the student, "What does it add that will help us answer the question?" the student replied:

> *"Uh, it could enter the nest on its own. The snakes are capable of climb, climbing up trees, and they can get to the nests on their own… and, if owls and snakes ever turn against each other, they could use that as an advantage for like, uhhh, battle and stuff."*
>
> Kay: "He's saying that the snakes are making the choice to go there. Like I…"
>
> Mark: "Right, that's what I read here."
>
> Kay: "Right, and then that's what's important about it to him…"
>
> Jack: "Right, so right. I see where that is important but I don't know if [he] understands that… he says, 'Yeah, they can climb trees'… but then line 23 I don't understand what he was meaning there because [he's] like, 'If they ever turn against each other they can use that to their advantage.'"
>
> Maria: "He probably means they could just climb back down to escape."

Kay interpreted the importance the student was placing on choice, but Jack questioned whether the student understood why it was an important idea. Maria interpreted the student's idea about why climbing trees was advantageous to the snake. The point of this snippet is not to definitively interpret and evaluate the student's idea. The point is that the candidates were focused on trying to understand the student's unconventional idea and truly attending to his meaning -- with little scaffolding from Levin nor the participation of Alex and other participants who had dominated the earlier conversations about student thinking.

## Conclusions and future study

This work contributes to a growing understanding of novice teachers' abilities to attend to the substance of student thinking and provides insight into how their practices of doing so develop and change over time. We show evidence that novice teachers can identify, interpret, and evaluate the substance of student thinking when they participate in pedagogy courses designed to draw attention to this topic. Additionally, the candidates in our pedagogy courses became more adept at drawing specific interpretations of student thinking and using these interpretations to warrant general claims and evaluations of student understanding.

However, a particularly important aspect of our data is that the cohort of teacher candidates attended to student thinking from the very beginning of the pedagogy course sequence. We believe that this finding has important implications in terms of how to best conceptualize learning to attend to the substance of student thinking. The predominant assumption in the noticing literature is that noticing is a "skill" (e.g. Jacobs et al., 2007; van Es & Sherin, 2008). We challenge the use of the term "skill," which typically implies something that teachers do not know how to do until they have been taught. Even if the use of the term "skill" in the noticing literature is not intended in this manner, we argue that conversations about learning should always be explicitly connected to a strong theoretical base, and we do not believe that the term "skill" accurately captures what is learned or how learning occurs.

Our data from this study support the presence of resources that teachers have to attend to the substance of student thinking. To us, the existence of these resources is important because it suggests that teachers do not learn a new skill in professional development or teacher education contexts, but that these contexts instead activate resources that teachers already have. That is, focusing on the substance of student thinking is not something developed de novo, but rather an activation of the resources that all people have for listening to the meaning that another person is trying to convey. Thus, an important task for teacher education is to help pre-service candidates draw upon these resources to support a framing of teaching in terms of attending to student thinking.

We suggest that the framing of teaching in terms of attending to student thinking was not simply put in place by Levin, the instructor, but was supported collectively through interaction among the participants in the group. Alex and some other candidates, perhaps because of prior experiences in similar settings, entered into the conversations very quickly and helped to support the framing that Levin was trying to establish. Over time, Levin's voice became less prominent as candidates pushed each other to articulate the specific evidence in student thinking that warranted claims of students' reasoning and understanding. The spirit of these exchanges over case studies continued into the third semester of the program, where candidates presented case studies from their own classrooms.

Our findings also suggest productive avenues for further research. As we noted, there were differences in the ways that individual candidates attended to student thinking. Some, like Alex, offered substantive interpretations of students' ideas from the very beginning. Others had difficulty doing this at first and seemed to become better at it as they engaged more with the group and saw the practices modeled by other candidates. We are pursuing more in-depth case studies of particular candidates in order to address these distinctions.

We are also examining candidates' practices of attending to the substance of student thinking while they are teaching in their own classrooms, where they must listen to student ideas in real time while trying to manage other facets of the classroom and the curriculum. We have followed several candidates into the classroom, and we plan to continue following them through induction and the early years of their teaching careers in order to better understand how and when teachers attend and respond to the substance of student thinking while teaching science.

# Collaborative Productivity as Self-Sustaining Processes in a Grade 4 Knowledge Building Community

Jianwei Zhang, State University of New York at Albany, USA. jzhang1@albany.edu
Richard Messina, Institute of Child Study Laboratory School, Toronto, Canada. rmessina@oise.utoronto.ca

**Abstract**: This study elaborates collaborative productivity as self-sustaining processes along with the role of the teacher in a knowledge building community. The participants were 22 fourth-graders, who investigated light over a three-month period facilitated by a veteran teacher with the support of Knowledge Forum®. Content analysis of the students' portfolios indicates significant advancement of understanding. Qualitative analysis of classroom videos, online discourse, and the teacher's reflection journal identifies community interactions and teacher scaffolding related to four interrelated processes. These include: (a) accumulating a highly variable stock of information and ideas and mobilizing information connection; (b) sustained, incremental idea development; (c) critical examination and selection of ideas; and (d) distributed emergent control. These processes elaborate self-organization mechanisms underpinning collaborative productivity, informing new ways to scaffold knowledge building.

## Introduction

With knowledge-based organizations pervading a knowledge economy and society, education is facing an unprecedented demand of preparing students for collaborative and creative knowledge practices. Various inquiry-based collaborative learning programs have emerged to achieve high-level collaborative productivity in a learning community. Students engage in productive sharing, conversation, and collaborative problem solving that lead to deep understanding and advancement of collective knowledge (Barron & Darling-Hammond, 2008; Hmelo-Silver & Barrows, 2008). Efforts to explain and support collaborative productivity often focus on the teacher/designer's role in charting, organizing, and guiding the processes, with student collaborating in fixed groups following specific scripts. This focus on "strong leader" is further heightened by the argument that "minimally guided teaching techniques" do not work (Sweller et al., 2007). Alternative to this "strong leader" explanation is a self-organization perspective: collaborative productivity emerges from complex, distributed interactions with the teacher as an important participant; small intellectual input from the members builds on one another to enable increasingly complex work and emergent progress. This self-organization perspective gains support from the recent studies on creative research teams and professional communities (Dunbar, 1997; Sawyer, 2007). In line with these studies, our recent design research traced the improvement of knowledge building in a Grade 4 classroom. Over three years, the designs evolved from fixed-group collaboration that involved extensive teacher-coordination to distributed, opportunistic collaboration. The third year design led to most productive knowledge advancement (Zhang et al., 2009). The present study analyzes an extended iteration of the above design experiment. The goal is to provide an elaborated account of collaborative productivity as self-sustaining processes, which will inform new and expanded ways to scaffold knowledge building.

Our exploration of collaborative productivity as self-sustaining processes was inspired by recent research on creative communities, such as productive research labs (Dunbar, 1997) and innovative professional communities (Engestrom, 2008). A creative community works as a system that is further embedded in the larger systems in a field (Csikszentmihalyi, 1999). Collaborative knowledge creation in these communities unfolds as self-organizing and emergent processes. "[T]he most innovative teams are those that can restructure themselves in response to unexpected shifts in the environment; they don't need a strong leader to tell them what to do." (Sawyer, 2007, p. 17) The mechanism of self-organization "is basically the combination of an evolutionary raw material—a highly variable stock of information from which to select possible patterns—and a means for experimentation, for selecting and testing new patterns." (Meadows, 1999, p.15) In light of the notion of self-organization, we synthesize four essential processes that sustain knowledge creation drawing on the literature on creativity and knowledge creation.

(a) Accumulating a highly variable stock of information and ideas, with dynamic information flow. Creativity emerges when individuals, often working in teams, produce novel variations to the domain that are recognized by the field composed of peer workers (Csikszentmihalyi, 1999). Each domain (e.g., physics) evolves a public knowledge base representing the state-of-the-art understanding (Bereiter, 2002). The public knowledge space gives knowledge and ideas an out-in-the-world existence (e.g., in books). The current knowledge base is the evolutionary outcome of the past work and meanwhile thinking resources and devices for future advancement, with new advances rooted in the past and further informing ever deeper inquiries.

(b) Positive loops fueling idea generation and development: Positive feedback loops are self-reinforcing, with the output of one operation becoming the input to another. As Dunbar (1997) observed in high-performing research labs, researchers perform cognitive operations and pass the results on to peers, who then use the results as the input to further cognitive operations to create new theories and experiments. A series of small operations may lead to major, often unexpected advances, which often cannot be attributed to any individual. As a part of the positive loops, the knowledge gained about a topic helps knowledge workers to further identify what is not known and ask deeper questions (Miyake & Norman, 1979), which lead to further actions to advance knowledge (Bereiter & Scardamalia, 1993).

(c) Negative loops that enable critical examination and selection of ideas. Positive loops in a creative system need to be coupled with, and slowed down by, self-correcting negative feedback loops in order to keep important system states within safe bounds (Meadows, 1999). In academia, the negative loop is partly played out through blinded peer review and critical academic discourse. The specific criteria used to judge whether a contribution is an improvement/advancement differ across domains. Such criteria and related rules of knowledge work are further internalized by individuals and become a part of their reflective thinking and discourse, so that they can make smart decisions to tease out good ideas from bad ones and choose the most promising ideas to work on in a way that can be accepted by peers (Csikszentmihalyi, 1999; Sternberg, 2003).

(d) Distributed emergent control. Innovative teams perform spontaneously (Sawyer, 2007). Team members take on high-level collective cognitive responsibility: They collaboratively monitor their progress and emergent goals, develop and refine work processes and procedures, and group and re-group in the service of the emergent needs (Chatzkel, 2003). They invent and adopt various knowledge tools and artifacts to support their productivity and expand the scope and sophistication of thinking (Hakkarainen, 2009). They critically reflect on the social norms that specify accepted ways of conducting research and other knowledge practices, adjust existing norms, and strive for new paradigms as needed (c.f. Sternberg, 2003).

Using the self-organization mechanisms as a lens, this study views into a knowledge building community to understand how collaborative productivity occurs and can be enabled. In a knowledge building community, students engage in continuous idea improvement to advance the state of the art of the community's knowledge, mirroring the socio-cognitive dynamics of knowledge creation in the real world (Bereiter, 2002; Scardamalia, 2002). This process is augmented through technology-based environments such as Knowledge Forum, which provides a communal knowledge space and related interaction tools for knowledge building discourse (see Scardamalia, 2004). This study analyzes the knowledge building work of a Grade 4 classroom facilitated by a highly accomplished teacher. The research questions include: (a) To what extent is the knowledge building community productive, gauged based on communal and individual knowledge advancement? (b) What are the essential community interactions that sustain productive knowledge building? (c) What role does the teacher play in support of the above community dynamics?

## Method

### Participants

The participants were a class of 22 fourth-graders and their teacher at an elementary school in downtown Toronto. This study analyzes their knowledge building work in optics conducted over a three-month period supported by Knowledge Forum. The students had been using Knowledge Forum to conduct knowledge building since Grade 1. The teacher had accumulated strong expertise in facilitating knowledge building. An earlier study analyzed his three-year design experiment on improving classroom designs for knowledge building in optics, with significant improvement found each year (Zhang et al., 2009).

### The Knowledge Building Implementation

The optics inquiry was conducted in line with the knowledge building principles (Scardamalia, 2002). The teacher particularly focused on enhancing student collective responsibility for advancing community knowledge. Instead of having students work in fixed small groups, the teacher adopted an opportunistic collaboration design that encouraged students to define and elaborate progressive inquiry goals and, accordingly, adapt their participation structures over time (Zhang et al., 2009). As a result, the knowledge building process involved a dynamic flow between individual inquiry, small group work, and whole-class conversations and allowed students to group and re-group spontaneously based on their evolving goals. The students engaged in knowledge building discourse in Knowledge Forum to contribute and improve their ideas, mirroring and extending their discourse in the classroom. Their idea improvement was further supported by constructive use of authoritative sources (e.g., books) and experimental work. Student ideas, problems, data, and reading information were contributed to Knowledge Forum for sustained online discourse.

### Data Analyses

To analyze the growth of the community's knowledge space, we traced the online discourse in the seven views (workspaces) to identify progressive questions and ideas and, then, compared the questions and ideas against the curriculum guidelines. Individual knowledge growth was further assessed based on their portfolio notes. Each student wrote three portfolio notes online that summarized their understanding of light in the first, second, and third month of the inquiry, respectively. The analysis first looked at whether a portfolio note addressed each of the eight focal knowledge goals identified by the community (e.g. how lenses work). Following content analysis (Chi, 1997), student writing related to each goal was then coded based on two four-point scales (Zhang et al., 2007): (a) scientific sophistication (1 - pre-scientific, 2 - hybrid, 3 - basically scientific, and 4 - scientific) and (b) epistemic complexity (1 - unelaborated facts, 2 – elaborated facts, 3 – unelaborated explanations, and 4 - elaborated explanations), measuring effort to produce not only descriptions of the material world but theoretical explanations of hidden mechanisms (Salmon, 1984). Two raters independently coded 12 portfolio notes to assess inter-rater reliability, with full agreement for the coding of knowledge goals/themes, *Cohen's Kappa* = .83 for scientific sophistication, *Cohen's Kappa* = .75 for epistemic complexity.

We analyzed classroom video transcriptions, online discourse, and the teacher's reflection journal to identify community interactions and teacher scaffolding that had sustained productive knowledge building. The analysis integrated multiple levels and timescales, with holistic analysis of the whole initiative and detailed analysis of activity components informing each other (Lemke, 2000). In the first phase, the focus was on the community's three-month inquiry, as a whole, to understand how it started and evolved and its changing conceptual landscape. In the second phase, the focus was on each videotaped classroom episode, such as a whole-class conversation, a small group activity, or a computer lab session, to identify its focus, context, storyline, and connections with other episodes. In the final phase of detailed analysis, the focus was on each conversation turn in an episode to understand the nature of the discourse move in relation to its preceding and following conversation as well as the storyline of the episode identified in Phase 2. A more narrow approach to conversation analysis (Sawyer, 2006) was used to identify patterns through an emergent inductive process (Strauss & Corbin, 1998) without applying a predefined coding scheme and counting each code. Specifically, we read and re-read the transcriptions and coded specific moves (e.g., asking a challenging question about a peer's idea, providing evidence) represented by different conversation turns, with the speaker of each turn identified as either a student or the teacher. We then searched for connections across the specific codes in light of the contexts of the episodes and the evolution of the whole inquiry, and aggregated the codes into fewer, more encompassing themes, representing community-level (system-level) processes sustaining knowledge building. Each theme involved multiple sub-themes, with the encompassed specific moves of the teacher and those of the students considered side by side. The initial themes and sub-themes were then refined, elaborated, and validated through theme to theme, theme to data, data to data comparison, including triangulating the identified themes and sub-themes to the analysis of the teachers' reflection journals and the online discourse.

## Results

### To What Extent is the Knowledge Building Community Productive?

Tracing the online discourse helped to understand the conceptual scope and depth of the community knowledge space. Over the three months, a total of 168 notes (excluding the 66 portfolio notes) were created by the community in several views in Knowledge Forum. In each view, the students identified deeper questions leading to progress in understanding. For example, in the view of "Colors of Light and Rainbows," the students progressively examined how rainbows are created, why the colors are always in the same order, primary and secondary colors, the nature of white light, and how we see colored objects. The student discourse addressed all the expectations for Grade 4 in the Ontario Curriculum and further led the students to understanding many issues expected for Grades 6 and 8, such as light waves, color vision, colors of opaque objects, concave and convex lenses, the law of reflection. Individual knowledge advancement was assessed based on content analysis of student portfolio notes written in the three months, respectively (Table 1). Repeated measures ANOVAs revealed significant growth across the three months in the number of focal issues/goals addressed ($F$ (2, 42) = 43.03, $p < .001$, partial $\eta^2 = .67$), epistemic complexity ($F$ (2, 42) = 69.20, $p < .001$, partial $\eta^2 = .77$), and scientific sophistication ($F$ (2, 42) = 70.60, $p < .001$, partial $\eta^2 = .77$).

Table 1: Student knowledge advancement measured based on their portfolio notes.

| | 1st Month | 2nd Month | 3rd Month |
|---|---|---|---|
| # of focal issues addressed so far | 4.27 (1.83) | 6.41 (2.02) | 7.36 (.95) |
| scientific sophistication (1- pre-scientific to 4 - scientific) | 1.48 (.66) | 2.25 (.74) | 2.81 (.48) |
| complexity (1-unelaborated fact to 4-elaborated explanation) | 1.32 (.64) | 2.04 (.78) | 2.91 (.70) |

*Note*. Numbers are means and standard deviations.

### Community Dynamics and the Role of the Teacher

We analyzed the video transcriptions, teacher reflection, and student online discourse to understand how the productive knowledge building was achieved. A specific focus was on identifying significant moments of progress and then tracing backward and forward across activity contexts to understand how the process came about and where it further went. For example, a whole class conversation was conducted on May 16 that led progress in understanding how light interacts with opaque materials. The conversation began with students sitting in a circle and sharing observations of different materials. The teacher then highlighted a question originally raised by a student in Knowledge Forum: "Are all opaque things reflective like mirrors? " The following shows the first four of the 30 minutes or so discussion to address this and related problems.

Table 2: A Section of the Transcriptions of the May 16 Whole Class Conversation.

| Transcription | Analysis highlight |
|---|---|
| 2:20 GM: Well, there'[re] bricks, which are still opaque. But they're not reflective. But I don't know what they are called, like that kind of opaque. JL | Identifying non-reflective opaque materials, using a tentative voice. |
| 2:31 JL: I think all opaque materials are reflective, except not all of them reflect light back. … OK, let's just say um like…a yellow carpet… your eyes would be able to see the yellow of it because it would only reflect yellow light. That means like that sort of like a tissue for example that would only reflect white, except the yellow carpet, since it's like green mixed with red, I believe. Then the beam of red [and green] light would touch us and your eyes would take it in as yellow. | Contributing an alternative idea: All opaque materials are reflective, by analyzing a thought experiment (yellow carpet), drawing on knowledge of primary and secondary colors. |
| 3:58 Teacher: So you're saying everything is reflective then. Every opaque object is reflective to some degree. Oh, I hear some people disagree. Can you pass it on? [JL: SG.] | Revoicing student idea; highlighting contrasting perspectives. |
| 4:07 SG: What about wood? Wood isn't reflective. JL. | Bringing in an anomaly. |
| … | |
| 4:53 FJ: I think if wood is shiny and polished, you could see your reflection. I think it's mostly just shiny objects so it depends on what kind of wood you have, what kind of table you have, if you see your reflection. SG. | Re-analyzing and interpreting the instance as non-anomalous. |
| 5:12 SG: Like if you had a glass table. | Supporting fact. |
| 5:16 Teacher: The question is: Are all opaque objects reflective? Have we answered that? … Do all opaque objects reflect light? Anyone has a theory or evidence to support that? So, SG, it's yours to pass. [SG: DN.] | Highlighting/reminding a focal problem and promoting reflection on progress. |
| 5:35 DN: Um, actually all opaque objects do reflect light, because they reflect their own color. So we see them as whatever color they are. TS. [inaudible student talking] | Articulating an idea and its supporting thoughts. |
| 5:57 Teacher: Hold on, let's hear him talk. | Maintaining conversation norms. |
| 5:59 TS: If they didn't reflect their own color, you wouldn't see a brick of red, or someone's t-shirt as purple or whatever. RP. | Extending and elaborating idea. |
| 6:11 RP: What about black? | Bringing in an anomaly. |
| 6:14 Teacher: Don't throw it back to him. Give your theory. | Maintaining norms; encourage initial thoughts. |
| 6:18 RP: I don't think black reflects. I think that black might reflect light, but it might not. Because we had a reading today that um all the colors of the rainbow make white light and there is a note in the database about that, and everything reflects its own color. But it didn't say anything about black. EY. | Summarizing a reading and an online note and identifying black as an unaddressed issue. |

A number of important ideas emerged from the conversation (e.g., all opaque things are reflective, expect black ones). Tracing each of these ideas back into the prior inquiry activities revealed striking historical connections and incremental moves. For example, the idea that all opaque things are reflective is rooted in a small group reading and related experiments on transparent, translucent, and opaque materials conducted on May 9; the notion that opaque objects reflect light of their own colors traced back to May 12 when group readings and discussions occurred focusing on how people see colored objects. These ideas were circled back into the current conversation leading to new inferences, connections, and meanings and further informing deeper problems and ideas.

Analyzing community interactions with each episode, such as the one shown above, and searching for cross-episode connections helped to identify essential processes/patterns enabling collaborative productivity in the community. Four thematic processes emerged, in consistence with the self-organization mechanisms sustaining knowledge creation synthesized in the beginning of this paper.

## Process 1: Accumulating a Highly Variable Stock of Information and Ideas and Mobilizing Information Flow and Connection

*Sub-process 1a: Accumulating a communal knowledge base that involves a richly connected history of ideas, with new inquiries evolving out of the old.* The students accumulated a communal knowledge base—supported by Knowledge Forum—that helped to enable historical continuity between the old, current, and future work. Rich information flow took place on the basis of the community's knowledge base. Specifically, the students shared their understanding and challenges so as to construct a common ground while shaping emergent ideas and goals. Old ideas, problems, and inquiry works were constantly referred to and circled back to advance the current inquiry and discourse and further inform emergent goals (e.g., "going back to what X said about… , so…"). There was rich cross-referencing between the online and offline spaces and between different inquiry activities, as illustrated through the May 16 conversation analyzed above.

The teacher modeled making connections across ideas and activities and attempted to anchor all his major input in student history of inquiry. Specifically, he worked with the students to formulate emerging inquiry focuses/themes in the contexts of student prior inquiry and current interesting events. He helped to ground classroom conversations in relation to students' accumulated work and ideas, and highlighted connections between current inquiry and prior readings, experiments, and discussions. He also facilitated the online-offline connections, with important ideas and related inquiry work recorded in Knowledge Forum for further discussion and inquiry (e.g. "Is anyone writing a note about this experiment?"). When multiple small groups were conducting different investigations in the classroom, the teacher was often called upon by the students, who wanted to share with him their wonderments and excitements. He captured important progress of understanding and then catalyzed community wide discussion, online and offline.

*Sub-process 1b: Making constructive use of information from reading.* Efforts to accumulate a vibrant knowledge base were advanced through student constructive use of reading. To address important problems emerged from their inquiry, the students found and read a large amount of material. They worked in groups to understand difficult text, using reading strategies (e.g., questioning, reviewing, summarizing) to deepen their comprehension and discussion. Reading professional text and bringing important concepts and information to the community discourse helped the students to expand the knowledge base they could work with and appropriate sophisticated language to represent and process their ideas. It further engaged the students in reflective dialogues between their local understanding and knowledge out in the world (e.g., science communities). Consistent findings from the readings were synthesized and used by the students to support and extend their ideas. Inconsistencies were identified leading to further idea development.

The teacher modeled monitoring knowledge gaps in the community's knowledge space and introduced new readings by talking about existing questions and related ideas. As the inquiry went deep into the domain, many of the students-generated problems required readings above their current grade level. The teacher communicated his deep trust and high expectation and inspired students to collaboratively deal with difficult text for deep understanding. He consulted student interest in the readings to set up reading groups. Occasionally, he participated in the small groups to co-analyze and reflect on key information from readings, design related experiments, model various reading strategies. Across the inquiry activities, he helped the students to see connections between the current work and what they had read.

## Process 2: Sustained Idea Development, Powered by Positive Feedback Loops

*Sub-process 2a: The more we know, the more we can learn and generate: incremental idea development.* The students connected to and made use of their shared knowledge base and peers' intellectual input to generate new ideas and deepen understanding. In the online and offline discourse (e.g., Table 2), the students made connections to and drew upon existing ideas and inquiry work to generate new ideas to address the focal problems. They often contributed ideas in the form of tentative conditional statements (e.g., maybe…) open to critics and further input (Engestrom, 2008). Their peers then responded to extend and elaborate these ideas; to contribute related thought experiments (e.g., what will happen if…), analogies (e.g., between eye and camera), observations, and supporting facts; to present alternative ideas and anomalies; to identify subordinate questions and distill challenges; and to summarize different perspectives for deeper conceptualizations. These interactive moves are characteristic of distributed reasoning observed in productive research teams (Dunbar, 1997), with existing ideas and knowledge operations constantly taken up by peers to enable further advancement.

The teacher nurtured among his students a sense of epistemic agency and empowerment. He communicated his deep trust that everyone had something worth saying and could contribute to knowledge advancement. In classroom conversations, he (a) engaged in active listening to and reading of student ideas; (b) expressed encouragement, interest, and excitement; (c) asked questions on student ideas for clarification and deeper thinking; (d) highlighted interesting ideas (including misconceptions) and questions, along with possible connections, controversies, and gaps; and (e) re-voiced student ideas (see Table 2) to make them more explicit and formal in light of related domain concepts (Hmelo-Silver & Barrows, 2008; O'Connor & Michaels, 1992).

*Sub-process 2b: The more we know, the more we realize that we do not know, driving us to know more: Progressively identifying problems and formulating deeper goals.* The students actively monitored and distilled challenging questions emerging from their discussions, reading, and experiments. Integral to their classroom conversations, they participated in meta-discourse to identify emergent questions and review conceptual connections among the questions so as to evolve interconnected deeper goals. For example in the May 16 conversation, the students identified questions such as: Does light reflect off of black opaque objects? How comes a mirror reflect light of all colors? Identifying these issues led to further idea development in the subsequent discourse, which then brought further problems of understanding to the fore.

The teacher explicitly encouraged students to take on high-level responsibilities and knowledge operations for sustained deepening of understanding. He encouraged students to ask 'why, why,' and not to be content with a superficial answer. He built on student discussions of emergent questions to propose his framing of focal inquiry goals, which was then discussed by the community. He engaged in deep listening to and reading of student ideas and questions, highlighted important problems emerged from classroom conversations, and asked questions to deepen student-generated ideas instead of directing the students to new tasks (Zhang et al., 2009). He also reminded/brought back problems that had not been addressed and requested reflective review of progress (e.g., "Could someone summarize what we've come to so far at this talk?"). The students oftentimes did the same supported by the teacher's modeling.

## Process 3: Critical Examination and Selection of Ideas, as Negative Loops

*Sub-process 3a: Individual reflection and critical idea examination in the discourse*. Individual reflection appeared to function as a bottom-level mechanism of idea examination and selection to make sure that everyone contributed clearly presented and carefully reasoned out ideas addressing communal goals. When presenting information and ideas, the students acknowledged the sources and connections to prior work of peers. They used conditional statements and indicated both what they knew and what they were not sure about, in reflection of the "half-baked" nature of their ideas. Student idea input was further examined and selected through critical dialogues. In the dialogues (e.g., Table 2), the students challenged peer ideas by presenting alternative explanations, identified and analyzed anomalies, and raised questions that challenged existing explanations. The competing explanations, possible anomalies, and challenging questions *per se* then became objects of critical discourse. The examination of two competing explanations might lead to giving up one of them; but in many other cases, it led to rising above different perspectives towards more complicated explanations.

Related to idea examination and selection, the teacher was cautious not to be the judge of student ideas. But rather, he highlighted rules of reflective contributions (e.g., contribute ideas with details) and engaged his students in meta-discourse to review ideas, monitor gaps, conflicts, and challenges, and reflect on progress, using identified contrasting perspectives to stimulate deeper examination and analysis.

*Sub-process 3b: Empirical testing of ideas.* Focusing on important questions and ideas about light, the students designed and conducted experiments and observations, often in small groups. The students collaboratively identified focal problems and deeper questions to be addressed, generated theories, designed experiments, interpreted findings, and discussed new insights. They brought their new understanding and supporting evidence to the subsequent discourse for broad sharing, collective scrutiny, and further build-on. Their experiments were emergent and idea-centered instead of as pre-scripted tasks, with the goal of collecting data to examine and develop explanations.

The teacher listened to and read student ideas and suggested the need of evidence to examine different ideas, such as by saying: "I'm interested in your theory. Can you design an experiment to test this idea?" He listened to student proposals for experiments and promoted reflective thinking, such as by asking: "What are the questions you are trying to answer?" "What are the steps you will go through?" Based on the students' proposals, the teacher helped them to find needed materials and instruments.

## Process 4: Distributed Emergent Control

*Sub-process 4a: Co-constructing principles, strategies, and support structures*. In all types of inquiry work, the students reflected on and talked about how things should be done, and why, leading to deep understanding of what it means to work as a knowledge building community. They talked about collective ownership over inquiry questions and ideas, so that a community member might read and find information that was beyond his/her immediate personal focus. They talked about norms of knowledge building discourse, such as active listening/reading, contributing ideas in full paragraphs with evidence and details, and making connected and non-redundant input (e.g., do not write a note that simply repeats a question or idea). The community members also co-developed and utilized a variety of externalized structures to guide, assist, and deepen knowledge building. For example, to represent knowledge goals and guide their writing of reflective portfolio notes, the students collectively generated a list of thematic questions (e.g., how mirrors work) in line with their focal goals and then turned the questions into a set of new scaffold labels in Knowledge Forum. To assist experimental design and reporting, the teacher and his students discussed and agreed on key elements of a scientific experiment (e.g., theory, steps, results). The elements were then listed by each student in the front page of his/her laboratory notebook.

In the classroom discourse/meta-discourse, the teacher discussed, modeled, and reminded students of the basic conversation norms and rules, which encouraged collective engagement, reflective thinking, and sustained improvement of ideas. He shared with the students his classroom design ideas open to their input.

*Sub-process 4b: Collective responsibility, adaptive roles, and opportunistic planning.* The students monitored progress of understanding, identified challenging issues to be addressed, and synthesized important knowledge advances in each Knowledge Forum view. They brought the advances and challenges to whole-class conversations to look into possible deep connections and formulate further inquiry goals. Individuals then decided which aspects of the inquiry goals they wanted to contribute to and in what ways (e.g., theorizing, experimenting, reading), with those who had shared interest often forming into temporary small groups. The community awareness of who was working on what further created a social pressure that helped to increase individual accountability (Zhang et al., 2009). Sometimes, student peers would ask a student/group: "You have been working on this for a long time. You need to tell us what you have found."

The teacher's classroom design was characteristic of opportunistic planning (Sawyer, 2007). He identified related "big ideas" in the domain and thought about how the ideas might be approached in light of his understanding of knowledge building principles (Scardamalia, 2002) and observations of previous classes. Doing so helped him to create a big picture in mind about how the inquiry might evolve while leaving all detailed processes open and co-improvised with his students (Zhang et al., 2009). He actively observed student work and listened to their ideas to understand their progress and challenges; contributed to meta-discourse to formulate, distill, and highlight knowledge goals; created, linked, and adjusted view structures in Knowledge Forum in line with the evolving goals; listened to student inquiry plans and gave suggestions; and walked between small groups to understand their progress and offer on-site advising. Sometimes, he also proposed action plans. When doing so, he always connected his proposals to existing ideas, questions, and input from the students, such as by saying "I'm interested what X said earlier about…"

## Discussion

The content analysis of the students' online discourse and portfolio notes revealed high-level collaborative productivity achieved by the community. The qualitative analyses of the classroom videos and teacher reflections further elaborated four interrelated processes that sustained the collaborative productivity, with the teacher's roles identified in each of the processes.

Efforts to engage students in distributed, opportunistic collaboration for knowledge building often face the questioning of how students possibly know what to do to make productive progress. Such questioning is rooted in a common belief that students need a "strong leader" to chart and organize the process of knowledge building and tell them what tasks/sub-tasks to be done and in which ways (e.g., using scripts). This study elaborated collaborative productivity as emergent, self-organizing processes. Neither the teacher nor the students knew beforehand how the inquiry would exactly unfold. The course of inquiry and collaboration and the key moments of progress emerged from an interactional process in which the teacher and his students co-contributed to the unfolding classroom flow. Student interactions augmented through the shared knowledge space in Knowledge Forum enabled continuous and incremental idea development. They identified important and relevant ideas from the past as the stepping-stones of their new inquiry, triggering deeper ideas and problems. Each major idea was embedded in the evolving intellectual history of the community, gaining support from the past work and further informing and enabling future idea development (Tabak, 2004). As a result, new deepening goals and plans emerged as the inquiry history unfolded. Instead of having the teacher make high-level decisions regarding the rules, structures, goals, and procedures, the community members took on collective responsibility for evolving goals and developing productive practices and structures.

The significant advances in the community's knowledge did not come about through sudden insights that departed from existing knowledge, but through historical build-on, incremental refinement, and accumulative selection of ideas (Cziko, 1995; Dunbar, 1997; Sawyer, 2007). Student ideas and questions were constantly taken up by peers and used as the input to further operations of knowledge, leading to idea generation, elaboration, diversification, and improvement. The advanced understanding further helped to inform deeper problems at the frontier, enabling sustained cycles of progressive problem solving. Thus, the more they knew, the more they could generate; and the more they realized that they needed to know. These positive loops fueling sustained idea generation were coupled with critical idea examination and selection. In the knowledge building discourse, ideas were often contributed in a tentative voice open to critics and further input; competing explanations, possible anomalies, and challenging questions were raised calling for further examination of ideas; empirical evidence was collected and brought to discussions.

Elaborating the self-organization mechanisms underpinning collaborative productivity sheds light on various aspects of community scaffolding—the community as the provider as well as recipient of scaffolding—through emergent, distributed processes (Davis & Miyake, 2004; Tabak, 2004). Members use their historically accumulated ideas to support the current work and inform deepening goals; New ideas and inquiry strategies are objectified and selectively retained to enabled further advances; Collaborative discourse among the members enables sustained chains of distributed reasoning (Dunbar, 1997); Supportive principles, rules, and external scaffolding structures are developed, monitored, and adapted through reflective discourse. The roles of the teacher aligned with each of the processes exemplify specific teaching designs and strategies to nurture and support knowledge building. Viewing these specific roles and strategies through the lens of self-organization helps to understand how these roles synergize with one another (Tabak, 2004) and how teacher scaffolding leverages community scaffolding for productive knowledge building.

Future work needs to further examine the self-organization mechanisms that sustain collaborative knowledge building in different grade levels and explore if some of the processes (e.g., positive and negative loops) can be used as leverage points to help transform classrooms into creative communities.

# Extending the Self-Explanation Effect to Second Language Grammar Learning

Ruth Wylie, Kenneth Koedinger, Teruko Mitamura
Carnegie Mellon University
5000 Forbes Avenue, Pittsburgh, Pennsylvania 15217
Email: rwylie@cs.cmu.edu, koedinger@cmu.edu, teruko@cs.cmu.edu

**Abstract:** Self-explanation is an instructional strategy that has shown to be beneficial for math and science learning. However, it remains an open question whether these benefits will extend to other domains like second language grammar learning. Within the domain of the English article system (teaching students when to use *a*, *an*, *the*, or no article at all), we compare two computer-based tutoring conditions in an in vivo classroom study. In the article choice condition, students select the correct article to complete the sentence. In the explanation choice condition, students are given a sentence with the correct article highlighted and choose the rule or feature that best explains the article use. Students (N=101) in both conditions show significant learning on both procedural (article choice) and declarative (explanation choice) tasks. Not surprisingly, we found that declarative instruction (explanation choice) led to significant learning of explanations, while procedural practice (article choice) led to significant learning of the procedures. More interestingly, we also found evidence of cross-type transfer such that declarative practice led to procedural gains and procedural practice led to better understanding of the declarative rules. In general the effects of prompted self-explanation appeared somewhat stronger than those of procedural practice.

## Introduction

Self-explanation is an instructional strategy that has lead to increased learning by encouraging students to focus on key features of the material (Roy & Chi, 2005). However, the majority of this work has been done in math and science domains like physics (Chi, et al., 1989; Conati &VanLehn, 2000), geometry (Aleven & Koedinger, 2002), and biology (Chi, et al., 1994), with little existing work in domains like second language grammar learning. The first self-explanation studies were correlational studies that demonstrated that students who self-explain more learn more (Chi, 1989). Follow-up studies have shown that prompting students to self-explain increases learning (Chi, et al., 1994), and that having students select explanations from a list of options (rather than constructing free-formed responses like in previous studies) is also a successful technique (Aleven & Koedinger, 2002; Renkl, 1999). However, despite being called a domain general strategy (Roy & Chi, 2005), the self-explanation effect has not been extensively tested in domains other than math and science with the exception of McNamara's (2004) work on reading comprehension. Our work differs from previous work in its focus on second language grammar acquisition, a problem-solving domain where there is a strong intuition that immersive practice, without reflection on rules, is more natural and perhaps best.

In this paper we compare math and science learning and second language grammar acquisition and discuss why self-explanation may or may not be beneficial for learning English grammar constructs. We then describe two systems that we built to evaluate the self-explanation effect in an empirical classroom-based study within the context of learning the English article system (teaching students when to say "a pencil" versus "the pencil"). As expected, students in both conditions demonstrate significant learning gains on their tutored skill: students in the tutored-practice (article choice) condition learn how to select the correct article, and students in the self-explanation condition learn how to select correct explanations for article use. More surprisingly, students in both conditions also show cross-type transfer with students in the article choice condition learning how to select explanations and students in the self-explanation condition learning how to select the correct article. These results are promising and suggest that self-explanation is beneficial for second language grammar acquisition and leads to the refinement of both procedural and declarative knowledge.

### Article Domain

We chose to focus on the domain of non-native English speakers learning the English article system because of the importance of acquiring article use skills, the rule-based structure of the article system, and second language acquisition theory that suggests articles are particularly well suited for a rule-based instructional approach. Grammar errors can cause writing to become "intelligible", "irritating", or both (Ellis, 1994), and articles are one of the last grammar points for English language learners to acquire (Master, 1997). We also chose article use as a domain because its rule-based nature makes it a good candidate for studying the effects of self-explanation in language learning. In contrast to domains like vocabulary learning where students must memorize arbitrary mappings, article usage is generally determined through a set of heuristics based on features of the sentence (although many exceptions exist). For example, in the sentence, "Yesterday, I bought a car. Today, *the* car broke," the article *the* is used because the noun *car* has already been mentioned. Furthermore, according to second language acquisition theory, some grammar constructs are better suited for rule-focused instruction than others. For example, articles are a type of grammar construct that is often not required for successful communication (i.e. readers likely understand the sentence, "Yesterday, I went to (no article) store" even though "Yesterday, I went to *the* store" is correct), and thus articles and their function within a sentence are unlikely to be noticed by learners without formal, rule-focused instruction (Williams & Evans 1998).

## Domain Differences

While self-explanation has been very successful at increasing learning in math and science domains, there are inherent differences between math and science and second language learning which may affect the success of self-explanation in this new domain. One key difference lies in the pedagogical goals of the domains. In math and science, often students are expected to be able to solve problems *and* explain the underlying principles. A typical example of this expectation is in geometry where students are asked to determine the angles of a triangle and provide the reason or rule(s) for their answer. However, the marker of a successful language learner is fluency, and knowing when and how to use a particular construct is much more important than knowing why. In fact, most native speakers of a language have no explicit knowledge of the rules driving their article decisions yet rarely make mistakes. Another difference lies in the presence and absence of exceptions to rules. In math and science, there are no exceptions. Provided that the proper conditions are met, a given rule will always apply. However, there are frequent exceptions to grammar rules. For example, one rule listed in an English as a Second Language grammar book states that no article should be used before the name of a disease (Cole, 2000); for example, *He has (no article) diabetes.* However, many exceptions exists (e.g. *He has* ***the*** *flu*, *She has* ***a*** *cold.*) Perhaps encouraging students to focus on rules and features of the sentence, which may sometimes prove to be unreliable, is not an effective learning strategy.

## Tutor Designs

In our study, we compared a condition where students were tutored on which article to use in a sentence (*article choice*) to a condition where students were tutored on the features of the sentence relevant to article use (*explanation choice*). Both tutors were developed using the Cognitive Tutoring Authoring Tools (Koedinger, et al., 2004) and deployed online using Java WebStart. All student actions (answer selections, hint requests) were logged and time-stamped. Both tutors had 56 example sentences and addressed eight rules for making article decisions (e.g. "If the noun has already been mentioned, use *the*" or "If the noun is general and plural, use *no article*."). In order to finish working with the tutor, students must have answered all questions correctly.

The article choice condition (Figure 1) mimics cloze or fill-in-the-blank activities found in many second language learning textbooks. Using dropdown menus, students select the article ("a", "an", "the", or "no article") that best completes the sentence. They receive immediate feedback on their selection and have access to a series of on-demand hints. This form of instruction is designed to give students practice using articles but does not require them to give a reason or explanation for their choice.

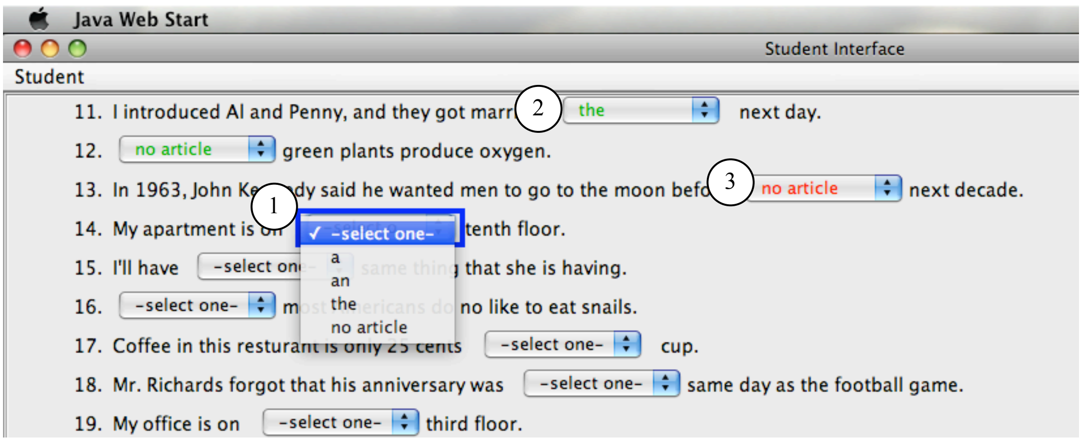

Figure 1. In the article choice condition, students choose the article (a, an, the, no article) that best completes the sentence (1), and receive immediate feedback on their selection. If the answer is right, it turns green (2), and red if it is wrong (3).

In this study, we chose to operationalize self-explanation in the form of a menu-based explanation choice tutor. In this condition (Figure 2), students are presented with a sentence with the target article highlighted and asked to choose the rule that best explains the article use. Again, students receive immediate feedback on their selection and have access to hints. In this condition, students see examples of correct article use but do not make any article decisions of their own.

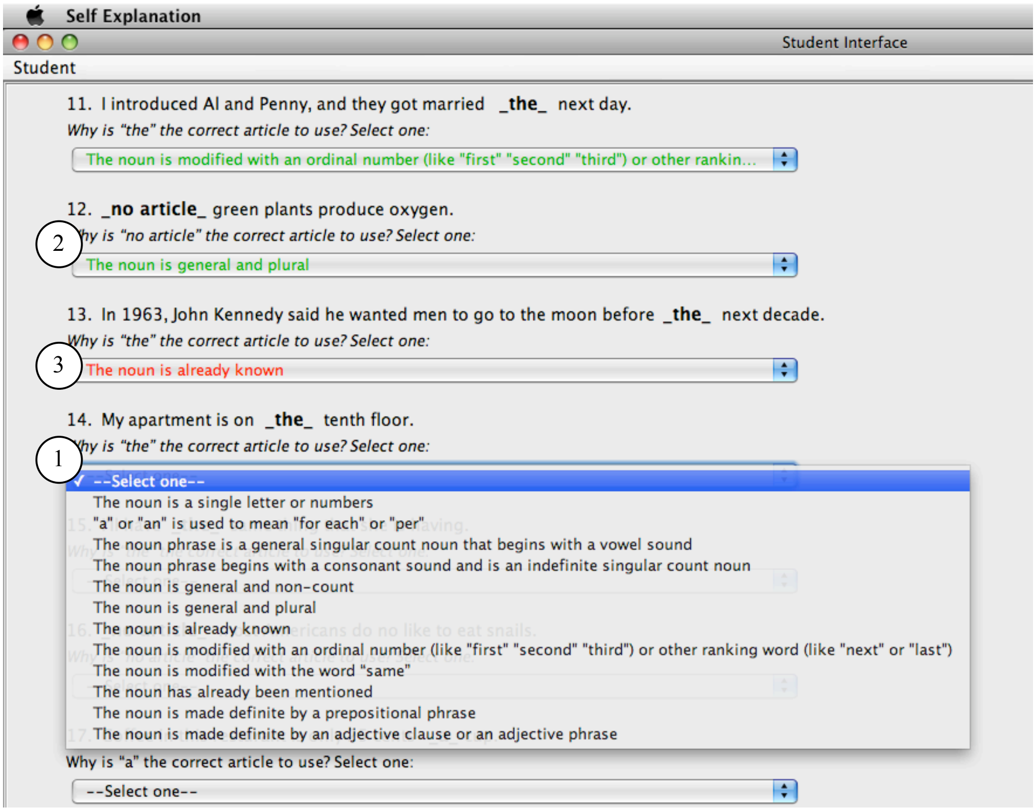

Figure 2. In the explanation choice condition, students choose the feature of the sentence that best explains the article use (1). Identical to the article choice condition, students receive immediate feedback on their selection. If the answer is right, it turns green (2), and red if it is wrong (3).

Both tutors employed a similar series of hints that were presented upon student request. The hints first identified the key feature(s) of the sentence, then provided the rule, and finally, in the article choice condition, told students which article to select (Table 1).

Table 1: Example hint sequence for the article choice and explanation choice tutors.

*Target Sentence: My office is on the third floor.*

| Article Choice Hints |
| --- |
| 1. "Third" is an ordinal number. |
| 2. Use "the" with ordinal numbers and other ranking words like "next" or "last". |
| 3. Please select "the" from the highlighted menu. |

| Explanation Choice Hints |
| --- |
| 1. "Third" is an ordinal number. |
| 2. Please select "The noun is an ordinal number (like "first", "second", "third") or other ranking word (like "next" or "last"). |

## Hypothesis

Our study addresses the question of whether self-explanation is a helpful instructional strategy for second language grammar learning. We hypothesize that students in the explanation choice condition will show greater learning gains on article choice and explanation choice tasks than those in the article choice tutor. One hypothesis for how prompts for self-explanation enhance learning is that they encourage students to notice relevant features of the problem and enable students to become aware of gaps in their own knowledge (Roy & Chi, 2005). This feature focusing technique may be beneficial to second language learning students by helping them attend to parts of the sentence that are important for making article decisions and ignore irrelevant parts.

Within the field of second language learning, there have been several studies that have investigated the differences between explicit and implicit grammar instruction. The findings from this study also contribute to this debate, since although both conditions are examples of focus on form instruction (Doughty, 2001), the explanation choice condition which supports explicit practice of rules is an example of explicit instruction, while the article choice condition affords a more implicit approach to learning. While both approaches have their own merits, according to a meta-analysis by Norris and Ortega (2000) instructional strategies that include explicit focus on rules, like the explanation choice condition, are more effective than strategies that are more implicit in nature, like the article choice condition.

Self-explanation may also help students by strengthening multiple processes by which to make article decisions. For example, students could solve the problem through an implicit strategy in which they choose the article that sounds the most correct, or, if they become proficient at the rules, they could use an explicit strategy and make their article decision based on the features of the sentence and the rule that applies. Thus, even though the ultimate goal is to create expert *users* of the rule and not expert *explainers* of the rule, self-explanation may still be a beneficial instructional technique.

## Method

The study took place during one 50-minute class period. Students (N=118) were adult English language learners (mean age = 27.9, SD=7.2) enrolled in the University of Pittsburgh's English Language Institute who came from a variety of first language backgrounds. In total, there were 13 first languages represented; however the majority of students spoke Arabic (37%), Korean (18%), or Chinese (15%) as their native language. Students participated in the study as part of their normal grammar class. There were three class levels: intermediate (n=30), intermediate-advanced (n=61) and advanced (n=27). The session started with an introduction to the tutoring and testing interfaces as well as a brief overview of the rules covered by the tutor. As adult language learners, all of the students had received some prior instruction on article use, and the goal of the demonstration was simply to introduce the vocabulary that was used in the tutors and to explain the tasks that the students would be completing. Students then completed the article choice and explanation choice pretests. Next, students were randomly assigned within each class to either the article choice or explanation choice condition and completed the tutored problems. Finally, students did the article choice and explanation choice posttests (Figure 3). Pre- and posttest forms were counterbalanced.

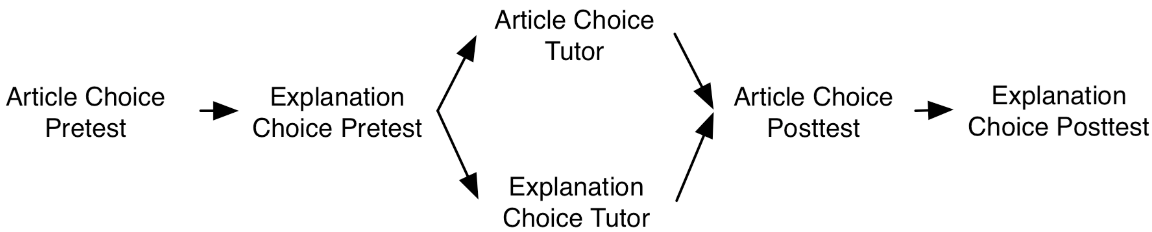

Figure 3. The sequence of tasks students completed as part of the study.

### Measures

All students were assessed on both procedural knowledge (article choice) and declarative knowledge (explanation choice) items. Article choice items were isomorphic to those in the article choice tutoring condition, and students chose the article that best completed the sentence. The explanation choice items were also identical in form to those in the explanation choice tutoring condition, where students were given a sentence with the correct article highlighted and asked to explain why that article was used. Two test forms were created, each with twelve article choice and twelve explanation choice items. For each problem type, there were eight questions that used rules taught in the tutor (tutored items) and four questions that used rules that were not taught in the tutor (control items). These items were included in order to measure effects other than those from the tutoring system (e.g. students becoming familiar with the interface or students becoming fatigued).

### Data Sample

Since students participated in the study as part of their normal class activity, there was limited time within which to collect data. Overall, 86% (101 out of 118) of the students completed all tasks; however, attrition between conditions was not the same with 95% (55 out of 58) of students in the article choice condition and 77% (46 out of 60) of students in the explanation choice condition completing all tasks ($\chi^2(1, N=118) = 7.9$, p = 0.005). Pretests scores for the remaining students were not significantly different ($t(1, 99) = 1.31$, p = 0.192) (Table 2), but the trend is the direction of concern (i.e., consistent with the hypothesis that low prior knowledge students were dropped from the explanation choice sample) with the explanation choice group having an average pretest score of 62.9% and the article choice group at 58.9%. Based on observation and anecdotal comments from the classroom teachers, students who ran out of time before completing the posttests fell into one of two categories: students with low prior knowledge and students with high prior knowledge who were very meticulous and conscientious in their choices. One student did not take the pretest due to technical error and was dropped from analysis.

Table 2: After attrition, the pretest scores were slightly higher than before attrition but there was no significant difference between conditions.

| | Total Sample | | Sample After Attrition | |
|---|---|---|---|---|
| Tutoring Condition | N | Pretest Mean (SD) | N | Pretest Mean (SD) |
| Article Choice | 58 | 0.583 (0.162) | 55 | 0.589 (0.159) |
| Explanation Choice | 59 | 0.604 (0.145) | 46 | 0.629 (0.137) |

Even though the pretest scores were not significantly different and we have reason to believe that attrition may also occur because of the diligence of good students, we thought it best to use a statistical analysis designed to address such a situation. Propensity score matching (PSM) is a technique that is often used in quasi-experimental designs to correct for bias. PSM is similar to other types of matching but it combines several variables into one score on which to cluster participants. Prior work has shown that using propensity scores to divide students into five groups and then using this subclassification as an additional variable often removes over 90% of the bias caused by each of the covariates (Rosenbaum & Rubin, 1984). In our study, we wanted to account for bias due to attrition and thus first calculated a propensity score (1 = highly likely to complete the study, 0 = very unlikely to complete the study) for each student by running a logistic regression with the binary variable of whether or not students completed the posttests as the dependent variable. Covariates used in the regression include: the log of the time spent on the article choice pretest, the log of the time spent on the explanation choice pretest, the log of the time spent using the tutor, article choice pretest score, explanation choice pretest score, and course level (intermediate, intermediate-advanced, advanced). The participants were then divided into groups based on propensity score and this value was used as a between-subjects variable in the all the analyses.

The main reason for grouping students using propensity score and not a single measure was that individually none of the other variables were highly correlated with completion rate. However the propensity score, which combines several measures, is highly correlated with whether or not a student would complete the posttests ($r(115)=0.84$, $p < 0.001$) and thus a better metric on which to group.

## Results

The following analyses were done with and without the PSM variable and resulted in the same conclusions. Because we believe they are less biased and thus a more accurate description of the findings, here we report the results that include the PSM variable.

### Learning Gains

Repeated measures ANOVA analyses show that students in both conditions demonstrate significant pre to posttest improvement on both the article choice measure ($F(1, 95) = 29.44$, $p < 0.001$) and the explanation choice measure ($F(1, 91) = 15.09$, $p < 0.001$). In order to determine if tutoring condition had an effect on posttest scores, a MANCOVA was calculated using article choice and explanation choice posttest scores as the dependent variables, propensity group and tutoring condition as the independent variables, and article choice and explanation choice pretest scores as covariates. This reveals a significant effect for condition ($F(2, 88) = 5.38$, $p = 0.006$). Finally, in order to understand the specific affects of the conditions, we ran univariate between-subjects tests for each test type. These showed that condition significantly affected explanation choice posttest scores ($p=0.023$) but not article choice posttest scores ($p=0.153$).

Figure 4 uses normalized gain (Hake, 1998) scores to illustrate these results: both groups are learning the skill on which they were tutored (article choice students show improvement on the article choice task, and explanation choice students show improvement on the explanation choice task). More surprisingly, both groups are also learning the transfer skill (article choice students show improvement on the explanation items, and explanation choice students show improvement on the article choice items). Furthermore, the effects of the self-explanation condition appear stronger than those of procedural practice. Despite having no tutored practice on article choice items, students in the explanation choice condition are showing equal gains on the article choice measure compared to students in the article choice condition and significantly higher gains on the explanation choice measure.

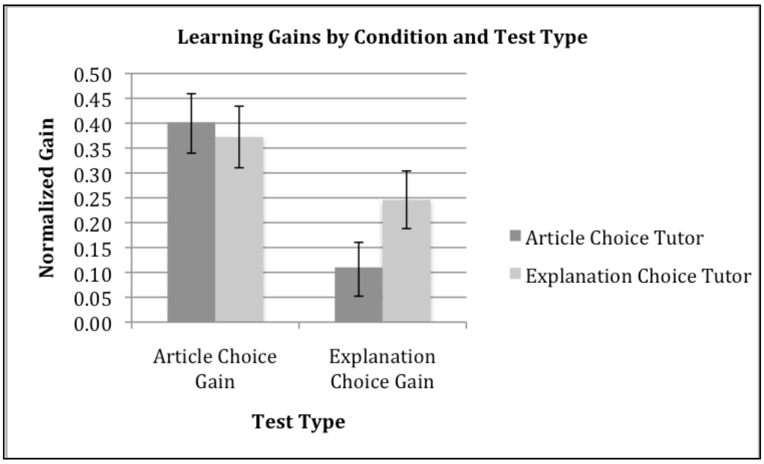

Figure 4: Normalized gains scores for article choice and explanation choice measures.

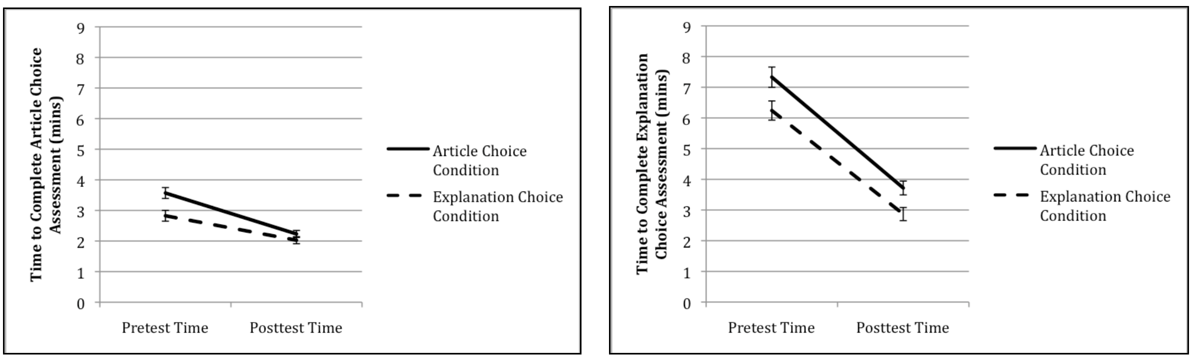
Surprisingly, we see cross-task transfer for both conditions: students using the article choice tutor show a small but significant gain on the explanation choice items, and students using the explanation choice tutor, who had no tutored practice with the article choice task, are showing equally high gain scores as those who used the article choice tutor. In addition to the tutored rules, students were also assessed on four control rules that were not included in the tutored material. These items were included in order to measure effects other than those from the tutoring system (e.g. students becoming more familiar with the interface, fatigue, etc.). For these untutored items, results of a repeated measures ANOVA investigating pre-to-post change across both conditions showed no improvement for the article choice items ($F(1, 95) = 0.01$, $p = 0.931$) and a significant decrease on the explanation choice items ($F(1, 91) = 7.59$, $p = 0.007$). These results support the conclusion that the observed learning gains on the tutored rules were the result of students' experiences with the tutors and not an unobserved, external factor. The decrease in explanation performance on untutored items may reflect students' tendency to use explanations consistent with the tutored items, which, of course, are incorrect for the untutored items.

## Processing Time

We also recorded the amount of time it took students to complete each assessment. Since measures of fluency include both accuracy and speed, reducing the amount of processing time that a student requires is an important goal. One concern with using self-explanation for teaching grammar is that it might take students longer to generate a response if they use an explicit, rule-based strategy than if they use an implicit one. A repeated measures ANOVA with log-transformed pre and posttest completion times as the dependent variables and condition and propensity group as the independent variables, show that students in both conditions are significantly faster at completing the posttest than the pretest for both measures (article choice: $F(1, 95) = 76.28$, $p < 0.001$, explanation choice: $F(1, 91) = 275.32$, $p < 0.001$) (Figures 5 & 6). A MANCOVA analysis with log-transformed completion times for article choice and explanation choice posttests as dependent variables, condition and propensity group as independent variables, and the log-transformed completion times for the pretests as covariates shows no main effect for condition ($F(2, 88) = 0.37$, $p = 0.689$). While students in both tutoring conditions are completing the posttests significantly faster than they complete the pretests, students in the self-explanation condition are completing the posttests just as fast as those in the article choice condition.



Figures 5 & 6: Students in both conditions and for both measures completed the posttest significantly faster than the pretest. More importantly, self-explanation instruction does not appear to be hinder students' speed in completing the mesures.

## Hint Usage

As mentioned above, the hint structure of the two tutors was very similar, and thus if students in both groups heavily relied on the hints, their experiences with the tutors might be similar despite the task (article choice vs explanation choice) differences. However, the log data show that students rarely request a hint (Figure 7). Approximately 80% of students using the article choice tutor and 75% of students using the explanation choice tutor requested hints on fewer than five problems (out of a total of 56 problems) and approximately 50% from each group never requested a hint. This suggests that any similiarities seen in learning between the two conditions is not a result of students seeing similar hints.

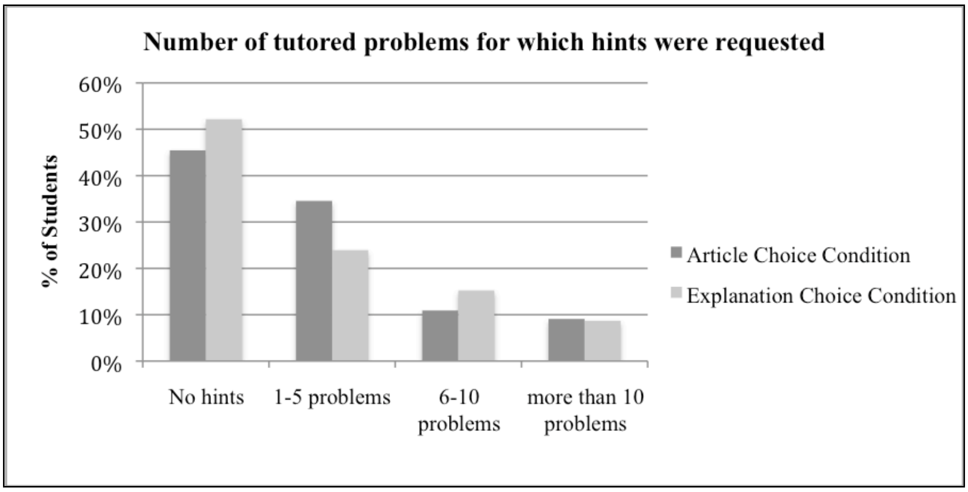


Figure 7: Overall, students using either tutoring system rarely asked for a hint to complete the problems.

## Effects of First Language

Finally, in order to determine if a student's first language (L1) had an effect on learning or if there was an interaction between tutoring condition and first language, we first classified participants' first languages into one of three categories: L1 has both a definite and indefinite article, L1 does not have a definite but does have an indefinite article, or L1 has neither a definite nor indefiniet article (Dryer, 2008) and then repeated the MANCOVA analysis described above, adding first language category as an additional independent variable. Results show no main effect for first langauge ($F(4, 104) = 1.31$, $p = 0.270$) and no interaction between first language and tutoring condition ($F(12, 104) = 0.683$, $p = 0.765$).

# Discussion

Both tutoring conditions were successful at increasing students' procedural knowledge (article choice) and declarative knowledge (explanation choice). These results suggest that students can learn from self-explaining not only in math and science domains, but also in new domains like second language grammar learning. The self-explanation prompts help students both to correctly use articles and to explicitly identify the rules driving these decisions. Further supporting this finding is the timing data that shows students in the explanation choice condition are solving the posttest problems just as quickly as their article choice counterparts. Thus, self-explanation improves both facets of fluency, speed and accuracy, just as well as practice.

While one might expect students in the article choice condition to improve on the article choice posttest and students in the explanation choice condition to improve on the explanation choice posttest, the fact that we see cross-task transfer for both tutoring conditions is somewhat surprising, although not unprecedented. In their study looking at the effects of self-explanation in geometry learning, Aleven & Koedinger (2002) saw similar results in that students in both the self-explanation condition and problem-solving condition showed significant learning in their ability to problem solve *and* in their ability to provide explanations or reasons. One key difference is that in the geometry study, students in the self-explanation condition had practice with both procedural (problem solving) *and* declarative (explaining) skills, while in our study, students in the self-explanation condition did not have any procedural (article choice) practice and were tutored on declarative skills (explanation choice) only. We hypothesize that the combination of worked examples (i.e. seeing the correct article highlighted in the problem sentence) and self-explanation prompts encourages students to focus on the features of the sentence that are important for making article decisions. They are then able to recall and apply these rules when presented with procedural items on the posttest.

We see a similar but smaller effect for students in the procedural (article choice) condition in that despite having no tutored practice on choosing explanations, they show significant improvement on the declarative items in the posttest. We hypothesize that the procedural instruction may have led to an increase in declarative knowledge through students inductively learning the rules and perhaps a priming effect by the pretest. Since all students took the explanation choice pretest, which asked them to use declarative knowledge, students may have been looking for and inductively generating the rules from the tutored problems they completed, accounting for the small but significant increase in declarative knowledge.

One limitation of this work is the generalizability of the results. Since the entire study was conducted during one class period, we had limited time within which to collect data. Due to this limitation, less than 80% of the students in the explanation choice condition finished all five stages of the study. While we used propensity score matching to account for the attrition in the analysis, we cannot make strong claims about those students for whom we have no posttest measures. As noted by the classroom teachers, students who did not finish likely fell into one of two categories: those with low prior knowledge and those with high prior knowledge who were very diligent. Perhaps self-explanation is not appropriate for all students. The metalinguistic challenges involved in choosing explanations in a foreign language might be too difficult for the low prior knowledge students, and asking very diligent students to self-explain each step may be an inefficient use of class time. To address these issues, on-going research is investigating interventions designed to foster feature-focusing behavior while minimizing metalinguistic difficulties as well as interweaving procedural and declarative tasks in order to reduce the amount of overall time needed to complete the tutor.

In conclusion, this study is one of the first to investigate the effects of self-explanation on language learning and presents promising results that prompted self-explanation helps students with procedural skills and enables them to develop explicit knowledge of the rules. Further work is needed to investigate the robustness of this effect and the extent to which this knowledge transfers to real-world production.

# Stressed yet Motivated: Web-Based Peer Assessed Competition as an Instructional Approach in Higher Education

**Abstract:** The study explores peer assessed artifact competitions conducted in a college setting. The competitions utilized a web-based environment for designing and enacting collaborative online activities. Since peer assessed team competitions are extremely effective in promoting learning yet are rarely conducted in higher education the study aimed at disclosing students' feelings about such potentially stressful circumstances. The peer assessed competitions were favorably accepted by most of the students who claimed that it improved their performance. Moreover, students level of stress was correlated with putting more efforts into the products and feeling that as a result its' quality improved. In addition, peer assessments were highly correlated with the instructor's assessments and students reported they trusted them regardless the rating received. Finally, Fear of Failure, as a personality trait, predicted which students would report being anxious about the competition. Implications for supporting such students are discussed.

## Introduction

Research indicates that team competition as an instructional approach produces higher learning performances than cooperative learning or competition among individuals (Slavin, 1980; Slavin et al., 1984; Fu et al., 2009; Ke & Grabowski, 2007). In team competitions a certain number of individuals cooperate as a group to compete against other groups. Such competitions are reported to be designed and successfully applied across various higher education programs such as Business Management (Corner et al. 2006; Casile, & Wheeler, 2005), Engineering (Cramer & Curten, 2005; Sansalone, 1990), Computing (Fu et al. 2009), and Instructional Design (Kinzie et al. 1998; Rowland, 1994). For instance, Corner et al. (2006) describe a case team competition that takes place every year where business management students analyze real-world complex case faculty members produced with the help of local businesses. Students give excellent evaluations to this activity and faculty members believe it is a wonderful experience. Cramer & Kurten (2005) too, describe a team competition occurring each year - where engineering students design , develop and test a Canoe made of concrete - as a peak experience in the program. However, all these studies ignore one of the most important pedagogical resources relevant to team competition – peer assessments; typically, students' teams are assessed and ranked by juries or faculty member, but not by the students themselves.

In higher education, peers have almost no input regarding their friends' projects flaws and merits, ways to improve it, etc. Yet, socio-constructivists theories argue that peers are one of the most influential factors in knowledge construction (Cole, 1996; Lave & Wenger, 1991). Peer assessment, in particular, has been shown to have many advantages. Studies have indicated that peer assessment assists students to create higher quality artifacts, as a consequence of better understanding of assessment criteria which they use when they play the role of assessors (Falchikov, 2003; Smith et al. 2002; Kali & Ronen, 2008). Since peer assessments are rarely used in competitive settings in higher education there is hardly any study that explored how students feel about exposing their work to peers under such circumstances. One of the purposes of this study is to answer this question.

Assuming that peer assessed competitions might have pedagogical advantages, orchestrating it (assigning artifacts for peer assessments, calculating and publishing the results, etc.) is logistically complex, hence, decrease faculties' incentive to embrace such an initiative. Recent e-leaning environments may provides an efficient solution to this challenge, by facilitating the design, orchestration and enactment of peer assessed competition activities, especially when dealing with artifacts that are produced in digital formats.

The CeLS (Collaborative e-Learning Structures), a web-based environment for designing and enacting collaborative online activities (Ronen et. al., 2006), provides an efficient solution to such a challenge. Using a friendly and intuitive interface lecturers use the CeLS to plan the competition and afterwards the successive stages are automatically handled by the system, e.g., students submit their product (the environment is designed to absorb multimedia artifacts), then, the environment randomly assigns a predetermined number of anonymous artifacts for each student to assess, then, the students submit their assessments. Finally, each artifact is publicly presented with peers' mean score plus anonymous verbal comments, adjacent to it. Typically each student receives scores and verbal comments form about 10-20 peers - depending on number of students in the class and number of artifacts each student is required to assess. Such a process allows for each artifact to be analyzed from multiple perspectives and gives each student a rich and multifaceted feedback. Since the CeLS environment supports the lecturer in structuring the activity and automates its enactment - using peer assessed competition as an instructional strategy hardly puts extra demands on the lecturer. In our study the CeLS environment was used to handle peer assessed competition activities in college level courses.

## The study

This study explores the pedagogical aspects of a peer assessed competition as an instructional approach in higher education. Our aim was to assess the quality and perceived value of the feedbacks students give their peers, and to figure out some of the motivational factors related to the fact that students know that their products will be assessed and ranked by their peers, and eventually will be publicly discussed in front of the whole class. How do students feel about such circumstances? Do they feel intimidated? Does it energize them? Do they put more effort into the project then they would normally do? Are personality traits, such as fear of failure, related to the ways they deal with the knowledge their products will be 'exposed' and assessed by their peers? Does fear of failure inhibit competitiveness? Do they appreciate their peers' feedback? In particular the study addresses three issues:

- How reliable are peer assessments? Do they correlate with the instructor's assessments? Do students trust peer judges?
- To what extent students feel that the web-based competition motivated them and encouraged them to submit better artifacts or, on the contrary, inhibited them and harmed their performance?
- Is Fear of Failure, as a personality trait, related to students' attitudes toward web-based competitions? Better understanding of the psychological dynamics related to such competitions might help us support students who dislike such activities and experience excessive stress related to them.

### Participants & Activities

Participants were 1st and 2nd year undergraduate students in an Instructional Technology B.A. program in a technological college. The program's curriculum is fully dedicated to instructional technologies (there are no other majors or minors) and students are involved in many team projects during their 3 years study. In the first two years all students take the same compulsory courses, while elective courses are offered only in the 3rd year. As a result of these circumstances students' cohorts form very cohesive groups. This fact may have implications on the ways students' experienced different aspects of the activity, such as the need to assess peers, the experience of being assessed by peers, and the experience of overt competition, as will be demonstrated in students' quotes reported later on.

41 1st first year students participated in an Introduction to Psychology course. As part of the social psychology unit students were asked to apply attitude-change theories and design a poster and a brochure that encourage parents to consider sending their children to schools that adopt constructivists' principles. Peers' assessment and competition in this group dealt with the poster and its efficacy and potential impact for raising awareness and attitude-change.

44 2nd year students participated in a Web based Inquiry Learning course. As part of the course the students were asked to design and develop a prototype of a WebQuest (Dodge, 1995) dealing with an historical dilemma (related to world war II) the lecturer provided. Peers' assessment and competition in this group dealt with the WebQuest design. Students were encouraged to use a rubric (Dodge, 2001) to support the design and the assessments process. The rubric contained assessment dimensions such as the effectiveness of motivational strategies used to provide an engaging webquest, the appropriate use of collaborative learning strategies, the sophistication of the task design in terms of encouraging higher-order thinking, etc.

## Method & Tools

At the beginning of the semester students completed a Fear of Failure personality questionnaire (Performance Failure Appraisal Inventory, Conroy, Willow & Metzler, 2002). The questionnaire measures the strength of individuals' beliefs in five aversive consequences of failing: fear of experiencing shame and embarrassment, fear of devaluing one's self-esteem, fear of having an uncertain future, fear of important others losing interest and fear of upsetting important others. The scores obtained from these five consequences are moderately- to strongly-correlated with each other and their common variance can be modeled with a single higher-order factor representing a general fear of failure. The breakdown of Fear of Failure to such 5 scales enables one to better understand the exact cause of fear and properly address it (Conroy, Willow & Metzler, 2002). Fear of failure, general, is believed to intimidate need for achievement and compositeness (McClelland, 1961).

During the semester students participated in the competition activity and were asked to assess their peers' projects and grade the artifacts. The specific activities and their web-based implementation are detailed in the next section. The competition activities were an integral part of the courses; participation as assessors was credited while the actual grades for the artifacts were given *only by the instructor* and students' assessments and ranking did not influence it.

Following the experience students answered a questionnaire (14 multiple selection items and one open question) reflecting on their feelings and attitudes related to participating in the web-based competition and their preferences regarding such projects. The questionnaire asked students to provide Likert type ratings to items such as: "the fact that my artifact was rated by my peers: stressed me, made me put more effort into the project, made me conduct more improvement trials, ended up improving my artifact", "peers' assessments seem valid to me", "I would like to have more such competitive-like activities". The open question asked for students' opinion about the competitive activity.

## Web-Based Competition: Instructional Design and Implementation

The competition activities were performed with CeLS (Collaborative e-Learning Structures), a web-based environment for designing and enacting collaborative online activities (Ronen et. al., 2006). The system offers content free templates and a searchable repository of sample activities that were implemented with students. Teachers can explore these resources and adapt them to suit their needs or create new activities from basic building blocks. CeLS unique feature is the ability to design activities that use learners' artifacts from previous stages according to various Social Settings (e.g., one team accesses another team's project, a whole class gives improvement ideas to one team, etc.). The Social Settings determine which and how many artifacts would be presented to each participant for further interaction. This feature is exploited in order to design the competition activities and to facilitate their enactment in a real setting. The general structure of a competition activity consists of three stages (Figure 1):

*Stage 1* presents the activity and provides a dedicated place for the artifacts submission. The submission interface is adapted by the teacher to suit the artifact's requirements: in the posters competition, in our study, the interface invited students to summit JPG files up to 300kB and in the WebQuest competition a the interface provided a location for submitting a proper link to a website. The artifacts submitted can be individual or group products, as defined by the Social Settings. In our case the artifacts were group products. This definition would enable either of the group members to submit the artifact then ensure that in the assessment stage a student would not be presented with her own group's artifact.

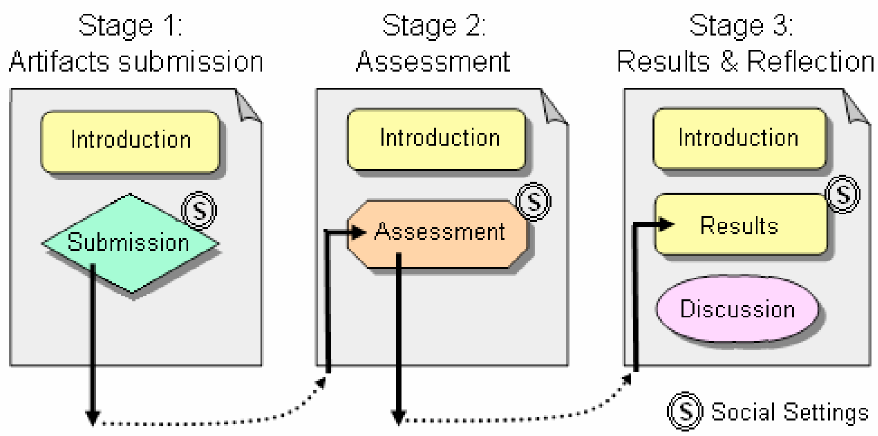

Figure 1. The general structure of a competition activity implemented with CeLS.

*Stage 2*: The Assessment stage starts with relevant instructions, then (some or all) peer artifacts are presented for voting (see Figure 2a). The artifacts are presented anonymously to the peers. If the activity involves assessing many artifacts (as in the Poster competition) or if the artifacts are complex and their assessment requires considerable effort (as in the WebQuest competition), it would be advisable to restrict the load and present each judge with a limited number of artifacts. Therefore, each judge in the Poster competition was asked to assess 8 artifacts (Figure 2a) while in the WebQuest competition only 5 artifacts were assessed by each student. Students were allowed a couple of days for these assessments. The Assessment interface in our competition activities was adjusted so that each assessor had to provide an overall grade and verbal justifications and explanations. If an activity would require a more detailed evaluation addressing various criteria, the Assessment interface could be a questionnaire or a rubric.

*Stage 3* presents the competition overall results (see example Figure 2b). The teacher can show the assessment details (grades and justifications) for all artifacts (presented anonymously) to all students or to present each participant only with the details for his own product.

Figure 2 presents partial sample screens from Stage 2 and Stage 3 of the poster competition.

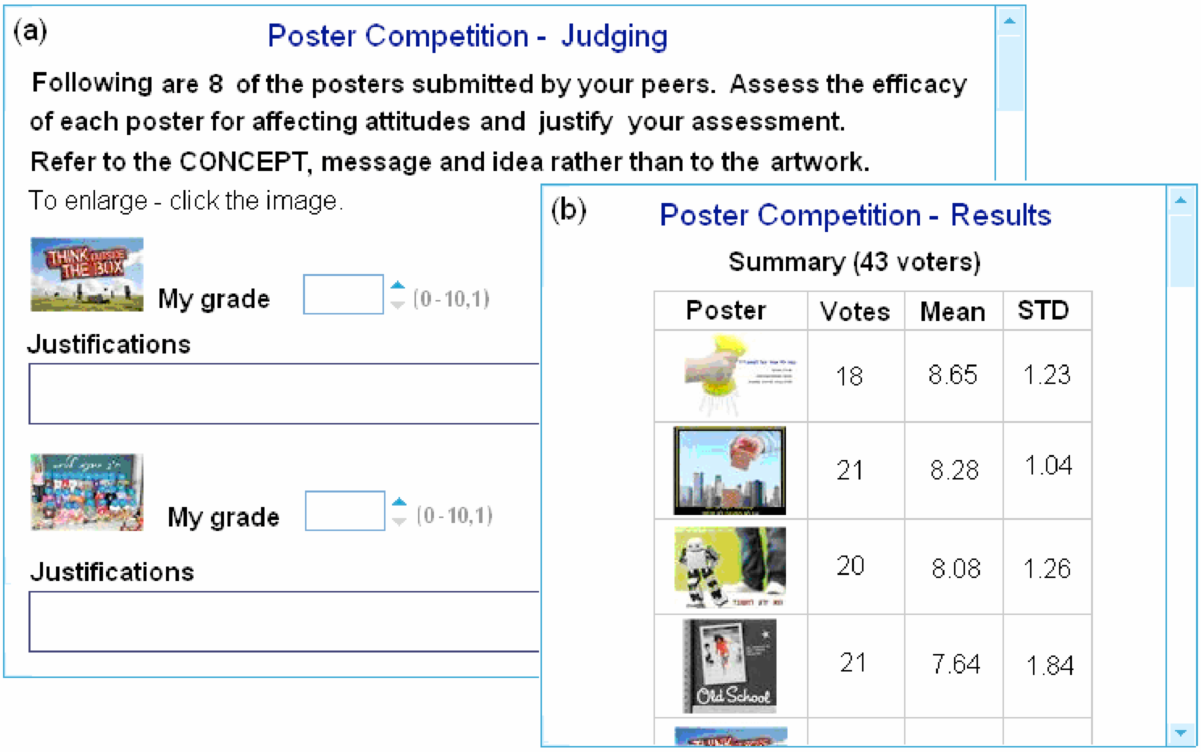

Figure 2. Sample screens from the poster competition. (a) Stage 2 (b) Stage 3.

## Results

First we will present data regarding the quality and worth trustfulness of peers' assessments and to what extent they feel their peers judged their artifact fairly. Then we will present students' attitudes toward competing and being assessed by peers and their perception of the impact of the competition approach on the quality of the artifacts. Finally, we will report about the relationships between Fear of Failure as a personality trait and students' attitudes toward web-based competition activities.

### Students as Assessors

Table 1 presents the correlations between students' mean ratings of artifacts and the lecturer's independent ratings. Similar to Kali & Ronen (2008) findings, students' mean ratings seem to be valid and correlate nicely with the instructor's grades.

Table 1: Correlations between students' mean ratings of artifacts and the lecturer's independent ratings.

| Activity | # of Artifacts | r | p |
|---|---|---|---|
| Year 1: Poster Competition | 20 | 0.82 | 0.000004 |
| Year 2: WebQuest Competition | 24 | 0.68 | 0.0001 |

There is a noticeable difference between the two correlations presented in Table 1. The higher correlation between students and instructor in the Poster competition is probably due to the fact that the artifact is less complex and less multi dimensional then the WebQuest one. In the WebQuest activity the assessment process was much more demanding. As a result some students were biased by salient features (such as interface and visual design) rather than assessing factors such as the pedagogical value of the WebQuest, resulting in a lower correlation between students' and instructor's assessments.

Students' comments to artifacts were interesting, non-repetitive, and provided an enriching and insightful analysis of the artifacts. It seems that a feedback given only by the instructor could not provide the intellectual and emotional impact of such a multiple perspectives feedback to many artifacts (see examples in Figure 3).

| A poster ranked highly by peers and instructor | | A poster ranked poorly by peers and instructor | |
|---|---|---|---|
|  | |  | |
| Peer grade | Justification | Peer grade | Justification |
| 9 | A very nice way to represent symbolically the idea (the sponge), plus a strong appeal to emotion. The verbal information is also very focused; it offers an alternative which emphasizes experiential, constructivist learning principles. Alfi Kuhn's ideas are very well represented in this poster. | 6 | It seems that the message intended to be delivered is that classroom materials are neither interesting nor relevant to children. They have big dreams and should be provided with means to reach these dreams. An alternative is missing: What should be done in order to bring relevance to the educational system? |
| 9 | I love the message which brings me back to the time where I studies History and had to learn by heart many 'dry' facts. It stresses the point that students absorb the material using rote learning and then they 'vomit' it. Loved it. | 5 | Overload of text and of visual elements as well. There is no clear saying. It is impossible to understand from the poster what is the problem and how to deal with it. The graphic design isn't impressive either. |
| 8 | This poster may cause actual attitude change! Parents would not want their children to be like a sponge with no understanding! Parents would like their child to learn, develop, understanding. The idea is very well capsulated and is very clear. The message will have a strong emotional impact on parents. | 5 | Although it is obvious that a lot of work and thought was put in the poster no real message is delivered, particularly when the topic we are dealing with is considered. One has to 'shock' the audience more heavily with clear-cut sentences that indicate what is the problem and what should be done to fix it. |
| 9 | Uses humor in an effective strategy. Does not use a simplistic one-sided attitude change strategy but rather a sophisticated message delivered lightly and clearly. | 7 | Good idea but it is somewhat unclear – the conformity on the one hand versus the over-emphasized wish to be unique on the other – but who/what could help children become unique? What is the next step? |

Figure 3. Examples of posters and few sample peers' assessments.

Most students in both classes (about 80%) felt that peer assessments to their own artifacts were valid and fair. No significant correlation was found between the appreciation of peer grades' validity and the actual grades granted by the peers, meaning that this view was shared also by students whose artifacts were judged less favorably by their peers.

## Competition as an Instructional Strategy – Student's Views

The analysis of 1st and 2nd year students' responses to the reflective questionnaire and interviews revealed very similar distributions, therefore we shall refer to both groups as a whole (N=85).

Most students felt that the awareness to the fact that their artifacts would be exposed and assessed by peers resulted in a better product (Table 2).

Table 2 : Perceived impact of the awareness that the artifacts would be assessed by peers on artifacts' quality.

| Perceived impact on artifacts' quality (%) | | | | |
|---|---|---|---|---|
| None | Little | Some | Large | Very large |
| 14 | 20 | 40 | 22 | 4 |

Only few students (4%) reported that the competition was somewhat "paralyzing" resulting in a detrimental effect upon their artifacts.

As could be expected, self reported motivation caused by the competition (items such as "the fact that my artifact was rated by my peers: made me put more effort into the project") was significantly correlated with the perception of positive effect on products' quality (r=0.72 p<0.000001). The more interesting finding is related to the perception of stress caused by the competition activity (based on the item: "the fact that my artifact was graded by my peers stressed me"). Even if no correlation was found between the degree of stress caused by the activity and the perceived impact on products' quality, the estimation of stress was significantly correlated with the perception of effort devoted to the creation of the artifacts (r=0.33 p<0.001), meaning that students who admitted to being more stressed also felt that they have devoted more time and effort to the activity. The beneficial effect of "some stress" is demonstrated in Table 3 that presents the student's perceptions of the competition activity as motivating and as stressing.

Table 3: Student's perceptions of the competition as a motivating and as a stressing activity (N=85).

| | | Motivation (%) | | | |
|---|---|---|---|---|---|
| | | none | some | much | Total |
| Stress (%) | none | **4** | **23** | **23** | 50 |
| | some | **2** | **20** | **24** | 46 |
| | much | **1** | | **3** | 4 |
| | Total | 7 | 43 | 50 | 100 |

Even if most (60%) would favor using competition activities in academic courses, in their detailed comments many recommended not to "overuse" this strategy and to restrict it to once in a semester in order not to impose an "exaggerated" workload. The quantitative aspects were supported by students' written comments. Following are few examples of students' opinions regarding peer judged competition as an instructional method:

**Positive opinions:**

- It is very motivating. It made me put lots of effort. I think that without the competitive factor I wouldn't have achieved such a success in this WebQuest activity. In addition the CeLS environment allowed us all to see each others' products, which is very nice for comparing and learning.
- The number of WebQuests we had to assess (5) was just right. I would not ask students to assess more then that. I believe competition is always a good idea. The fact that the leading products were presented and discussed in class made me feel really good after all the effort I have put in it.
- I am a competitive type so this method really helped me to achieve a meaningful product. I was enriched by viewing the elaborated products of my peers. To summarize, it was fun and educative.

**Ambivalent opinions:**

- I think the competitive activity is useful, efficient and contributing as long as a rubric is provided and the grading process is led by it. In this WebQuest activity we were encouraged to use a rubric. According to the competition results, it seems that not everyone used it - so there isn't enough uniformity in the grades given by peers and in some cases there weren't sufficient explanations to support assigned grades.
- I think that to some extent the competition did stimulate interest and encouraged teams to produce better WebQuests – yet, personally I believe that it is not always good to conduct such competitions since it might create tensions between class members, create uncomfortable situations, or unreliable results.
- I don't like so much competitive activities. Working in a primary school I saw cases where students gave up in advance, since they thought they don't have a chance. On the other hand – I think that from time to time, such an experience could be a fun and refreshing.
- Competition could paralyze people with low self-confidence – yet, with right team work such a problem might be less dominant. I believe in competition, believe it motivates, and produces higher quality products. Of course one shouldn't exaggerate and put people into too much pressure.
- Competition is a good yet problematic method. It was difficult for me to assess close friends from our class. In addition, competitive students would not want to give high grade to others that might surpass them. In a small and cohesive class as ours - it is hard to critique others.

**Negative opinions:**

- Some people need to learn how to provide feedback to others – and the lecturer needs to stress it.
- After reading the feedback given to our WebQuest I was pissed off. I realized that people drastically punished us for criteria that weren't relevant. It seems that people didn't realize what the purpose of the activity was. Some groups created a fully functioning web site rather then a prototype. As a result feedback focused on usability and visual design aspects rather then the criteria defined by the rubric provided.
- The problem with competition is that it puts pressure on those who are highly anxious. I am sorry that in our class (1$^{st}$ year, poster project) anxiety is more salient then healthy competition. But maybe it is only our class and when time passes it will change.

One can see the competitive activity raised some intense emotions. Some students loved it while others were skeptical about their peers' feedback and worried about augmenting the anxiety level in class. It seems that most of the students felt that activity was refreshing and fruitful yet shouldn't be implemented too often.

## Fear of failure and students' attitudes toward Web-based competition

Fear of failure was found to be related to participants' negative attitudes towards web-based competition. There was a considerable correlation ($r=.47$ $p<.01$) between Fear of Failure (sub-scale related to devaluing one's self-esteem) and participants' reporting that the competition paralyzed them. Similarly, Fear of failure (sub-scale related fear of upsetting important others) was correlated to students' preference to have peers assessments without numeric grades and competitive aspects ($r=.4$ $p<.01$). On the other hand, Fear of Failure (sub-scale related to fear of experiencing shame and embarrassment) was correlated with reporting about conducting more improvement trials ($r=.32$ $p<.01$).

It seems, thus, that fear of failure has different dimensions and is not a holistic psychological phenomenon with uniform consequences. Some dimensions (e.g., devaluing one's self esteem, or fear of upsetting important others) might inhibit students and consequently cause a decline in performance, whereas others (such as fear of experiencing shame and embarrassment), on the contrary, might boost students' motivation and make them invest more effort in their artifacts. Such fine differentiations might give instructors a clue regarding ways to support students who experience excessive stress related to peer-assessed competitions. For instance, instructors could encourage anxious students to try and diminish the direct, and at times painful, connection between their products and their self-esteem. Alternatively, an instructor could gently suggest that as grownups, important others might perceive such students more favorably then dominant persons related to their past.

## Discussion

The findings support previous reports which provide evidence that peer assessments are trust worthy, reliable, and in many cases highly correlate with instructors' assessments (Kali & Ronen, 2008). Students' verbal comments in our study demonstrate the emotional and intellectual advantage of feedback provided from multiple perspectives as compared to feedback provided exclusively from the instructor. Students' comment to peers' artifacts seem to be enriching, interesting, stimulating and honest. Despite the concerns of few, most students reported they trusted their friends' feedback, and this was true also for students who did not do so well.

Most students believe that the awareness to the fact that their products would be assessed by their peers boosted their motivation and as a result they submitted better artifacts. The fact that the experience of stress was positively correlated with effort invested supports the famous inverted U theory (e.g., Muse et al., 2003) which claims that moderate amounts of stress improves performance. However, our data suggests that some students might experience intense stress related to peer ranking and competition; Students who tend to devalue themselves as a result of failure, and students who tend to fear they upset important others when they fail – seem to have experienced the competition as paralyzing and would prefer not be ranked by their peers. On the other hand students who tend to feel embarrassed as a result of failure seem to put more effort and improve their performance. These findings shed some light on the possible dynamics causing some students to be paralyzed by competitive-like activities and provide some clues on how an instructor might support them.

The academic grading system is based on competitive sorting. Many believe that competition is detrimental to learning and to intrinsic motivation and call for the minimization of its effects by means of educational strategies such as collaborative learning (Kohn, 1992). Do competitive learning activities augment the harmful effects of grading and competitive sorting? Our quantitative and qualitative data supports studies that claim the team competition is and effective and engaging experience (Slavin, 1980; Slavin et al., 1984; Fu et al., 2009; Ke & Grabowski, 2007). Recent motivation theories (Covington & Wiedenhaupt, 1997) argue that intrinsic and extrinsic motivations are two independent dimensions (they suggest a quadripolar model rather than a bipolar one). Thus, despite the fact that competition factors might increase extrinsic motivation, one might still be intrinsically involved in a task, as long as it is intriguing, fun, and more similar to 'play' rather then 'work' (Covington & Wiedenhaupt, 1997). One can be stressed yet intrinsically motivated at the same time. Nemerow (1996) reached similar conclusions: In a study applying both competitive and noncompetitive games, students were surveyed to find out how they felt about the games and what they learned from them. Results indicated that competitive games helped students improve self-esteem, peer relationships, and learning, yet, the students described the competition as motivating but also producing pressure.

The competitive learning experience in our study seemed to endorse a playful climate and to intrinsically engage most of our students and caused many of them to believe they improved their performance. Other higher education studies which experimented with similar, fun, team competition activities support this notion (e.g., Corner et al. 2006; Casile, & Wheeler, 2005; Cramer & Curten, 2005; Kinzie et al. 1998).

## Summary & Concluding Remarks

The fact that the team competition activities energized students in our study and made them believe that it improved their products might indicate that when a favorable social climate is created most learners might enjoy and benefit from the 'public' exposure and competitive situation involved with peer ranking and assessments. The rich and divers nature of multiple perspective feedback seems to have a good potential of augmenting learning processes and meta-cognitive self-assessment abilities (White & Frederiksen, 2000). Teachers in higher education should consider using more often such strategies in any discipline where the creation of original artifacts is relevant. As long as they succeed to create a playful, psychologically safe learning environment, chances are most students will get intrinsically involved, enjoy the experience, and as a result of assessing others' work, become more reflective about their own learning. Using a web-based environment such as CeLS takes care of the logistic hassles and increases the chances that faculty members will enjoy the experience as well.

# Assessing Change in Learner's Causal Understanding Using Sequential Analysis and Causal Maps

Allan Jeong, Florida State University, Department of Educational Psychology & Learning Systems, Instructional Systems Program, Stone Building Rm. 3205E, ajeong@fsu.edu

**Abstract**: New methods are needed to assess how group discourse triggers changes in causal maps and to measure and visualize across time how changes in causal maps of individuals or the collective group progress toward the group or target map. The software tool, jMAP, was developed to enable learners to individually produce causal maps, download and aggregate the maps across learners. It aggregates learners' maps to reveal similarities between individual/group maps, the percentage of maps sharing particular causal links, average causal strength assigned to specific links, and degree of match between maps of the collective group and target/expert diagram. jMAP produces data to create transitional state diagrams for visualizing how causal maps change over time and the effects of specific dialogic processes. This paper presents findings from two case studies to illustrate how jMAP can be used to support the assessment of causal understanding, and identifies areas for future research.

## Introduction

Each one of us holds different beliefs and theories about the world. Learners' theories can be conceived, articulated, and assessed more efficiently in the form of causal maps - networks of events (nodes) and causal relationships (links) between events – than in the form of linearly written text. Some causal maps may be more accurate than others—depending on the presence and/or absence of supporting evidence; and some maps and the causal links within the maps may be more or less firmly held—depending on both the strength of the supporting evidence and the strength of specific causal relationships. Furthermore, causal maps are not fixed and unchanging. Instead, they are incomplete and constantly evolving; may contain errors, misconceptions, and contradictions; may provide simplified explanations of complex phenomena; and may often contain implicit measures of uncertainty about their validity (Seel, 2003). As a result, causal maps can change, but usually not randomly. That is, we presume that events trigger and provide the impetus for change. Causal maps and other similar forms of visual representations are being increasingly used to help assess learners' understanding of complex domains and/or learners' progress towards increased understanding (Spector & Koszalka, 2004; Nesbit & Adesope, 2006). However, the methods and software tools to measure how learner's maps change over time (Ifenthaler & Seel, 2005; Doyle & Radzicki, 2007) and how specific events (e.g., pedagogical discourse) trigger changes in learners' causal maps (Shute, Jeong, & Zapata-Rivera, in press) have not yet been adequately addressed.

To address some of these methodological challenges, Ifenthaler and Seel (2005) used transitional probabilities to determine how likely learner's maps (when examined at as a whole) changed in structural similarity across eight different time periods. Raters were given a specially designed questionnaire to determine if a learner's map at one point differed in structure from the learner's map produced from the most previous point in time. The study found that maps were most likely to change in structure at the early stages of the map construction process with the likelihood of changes dropping from one version to the next. However, Ifenthaler (2008) found that changes in scores on seven of nine measures of structural quality (e.g., total number of links, level of connectedness, average number of incoming and outgoing vertices per node) had no correlation to the degree to which the learners' maps matched the expert map. Not surprisingly, the one aspect of the learners' maps that did correlate to learning was the number of links shared between the learner's map and the expert map. These findings altogether suggest that measures used to gauge changes at the global level (where the unit of analysis is the map as a whole) and measures that are not scored in relation to a target map (e.g., expert or collective group map) may have little or no value as an assessment tool.

One alternative approach is to measure changes at a more micro-level using the node-link-node as the unit of analysis and unit of comparison between learners' and target maps. At this level, we can examine how likely links between specific nodes are to change from one state to another (e.g., strong vs. moderate vs. weak vs. no causal *impact*; or high vs. moderate vs. low *probability/confidence*) as maps change over time. We also see to what extent the observed changes in the values of each causal link converge towards the target causal link values present in the target map. For example, we expect that the causal link values for links representing learner's misconceptions (e.g., erroneous links *not* observed in the target map) or learners' shallow understandings (e.g., links between two nodes not directly related and/or better explained by inserting a mediating node) will converge towards a value of 0 (no causal link) over time, following a close examination and critical discussion of the causal relationships. At the same time, the expectation is that the causal link values of the links *not* observed in a learner's map (but present in the target map) will progress from a value of 0 to the value observed in the target map. Using the node-link-node as the unit of analysis enables a precise examination of how and to what extent observed changes in targeted links help and/or inhibit learners from achieving the target learning outcomes (e.g., deeper and more accurate understanding). Furthermore, this approach enables us to examine how specific interventions/events (e.g., depth of argumentation, the production of supporting evidence) affect the direction and magnitude of changes across links that are missing or links that are valid or invalid.

For example, Shute, Jeong & Zapata-Rivera (in press) conducted a study to examine the processes of collaborative theory construction in an online graduate course on instructional technology. In this study, each student used jMAP to individually construct a causal diagram (at the beginning, middle, *and* end of the semester) that explains the complex events and conditions (including intermediate events and their causal relationships) that determine when the use of media technology increases learning and achievement. In the causal maps, students assigned a strength value to each causal link (1 = weak, 2 = moderate, 3 = strong impact) based on personal experiences and empirical literature examined in the course. In addition, students were instructed to specify with each causal link added to the causal diagram the quality of evidence they possessed and/or compiled to justify the plausibility of each given link (0 = no evidence, 1 = weak evidence, 2 = moderate evidence, 3 = strong evidence). In this case study, the experimenters coded all the maps by hand and causal links into adjacency matrices because the early versions of jMAP did not perform this function. Once coded, jMAP was used to tabulate the sequential changes in causal links observed in each student's causal diagrams produced *prior* to and *subsequent* to collaborative work (identifying factors; collecting, annotating, and sharing supporting evidence; cross-examining the evidence; interpreting the evidence; consensus making).

The Discussion Analysis Tool (Jeong, 2005) was then used to sequentially analyze the data to produce the transitional state diagram presented below. The state diagram in Figure 1, for example, shows that 50% of all causal links that were assigned a strength value of one remained the same between the first and second, and between the second and third causal diagrams, when *no* evidence was presented nor discussed in the online group discussions to establish the plausibility and the strength of the link. In contrast, the state diagram on the right shows that when evidence was presented with the causal links, these same links with strength value of one were much more likely to remain the same (86% instead of 50%). Overall, this preliminary study illustrates how the jMAP environment – when combined with sequential analysis – can produce a potentially powerful method to studying the *processes* of theory construction and the factors and conditions that both support and inhibit the process.

This presentation will demonstrate the software tool called jMAP that can be used to identify differences between learners' causal maps, initiate collaborative argumentation to produce justifications for proposed causal links, and produces changes in learners' causal maps that better reflect/represent complex phenomena. Similar to the Cognizer program (Nakayama and Liao, 2005), jMAP enable each learner to produce a causal map with numerically weighted links (Figure 2) thus reducing unwanted biases and influences of other learners (Doyle & Radzicki, 2007). jMAP can then be used to: 1) automatically code diagrams into adjacency matrices; 2) upload, download, and aggregate multiple matrices so that the maps of an individual, the collective group, and/or expert (in any paired combination) can be graphically superimposed to determine for example the degree to which a learner's diagram matches that of the expert or the collective group at a given point in time; 3) view the superimposed maps across different time periods to both visualize and quantitatively assess how learners' causal diagrams change over time and the extent to which the changes are converging towards the maps of the expert or the collective group; and 4) sequentially analyze and visualize how particular learners' causal diagrams and causal understanding of complex phenomena change over time under different instructional processes, events, or conditions (Jeong, 2008).

jMAP also enable researchers and teachers to: (a) graphically superimpose an *individual* learner's map over the expert/target map to visually identify and highlight changes occurring over time in the causal maps of an individual or group of learners; (b) determine the extent to which the observed changes progress toward a target or collective model; (c) determine precisely where, when, and to what extent changes occur in the causal links within the causal maps; and most importantly; and (d) identify and measure how and to what extent specific events (e.g., viewing consensus data, discussing evidence, engaging in specific and critical discourse patterns) trigger changes in the causal links between various states (e.g., strong, moderate, weak, and no causal link) as demonstrated in Figure 3.

The following case study illustrates how jMAP can be used to assess how differences in the quality of learner's argumentation affect changes in learner's causal diagrams. Furthermore, this paper will also demonstrate how jMAP can be used to compare causal maps between learners, identify differences between learners' maps and initial/current consensus on map links, and to initiate and structure learners' discussions in ways that might help to improve their causal maps. The case study presented in this paper presentation addressed the following research questions:

1. *What are the effects of consensus observed in initial maps on the level of consensus in subsequent maps?* When learners use jMAP to determine which causal links are shared most among everyone's initial maps, are the most commonly shared links more likely to remain in learners' subsequent maps than the less commonly shared links?

2. *What is the relationship between initial levels of consensus and level of argumentation?* Do learners engage in more argumentation when a causal link is more or less commonly shared between learners? In other words, do higher or lower levels of initial consensus trigger higher levels of argumentation?

3. *What are the effects of argumentation levels on consensus in subsequent maps?* Do high levels of argumentation lead to higher or lower levels of consensus in maps produced subsequent to group discussions/debates?

# Method

## Participants

Nineteen graduate students (8 male, 11 female) enrolled in an online course on computer-supported collaborative learning at a large southeastern university participated in this study. The participants ranged from 22 to 55 years in age, and the majority of the participants were enrolled in a Master's level program in instructional systems/design

## Procedures

The course examined factors that influence success in collaborative learning and instructional strategies associated with each factor. In week 2, learners used a Wiki webpage to share and construct a running list of factors believed to influence the level of learning or performance achieved in group assignments. Students classified and merged the proposed factors, discussed the merits of each factor, and voted on the factors believed to exert the largest influence on the outcomes of a group assignment. The votes were used to select a final list of 14 factors that learners individually organized into causal maps.

In week 3, students were presented six example maps to illustrate the desired characteristics and functions of causal maps (e.g., temporal alignment, parsimony). Students were provided the jMAP program (pre-loaded by the instructor with nodes for each of the 14 selected factors) to construct their first causal diagram (map 1). Map 1 allowed students to graphically explain their understanding of how the selected factors influence learning in collaborative settings. Using the tools in jMAP, learners connected the factors with causal links by: (a) creating each link with varying densities to reflect the perceived *strength* of the link (1 = weak, 2 = moderate, 3 = strong); and (b) selecting different types of links to reveal the level of evidentiary support (from past personal experiences) for the link. Personal maps were completed and electronically uploaded within a one-week period to receive class participation points (class participation accounted for 25% of the course grade). The maps were also used to complete a written assignment describing one's personal theory of collaborative learning (due week 4, and accounting for 10% of course grade).

Using jMAP, the instructor *aggregated* all the initial maps ($n$ = 17) submitted by students into a group matrix. The group matrix was shared with students to convey to the students the percentage of maps that possessed each causal link. The links enclosed in boxes in the right side of the figure are *common links* observed in 20% or more of the learners' maps. For example, the causal link between 'Individual Accountability' and 'Learner Motivation' was observed in 47% of learners' maps. To select this 20% cut-off criterion, the instructor ran multiple aggregations of the learner maps at different cut-off criterion until the instructor felt that a sufficient number of links were present for group discussion and to discriminate between links that were more versus less shared between learners. A corresponding group matrix was also produced in jMAP to report the mean strength values of the links observed in 20% or more of the maps. The values were highlighted by jMAP to reveal which links were present in the expert's map but missing in the group map (i.e., dark shaded cells with values = links shared and strength values match, lightly shaded with values = links shared with non-matching values, lightly shared boxes with no values = missing target links).

In week 9, learners were shown the matrix that revealed the percentage of maps (map 1) that possessed each link. Students posted messages in an online threaded discussion forum to explain the rationale and justification for each proposed causal link. Each posted explanation was labeled by learners with the tag 'EXPL' in message subject headings. Postings that questioned or challenged explanations were tagged with 'BUT.' Postings that provided additional support were tagged with 'SUPPORT.' In weeks 9 and 10, learners searched for and reported quantitative findings from empirical research into a group Wiki that could be referenced and used later to determine the instructional impact of each factor.

Students received instructions on how to use jMAP to *superimpose* their own map over the aggregated group map (Figure 2) to visually identify similarities and differences between their own maps and the collective conception of the causal relationships between factors and outcomes. For example, figure 2 reveals the similarities and differences between an individual student's first map (student #4) and the group map (g1) generated by the aggregation of all the maps produced by all students at the first time period. The course instructor used jMAP to superimpose his expert map over the group map produced at time period one (g1) and in time period two (g2) by using the control keys (ctrl-h, ctrl-j, ctrl-k) to toggle between maps g1 and g2. By using the navigational tools to toggle between the two group maps, the instructor was able to visually and quantitatively observe the progression of changes averaged across all the students' maps in order to assess the extent to which the observed changes converged towards the expert map. Jeong (2008) presents more detailed information on how to use jMAP to visualize and animate progressive changes in maps created by a select learner (or group of learners) across multiple time periods relative to a target map.

In week 10, students reviewed the discussions from week 9. Within a discussion thread for each examined link, learners posted messages to report whether they rejected or accepted the link (along with explanations). At the end of week 10, each student posted a revised causal diagram based on their analysis of the arguments presented in class discussions.

### Data Analysis

To measure the level of change in learners' maps, link frequencies from each learner's second map (*n* = 15) were aggregated to determine the percentage of maps that shared each link. Differences in the reported percentages between maps 1 and 2 were computed and presented in a matrix. Overall, the percentages in 19 of the 24 commonly shared links increased by an average of 26%. Four of these shared links changed by an average of -10.75%.

The level of critical discourse produced within each discussion on each link was determined by the number of observed EXPL-BUT, BUT-BUT, BUT-EXPL or SUPPORT, and BUT-SUPPORT exchanges. Challenges to explanations, and explanatory responses to challenges were used as a measure of critical discourse because explanations, when generated in direct response to conflicting viewpoints, have been shown to improve learning (Pressley et al., 1992). Pearson correlations between variables are presented below.

Table 4. Correlations (*n* = 24) between level of initial agreement, critical discourse, and change percent of learners sharing each causal links

| | | LevelAgree | CritDisc | %Change | Expl | But | Support | Expl-But | But-Ex/Sup | But-But | Expl-Sup |
|---|---|---|---|---|---|---|---|---|---|---|---|
| LevelAgree | *r* | 1 | .385 | -.089 | .233 | .328 | .291 | .330 | .365 | .177 | .153 |
| | *signif* | | .063 | .679 | .272 | .118 | .168 | .115 | .079 | .409 | .476 |
| CritDiscourse | *r* | .385 | 1 | -.152 | .339 | .921 | .120 | .867 | .921 | .494 | -.135 |
| | *signif* | .063 | | .478 | .105 | .000 | .575 | .000 | .000 | .014 | .530 |
| PercentChange | *r* | -.089 | -.152 | 1 | -.058 | -.173 | .313 | -.051 | -.167 | -.219 | .386 |
| | *signif* | .679 | .478 | | .788 | .420 | .136 | .814 | .435 | .304 | .063 |

## Findings

### Effects of consensus in initial maps on level of consensus in subsequent maps.

Based on links (*n* = 24) that were observed in 20% or more of students' maps and discussed by students on the discussion board, the correlation (Table 4) between the percentage of students that shared a causal link in the first map and the average change in the percentage of students that shared the causal links was not significant ($r = -.089$, $p = .679$). The opinions of the majority did not appear to influence learners' decisions to include or exclude causal links into their revised maps. This suggests that the use of jMAP to reveal the similarities and differences between students' maps did not foster group think.

### Relationship between initial agreement and level of critical discourse.

The correlation (*n* = 24) between the percentage of students that shared a causal link in the first map and the level of critical discourse that was generated by students to exam the strength of each causal link approached statistical significance ($r = .385$, $p = .063$). The students engaged in more critical discussion over the causal links when the causal links were shared by more students rather than less students. This finding suggests that students did not simply accept or give into the status quo. Conversely, the finding also suggests that students exhibited some tendency to engage in *less* critical discussion over the causal links when the casual links were shared by *fewer* students. One possible explanation for this finding may be that the causal links shared by the fewest number of students where those that exhibited the most obvious flaws in logic and as a result, these links did not warrant much debate to omit the causal link from the causal maps.

### Effects of argumentation on changes in agreement in subsequent maps

No significant correlation was found between the level of critical discourse over each causal link and the change in the percentage of maps sharing each casual link ($r = -.152$, $p = .478$). This finding suggests that the level of critical discourse over each causal link neither increased nor decreased the percentage of students that rejected a causal link.

However, post-hoc analysis on the individual effects of each of the four types of exchanges (all of which were aggregated and used to measure the level of that critical discourse) revealed the frequency of EXPL-SUPP exchanges observed in discussions over each link were moderately and positively correlated (*r* = .386, *p* = .063) with changes in the percentage of students that shared each causal link. Supporting statements that were specifically posted in direct response to other learners' causal explanations (e.g., presenting supporting evidence, simple expression of agreement) were the types of events/exchanges that were most likely to persuade learners to adopt new links into subsequent causal maps. This finding is consistent with the findings from a previous case study in which causal link strength values were more likely to remain the same or increase in value when links were supported with evidence. Worth noting here is that the frequency of supporting statements alone in the discussions over each causal link (without regard to what messages they were posted in response to) revealed a similar correlation but of lesser statistical significance (*r* = .313, *p* = .136). This suggests that message-response exchanges as opposed to simple message frequencies alone could provide more explanatory power when analyzing the effects of critical discourse on causal understanding.

### Additional findings

To be included at the time of presentation will be the findings produced from the visual comparison of the transitional state diagrams (like Figure 1) depicting how the causal maps (or more specifically, the strength values of each causal link) changed over time resulting from the high vs. low presence of EXPL-SUPP exchanges observed in the discussions of each causal link.

## Implications

The findings in this case study illustrate how jMAP can be used to assess the impact of critical discussions or other instructional events/interventions on learners' causal understanding. When used as a research tool, jMAP provides insights into the processes of learning (e.g., causal understanding) and insights into how specific processes (e.g., EXPL-SUPP) lead to specific learning outcomes/behaviors. At the same time, this case study illustrates how jMAP can help learners work collaboratively to build and refine their causal understanding. Learners can identify similarities and differences in their causal understanding relative to others. Then they can use the differences as the starting point to discuss and explore the causal relationships.

### Directions for Future Research & Development

The findings in this case study are not conclusive given the limited sample size. Nevertheless, this study illustrates how jMAP can be used to assess how causal understanding evolves over time and how specific processes of discourse (including processes of scientific inquiry) influences causal understanding. More research is needed to identify the specific discourse processes and interventions that foster critical discourse that can trigger changes in causal links – particularly changes that converge towards the expert and/or group model.

To support future research, online discussion boards could be integrated into jMAP to automatically create discussion threads for each causal link observed in learners' causal maps, to seed discussions with learners' initial explanations, to support message tagging, and to compile and report scores that measure certain qualities observed in the group discussions for any given set of causal links. Such a system could be used by instructors to assess not only the quality of learners' causal maps and understanding, but also the quality of learners' discourse and its impact on their causal understanding. Additional functions can be added to jMAP to recognize nodes that are indirectly linked via mediating nodes to fully account for observed differences between learner and expert maps. Another useful function would be one that can identify and measure to what extent and in what temporal direction changes in causal links propagate subsequent changes in adjacent links – a measure that could be used to determine to what extent learners apply a systematic approach to break down the causal relationships. To examine this issue in more detail, a function can be added to jMAP that captures and logs every action performed in jMAP as learners construct their maps.

In addition, refinements to the jMAP user interface will be necessary to make map construction easier, more intuitive, and less time consuming if systems like jMAP are to be used in school-based applications – particularly for learners at younger ages. Instructions and guidance on how to conceptualize a coherent causal map/model (e.g., temporal flow, parsimony) should be embedded directly into the jMAP interface to assist learners that lack the skills needed to construct a causal map. Other useful functions to add to jMAP include: swap and change the target map so that one can compare different combinations of maps (individual, collective group, expert); show the percentage of students' maps that possess each target link by varying the density of each link to reflect the observed percentages; and select links to include in the aggregate/collective group map based on link frequencies that are significantly higher than the expected frequencies based on a user-selected critical z-score.

**Abstract:** Preparing citizens to address the complex problems inherent in cities requires our changing society to embrace a new kind of education. One way to train people to think about complex problems is to identify and study how professionals who think in those ways develop their *epistemic frame*. In this paper, we examine one of the ways urban planners master and appropriate relevant expertise through an ethnographic study of an urban planning practicum. Specifically, we use a new method called *epistemic network analysis* to look at presentation feedback sessions during two weeks of the practicum to explore emergent relationships between the teacher's planning expertise and the students' expertise. The results of this study indicate that epistemic network analysis offers a technique for analyzing the kinds of situated understanding that result from sociocultural learning and for observing the translation of pedagogy into practice in various types of learning environments.

## Major issue(s) addressed

Measuring learning in a practicum environment can be challenging, and a growing body of research suggests that a new method called epistemic network analysis (Shaffer et al., 2009) can inform our understanding of how professionals-in-training learn in a practicum environment. According to Donald Schön (1983; 1987), a practicum environment is explicitly designed to forge the links between knowing and doing that are central to the reflective practice of a profession. In a practicum, novices are initiated into a professional community of practice and extend their knowledge through tackling complex problems.

John Friedmann (1973) argues that our changing society requires a new kind of education where knowledge is extended and people are trained to think about and address the complex problems inherent in cities. One group of professionals tasked with addressing several of these challenges is urban planners, and studying how professional urban planners learn in a practicum environment can help us better understand how to train people to address complex problems.

In this paper, we examine one of the ways urban planners develop expertise through an ethnographic study of Urban and Regional Planning (URPL) 912, a graduate level practicum at a large Midwestern university. The main goal of the study was to explore the learning processes experienced by the 20 graduate students in the practicum. The students were guided in the production of a site plan for a developing area by a planner with 34 years of planning experience. In the study, we used epistemic network analysis to examine the presentation feedback sessions during weeks four and five and to explore emergent relationships between the teacher's planning expertise and the students' expertise.

## Potential significance of the work

The results of this study have the potential to influence the future design of professional practicum environments as well as the broader landscape of education.

## Theory

A major goal for educators is creating instructional contexts in which skills are both mastered and appropriated (Herrenkohl & Wertsch, 1999). Mastery and appropriation, according to Wertsch and Polman (2001), are part of mediated action—human action that is fundamentally characterized by a tension between active agents and the cultural tools they use to carry out action. Wertsch and Polman (2001) define mediated action as forms of action such as speaking, reasoning, and calculating that inherently involve agents actively using cultural tools. Herrenkohl and Wertsch (1999) stress that mastery of a cultural tool involves having the skill to use a cultural tool effectively, "knowing how" as opposed to "knowing that," or in other words, procedural versus declarative knowledge. In contrast, appropriation focuses on an agent's tendency to use a cultural tool, which can be distinct from the level of mastery involved. Using Bakhtin (1981), Herrenkohl and Wertsch (1999) claim that appropriation means to adopt, imitate, or pick up someone else's accent. Thus, appropriation is a process of making something, such as a historical narrative, one's own.

High levels of mastery are frequently associated with appropriation; however, some forms of mediated action are characterized by mastery but not appropriation of a cultural tool. Bakhtin argues that cultural tools are often not easily and smoothly appropriated, and that an agent may use a cultural tool but with a feeling of resistance or even outright rejection. When such resistance grows sufficiently strong, the agent may refuse to use the cultural tool altogether (Wertsch, 1998). However, Wertsch (1998) writes, "it has become increasingly clear that interactional contexts involving resistance and rhetorical opposition may provide some of the most productive settings for developing mastery and appropriation of cultural tools" (p. 182).

Herrenkohl and Wertsch (1999) believe that one of the most effective ways to foster the appropriation, and not just the mastery of cultural tools is to coordinate these cultural tools with sociocognitive roles. They claim that sociocognitive roles can be understood in terms of rights and responsibilities, where people have opportunities to exercise their rights as a way of being responsible to their community. Herrenkohl and Wertsch (1999) offer the example wherein a building inspector exercises her right to stop construction on a building because the contractor is suspected of using sub-par materials. In this example, the inspector is exercising a right in the context of her responsibility to protect public safety. Or, put simply, she is performing her job.

Herrenkohl and Wertsch (1999) propose that by promoting the idea of "doing one's job" and emphasizing the responsibilities to one's community and the set of rights that accompany those responsibilities, students will practice skills important to the sociocognitive role and begin to master and appropriate them. Unfortunately for educators hoping to introduce sociocognitive roles into their classrooms, Herrenkohl and Wertsch do not outline a specific process for creating the sociocognitive roles or offer suggestions about the types of skills that could be mastered or appropriated through students assuming roles.

Schön (1983; 1987) argues that, in most professions, people begin to master and appropriate skills in professional practicum experiences. In a professional practicum, novices engage in simulations of professional work. Their work is guided by repeatedly taking action and explicitly reflecting on that action with peers and mentors, what Schön refers to as reflection-on-action. The process of explicit reflection-on-action allows one to look back on a completed task or process to consider the implications and consequences of actions. Schön (1983; 1987) argues that the goal of the professional practicum is to bind action and reflection together to produce professional expertise particular to each profession.

Extending Schön, Shaffer (2004a; 2004b; 2006) argues that a professional practicum is a key step to developing the epistemic frame—or the ways of knowing, of deciding what is worth knowing, and of adding to the collective body of knowledge and understanding—of a particular community of practice. In a practicum environment, experienced mentors explicitly reflect-on-action as a way to model the epistemic frame of a profession. For novices, iterative cycles of action and explicit reflection-on-action with peers and mentors bind together the elements of the epistemic frame—the skills, knowledge, values, identity, and epistemology—that an individual takes on as a member of a community of practice. This collection of cultural tools forms the epistemic frame of the community, which, once appropriated, can be used when an individual approaches a situation from the point of view (or in the role) of a member of the community (Shaffer 2004a; 2004b; 2005; 2006).

Thus, Schön (1983; 1987) and Shaffer (2006) have a model of learning in a professional practicum that involves iterative cycles of action, explicit reflection-on-action, and the construction of a profession-specific epistemic frame. Their model extends Herrenkohl and Wertsch's (1999) assertion that coordinating cultural tools with sociocognitive roles can lead to both mastery and appropriation. Specifically, Schön and Shaffer move beyond a conversation about rights and responsibilities and into a discussion about designing professional practica and building epistemic frames. However, Schön and Shaffer's model does not address the role resistance plays in the mastery and appropriation of an epistemic frame.

While it is possible, and often quite important, to analyze how well students and others have mastered a cultural tool, such analyses can be quite limited in that they do not consider all of the complexities in the relationship between agents and the cultural tools they use (Wertsch, 1998). Thus, measuring appropriation in a practicum setting requires analysis of the process over time to see if there are instances of resistance that are inhibiting the appropriation of the epistemic frame. One way to analyze those components is through an epistemography, an analysis of the structure of a professional practicum through the lens of epistemic frames where one can examine the kinds of action and reflection-on-action that develop the epistemic frame of a profession (Shaffer, 2005; Svarovsky, 2006; Hatfield, 2008). An epistemography allows one to see learning principles at work and recognize some features of the practicum as being more essential than others in developing the professional epistemic frame. However, as Wertsch (1998) noted, the relationships between agents and their use of cultural tools are complex, and traditional statistical methods do not account for the complexities.

The kinds of professional understanding that a practicum develops are complex because they are not merely a collection of disconnected skills and knowledge. Rather, the power of an epistemic frame is in the connections among its parts, a network which consists of relationships among conceptual, practical, moral, personal, and epistemological parts (Shaffer et al., 2009). Thus, analytical methods such as social network analysis provide a robust set of tools for representing networks of relationships, including complex and dynamic relationships of the kind that characterize epistemic frames (Shaffer et al., 2009). In social networks, individuals are considered nodes in the network and relationships between individuals are represented as arcs or links between nodes (Haythornthwaite, 1996). For example, a social network analysis of an urban planning practicum might examine the relationships among students and the teacher throughout class meetings. Within each class session, different configurations might emerge as old friends connected, new friendships emerged, and different team projects occurred. The amount of time individuals spend with each other could be taken as a proxy for the strength of their relationship by analyzing the different connections among and between nodes and links. That type of analysis would provide a quantifiable way of comparing social relationships across time and a means for better understanding the informal information flows that supplement the formal practicum curriculum.

However, as Shaffer (2009) argues, social network analysis was developed to provide insight into relationships among and between individuals and groups, rather than relationships within the conceptual, practical, moral, and epistemological world of an individual. Therefore, building on social network analysis, Shaffer (2009) has developed epistemic network analysis, a computational modeling technique for the development of epistemic frames.

Epistemic network analysis is based on two key concepts: (1) that thinking can be characterized by the application of an epistemic frame composed of the linkages between professional skills, knowledge, identity, values, and epistemology; and (2) that the development of professional thinking can be quantified, analyzed, and visualized with a dynamic network model of the developing epistemic frame (Shaffer et al., 2009). Epistemic network analysis has been used to trace frame development in elementary and middle school students during epistemic games based on engineering and urban planning (Nulty & Shaffer, 2008; Nash & Shaffer, 2008). A preliminary re-analysis of qualitative data collected on a science journalism practicum suggests that epistemic network analysis will be a useful tool for analyzing epistemic frame development in professional practica (Hatfield, 2008).

This study extends the ideas of Wertsch, Schön, and Shaffer by examining the relationships between appropriation, resistance, reflection-on-action, and epistemic frames in a professional planning practicum. The aim of this study—the epistemography of URPL 912—is to uncover the learning process within a graduate urban planning practicum. In particular, we investigate how one teacher communicated his urban planning epistemic frame in the face of resistance by describing the students' initial resistance to the teacher's frame, the teacher's explicit reflection-on-action, and the students' appropriation of the teacher's frame. We then use epistemic network analysis to examine the teacher's role in the students' epistemic frame development by tracking how specific features and events in the practicum led to significant changes in frame development. We argue that epistemic network analysis can provide a computational model of the extent to which participants appropriated the ways of knowing, being, talking, and acting that characterize a particular community of practice. Finally, we discuss how the results of this study may contribute to the design of reflective learning environments and experiences that promote the development of the next generation of urban citizens.

## Methods

Urban and Regional Planning (URPL) 912 was a three credit course that met once a week for 14 weeks for approximately three hours. We chose to study URPL 912 because the course gives graduate students an opportunity to work in a practicum setting and is a prerequisite to entering the professional field of planning. The teacher was a professional planner with 34 years of planning experience across the United States.

In the course, 20 graduate students from the URPL masters program prepared a site plan for a developing area of approximately 3,000 acres on the northeast edge of Madison, Wisconsin. In the syllabus, the teacher wrote that he expected the students to "read the landscape" and expand upon the City's draft neighborhood plan for the area. Most of the class sessions began with the teacher's lecture, class discussion, or a professional planner guest speaker for the first hour and team work time for the remaining two hours.

Classroom data were collected in digital audio recordings and supplemented with field notes. Recordings were transcribed to provide a detailed record of interactions, and field notes were used to capture meaningful non-verbal aspects of the context and to supplement the transcripts. No information on specific career plans was collected; however, several students mentioned plans to pursue planning in city departments, non-profit groups, and state agencies. No other demographic information was collected about the students.

The data were segmented into interactive units which were defined as strips of activity with a consistent interactional structure and topical focus. For example, if the class started discussing the capacity of a proposed wastewater treatment plant and then switched to discussing the location of bike and pedestrian paths, the switch in discourse topic would indicate two separate interactive units. If an interactive unit represented more than one category, it was coded for all applicable codes. Within each interactive unit, the students' comments were coded cumulatively instead of individually in order to compare the students' cumulative frame to the teacher's frame.

This study's goal was to observe students learning to become planners through participation in a practicum. To capture interactions between the expert teacher and the novice students, we decided to focus on the communication between the teacher and the students during presentation feedback sessions. Presentation feedback sessions were occasions for the teacher and the students to offer feedback on information teams collected and for the teacher to explicitly reflect-on-action. Those sessions occurred in four classes throughout the semester: weeks 4, 5, 11, and 13. We chose to analyze data from the presentation feedback in weeks four and five because the feedback given during those weeks focused on the information needed to create successful site plans whereas the feedback given in weeks 11 and 13 was more focused on the logistics of preparing for the final presentations. The specific activities in weeks four and five are outlined in more detail in the results section.

We used the teacher's epistemic frame in week four as the comparative model for the students' cumulative epistemic frame in both week four and week five because we were interested in seeing if the epistemic frame the teacher used during week four influenced the students' epistemic frame in week five. Additionally, after giving his initial lecture in week five, the teacher did not contribute as much as in week four. To measure the teacher's contribution in weeks four and five, interactive units were coded for the presence of the teacher's comments.

Table 1: Analytic codes applied to segmented interactive units for qualitative data analysis.

| Code | Description | Example |
|---|---|---|
| Resistance | Student references to their conception of how the planning process should progress in a way that was contrary to the teacher's conception of how the process should move forward | …I sort of got the sense that they [the City] want us to deliver to them a set of policy recommendations and other higher level stuff to help them move this process along rather than our own design. |
| Reflection-on-action | References where the teacher looked back on a completed task or process to consider the implications and consequences of actions | …I'm just saying that when you look at the land use pattern, based on uses like that quarry, there's real limitations on residential in a large part of the area...Maybe this needs to be a place with a real employment center instead of just a bedroom community. I'm not saying that you don't have residential, and I'm not even saying you necessarily start in one place or the other, but I'm saying that it's gotta be in the thought process here. |
| Skill of reading a landscape (S/L) | Ability to use the landscape to inform the planning process | …I that it's very important that we step back and say, "How does this landscape speak to us?" Rather than letting someone else give it to us. |
| Skill of suggesting alternatives (S/A) | Ability to use a specific strategy or an alternative way to approach creating a plan | Shoehorning residential onto the North end won't work. Let's see if we can put some jobs up there so that the people who live further south, where it's easier to do residential development have a place to go that's a mile away or a mile and a half away instead of coming down to Madison. With that, make it a more sustainable community. |
| Skill of questioning assumptions (S/QA) | Ability to identify the assumptions the students made in their analyses | You guys all have to make some recommendations, but I don't want us to go into this without making sure that we are comfortable with the assumptions they [the City] are operating under…I'm not comfortable with all of the assumptions they are operating under and I think that their assumptions are no longer evidence-based… |
| Knowledge of additional information (K/AI) | References to specific information that might be useful for creating the site plan. | This is what we think is important to identify: Property values and who owns it to see if there's any correlation there. Target areas for potential development areas etc... Changes in zoning with different incentives for developers, transfer of development rights. Existing viewshed protection… |
| Knowledge of past process (K/P) | References to the process used by the City of Madison to create a plan for the same redevelopment area. | We saw a map of what they [the City] have in mind, and they already have land uses plotted out. They are presenting that to the mayor in the next few weeks. In that land use map, they have mixed use housing and TODs [transit oriented developments] and lower density housing, and the majority of it is also going to be lower density acreage. |

| | | |
|---|---|---|
| Value of serving the public interest (V/PI) | Stating that the needs of people affected by the planning process are important to urban planning practice | The developer has to be involved in this association. It's not optional. They have to be part of the deal, and you are going to have to figure out what the City of Madison would say to one or more private land owners. |
| Epistemic statement about stakeholders' desires (E/SD) | Justifying decisions based on how participants thought a particular stakeholder group would respond. | …Businesses that might be developing through the university or incubator or something. They are going to need production and assembly facilities. They are going to need distribution facilities. And that might not be stuff they can get either on campus or in that incubator. This might be an ideal spot for them… |
| Epistemic statement about principles of good urban form (E/UF) | Justifying decisions based on the principles of good urban form | The city is planning the East Wash. build out in terms of employment…which means that it would have to put itself on the periphery because of the land loss. They could have an office near their production facilities. We see that as a potential benefit. |

The result of the coded segments was a database of interactive units showing the presence of the teacher's comments, resistance, reflection-on-action, and epistemic frame elements. The relationships among these different components were then analyzed using epistemic network analysis to identify salient themes.

Epistemic network analysis adapts the framework of social network analysis for use with cognitive, rather than social, elements (Hatfield, 2008; Shaffer et al., 2009). As discussed in the background section, Shaffer (2009) has developed epistemic network analysis, a computational modeling technique for the development of epistemic frames. For details on the computations involved in epistemic network analysis, please see Shaffer (2009).

Once an epistemic frame is represented as a series of cumulative adjacency matrices showing the strength of association between each pair of frame elements for a given participant in the data set, the characteristics of the network can be quantified using concepts from social network analysis, such as network density and centrality of individual nodes (Shaffer et al., 2009). The overall structure of an epistemic frame can then be quantified by computing the relative centrality of each node: the square root of the sum of squares of its associations with its neighbors expressed as a percentage of the weight of the heaviest node in the network.

For this study, the relative centrality of each frame element and sub-element at the final time slice of the presentation feedback activity was calculated in order to compare the cumulative students' frame in weeks four and five to the teacher's modeled frame in week four. Calculating the relative centrality exposed which frame elements were further or closer to the center of the epistemic network (relative centrality values closer to 100) since epistemic frames consist of elements linked together with some elements more central than others. Using only the final time slice of relative centrality offered the most accurate picture of the students' cumulative frame development during weeks four and five since relative centrality is a cumulative measure of the changes in centrality to the epistemic network graph.

The frame similarity index (FSI) is an extension of epistemic network analysis. In this study, the FSI was calculated using the relative centrality which allowed comparisons between the students' frame development in weeks four and five and the frame modeled by the teacher in week four. The FSI was computed by using the difference between the cumulative students' final relative centrality calculations for each frame element in weeks four and five and the teacher's final relative centrality calculations for each frame element in week four. The absolute value of the difference of the values was then calculated. In order to make claims about skills, knowledge, values, and epistemology as a whole, the average of the frame sub-elements (e.g. E/SD and E/UF) was computed, and the results were graphed as cumulative frame elements (e.g. epistemology instead of E/SD and E/UF).

The FSI affords us the ability to use qualitative data to compare the development of complex thinking quantitatively. The FSI can be visualized using a radar plot where the optimal frame is represented as the origin and the developing frame is shown as something. This type of representation allows us to visualize the movement of novices' epistemic frame development in relation to the expert's epistemic frame. In the radar plot below, the teacher's frame is represented as the origin, and the closer the students' cumulative FSI is to zero, the more closely the students' frame resembles the frame the teacher modeled in week four.

## Results

We describe our observations of URPL 912 in three parts below. First, we identify and describe the interactive units in which the students resisted the teacher during weeks four and five. Next, we identify and describe the interactive units in which the teacher reflected-on-action during weeks four and five. Finally, we describe the changes in the students' cumulative epistemic frame from week four to week five.

At the beginning of the semester, students in URPL 912 worked in teams to gather information about the redevelopment site. During the first class session, they learned that the City of Madison had been working on a plan for the site for three years, and the students were expected to "read the landscape" and expand upon the City's draft neighborhood plan for the area. The students continued to learn about the site through the teacher, guest speakers from the City of Madison planning department, out of class site visits and meetings with city officials, and targeted internet research. The teams were expected to present their initial findings during week four and their more specific findings during week five.

While presenting and giving feedback during week four, the students referred to the approach the City of Madison was using for the redevelopment site. When the teacher suggested alternative approaches that were contrary to the City's approach, the students began to resist his suggestions. Overall, in week four, 3 of the 11 segmented interactive units in the presentation feedback activity were coded for the students resisting the teacher's ideas, accounting for 54% of the time when both the students and the teacher were talking about the same topic. In contrast, in week five, the students did not resist the teacher's suggestions in any of the seven segmented interactive units in the presentation feedback activity when both the students and the teacher were talking about the same topic.

During the presentation feedback activities, the teacher often explicitly reflected on the students' findings, gave suggestions for additional information they could gather, and shared anecdotes about how the problems they were facing were similar to problems he had faced with previous projects. In week four, 11 of the 12 total segmented interactive units were coded for the presence of the teacher's comments, and 8 of the 11 segments during which the teacher spoke were coded for him reflecting-on-action. By reflecting-on-action, the teacher specifically pushed the students to question the City's assumptions and to consider how the population projections would affect traffic, jobs, and the overall development trajectory. By explicitly questioning the City's assumptions and offering suggestions about how to deal with multiple possibilities, the teacher spoke directly to the students' resistance in week four and strengthened the case for having the students' use his approach rather than the City's approach.

Unlike week four, in week five, the teacher started the class session by giving a lecture. During his lecture, the teacher reflected-on-action and explicitly addressed the students' resistance from week four. He reflected on the actions the students took in week four and referred to his experience as a planner in order to address the students' anxiety about using his approach instead of the more familiar City's approach. Specifically, the teacher suggested that taking time to gather information early in the process would have positive implications for the final site plan. To address their anxieties, he encouragingly reflected on the work the students completed in week four, told them he was expecting to be pleased in week five, and assured them that though they were at a slow part in the process, they were on course. To attend to the students' concern that his approach would not relate to the work the City had already accomplished, the teacher suggested that the students: "…Let this piece of land speak to us [because]…If we try to decide what it's going to look like before then, what you're going to end up with is exactly what you don't want to end up with which is something that doesn't relate."

Following the teacher's lecture, the students presented the information they gathered about the site and gave feedback on the information presented. During the presentation feedback, 8 of the 14 total segments were coded for the presence of the teacher's comments, and in one of the eight segments, the teacher was the only person speaking. Two of the seven segments wherein the teacher spoke were coded for the teacher reflecting on action. During the presentation feedback in week five, a student asked about the City's assumptions, and the teacher reflected-on-action by explicitly considering the implications and consequences that information would have for the recommendations they could make in their final site plans. By explicitly reflecting-on-action and addressing the student's resistance before they rejected his process outright, these data suggest that the teacher created a space where the students could begin to appropriate the epistemic frame he modeled in week four.

Using epistemic network analysis, Figure 1 provides a summary representation of the frame similarity index (FSI) of the difference between the students' cumulative epistemic frames in weeks four and five and the teacher's modeled epistemic frame in week four, which is represented by the origin of the radar plot. The total FSI was 165.8 in week four, but in week five, the FSI decreased to 90.3 suggesting that the students' frame became more similar to the frame the teacher modeled in week four. There was not a significant change in value development from week four to week five for the students; however, skills, knowledge, and epistemology frame elements began to look more like the teacher's modeled frame.

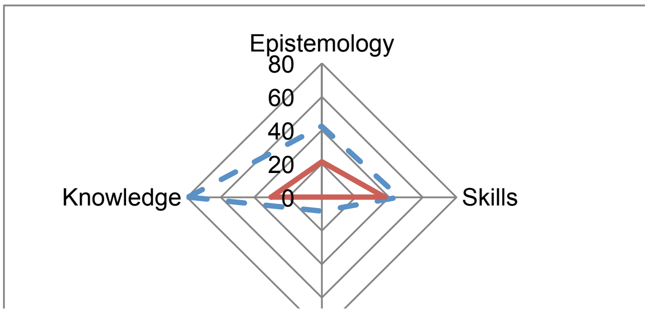

Figure 1. The origin of the radar plot represents the teacher's frame, and as the cumulative students' FSI moves closer to zero, their frame begins to look more like the frame the teacher modeled in week four.

By separating the epistemic frame elements into sub-elements, a more complete picture emerged about which specific sub-elements became more or less central to the students' epistemic frame from week four to week five (Table 2). As discussed above, for the teacher, V/PI, S/QA, S/Land, K/AI, and E/UF were the most central sub-elements in his epistemic frame in week four while the most central sub-elements in the students' epistemic frame were V/PI, E/SD, and K/P. In week five, instead of having a strong central core consisting of V/PI, E/SD, and K/P, the students exhibited a new configuration of their epistemic frame which looked more like the teacher's and included sub-elements such as S/Land, S/Alt, K/AI, and E/UF increasing in centrality. The order of centrality of frame elements also changed from week four to week five.

According to Shaffer (2009), the relative centrality of a node within a network represents the extent to which the node is or is not part of the dense central core of the network. Thus, though some of the sub-elements became more central to the students' epistemic frame, the relative centrality values of the sub-elements in the students' frame in week five were consistently lower than the teacher's values. Presumably, the teacher had higher relative centrality values for frame elements in week four because his 34 years of planning experience necessitated that his epistemic frame start out more richly interconnected than the students' epistemic frame. Therefore, the 'looseness' of the students' epistemic frame may be due to the students beginning to appropriate the sub-elements, and since the dense core is central to the strength of the epistemic frame, their epistemic frame will likely strengthen over time.

Table 2: Cumulative relative centrality calculations for eight epistemic frame sub-elements for the students in weeks four and five and the teacher in week four.

| | V/PI | S/Alt | S/Land | S/QA | K/AI | K/P | E/SD | E/UF |
|---|---|---|---|---|---|---|---|---|
| Students Week Four | 91.65 | 44.72 | 0 | 60 | 28.28 | 91.65 | 100 | 44.72 |
| Students Week Five | 100 | 73.38 | 55.47 | 55.47 | 83.21 | 48.04 | 55.47 | 55.47 |
| Teacher Week Four | 100 | 46.71 | 96.30 | 100 | 95.35 | 0 | 61.79 | 91.45 |

These results suggest that examining changes in epistemic frame development across time was a useful way of seeing the process of appropriation in the midst of student resistance in URPL 912. Through explicit reflection-on-action, it appears that the teacher addressed the students' resistance, enabling them to appropriate his epistemic frame.

## Conclusions and implications

This study extends Wertsch's work on resistance and appropriation. Wertsch (1998) writes about the productive role of resistance in the process of appropriation, and in week four, there was student resistance. However, looking across weeks four and five shows that the students' resistance subsided, and the bridge between the students resisting and not resisting was the teacher's lecture. The teacher's lecture was essentially an explicit reflection on the different frames held by the teacher and the students and provided a map of the professional vision of the planning practice. However, it seems unlikely that his lecture immediately helped the students understand the epistemic frame of planners in a new light and enabled them to put their new knowledge into practice in their presentation feedback. Therefore, the students must have started appropriating aspects of the teacher's epistemic frame in week four despite their resistance.

Thus, these results also suggest that the kind of reflective mentoring that Schön and Shaffer describe in professional practicum settings accomplishes the task of helping students appropriate a new frame in the face of resistance. Specifically, the results of this study indicate that identifying practicum activities that evoke evidence about certain aspects of an epistemic frame will provide valuable information for designing effective practicum environments and learning in general. For example, practitioners thinking about ways to enhance their practice might consider including iterative cycles of action and reflection-on-action which may lead to appropriation and mastery.

This study demonstrates that epistemic network analysis can be a productive way of tracking how specific interactions within learning environments lead to significant changes in cognitive development. Building on initial work (Hatfield, 2008; Shaffer et al., 2009), this study adds frame similarity index to epistemic network analysis' set of techniques, in this case to compare the students' frame development in weeks four and five to the frame modeled by the teacher in week four. Specifically, the differences between the students' and the teacher's relative centrality values suggest that indices from epistemic network analysis can be useful for group comparisons and experimental studies of interventions. In other words, epistemic network analysis provides a computational model of the process and extent to which participants appropriated the ways of knowing, being, talking, and acting that characterize a particular community of practice. Thus, epistemic network analysis offers a technique for analyzing the kinds of situated understanding that result from sociocultural learning.

This study's findings can expand epistemic network analysis to provide a computational model of the extent to which participants appropriate a professional epistemic frame in the face of resistance with the help of a mentor's explicit reflection-on-action. Thus, epistemic network analysis points towards a promising new way of observing the translation of pedagogy into practice in various types of learning environments. These findings—and future studies investigating reflective practica and the development of epistemic frames—can shed light on how to better prepare citizens to think about and address the complex problems inherent in cities because as John Friedmann (1973) wrote, "the reconstruction of society must begin with man's re-education."

# Assessing the Development of Expertise in an Historical-Based Science: The Case of Integrative Archeology

Inbal Flash-Gvili, Jeff Dodick, Science Teaching Center, The Hebrew University of Jerusalem, Israel
finbal@cc.huji.ac.il, jdodick@vms.huji.ac.il

Developing inquiry-based skills in science students is a key focus of science education. This study examines the process whereby such skills are acquired by exploring the case of graduate training in the discipline of integrative archeology. To do this, we focus on the questions that the students posed during their field research. Our results show that some students attempt to bypass an initial phase of their research by trying to solve the final goal of reconstructing human behaviors, rather than focusing on material remnants that make such reconstruction possible. In the field, this was observed when the students attempted to reconstruct events via their own logic, rather than using the technical tools at their disposal to analyze the site's (chemical) properties. However, as their expertise grows, the students learn about the importance of foundational questions; this is reflected in a change in the frequencies of their questions, which in turn reflects a change in their research strategies.

## Introduction

Scientific inquiry can be defined as "the diverse ways in which scientists study the natural world and propose explanations based on the evidence derived from their work" (NRC, 1996 p. 23, 2000 p.1); thus, the NRC defines inquiry-based learning as a process where "students actively develop their understanding of science by combining scientific knowledge with reasoning and thinking skills" (NRC, 1996 p. 2). The same source also claims that: "Inquiry into authentic questions generated from student experiences is the central strategy for teaching science" (NRC, 1996 p. 31). These definitions create a picture of a type of learning strategy, which should reflect the nature of science via scientific inquiry. Yet, the question remains as to what exactly are 'the correct' characteristics of scientific inquiry in practice?

A simple model of scientific inquiry is based on *the scientific method*. Broadly speaking, it is described as a process in which the following events occur in sequential order: (1) observing, (2) developing a question, (3) developing a hypothesis, (4) conducting an experiment, (5) analyzing data, and (6) stating conclusions. This process continues as new questions are generated based on previous findings. This model, with different variations is repeated in many of the US standards documents (NRC, 1996, 2000).

However, since its development, this model, with its rigid series of stages, has been criticized by philosophers and science educators, who have produced alternative lists of process skills that were considered more flexible. An example of such an alternative list is presented in the *Science: A Process Approach* program (AAAS, 1967). One example of an alternative process skill is controlling variables, a strategy which has received enormous attention in research on the development of scientific reasoning (Kuhn and Dean, 2005). Still, these lists are problematic as they define *the scientific method* as a coherent entity with regards to different scientific disciplines (such as geology or physics). This problem is reflected in the way scientific inquiry is defined by the NRC (1996; 2000). From one side, it talks about multiple methods; yet, concurrently it adheres to a single scientific method. Thus, if one of our science education goals is to create future experts by enhancing their ability to acquire scientific inquiry skills, we need to teach in a much more authentic way that reflects the methodological diversity of the sciences. As Sternberg (2003) suggests:

> If we wish to teach and identify expert students, we need to identify expertise in a way that is closely aligned with the way experts are identified in the disciplines students study. For starters, this means having students do tasks, or at least meaningful simulations, that experts do in the various disciplines. Second, it means teaching them to think in ways experts do when they perform these tasks.

Following Sternberg's (2003) recommendations, if we want to understand the development of expertise, we must first characterize the tasks that experts do in different disciplines, as well as the inquiry skills that they apply while engaged in those tasks. One research method that has been used to understand expert inquiry skills in the sciences is by studying the practices of scientists while they pursue their research agenda in real time (the *in vivo* method). Thus, in this study, we ask the following question: how do inquiry skills develop within a team of graduate student researchers in the *historical-based* science of integrative archeology? To answer this question we followed these students as they conducted their research.

There are many instruments for assessing the development of scientific inquiry skills, and in this study we used (among other sources of data) the scientific questions our research subjects generated about their field-based work. Students' ability to ask high-level questions about scientific phenomena has been shown to be a good indicator of science learning in students from the high school to university level (Brill & Yarden, 2003; Chin, 2004; Hofstein et al, 2005; Marbach-Ad & Sokolov, 2000). However, such question-asking must be put in context; to do this, we will also describe the research process of the team as a whole, as well as add important observations from the field and our interviews with the team members which further validate this analysis.

### Understanding the Development of Scientific Expertise

Our understanding of what it means to be an expert in a domain has grown ever since DeGroot's (1946) classical studies of chess players. Thus, Chi and Glaser (1988) described experts as excellent performers who have superior short and long-term memory and represent problems in deeper, more principled way than novices who tend to build superficial representations. Concordantly, it was found that experts spend more time on constructing a good problem representation, while novices applied a suboptimal trial and error strategy (Van Gog et al., 2005).

Many theories were developed to explain these differences in performance (e.g.: Ericsson et al, 1993; Gobet and Simon, 1996). One such theory, the Model of Domain Learning (MDL) suggested by Alexander (1997), is important to our work because it portrays the nature of developing expertise in authentic academic domains rather than extracting it from carefully chosen problems in diverse nonacademic domains. In contrast to the traditional expert-novice theories, this model assumes that there are no sharp contrasts between experts and novices; rather, it is a graded transition toward expertise. It also considers both cognitive and motivational aspects as important factors in the expertise learning process, in contrast to traditional models which are "coldly cognitive" (Pintrich et al., 1993). Thus, it focuses on three components (i.e., knowledge, strategic processing, and interest) which are interrelated and play a role in this transition. In this paper, we focus on the first two components.

According to this model acquiring expertise has three stages (i.e., acclimation, competence, and proficiency/expertise). The most critical differences between experts and novices is the development of a broad and deep knowledge base, a shift in the kind of strategies used, from surface-level to deep-processing, and the increase in individual interest which permits experts to maintain a high level of engagement over time. The concurrent development of these components allows experts to be actively engaged in problem finding, posing questions, and instituting investigations that (sometimes) push their domain boundaries.

In terms of expertise studies examining scientific thinking in particular, the research have gone through considerable changes since its earliest period where the focus was on testing circumscribed aspects of the scientific discovery process (e.g. Wason, 1968). Within the last two decades, researchers have used simulated discovery tasks in complex domains in order to track participants as they explore, test hypotheses via experimentation, and acquire new knowledge in the form of revised hypotheses (Schauble, 1996).

However, such empirical research has a number of problems when used to generalize about scientific reasoning, such as the fact that scientific research is a collaborative enterprise taking months or even years to complete (Dunbar, 1995). Thus, researchers in the field of cognitive psychology (Dunbar 1995; Nersessian et al., 2003) and education (Bond-Robinson and Stucky, 2005; Feldman, 2008; LaPidus, 1997) have entered the laboratory to study scientists as they pursue research in real time.

Unfortunately, almost all of this research is weighted towards laboratory-based, experimental sciences; in fact, the only studies centered on field-based sciences are by Bowen and Roth (2007) in their examination of field ecologists. Thus, in this study we decided to focus on a field-based science with a strong *historical* component in order to better understand how expertise is learned in such fields.

As opposed to experimental-based sciences, such as chemistry which pursue experiments on natural phenomena under controlled laboratory conditions, the goal of *historical sciences* such as geology is to reconstruct past phenomena based on (mostly) un-manipulated evidence gathered as traces from the field. In fact, historical-based scientific methodologies were specifically developed to cope with problems that could not be solved experimentally. This has required the development of a whole set of methodological tools (both theoretical and practical) that help historical-based scientists overcome the constraints of their field-based evidence (Dodick and Argamon, 2009).. It has also affects the way graduate students are trained in the expert methodologies that historical scientists use to solve research problems, as we will show here.

## Methods

### The Research Sample

The research field of the team we investigated is *Integrative archeology*; a relatively new scientific domain, its goal is to use the (chemical and physical) properties of the materials accumulating at an archaeological site to better understand the humans who inhabited that site. Such materials include minerals, and organically produced materials such as bones, teeth, shells and plant remains.

The team's advisor (senior Professor) is trained in geology, biology and chemistry and has published extensively in the scientific literature. His team, at the time of this study consisted of two interacting groups:

expert scientists (2 junior colleagues), and novice scientists (1 M.Sc. and 3 Ph.D. students). Additionally, technicians, post-docs and summer students joined the team during summer fieldwork sessions.

As he advocates an interdisciplinary approach, the advisor accepts graduate students from most scientific fields; this approach is reflected in the team's background. "E" and "R", the two junior colleagues are trained in physics and archeozoology, respectively. Amongst the Ph.D students, "L" completed an M.Sc in Molecular biology; "D" has an M.Sc in Archeology and "A" in Materials Science. In this study we focus our analysis on the advisor and his 3 Ph.D. students.

## Data Collection and Analysis

The team pursues fieldwork at least once a year in order to collect samples for their analyses. To collect our data, we joined the groups' excavations (which typically lasted three-weeks during the summer) during a 4.5-year research period (2004-2009). We videotaped nearly 50 hours of interactions among research team members as they gathered and analyzed data in the field. Extensive field notes complement the video data. We also recorded the groups' seminars where members presented their works.

Semi-structured interviews were held with the team members after each field season. The interviews informed us of the researchers' individual feelings and understandings about various aspects of their research. It was also used to refine and validate our understanding of the field observations. All of the interviews were recorded and transcribed.

The interviews provided us with rich amounts of data touching upon a considerable number of themes which were analyzed using Shkedi's (2004) constructivist (ethnographic) method of qualitative research. In the first stage of this analysis, primary categories were developed following a first reading of the interviews allowing an initial coding. Careful attention to these categories produced a focused emergent framework, and the data was then recoded according to that framework. Our analysis concentrated on the major research challenges that the group members faced, as well as the strategies they employed to cope with these challenges.

A second analysis was done on the interviews and field observations using the questions that the advisor and students generated spontaneously about their research. Questions are identified as "an interrogative sentence or a declarative sentence with an embedded interrogative" (J. Dillon pers. comm.).

Two coding schemes were used in this analysis: (1) An emergent scheme (Table 1) which reflects both the questions connected to the research goals of the team, as well as to the strategies the advisor mentioned as promoting research. (2) A deductive scheme (Table 2) based on Dillon's (1984) classification of (scientific) research questions. Inter-rater reliability of these two schemes averaged 90%.

Table 1: Emergent categories of the questions asked by the team members.

| Category and Definition | Example |
|---|---|
| **Validity** questions are concerned with the extent to which the results of a research study can be generalized to situations beyond those involved in the study (*External validity*) **or** about the extent to which extraneous variables have been controlled by the researcher, so that any observed effects can be attributed solely to the "treatment" variable (*Internal Validity*). | What happened to the organic material since its initial deposition? (This question concerns whether the material changes were caused by chemical degradation.) |
| **Methodological** questions are concerned with procedures needed to solve a specific scientific problem. | How do we date plaster? |
| **Human Behavior** questions are concerned with attributes connected to human artifacts (e.g. Ceramic tools) or activities (e.g. Ways of cooking). | What were these ceramic vessels used for? |
| **Materials** questions are concerned with attributes of materials (e.g. color, IR spectra measurements). | What will be the ν-*Ratio* of the samples? |
| **Space and Time** questions are concerned with the spatial and temporal relationship between items such as Loci (areas), Layers, and Samples. | Which Archeological layer is above which? |

Table 2: Deductive scheme based on Dillon's (1984) categories for classifying scientific research questions

| Category and Definition | Example |
|---|---|
| **Property** questions are concerned with the properties of a specific "thing" (such as its shape, color, location). | What are the organic materials that were in this ceramic vessel? |
| **Comparison** questions deal with the comparative attributes between two "things". | What is the difference between the Calcite which was heated and the one that wasn't? |
| **Contingency** questions deal with the relationship (relational, correlative, or causal) between two "things". | Are the Copper rich sediments in situ or are they a product of post-depositional process of melting in water and going through the sediments? |

## Results and Discussion

### The Team's Research Process

Even though fieldwork happens only for a short period each year, it is critical to the team's research process (Figure 1). In the first research stage, physical and chemical traces of human activity are collected, analyzed in the (portable) lab and than reapplied to the field in order to locate a relevant research problem. In the second research stage, specific traces are collected in selected locations, followed (sometimes) by simulations in the lab and reapplication of the results to the field in order to solve the research problem. Both stages require at least two iterations, because lab analyses often require the team returning to the field and re-sampling a specific area in order to clarify and validate results emerging from the initial analysis.

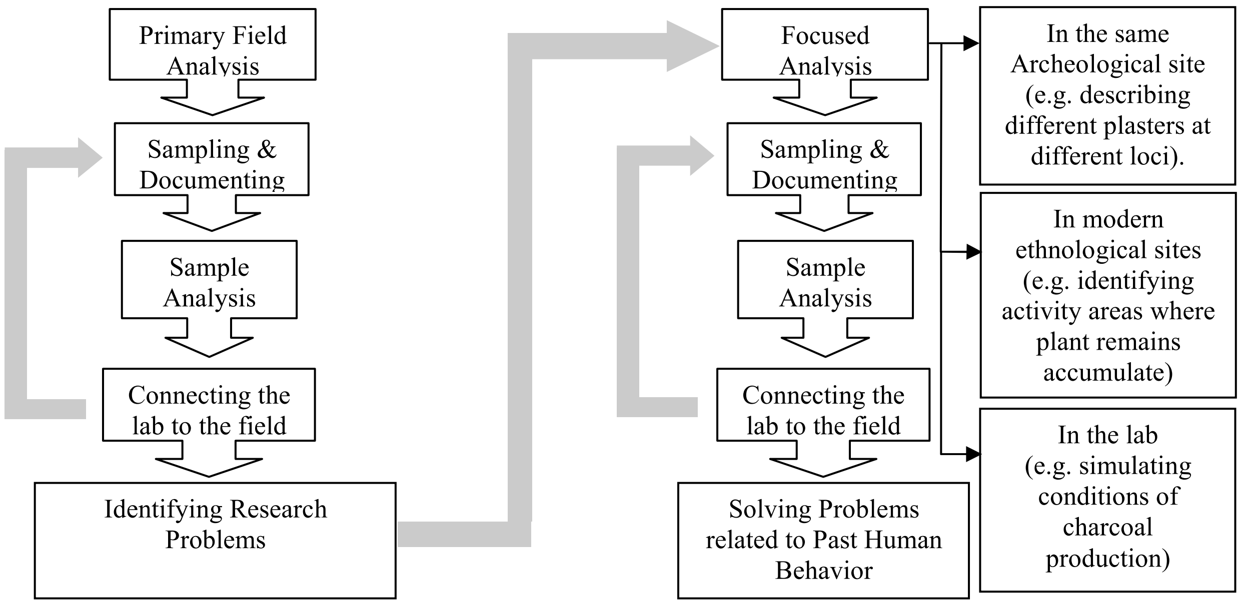

Figure 1: A schematic model of the team's research process

An example of a typical research problem was based on the observation that at certain site locations many of the sediments analyzed by IR-spectroscopy seemed to have been chemically altered by exposure to high temperatures. Solving this issue involved fully characterizing the phenomenon at different geographical and stratigraphical locations of the site, as well as modeling the effect of heat on sediments under both lab (using ovens) and field conditions (using natural fire); such simulations are intrinsic to the methodology of historical sciences. The aim of this problem-solving process was to create a tool enabling the researchers to reconstruct human behaviors from field materials, both at this site, and possibly at other sites as well.

## Assessing the Development of Expertise amongst the Students

Our data indicates that the advisor strongly stresses (24 times in a total of five interviews) the importance of problem identification as possibly the most critical element of field research and the most difficult one to teach (Dodick and Flash-Givili, 2008). Typical is his comment after the 2004 field season.

> This is "the state of the art" or "the name of the game" in science! It's not to collect observations, to summarize the details and to publish it; however, in these complex situations, without a direction, to identify the “thread” that will lead to something significant. If this would be something that I could teach in a lecture or a class...it would have been useful, than I think I don't need to teach further; the rest is technique."

We frequently noticed the advisor teaching this principle to his students. A typical example is his feedback (from field season 2006) to two of his students who immediately tried to solve the questions connected to a specific section even before mapping it and identifying the questions it elicited. "This is the wrong picture! In other words, even if we where there [at the problem solving stage] it's not for... I mean, if it's a serious problem we will do it, we will solve it, we will ask these questions, but maybe it's not even stratified..". Later, when asked to reflect on this event, the advisor said: "The big message is that you have to use the tools in order to do it in iterations, every time having a smarter question. Not in an automatic way." Thus, 'listening' to the questions presented by the field is a leading research strategy for him.

These observations led us to hypothesis that if we analyzed the questions posed by the students we would be able to better understand the progress they made in their research. Hence, we characterized the frequencies of questions asked by the three Ph.D. students' in the interviews (Table 3). Note that in 2006, the researchers surveyed a second site, in addition to the main focus site with which they began their research. It is important to take into consideration though, that this quantitative account is just a raw indicator of trends. This is not meant to be a fully quantitative study because of the small group size.

Table 3: Changes in the types of questions posed by the 3 Ph.D. students after each field season based on our emergent categories (presented as percentages of the total)

| | | **Interview 1** | **Interview 2** | **Interview 3** | **Interview 4** |
|---|---|---|---|---|---|
| | | 2004-2nd year* | 2005-3rd year | 2006-3rd year | 2007-4th year |
| Student A (PhD) | | N=13 | N=24 | N=17 | N=15 |
| | Materials | 38% | 17% | 40% | 40% |
| | Hum. Behavior | 62% | 29% | 12% | 27% |
| | Space & Time | 0% | 37% | 24% | 20% |
| | Validity | 0% | 0% | 18% | 0% |
| | Methodology | 0% | 17% | 6% | 13% |
| | | 2006 - 1st year* | 2007-2nd year* | 2008-3rd year | 2009-4th year |
| Student L (PhD) | | N=15 | N=20 | N=19 | N=12 |
| | Materials | 20% | 35% | 52% | 50% |
| | Hum. Behavior | 13% | 5% | 5% | 0% |
| | Space & Time | 53% | 20% | 0% | 8% |
| | Validity | 7% | 10% | 16% | 0% |
| | Methodology | 7% | 30% | 27% | 26% |
| | | 2005-4th year | 2006-4th year | | |
| Student D (PhD) | | N=30 | N=23 | NA (Ph.D. completed) | NA (Ph.D. completed) |
| | Materials | 13% | 17% | | |
| | Hum. Behavior | 30% | 17% | | |
| | Space & Time | 33% | 43% | | |
| | Validity | 17% | 17% | | |
| | Methodology | 7% | 6% | | |

Looking at the data, a number of important trends are seen. In the case of “A” there was a strong tendency at the beginning of her work to focus on Human (cultural) behavior. This is well reflected in the following quote from an interview after field season 2004 (the second year of her Ph.D.):

> I want to work on things: ceramics, tools, kilns, installations, technology, to understand technology, to see what happens to it, which materials did they use? Why did they use them? Where did they take it from? Those kinds of things…

These types of questions, as she noted, are not encouraged by the advisor as he prefers asking questions which will enable his team to create a universal tool, or research strategy which can be applied to many sites. However, even though she recognized his intentions, she still insisted on focusing on human behavior questions. This may have been due to her misconception that her immediate task, as an archeological problem-solver was to reconstruct human behaviors of the past. This also correlates with our field observations which showed that at the beginning of her Ph.D. this student worked very closely with the traditional archeologists, and this too may have swayed her thinking towards human behavioral problems. In fact, her advisor mentioned that at the beginning of her work, he needed to "separate" "A" from the archeologists".

However, the percentage of this question type tended to tail off through the third year of her Ph.D., as she began to understand the importance of analyzing the properties of field materials both in terms of content and their spatial-temporal relationships. This is clearly seen in the following quote from field season 2007, which was the fourth and final year of her Ph.D. research.

> Today I don't need someone to explain to me to know that this [layer] cuts this and this cuts the other, that this is early and this is late. This might sound trivial, but it wasn't at all like that for me at the beginning. I also have a little bit more understanding of the processes, of how they occur. Which kind of by-product you expect from a pile of dung which had disintegrated, or from metal that stayed in the ground. What to expect if I have a collection of metals? How the does the sediment around it look? All these little contexts are much clearer to me today.

In contrast to "A", "L" asked a smaller frequency of human behavior questions even at the beginning of his Ph.D. and the frequency of such questions rapidly declined through his research. Concomitantly, we see an increase in the percentages of materials, validity and methodological questions; this increase connects well to his interest in methodological problems, in which the ultimate goal is to create a tool that might be used to better reconstruct the temporal background of a site. As he noted in the first year of his Ph.D. studies: "If we could invent a scientific physical method that will really prove that one ceramic artifact is present before the other [...] it's a very nice idea to do". Indeed, "L's" research focused on validating a new tool for dating plaster compounds. Interestingly, at the end of 2008, his research focus shifted toward characterizing the chemical properties of plaster with no connection to developing a new tool. This change was forced upon him by circumstances in the field, as he encountered some major difficulties in the dating project, while at the same time he started identifying extraordinary examples of plaster in a specific site.

In essence, the shift in "A" and "L's" questions represent the influence of the advisor's research philosophy which emphasizes the importance of starting a project with a field-based material analysis before jumping to questions of human behavior or trying to invent a new tool. However, at least in the beginning of their studies, his students had a tendency to pose broad questions (i.e. what did people do here?) and immediately tried to solve them. Moreover, they were inclined towards using "actualistic" logic to answer their questions even before collecting data in the field. (Actualistic logic is used to reconstruct the past based on knowledge of present conditions. It is a widely used in all historical sciences). Indeed, the advisor often had to warn them "not to use their logic to come to a conclusion". Instead, he emphasized the importance of "using logic to ask a question" and "to try and get the data to support it".

Finally, "D" like her colleagues shows a decrease in human behavior questions, but unlike "A" and "L" she shows almost no change in materials-based questions. This may be due to her archeological background, which made it hard for her to look at the field from a materials perspective. Indeed, she admitted that although she had learned much in her Ph.D. she still needed to fill in considerable gaps in her understanding of chemistry. This connects well to the way her advisor characterized her progress towards her Ph.D., which was in the direction of becoming a "lab specialist"; this, contrasts with his research strategy which integrates both field and lab findings.

Another research element emphasized by the advisor (2006 interview) is connected to understanding the spatial and temporal context of the field, as he noted: "Excavation for everybody is the bread and butter of Archeology. I excavate, I can decipher the stratigraphy and can complete the picture. If you are doing mistakes in deciphering the stratigraphy than it's a big mess, that nobody can work out". In Table 3 we see that "A" asked no spatial-temporal questions at the beginnings of her Ph.D. because as she admitted she "didn't even understand where to start observing". This is supported by the lack of any stratigraphic diagrams in her field notebook at this time. It was only in the third year of studies that she began to ask relevant stratigraphic questions from her colleagues, and even began to draw field-based diagrams. In contrast with "A", "L", was highly focused on developing a good understanding of the spatial-temporal relationships of the field, and this is seen by the large frequency of questions he asked from the beginning of his studies. In fact, his advisor (interview, 2006) noted that he was “ready made for this type of work”. Finally, Student “D” was very focused on spatial-temporal relationships. This correlates well with her previous research experience in archeology.

We also used Dillon's (1984) scheme for classifying the questions; here, questions are classified to three levels: Properties (I), Comparisons (II), or Contingencies (III). The purposes of this teams’ research are identifying archeological materials and reconstructing human behavior; in contrast, the other types of questions (Validity, Methodology, and Space and Time) serve these purposes. For this reason, we decided to use Dillon’s (1984) scheme to focus in on materials and human behavior questions.

Our results show a very strong trend in (almost) every year, and every student towards level I Properties questions, both in the case of materials and human behavior questions. "A"'s Properties questions averaged 64% of her total materials-based questions across all the years we observed her, while her Properties questions devoted to human behavior averaged 71%. This situation repeats itself with "L" (77% and 100% respectively) and "D" (86% and 70% respectively). This supports the fact that the advisor is very careful in establishing the baseline properties of archeological materials before jumping to causal relationships (Level III questions). For example, one of his big research projects has been examining the material contents of an ancient (garbage) pit. However, much of the discussion connected to this work has been on defining the nature of “pits” in general. A similar issue arose around the definition of “metallurgic kilns” which was part of “A’s” research.

These results show that a good scientific research program does not necessarily have to concentrate on causal questions; establishing a phenomenon's properties is critical in of itself. This is especially important in field-based, historical sciences, where one doesn't control the evidence offered by the field; this forces the scientists to collect every important trace, while validating its properties prior to answering any causal question. In agreement with this observation, student "L" described the most important quality of this group's method as "Differentiating between [the phase of] documenting the data from its interpretation; first explain what was found, bring pictures, document everything, do everything properly and only after that stage, write in the conclusion what you think it is". This emphasis is also supported by the team’s publications, most of which have a strong descriptive character. The advisor hopes that his method will be applied to other archeological problems, providing his work with greater validity.

Finally, thematic analysis of the advisor’s interviews shows an abundance of strategies that he uses to identify research problems demonstrating that he is highly engaged in problem identification. Such strategies are either derived from the *disciplinary culture* (i.e. Identifying gaps in experts' knowledge) or the *data* itself (i.e. Following unexpected findings; Focusing on prominent data). However, at least at the beginning of their studies, most of the students’ strategies were not derived from *data* but rather from the *disciplinary culture* wherein they focused on problems previously identified by others; in other words they often expected their problem to be well defined by others, before collecting data. This is not surprising in that this is the first time that these students received an opportunity to fully develop a research program. Still, as they progress through their studies, the students adopt a more experiential based approach (i.e. focusing on data they know how to analyze, based upon 'what the field offers'). This shift demonstrates their transition towards greater expertise.

Our results correlate well with Feldman (2009) where he classified the highest level of graduate science research as creating "Knowledge Producers" who can, among other things, independently formulate research questions. Similarly, Alexander (1997) also defined the highest level of academic research (in general) as proficient experts who are actively engaged in problem finding. It also connects well with Van Gog et. al.’s (2005) research which showed that in contrast to novices, experts invest far more time representing a problem before solving it.

Nevertheless, our case study shows that such problem identification can be circumvented by the students’ misunderstanding of where their research truly begins, as they believed that their primary goal was solving human behavioral problems, when in fact they (first) needed to do a complete material analysis. Simply put, they attempted to by-pass a significant research stage. By misinterpreting their research goals they also sidetrack the process of formulating the questions that would ultimately guide their studies by immediately jumping into a problem solving mode. This is reflected by how their questions change over time.

These results emphasize that the first goal of inquiry learning, i.e., "identifying questions that can be answered through scientific investigation" (NRC, 1996) is a complex skill that novices need to develop before they become scientific experts. Thus, even before dealing with the second goal of inquiry learning, "design and conduct a scientific investigation", amongst which controlling variables is listed as a major skill, we need to invest more time in supporting students with experiences that will develop their ability to formulate effective research questions (Kuhn and Dean, 2005); we certainly cannot expect them to develop this skill by themselves.

Obviously this is a small, focused case study so more research needs to be done to provide increased validity to our results. Thus, we have started a comparative study analyzing another field based science – ecology. This will permit a fuller description of some of the in-depth problems that students experience while learning to become expert field scientists.

# Teachers Collaborating with Wiki: The Impact of Professional Status, Language, and Age

Yael Poyas, Oranim College of Education, 36006, Israel, yael_p@staff.oranim.ac.il

**Abstract**: Research indicated that Wiki-aided teaching has many advantages if supported by appropriate pedagogy. The present study examined the effect of this environment on the learning process during an M.Ed literature course for a multidisciplinary group of Jewish and Arab teachers in Israel. The findings were derived from the Wiki data, from learners' written and oral feedback regarding the experience, and from the lecturer's reflective diary. Although the learners' and lecturer's satisfaction was high, since the Wiki framework contributed to the learners' interest, involvement, and depth of their investigation, yet self-confidence in language use, cultural learning habits, age and professional status affected the learners' performance.

This article is about the use of the Wiki technology as an alternative platform for the construction of a shared interpretive space (Sumara, 2002) for the study of literature in the context of an M.Ed program for experienced teachers. It examines the data from the point of view of a teacher educator, investigating the experience of her teaching with the purpose of both improving her work and of contributing to the accumulating knowledge regarding the use of Wiki in professional development programs for teachers.

## Theoretical Background

### The Wiki Environment in Educational Settings

The Wiki platform is an environment enabling cooperative and collaborative learning, each participant being permitted to write, add, edit and alter any text written within its framework (Leuf & Cunningham, 2001). In this sense, Wiki's features create a "low risk" editing environment (Wang & Beasley, 2008), providing a multimodal and hypertextual writing platform, transparent to all readers. Studies examining Wiki-aided teaching found that this environment has many advantages. It fosters constructivist learning, as well as collaboration and interaction among the students themselves and between each student and the teacher. The knowledge constructed by students is made available to all the participants in the course for study and evaluation (Morgan, 2004; Watson, Boudreau, York, Greiner & Wynn, 2008). Moreover, it appears that the level of investigation by students using the Wiki platform improves, due to their being exposed to appraisal by their colleagues and others (Ravid, 2006). Recently researchers recommended the incorporation of Wiki as a platform for creating collaborative updated and course-oriented textbooks, in order to empower learners (Ravid, Kalman & Rafaeli, 2008). As Ruth and Houghton (2009) claim, Wiki is more than a tool, it is a way of learning.

Satisfaction with learning in the Wiki environment was found to be high, when supported by appropriate pedagogy (Ben-Zvi, 2007; Meshar-Tal & Tal-el-Hasid, 2006; Morgan, 2004). Studies dealing with learning language and literature with the help of Wiki show that this environment promotes high-level reading comprehension, a diversity of interpretations, and dialog among interpreters with various cultural backgrounds (Désilets & Paquet, 2005; Faranbaugh, 2007). It also increases writers' awareness of the effectiveness of critique in improving their written products, their meticulousness regarding spelling and syntax, and their sensitivity to different context-dependent modes of writing (Wheeler & Wheeler, 2009).

Researchers reveal that the success of educational Wiki-based learning projects or their failure depends on many factors; indeed, the same researchers may sometimes report success and at other times describe difficulties and discontent (Wang & Beasley, 2008). It was also reported that the learners' attitude towards Wiki and their time investment in posting varies from one learner to another (Ravid, Kalman and Rafaeli, 2008; Robertson, 2008). Studies also showed that the specific discipline and its culture of study affect the success in Wiki-aided learning (Rick & Guzdial, 2006).

### Culture and learning via interactive educational technologies

Culture influences its members' ways of thinking and interpreting (Branch, 1997; Matsumoto, 1996). When teaching with the aid of technological tools two cultural factors should be noted: effects of cultural attitudes concerning interpersonal communication, and the language and ways of coding and decoding knowledge (Wild, 1999), as well as the effects of the learners' epistemological and philosophical perceptions concerning teaching and learning.

*Effects of cultural attitudes* - Researchers proposed a variety of models to explain the differences between cultures, for instance between individualist and collectivist cultures, cultures with high-level context-dependent communication as opposed to cultures with low-level context-dependent communication, as well as cultures capable of accepting ambiguity and those avoiding it (Gunawardena, Wilson & Nolla, 2003; Hall, 1966, 1976; Hofstede, 1986; Matsumoto, 1996). Different cultural codes, culture-dependent information processing and expression, as well as culture-dependent networks of relationships and norms of interpersonal communication, may cause participants various problems while studying in multicultural groups in social technological interactive environments such as Wiki (Gunawardena, Wilson, & Nolla, 2001; Hall, 2006). There are cultures (like western cultures) in which language is perceived as a tool conveying precise meaning, and other cultures (like the Arab culture), where it is perceived as a system of linguistic forms, arousing feelings and visual images. Thus, while one culture pursues functional, precise, explicit and unambiguous use of language, another prefers affective language, implicit and rich in imagery (Dwairy, 2006; Zaharna, 1995). For instance, studies showed that students from cultures avoiding ambiguity find online learning environments more frustrating than students from cultures accepting ambiguity (Downey, Wentling, Wentling & Wadsworth, 2005), and that students writing in a foreign or second language participated less and were less confident in their contributions (Yilditz & Bichelmeyer, 2003).

*Effects of learners' perceptions concerning teaching and learning* - Studies report that while developing their pages on Wiki, many learners find it difficult to cope with the task of knowledge construction owing to the norms they had become used to, with the teacher not only providing them with the required knowledge, but also determining the framework for its organization and presentation (Farabaugh, 2007; Wang & Beasley, 2008). Such difficulties become acute when students, partaking in a collaborative interactive multicultural learning group, are accustomed to traditional spoon-feeding ways of teaching and learning; they encounter tremendous obstacles in attempting to adapt to the self-directed environment (Alsunbul, 2001). The characteristics of academic culture, which honors ownership of knowledge and copyright laws, were also found to affect activity in the Wiki environment; they minimize learners' willingness to allow peers to edit their Wiki pages and their own willingness to evaluate other students' work (Lindsey, 2006; Wang & Beasley, 2008).

*Educational technology and teachers' development*- Research on teacher education and educational technology including Wiki is growing rapidly. The teachers' attitude towards the benefits of technology for everyday school instruction is a crucial factor affecting technology implementation (Becker, 2000; Cuban, 2001). If the experience of learning with Wiki undergoes reflective processing and is integrated in the teachers' curricular thinking, it may be translated into effective use in the planning of teaching and in sharing experiences with colleagues (Darling-Hammond, Banks, Zumwalt, Gomez, Gamoran Sherin, Griesdorn & Finn, 2005). A positive experience of the use of the Wiki technology in teacher education programs will hopefully encourage teachers to subsequently use Wiki in their teaching.

The current study focuses on the impact of learning with Wiki on the process of the learners' writing and editing of their contributions as a result of a collaborative activity, within the framework of in-service M.Ed studies at a college of education in northern Israel.

## The Study

### Course Context

The M.Ed program of multidisciplinary instruction is intended for experienced teachers from Arab and Jewish schools from the northern periphery of Israel. The Arab and Jewish sectors in Israel have separate elementary and secondary educational systems, each one of them having its own language of instruction (i.e., Arabic, Hebrew). Only in higher education are Jews and Arabs engaged in multicultural encounters, sometimes in very conflictual political contexts. Studies examining the integration of Arab students in colleges and universities where the language of instruction is Hebrew, found that Arab students had to cope not only with high level and academic Hebrew, but also with reading material in English, teaching methods demanding more independent study, and more free and open relationships between students and between them and their teachers (Al-Haj, 1996; Peleg & Raslan, 2003).

*Course Participants* - 19 participants took part in the course under study, 9 Arab teachers and 10 Jewish teachers. Most teachers were women (typical of the state of the profession in Israel). Their ages ranged from 26 to 56 years, while half of them were between 41 and 55 years old. The teachers' professional experience ranged from three to dozens of years. Twelve of the teachers were teaching in primary schools and the rest in secondary schools. Only seven of them had studied literature for their B.A. degree. None of them had previously read the novel studied, nor had any experience of study in the Wiki environment. The affiliation of the group's members to Arab or Jewish society, their different mother tongue (i.e., Arabic or Hebrew), were the salient cultural factors distinguishing between them. As for other factors, such as age and professional identity, the participants had much in common.

*Aim and Content of the Course* - The aim of the course under study (14 weeks) was to engage the learners in an encounter with world literature (Cai & Sims Bishop, 1990), and to build up a group database about the novel *The Day Lasts more than a Hundred Years* by Chinghiz Aitmatov, sharing historical, geographical, cultural, and literary knowledge, as well as individual and group interpretations. The assignment was to write an entry about a broad topic in the novel, relating it to entries written by other colleagues, complementing or expanding them. Writing on the Wiki platform evolved alongside 10 weekly face-to-face lessons, lasting 90 minutes each. (In the other four weeks there were no F2F meetings.) Blended model of teaching & learning was preferred to reduce the difficulties of adapting to Wiki-based writing, and to enable whole group F2F discussions of the novel and the written products. The learners were also asked to respond to their colleagues' entries on the 'discussion board'. The writing process continued until a month after the end of the course sessions, altogether about five months. No specific guidelines for content, style and organization of the entries were provided, in order to give the learners freedom with respect to their style and interpretations.

### Research questions

This paper focuses on the development of the written products on the group's Wiki database.

1. What was the pace of the entry into activity in the Wiki environment and which factors affected it?
2. What steps did the learners take and which strategies did they employ in their writing when given free rein to carry out literary interpretive tasks in the Wiki environment?

### Data Collection and Analysis

The data were derived from three main sources:

*Data provided by the Wiki platform:* (a) The entries written by the teachers; (b) The remarks on each entry, written on the discussion board; (c) Data provided by the history of each entry regarding the number of posts, changes and editing operations made.

*Data derived from the teachers' reactions:* (a) The teachers' remarks in the course of the lessons, noted down in the lecturer's diary; (b) Feedback reports written by each teacher about his/her experiences; (c) The transcript of the discussion that took place during the summing up of the Wiki-based experience.

*Data from the lecturer's diary:* The lecturer's own notes about (a) teachers' remarks, (b) her conversations with them, as well as (c) the phenomena and problems identified by her during the course.

The Wiki pages' history boards were analyzed in order to learn about the teachers' pace of writing and editing throughout the course. The written entries were surveyed for the number of linkages made by the teachers at three points of time – during the first version, the final one and an in-between version. Utilization of linkages to their peers' entries (and/or other Internet sites) implied teachers' adjustment to some of the norms of writing in hypertextual environments as well as their familiarity with peers' products and contributions. The discussion boards were examined to identify the contributors and the topics discussed. Learners' responses, collected throughout the course and derived from their feedback pages and the final discussion, were categorized according themes concerning participants' (a) experiences of success, (b) apprehensions, (c) difficulties, and (d) ways of coping with these difficulties. Learners' responses were used to investigate the considerations they had in mind and to explain phenomena, related to features characteristic of the Wiki platform. The lecturer's diary assisted her in recalling her reasoning regarding the learners' difficulties, the phenomena mentioned in their' statements, and the evolvement of the writing throughout the course.

## Findings and Discussion

On the whole, the teachers displayed enthusiasm and interest in the Wiki assignment, and gradually developed a Hebrew database about the novel. The teachers' feedback at the end of the course was positive, and all of them emphasized that Wiki had increased their involvement in the course. However, a closer examination of their strategies and activity called attention to some factors that may have impeded involvement and performance, and they should be addressed.

## The Pace of Entering into the Activity

There were differences, related to teachers' specific cultures and languages, in the pace of their work and their readiness to write the opening paragraph of the entry, as can be seen in the following Table (see Table 1).

Table 1: Points in Time of Students' First Entrance into the Wiki Environment

Weeks of the Semester

| 2 | | 3 | | 4-5 | | 6-9 | | 10-14 | | Later | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Arabs | Jews | Arabs | Jews | Arabs | Jews | Arabs | Jews | Arabs | Jews | Arabs | Jews |
| - | 1 | - | 3 | - | - | 2 | 4 | 6 | 2 | 1 | - |

According to the participants' explanations, the slow entry into writing on the website was due to four main reasons: (a) less confidence in their knowledge of the language; (b) the felt need to become well acquainted with the text; (c); their habits of study, and (d) their attitude towards technology.

*Knowledge of the language* was mentioned repeatedly by four of the Arab teachers, their fear of writing in a faulty style, of making linguistic and spelling mistakes for all to see. When asked, the Arab teachers who were actually teaching Hebrew (6 out of 9 teachers) stated clearly they were more fluent and proficient in Hebrew academic writing than in their own language; however, when it came to exposing in public their writing in progress alongside that of their Jewish colleagues, they became less willing to participate in the activity.

*Knowledge of the novel*: Native Hebrew speakers read the novel fluently and did not wait for group discussions in order to continue reading, while eight out of the nine Arabic native speakers read the novel chapter by chapter, relying on classroom discussions to clarify the novel's content and the issues it raised. As a result they constructed their initial impression of the novel at a later stage of the course and started writing their entries later than most of their Jewish colleagues.

*Habits of study:* Three (33%) Arab teachers expressed frustration regarding the complexity of the task, which called for their own interpretation of a phenomenon in the novel or outside it, without any specific guidance regarding content or structure. Their explanations exposed their expectations that the lecturer would provide them with clear instructions, similar to those usually provided in an academic course regarding the final paper. The case of these teachers' slower and more cautious entry into the activity and the crutches they needed drew attention to the difficulty, caused by open assignments in the transparent Wiki environment as experienced by those who are not confident enough to cope with multidirectional and unstructured tasks. The Wiki technology transparency leaves no private space to those needing more time and guidance; rather it "exposes" them to the entire community. When the community of learners consists of self-aware experienced teachers, this exposure may mentally block some of them.

*Attitude towards technology*: Some older teachers who hesitated in their first steps explained their difficulties in their reluctance to use technology for writing.

According to the participants' responses, it appears that their mother tongue, age as well as learning habits were important factors, affecting the pace of entry into the writing activity.

## Steps and Strategies in Writing

*Using the word processor:* About a third of all participants admitted that they wrote their thought first on the word processor, placing them on the website only when they were entirely satisfied with what they had written. This phenomenon may also explain why many entries began to appear on the website only in the last third of the semester. Seven teachers, Arab and Jewish, mentioned they were incapable of showing their work in progress to others. Seven others began writing only after composing several paragraphs on the word processor, but from this point on continued to use the Wiki, without resorting to the word processor again. Only four Jewish and one Arab teacher presented their work in progress throughout the course. During the feedback discussion at the end of the course all the teachers agreed with one of their colleagues' assertion that it was very strange and unusual to skip the private, intimate and reassuring step of working on the draft papers, and that it needed courage to expose partial products in public.

Most participants (70%) reported that their apprehension regarding their colleagues' reactions affected their writing: "I am a teacher; I evaluate and give grades to my students. Am I supposed to let others see a slipshod piece of my work? That's totally out of the question. It took me a relatively long time to accept that it is possible to post on Wiki ideas not properly thought through. You [the lecturer] must understand the radical change we had to undergo to participate in Wiki". Another student remarked: “Writing is a very private matter for me. I can’t imagine exposing to others the process of the consolidation of my ideas”. Such remarks highlight the radical change in attitude required for work in the Wiki environment regarding the long-established habits that experienced teachers acquire in the course of their studies and professional development.

*Duration of writing, editing and revising:* The students not only started their task at different points in time, but also varied in the number of times they posted and edited their entries and in the duration of their Wiki-based writing periods, as is evident on the following Table (see Table 2):

Table 2: Length of time learners worked on Wiki and word processor assistance

| Duration | Arab Learners | Jewish Learners | Assistance of word processor |
|---|---|---|---|
| 4.5 Months | - | 4 | No assistance |
| 4 months | 2 | 4 | Partial assistance |
| 3 month | 3 | 1 | -"- |
| 1 month | 2 | - | Full utilization, with final editing work on Wiki |
| 1 Week | 1 | - | Full utilization |
| 3 days | - | 1 | Full utilization |

Teachers who wrote directly on the website edited their entries fifteen to twenty times in the course of the semester, worked on it for long periods and expressed explicitly their great involvement in the novel and their enjoyment of the course. Others posted or edited their posts only 3 to 7 times.

*Writing in a hyper-textual environment*: At first the entries resembled the usual type of academic writing, the students almost totally ignoring the hypertextual features of the Wiki environment. The awareness of the need to adapt their writing to a hyper-textual environment developed slowly. An overall survey of the entries' development revealed that it took seven or eight weeks before the participants realized what a hypertextual environment could offer. It occurred only after (a) the entries had grown to several paragraphs each; (b) participants were explicitly instructed to read their colleagues’ entries (c) devoting time to F2F review of several entries. At the same time the paragraphs in their own entries became denser and more in line with the definition of their topic. However, only small number of links was made by learners to external sites and the use of internal links was moderate (see Tables 3 and 4).

Table 3: Number of links to peers' entries related to specific points in time during the course

| | | No. of Links to peers' entries: 0 | 1-3 | 4-7 | 8-12 | 13-14 |
|---|---|---|---|---|---|---|
| No. of learners | Initial version | 13 | 3 | 1 | 1 | - |
| | In-between version | 2 | 5 | 10 | 2 | - |
| | Final version | - | 4 | 11 | 3 | 1 |

Table 4: Number of external links related to specific points in time during the course

| | | No. of external links: 0 | 1 | 2 | 3 | 4 | 5 |
|---|---|---|---|---|---|---|---|
| No. of learners | Initial version | 18 | - | - | 1 | - | - |
| | In between version | 11 | 3 | 3 | 1 | 1 | - |
| | Final version | 8 | 5 | 3 | 1 | - | 2 |

This phenomenon may be related to traditional academic writing habits and routines, and to difficulties to adjust to interactive hypertextual norms of writing. Reflections of six of the Jewish participants support this assumption.

*Contribution of exposure to colleagues’ entries and to discussion boards:* All participants mentioned in their feedback that reading their colleagues’ entries led them to consolidate their own and concentrate on the topic as defined. It enriched them with ideas and offered them new directions of interpretation. They had also found reading the conversations on the discussion boards between their colleagues and the lecturer very interesting. These exchanges provided them with new avenues of thought as well as guidance and direction.

*The written products as private property and the 'discussion boards' as private study rooms:* Almost all the participants were sensitive to their ownership of their entry and their colleagues' interference. They perceived the written text they produced to be the intellectual property of the writer. Seven of them even signed their names at the end of their entries. They argued that exposing the entries to public view permits their colleagues to read, but not to edit them. In this case, the teachers' comprehension of the principle of the sharing of knowledge and of collaborative editing was not translated into practice.

The discussion boards served mainly as a space for the lecturer's comments rather than a shared space for discussing content and ideas among group members. Writing their own evaluation of a colleague's work on his/her discussion board was perceived - as one of the learners put it - like "an invasion of someone's private study"; therefore they tended not to write feedback. The feedback session revealed that the participants discussed the written products with their colleagues and made critical comments, but used other channels, such as F2F talks, phone or e-mail, channels that keep feedback as a reciprocal act, taking place between two people, not as a learning space for all participants.

Only seven women (5 Jews and 2 Arabs) responded to 8 of their colleagues' entries, expressing their interest, suggesting more references, discussing the contents, and elaborating on connections between the entries. Only three of the teachers who received responses from others continued to converse with them. Only 10 responded to the lecturer's.

## Conclusions

The findings of this case study demonstrate that collaborative construction of a database about a literary work being studied on the Wiki platform enriches the learners' appreciation by providing them with diverse perspectives, and leads to a sharing of ideas and thoughts in the wake of their reading. The Wiki characteristics expose all the participants to a whole gamut of opinions, voiced throughout the course, while crossing cultural and social boundaries, owing to the possibility of reading the texts as they accumulate, and thus become acquainted with their colleagues' interpretations. Without the collaborative technological framework, many interpretations might not have been voiced.

A more cautious perusal of the results revealed that alongside the apparent success, certain limitations and problems must also be taken into account when teaching with Wiki in programs aimed at experienced teachers' professional development; the same is true in the case of multilingual and multicultural study groups.

The current study focused on the first experience on Wiki of a heterogeneous group of relatively experienced and older teachers, from different cultures and schools; it investigated the way they made use of the various devices available to them, to improve their written product. These learners had their own perceptions about a teacher's role and were liable to cling to their habits, and to act according to the rules and customs of the school in which they were working and the education system they were used to.

When such a group of experienced teachers, aware of their professional status, is to assimilate Wiki-based learning, it encounters obstacles, stemming from their habitual way of studying, their teaching cultures (Feiman-Nemser, & Floden, 1986), as well as their entrenched perceptions of the appropriate relations between teachers and students and their differing roles in the classroom. The findings reveal that the issue of ownership of knowledge prevented colleagues from becoming involved in the editing of the written text in progress. Moreover, the perception that evaluation is the teacher's right and also his/her obligation to the learners, but not the learners' to their colleagues, reduced the social-constructivist value of the Wiki technology.

The sense of fellowship among colleagues is not conducive to mutual criticism in the presence of the lecturer, responsible for giving grades (see also Brett, Forrester, & Fujita, 2009). In this sense, Wiki-based learning calls for alternative ways of assessment, different from the traditional academic one.

The study reinforced previous findings, which maintained that the ways of writing in the Wiki environment differ from customary academic writing and apparently more than one exposure to Wiki is necessary for assimilating the Wiki ways of creating a network of connections (i.e., an 'intertext'), enabled by this technology. Most of the learners remained inside the pages of the "group's book" they had written about the literary work. This phenomenon may be attributed to learners' limited experience with hypertextual non-linear environments due to their long established habits of learning (Dziuban, Moskal, & Hartman, 2005).

The study found that learners in the Wiki environment, not writing in their mother tongue, feel diffident; here this factor was salient and affected the ongoing process of group learning, since a part of the group, mainly the Arab learners, did not share with the others the development of their written product, but preferred to start writing later and base the text on previous attempts on the word processor. This resulted in the phenomenon that their late contribution was not discussed at the group's meetings, did not benefit from their colleagues' thoughtful comments and did not enrich other learners' products.

When the learners are teachers who have a high opinion of their ability to write and construct knowledge, the fear of exposure of their weaknesses may cause them misgivings about early posting on the website.

*Limitations of the study*: This study suffers from limitations characterizing 'messy' field conditions, since it is impossible to differentiate accurately among variables. Moreover, it tells a story of a single case study. Nevertheless, every case study of Wiki-assisted teaching may enrich our knowledge concerning the Wiki impact on learning in diverse contexts. Additional factors, such as the lecturer's way of teaching, the literary work chosen (its length, complexity and contents), as well as the academic backgrounds of each learner, call for further research in this field while using more modes of inquiry, such as in-depth interviews of the learners and their teacher.

# The use of a digital dance mat for training kindergarten children in a magnitude comparison task

**Abstract:** Previous studies demonstrated that basic numerical skills reliably predict children's future mathematical performance. The spatial representation of numerical magnitude, represented in the form of a mental number line, seems to be of particular importance. Our training program for kindergarten children used a digital dance mat as input device that required children to move their whole body to respond in a magnitude comparison task. By employing such a spatial embodied training method, in a parallel randomized cross-over design, our study with 19 kindergarten children revealed a significant interaction between training condition and repeated exposure to items, implying that children improved more strongly in the dance mat than in the control condition. These results suggest that the use of digital media to train embodied spatial numerical skills may be more effective in basic numerical tasks such as magnitude comparison. We suggest that the involvement of embodied spatial codes, shared by the representation addressed by the task at hand, aids acquisition of task-relevant basic numerical skills.

## Basic numerical skills

Arithmetic competencies are important cultural skills, comparable to reading and writing being a fundamental requirement not only for school success, but also for coping with everyday life. At the beginning of their first year of schooling, children's arithmetic skills already differ markedly, and these differences do have long term consequences. It has been repeatedly demonstrated that preschool numerical skills are a good predictor of a child's later arithmetic performance (e.g., Duncan et al., 2007). Findings so far suggest that arithmetic skills and processing of numbers involve various basic numerical competencies that are based on specific types of representations. For instance, the *Triple Code Model* by Dehaene (Dehaene & Cohen, 1995; Dehaene, Piazza, Pinel, & Cohen, 2003) suggested three types of number representations: (1) the visual Arabic number form (written digits); (2) a verbal representation (written or spoken number words); and (3) an analogue or semantic representation of number magnitude (representing the quantitative meaning of numbers). Over the years, the Triple Code Model has been revised several times, adding among other changes a spatial representation of number magnitude in the form of a mental number line that is activated whenever a number is encountered (Dehaene et al., 2003; Nuerk, Graf, & Willmes, 2006). This is illustrated best by the so-called *SNARC* (*S*patial *N*umerical *A*ssociation of *R*esponse *C*odes) *effect* that is usually observed in parity judgement tasks as a systematic interaction between the side of response and number magnitude. In a large number of studies (e.g., Dehaene, Bossini, & Giraux, 1993; Nuerk, Iversen, & Willmes, 2004a; Nuerk, Wood, & Willmes, 2005; see Wood, Willmes, Nuerk & Fischer, 2008 for a meta analysis), subjects have been found to respond faster to small numbers by the left hand and faster to larger numbers by the right hand. Note that in parity judgement, the magnitude of the numbers as such is irrelevant to solving the task. Nevertheless, response patterns suggest that perception of a number automatically activates a spatial mental representation of its magnitude, which cannot be suppressed willingly. The development of the mental number line (as indicated by the presence of a SNARC effect) is regarded as a key requirement for later arithmetic achievement (e.g., Bachot, Gevers, Fias, & Roeyers, 2005) and a precise spatial representation of number magnitude was found to be associated with better actual mathematics achievement and a better ability to learn unknown arithmetical problems (Booth & Siegler, 2008). Therefore, training of such basic numerical representations may be a promising approach. However, before turning to the embodied spatial training program developed for the current study previous approaches on how to train arithmetic capabilities shall be reviewed briefly.

## Training arithmetic skills

Griffin, Case, and Siegler (1994) developed *Rightstart*, an intervention program for kindergartens. They were motivated by their observation that children from low-income families enter school with less understanding of mathematical concepts than their middle-class peers. In order to counteract this discrepancy and the resulting disadvantage in these children's later school career, the authors also developed versions of *Rightstart* (later renamed *Number Worlds)* for older age groups (Griffin, 2003). The program consists of game-like exercises on number lines, number comparison and the semantic representation of numbers. It also contains specifically developed board games that children can play in pairs or small groups (see also Ramani & Siegler, 2008). These board games train skills related to counting and visualizing the distance travelled by the figures, thus connecting the semantic and spatial representation of number magnitude. Evaluation studies confirmed a positive effect of the program on arithmetic capabilities of preschoolers (Griffin et al., 1994).

In 2003, Samara and Clements developed a computer program, *Building Blocks,* for children of kindergarten age (see also Clements, Battista, Samara, & Swaminathan, 1997; Clements & Battista, 1989; Clements & Meredith, 1993). The underlying instructional approach is genuinely constructivist and constructionist (cf. Papert, 1980): Children are expected to understand numerosity by manipulating objects systematically. The computer program allows a variety of manipulations and visualizations that support children's understanding of numbers. They can move objects – comparable to the board game – and this movement leaves traces that visualize distances and thus the spatial and semantic meaning of numbers (see also the training program *number race*; Wilson et al., 2006a; Wilson, Revkin, Cohen, & Dehaene, 2006b). Summative evaluation of this program confirmed that the children's numeric achievement improved by almost 1 standard deviation (Clements & Sarama, 2007).

## Embodied cognition

One hypothesis of the present study is that the development of the spatial magnitude representation can be supported by motor processes. This assumption is based on findings on *embodied cognition*. In traditional theories of cognitive science, perception and action planning were regarded as two separate processes, and cognitive processes were thought to be exclusively based on mental representations. The possibility of a connection between cognition and action was largely ignored for a long time and thus, influences of action-related processes on the perception of information, and the influence of perception processes on motor action were highly underestimated. However, more recent embodied cognition approaches specifically address these possible connections. For instance, Hommel, Müsseler, Aschersleben, and Prinz (2001) propose a framework that is based on the assumption that the contents of cognition and action plans are encoded in a common architecture of representation, and integrated in a joint task-oriented network.

The most basic elements of this *Theory of Event Coding* (TEC) are so-called *feature codes* that represent all features of an event. These refer to different aspects or phenomena of a specific task which they represent. Certain *features* do not refer specifically and exclusively to one stimulus or response, but process sensory input from various different sensory systems and modulate activities of different motor systems. According to TEC, an event will activate several different feature codes, each of which modulates one specific aspect of perception *and* action. Processes of perception and action interact in the jointly shared representational medium of encoding when *features* of perception and motor functions overlap. Feature codes of both perceived information and action plans are then integrated in the same representational medium when they become part of an *event code*. Hommel and colleagues assume that event codes are accumulations of feature codes and that their temporary integration will depend on the respective context and task. Many features of events in the environment exist in different sensory modalities, so restrictions of one modality may be compensated by taking into account and integrating information from another modality. A task is thus solved more easily the more features stimulus and response have in common. On this basis, we can make assumptions about the supportive role of motor skills in learning. We expect target-oriented motor movements, combined with external representations of stimuli (in this case: of numerical magnitude) to lead to an integration of the respective *feature codes*. Thus, a joint representational architecture for number perception and motion will be built. While Hommel and colleagues inferred evidence for their theory from various empirical studies they did not take into consideration the specific connection between number magnitude processing and motor skills, or *embodied numerosity*. However, various empirical findings do suggest that such a connection exists. In many cultures, parts of the body – mostly hands and fingers – are used to represent numbers (cf. Menninger & Broneer, 1992). Furthermore, even adult number processing appears to be closely linked to finger counting (e.g., Domahs, Krinzinger, & Willmes, 2008; Noël, 2005; Wood, Willmes, Nuerk, & Fischer, 2008; Fischer, 2008) and the motor system of grasping (e.g., Badets, Andres, Di Luca, & Pesenti, 2007; Moretto & DiPellegrino, 2008).This indicates that numerosity is not only represented mentally, but also bodily, and that a corresponding connection between motor skills and number processing exists.

## Media for embodied cognition

Different new digital media provide input formats that enable an *embodied interaction* (Romero, Good, Robertson, du Boulay, Reid, & Howland, 2007; Dourish, 2001). Such interfaces have been developed in recent years mainly for computer games. For example, *digital dance mats* require subjects to move their whole body by stepping on different fields of the mat in a specific succession. Games using dance mats have become widespread as part of the Sony Playstation® 2 (PS2) or Microsoft XBOX. Low-price versions of dance mats are now available in supermarkets, and can be connected to any computer via USB. In addition, the so-called *Wii* hit the market in 2006. This gaming console includes a handheld pointing device that does not work by activating defined fields, but by moving a controller which contains sensors detecting movements, thus registering the player's position and actions. More recent systems of the same type detect movements and gestures via web cams (Hoysniemi, 2006; Moeslund & Hilton, 2006; Fitzgerald et al., 2006).

Comparable interfaces for embodied interaction have already been applied for games involving motion (e.g., Reidsma, Nijholt, Poppe, Rienks, & Hondorp, 2006), but also for training of physical fitness (e.g., Hartnett, Lin, Ortiz, & Tabas, 2006) and health education programs (e.g., Watters et al., 2006). In the U.S. dance mats were used in more than 760 schools in the context of physical education, hoping to achieve a long-term effect on the students' health behavior (Business Wire, 2006). To our knowledge, dance mats have never been used in a specifically instructional context before. We believe, though, that this input device that is including spatial and motor input components has potential for training the spatial representation of numbers. Additionally, digital dance mats have a high motivational potential. Children have fun training and moving with them, and they are thus particularly suitable for use in kindergarten and primary school.

## The current study

Based on the considerations described above, we expected that an embodied spatial-numerical training realizing shared features in both presentation and response format should be more effective in leading to a more pronounced decrease in error rates and response latencies. The specificities of the training program we developed will be described below.

We trained children on a magnitude comparison task in two conditions using different presentation and response formats. In the experimental (dance mat) condition, additional presentation of a number line and a spatial response format that required motor input supported children's performance. We designed the control (tablet PC) condition so that neither presentation nor response format involved explicit spatial information. In both conditions, we used two types of presentation material: Arabic numerals and assemblies of squares, which were presented inside a larger square to be perceived as an entity. Prior to the task, children were instructed not to count the squares in the assemblies but to estimate how many there were. To avoid giving the children perceptual cues, non-numeric factors of the assemblies were kept constant (as proposed by Xu & Spelke, 2000). For example, the white surface covered by black squares and thus, the luminosity of the stimuli was held constant in all items of the assembly variation.

### Experimental condition: Dance mat

At the beginning of each trial, children stood on the central field of the dance mat. Tasks were projected onto the floor with a data projector directly in front of them (see Figure 1). The presented tasks consisted of lines that had either numbers (*0* and *10* or *0* and *20*) or square assemblies (0 and 10 or 0 and 20 squares) marking the endpoints. Between the endpoints, one number/square assembly was marked as a standard for comparison. The children had to compare the magnitude of a second number/assembly that was presented above the line with the magnitude of the standard and to judge whether its position on the line was left or right of the standard. Responses were given by stepping on the left field of the mat with both feet when the number's/assembly's location was to the left and on the right field when it was to the right of the standard.

Figure 1: Experimental set-up in the dance mat condition.

## Control condition: Tablet PC

In the control condition, the same magnitude comparison task was administered in a different setup. The control condition's function was to provide a comparable task that involved new media as well, but did not provide as much of a strong connection between action and perception. Children were shown two numbers that were vertically aligned on the monitor of a tablet PC. In contrast to the dance mat condition, children merely had to touch the bigger number with an electronic pen. The same stimuli in pseudo-randomized order were used in the control and experimental condition. Figure 2 shows the stimulus formats used in both conditions (separated by type of presentation material) on the example of the comparison between 3 and 7.

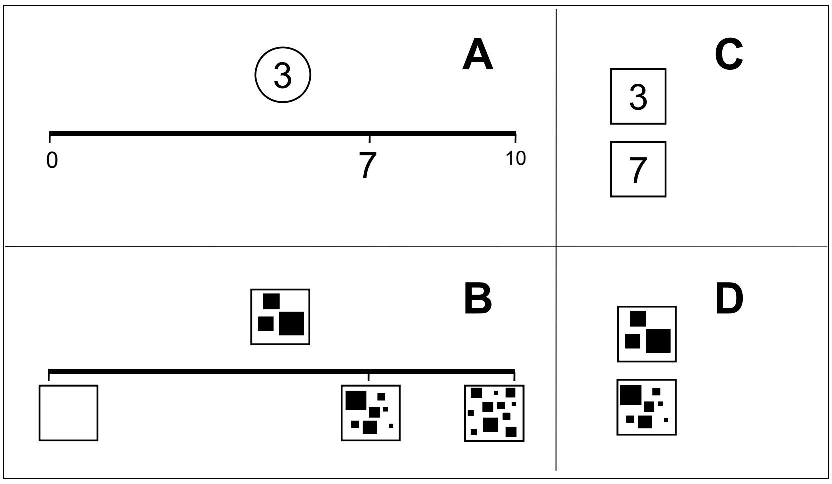

Figure 2: Examples of stimuli in both types of presentation material in the dance mat condition (with **A.** Arabic numbers and **B.** square assemblies) and in the tablet PC condition (with **C.** Arabic numbers and **D.** square assemblies).

## Procedure and Design

We chose a parallel randomized cross-over design to provide all children with the possibility of training with the dance mat, meaning that half of the children first received dance mat and then tablet PC training, while for the other half the order of training conditions was reversed.

The data presented in this paper were part of a large scale study. For reasons of brevity, the current article will address the results of the magnitude comparison task only. In this large-scale study, we also varied whether numbers/square assemblies had to be compared to a variable or fixed standard (with fixed standard magnitudes being either 5 or 10). In the scope of this paper, we will focus on items on which magnitudes had to be compared to a variable standard, because these items – unlike items with a fixed standard – were presented twice each and allowed for an evaluation of children's improvement from the first to the second time of an item's presentation. This way, we could analyze whether children improved similarly over training in either condition or whether one condition yielded a higher improvement than the other.

Each child received three training sessions with the dance mat and three sessions with the tablet PC, which consisted of 64 to 72 items each. The items of the first training session of either condition consisted of magnitudes ranging from 0 to 10, the items of the second session from 0 to 20, and every third session comprised half of the items of the first and half of the items of the second session (i.e., comparisons to a variable standard only). The six training sessions were carried out individually with each child on six different days within a period of three weeks. Training sessions took approximately 10 to 15 minutes per child and were administered before noon in rooms of the kindergarten. When a child missed or could not participate in a training session, the missed session was – if possible – carried out on some other day.

## Participants

Preschool children from two kindergartens participated in the study. The parents of 27 children gave their written consent. Because of prolonged illness or absence, 5 children dropped out of the study. Children were randomly assigned to the two conditions, 11 children were first trained on the dance mat and 11 started with the tablet PC. Subsequently, 3 children's data sets had to be excluded from the analysis due to absence in one training session that could not be carried out at a later point or poor understanding of task instructions, leaving the complete data sets of 19 children – 8 girls, 11 boys –, aged between 60 and 79 months, for analyses. Mean age of the children included in the analysis was $M = 70.74$ ($SD = 6.06$) months and did not differ between the two experimental conditions.

## Results

To analyze the learning effects of training with the dance mat as compared to training with the tablet PC, we compared children's improvement in accuracy (rates of correctly solved items) and reaction times between conditions on items that were presented twice. Improvement was computed by subtracting performance of all children at the first time of presentation from their perfomance at the second time of presentation separately for each item. Since means of reaction times differed between the two conditions due to the very different response formats, z-standardized reaction times were used to ensure comparability of conditions. Reaction times were only computed for correct trials. Children's rates of correctly solved items were arcsine transformed prior to all analyses to approximate normal distribution. We then conducted Analyses of Variance comparing each child's improvement in accuracy and reaction time between the two conditions ($F_1$). Furthermore, we analyzed the data across items ($F_2$). Where it was necessary, one-sided *t*-tests (i.e., $t_1$ and $t_2$, respectively) were used to evaluate our directed hypotheses.

### Children's Performance

First, we conducted ANOVAs on children's improvement in accuracy and on their decrease in reaction time with *condition* and *material* (digits or square assemblies) as within subject factors. We further tested for the predicted differences between the two conditions by means of one-sided *t*-tests. As expected, we found that children's z-standardized reaction times decreased significantly more in the dance mat than in the tablet PC condition [$t_1(18) = 6.19$, $p < .001$, tested one-sided; ANOVA: $F_1(18) = 24.14$]. Likewise, there was a significant main effect of condition on rates of correctly solved trials [$t_1(18) = 2.14$, $p < .05$; $F_1(18) = 2.94$], indicating that children's increase of accuracy from the first to the second time of presentation was larger in the dance mat than in the tablet PC condition (see Figure 3). We found a marginally significant main effect of material on accuracy [$F_1(18) = 3.18$, $p = .08$] that would have reached significance if tested one-sided, but no significant effect of material on reaction times [$F_1(18) = 2.32$, $p = .14$]; and there was no significant interaction between material and condition in either accuracy or reaction times [both $F_1(18) < 1$]. This lack of significant interactions implies that the differences between the conditions were not mainly caused by one type of material, but that children improved similarly on items consisting of both digits and square assemblies.

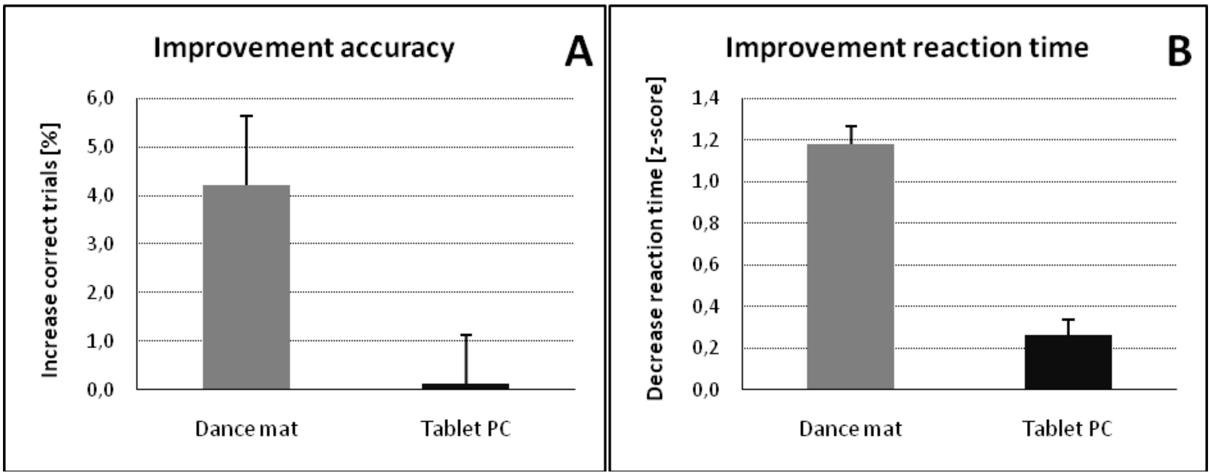

Figure 3: Comparison of children's improvement in **A.** accuracy and **B.** reaction time in the dance mat and tablet PC condition.

### Item analysis

For the Item analysis, repeated measures ANOVAs were conducted, this time with *condition* as the repeated measures factor and *material* as the between subject factor. Again, hypothesized differences were examined by use of one-sided *t*-tests. We found a significant main effect of condition on rates of correctly solved trials [$t_2(67) = 2.66$, $p < .01$; ANOVA: $F_2(1,67) = 5.54$], as well as on reaction times [$t_2(67) = 4.20$, $p < .001$; $F_2(1,67) = 16.03$]. *Material* was found to have a marginally significant main effect on accuracy [$F_2(1,67) = 3.48$, $p = .06$] and no significant main effect on reaction times [$F_2(1,67) = 1.74$, $p = .19$]. Again, material and condition did not interact significantly in either accuracy or reaction times [both $F_2(1,67) < 1$].

### Subjective evaluation

At the end of the study, we interviewed parents and kindergarten staff on their impression of the training. Both groups agreed that the children enjoyed both the dance mat and tablet PC training, but that children had more fun on the dance mat. Most children talked about the project at home and in the kindergarten; some of them spent more time on mathematical tasks than before. Parents and kindergarten teachers had the impression that the level of difficulty was adequate for the children's age and abilities, and the kindergarten staff approved of the idea of using the dance mat for future projects.

## Discussion

The present study showed that the magnitude comparison task can be trained in kindergarten children and that improvement in the magnitude comparison task is larger when this task is trained using an embodied spatial-numerical approach. Performance of children improved significantly more in the dance mat condition than in the tablet PC condition on both reaction times and accuracy. This superiority of the dance mat training was found in analysis of children's performance and also persisted when an item analysis was conducted. These results provide further support for Hommel et al.'s (2001) theory of event coding, indicating that the mental number line representation is indeed more strongly activated when presentation and response format share more features. In the present case mainly spatial attributes are enforced by motor movements and the presentation of the to-be-compared numbers on a number line. Thus, in accordance with Hommel et al., features of stimulus and response seem to be processed as parts of the same event code. Also, the lack of a significant interaction between condition and material (digits or square assemblies) speaks for a generalizability of the positive effects of the dance mat training across different types of stimulus material.

It should also be noted that our computations yielded marginally significant main effects for material (digits or square assemblies) on accuracy that would have reached significance had we employed a one-sided test. However, we did not have any expectations as to which material would produce higher training effects than the other. A trend was found for means of improvement to be higher on items consisting of digits than on items consisting of square assemblies. This might be due to the distinct nature of Arabic digits that allowed for children to remember them more accurately than square assemblies, which children were instructed to process only in an approximate manner. Thus, children might have remembered Arabic digits, but not patterns of square assemblies.

One might argue that the tasks we used were too demanding for kindergarten children, since the German curriculum for the last year of kindergarten states that children should be able to recognize the regular dice patterns. At the time they enter school, the children are thus expected to be familiar with the numbers from 1 to 6. The tasks used in the training program of the current study presenting magnitudes from 0-20 exceeded this level by far. However, since chance level of success was 50 percent on all the tasks, children did not experience failure too often keeping their motivation at a very high level. Furthermore, the fact that significant differences in learning outcome were observed between the two conditions when items were presented only twice argues for the high potential of the dance mat as a training medium for basic numerical skills.

A differentiation of which processes precisely differentiate the two training conditions should be the aim of further studies. In the present experiment, the dance mat and tablet PC condition differed in various features of both perception and action. The dance mat condition was combined with presenting the tasks in number line form, and children had to respond by using motor skills to move their whole body to one side or the other. In the tablet PC condition, items were presented without external representation of the number line, and the response format did not ask for any movement to the left or right. So, from the present study, the question remains whether it were either differences of perception *or* action that led to the performance difference between dance mat and tablet PC condition, or if it was the combination of these two features.

Furthermore, it would be of interest whether the improvements in children's performance on the magnitude comparison tasks may be transferable to other domains of numerical knowledge. We examined children's performance in pre- and posttest transfer measures, namely a number line estimation task and a standardized arithmetic test battery. These results, however, will be published separately and will therefore receive no further discussion in this paper. Seeing as children improved significantly more in both transfer measures in the dance mat than in the tablet PC condition, these transfer effects do enforce the assumption that children profit more from the dance mat than training.

Taken together, the present study showed that a digital dance mat can be used effectively for training of the spatial representation of number magnitude. Bearing in mind that the spatial representation of number magnitude is an important basic competence that reliably predicts later mathematics achievement (Booth & Siegler, 2008), training of this competency would be desirable in preschool education. Moreover, since subjective ratings clearly favoured the dance mat over the tablet PC as well, we conclude that exercise with the dance mat presents a possibility of such training that children experience as a highly motivating game.

On a general level, this study indicates that the theory-guided use of modern media improves learning even in basic tasks and thus supports the idea that multi-media tools can be an important mediator of learning success even in kindergarten children. Moreover, this study lends support to the idea that the inclusion of bodily experiences to represent abstract concepts may not only be helpful to represent those abstract concepts but that embodied cognition also aids their acquisition.

**Abstract**. This study investigated the effects of engaging students to collectively learn and work with knowledge in a computer-supported collaborative learning environment called Knowledge Forum on their views about knowledge building theory and practice. Participants were 24 teacher-education students who took a required course about theory and practice in teaching. Data mainly came from (1) student discourse recorded in a Knowledge Forum database, (2) a survey that examined students' views about knowledge building, and (3) interviews with regard to students' perceived barriers to implementing knowledge building theory in teaching. Findings suggest that with sustained discourse to construct their collective understanding of the relationships between theory and practice in teaching for a semester, the participants were able to attain more informed and practical views about knowledge building theory. In addition, students' perceived barriers to implementing knowledge building in teaching were identified and strategies to help overcome these barriers discussed.

## Introduction

Teaching has been viewed as a craft (Bereiter, 2002). As commonly observed in the classroom, most teachers tend to pursue "best practices" by practicing their teaching according to some known theories, and they are less inclined to go beyond "best practices" and assume the role of theory-building for their practice (Hargreaves, 1999; Sawyer, 2004). Recent literature, however, emphasizes the importance of viewing teaching as a knowledge-building enterprise (Hargreaves, 1999; Zhang, Hong, Teo, Scardamalia & Morley, 2008; Scardamalia, 2002). Related concepts have been introduced to support this idea, for example, creative teaching (Sawyer, 2004), adventurous teaching (Cohen, 1989), and teaching as progressive problem solving (Bereiter & Scardamalia, 1993) or as a sustained design process (Hong, Zhang, Teo, & Scardamalia, 2009). Yet, the idea of education as a progressive science and teaching as knowledge building is still new to most teachers (Sawyer, 2006).

One way to help teachers to develop a deeper conceptual understanding of teaching as a process of knowledge-building may be to engage them in the actual "knowledge-building" practice (Hargreaves, 1999; Hong & Sullivan, 2009). Knowledge-building is a social process focused on the production and continual improvement of ideas of value to a community (Bereiter & Scardamalia, 2003). The epistemological position underlying the knowledge building pedagogy is Popper's (1972) construct of World 3. Other than World 1 (the physical world) and World 2 (the subjective world inside the mind), Popper postulates a World 3 that is constituted of conceptual artifacts. The ideas and theories created by knowledge workers such as scientists, engineers and architects are among the conceptual artifacts. These theories and ideas, once created, have a life of their own in that they can be improved and transformed by people who interact with them. They are treated as tentative theories that should be subjected to error elimination under Popper's schema for the search for truth. In other words, all created knowledge is open to further inquiry and improvement. This epistemological stance is translated directly into the practice of treating all knowledge as ideas and as improvable in a knowledge-building community (Scardamalia, 2002). Bereiter (1994) argues that school focused on changing students' mind (ie, World 2) and neglected the enculturation of students' competencies to work in World 3. Arguably, teachers are unaccustomed to the ways of building knowledge as professionals, much less developing such competencies among students (Hong, Scardamalia, & Zhang, 2007).

To facilitate the process of knowledge building, a set of 12 knowledge-building principles have been conceptualized (Scardamalia, 2002). These principles have evolved over the last two decades: from an earlier focus on transformative discourse (Bereiter & Scardamalia, 1987), intentional learning (Scardamalia & Bereiter, 1991), and creative expertise as progressive problem solving (Bereiter & Scardamalia, 1993), to the most recent 12 knowledge building principles (Scardamalia, 2002). These 12 principles represent some innovative, pedagogical know-how to help transform a traditional class into a knowledge building community. They include (1) *Real Ideas, Authentic Problems*; (2) *Idea Diversity;* (3) *Improvable Ideas*; (4) *Epistemic Agency*; (5) *Community Knowledge, Collective Responsibility;* (6) *Democratizing Knowledge*; (7) *Symmetric Knowledge Advance*; (8) *Pervasive Knowledge Building*; (9) *Constructive Uses of Authoritative Sources*; (10) *Knowledge Building Discourse*; (11) *Concurrent, Embedded, Transformative Assessment*; and (12) *Rise Above* (see

Scardamalia, 2002, for more details). Fundamentally, knowledge building principles are designed to reconceptualize the behaviors of and relationships between three essential knowledge-building entities: the idea, the agent, and the community. For example, the principle of *Real Ideas, Authentic Problems* highlights the importance of viewing student ideas as conceptual artifacts (Bereiter, 2002) that are as real as things touched and felt, and that knowledge problems arise from efforts to understand the world and the ideas of other collaborators in the community, leading to problems of understanding that are quite different from textbook problems and puzzles. The principle of *Epistemic Agency* underscores that participants deal with the full range of knowledge problems (goals, motivation, evaluation, long-range planning, etc.), including knowledge problems normally left to teachers or managers. And the principle of *Community Knowledge, Collective Responsibility* emphasizes that contributions to shared, top-level goals of the community are prized and rewarded as much as individual achievements; team members produce ideas of value to others and share responsibility for the overall advancement of knowledge in the community. These principles represent design ideals and challenges that set the stage for the community's work in sustained knowledge advancement (Bereiter & Scardamalia, 2003), which is very different from conventional classroom work defined by pre-specified procedures, clear scripts and rules, or any highly-structured, ritualistic learning activities that represent fixed rather than improvable classroom procedures (cf. Hong & Sullivan, 2009).

A growing body of evidence has suggested that it is important to consider teachers' epistemological views since such views will influence classroom performance (Chai, Hong, & Teo, 2009; Pajares, 1992; Richardson, Anders, Tidwell & Lloyd, 1991; Wilson, 1990). The aforementioned principles represent essential concepts underlying knowledge building as a theory of knowing and as a way to transform traditional teaching practice. In order to help prospective teachers develop a more informed view of knowledge building theory and practice, instead of employing traditional direct teaching, the present study engaged the participants in self-initiated and self-directed knowledge work in a knowledge building environment (Hargreaves, 1999; Hong, Zhang, Teo, & Scardamalia, 2009). In particular, we are interested to find out whether knowledge-building environment and technology affects students' learning processes and outcomes. In terms of processes, we looked into participants' online performance patterns, social interaction patterns, and patterns in relation to their reflective understanding of the relationships between theories and practices in teaching. In terms of outcomes, we looked into pre-post changes in students' views about the importance and feasibility of knowledge building, and their perceived barriers to implementing knowledge building in class.

## Method

### Participants and context

The present research was conducted in a university course titled "Integrating Theory and Practice in Teaching" in Taiwan. The course was offered by the university's Center of Teacher Education to teacher-education students as its last required course before they start their teaching practicum. The university is ranked as one of the best universities in the nation. As such, the students enrolled in the subject university are all academically high-achievers. Based on the test results of the national Basic Competence Test for Senior High School Students (BCTSHSS), in order to enroll in this university, a student's test scores in BCTSHSS need to be ranked above the 95th percentile nationwide. Participants in the present study were 24 teacher-education students (14 females) who were planning to teach at the high-school level in the near future. Their ages range from 21 to 29 (M=24; SD=2.3).

### Instructional design and online knowledge building environment

By engaging students in building knowledge in Knowledge Forum, the two main insructional goals were: (1) to help students better understand the complex relationships between theories and practices in teaching; and (2) to help students develop a more informed and practical view about knowledge building. To these ends, an invited talk about knowledge building theory, pedagogy, and principles, and a tutorial workshop about how to use Knowledge Forum for knoweldge building were given in the beginning of the semester. The basic design features and functions of Knowledge Forum were demonstrated to students, for example, how to create a note or a "view" (i.e., virtual spaces for collaborative discourse among community members) and how to "build-on" to an existing note. Other major instructional activities included: (1) a weekly reading assignment in which students (a) reviewed literature related to various teaching theories, and (b) read teachers' interview transcripts in which in-service teachers share their successes and challenges encountered in their daily teaching practice; (2) an invited guest speaker (i.e., a veteran teacher) shared his personal teaching experiences; and, (3) most importantly, sustained online peer discussion about the relationships between theories and practices in teaching.

The technology platform used to support peer discourse is Knowledge Forum--a multimedia community knowledge space (Scardamalia, 2003), in which participants spend extensive time collectively constructing their knowledge. They contribute their ideas in the form of notes. The Knowledge Forum environment also enables participants to co-author notes, build-on, reference (i.e., citation excepted from other community members' notes), and annotate the work of others, set problem fields and add keywords, and create "rise-above" notes that bring greater coherence to the contents of the knowledge space. All these features are designed as different means to foster collaboration in depth. For example, the "rise-aboves" allow users to gather theories and ideas that have already been presented, synthesize these old ideas and point out new challenges to understandings. Operations such as reading, referencing, editing, rise-above etc. are recorded automatically in the database, and can be summarized statistically by means of an Analytic Toolkit (Burtis, 2002). The Knowledge Forum technology designs—in line with the overarching commitment to continual knowledge improvement—allow students to exchange ideas and continuously improve them.

## Study design and data sources

This research employed a mixed-method design. The rationale for using such a design is that "the quantitative data and results provide a general picture of the research problem; more analysis, specifically through qualitative data collection, is needed to refine, extend, or explain the general picture" (Creswell, 2005, p. 515). Data sources mainly came from: (1) students' online discourse which was recorded as notes in a Knowledge Forum database, (2) a survey, and (3) interviews. We describe each in detail below. First, a descriptive analysis and a social network analysis (SNA) were performed on the recorded dataset in the Knowledge Forum to describe in general the overall online knowledge building process. In addition, all notes in the Knowledge Forum database were content-analyzed to examine if students gained a deeper understanding of the relationships between theories and practices in teaching. To do so, an open-coding procedure (Strauss & Corbin, 1990), using the note as the unit of analysis, was adopted. A two-level coding scheme based on Anderson & Krathwohl's (2001) revision of Bloom's (1956) Taxonomy of Educational Objectives was adopted. The two levels are: (1) lower-level cognitive activity/responsibility (including remember, understand, apply teaching theories), and (2) higher-level cognitive activity/responsibility (including analyze, evaluate, and create teaching theories). Two researchers repeatedly read and re-read all students' notes and then categorized each note into a level. An inter-coder agreement was computed to be 0.89 (with all differences resolved by discussion). Table 1 shows the coding scheme. To determine whether there were any changes in terms of students' discoure levels, the whole semester was divided into two stages: an early and a later knowelge-building stage (using the midterm exam as a point of seperation). A Chi-square was computed to decide if there were any differences between the two stages in terms of the discoure levels.

Second, a survey that measures students' views about the importance and feasibility of knowledge building was administered in the beginning and at the end of the semester as a pre-post assessment. This survey was designed by the authors to assess participants' mindset about the importance and feasibility of knowledge-building. There are 12 items in this survey, each is represented by a knowledge-building principle (see Scardamalia, 2002, for details). Using subjects (N=22) from another teacher education program of a comparable university, the Cronbach Alpha reliability estimates were calculated to be .87 (for the "importance" dimension) and .74 (for the "applicability" dimension). All items in both surveys employed a 5-point Likert scale (1=strongly disagree; 5=strongly agree). T-tests were conducted to see if there were pre-post changes in students' views.

Third, an approximately one-hour long interview was conducted as a follow-up investigation to further explore the perceived barriers and challenges among the teacher-education students who have expressed concerns about implementing knoweldge building in their future teaching. Six (out of total 24) participants who rated knowelge building as important but less feasible in their surveys were approached and they agreed to participate in the follow-up interviews. The interview data were transcribed verbatim and qualitatively used to help uncover some major barriers to implementing knowledge building.

Table 1. Coding scheme for analyzing relationships between theory and practice in teaching

| Level | Focus | Description | Example (Translated from Chinese) |
|---|---|---|---|
| Lower-level cognitive activity/ responsibility | Remember/ understand | Teachers should know and understand theories; | Teacher should understand some basic theories, such as behavioral learning and collaborative Learning. |
| | Apply | Teachers should be able to apply theories in teaching | I think teachers need to apply different theories in different conditions. |
| Higher-level cognitive activity/ responsibility | Analyze/ Evaluate | Teachers should be able to analyze theories and practice | Experience and theory are like Na-Kon-Hsin-Fa [a type of Chinese Kung Fu]. After one masters some theories, they can help supplement and/or be integrated into one's own personal teaching experience. |

| | | |
|---|---|---|
| Create | Teachers should be able to improve and even create theories | Teacher's experiences and self-reflection can help with the development of new theories. |

## Results and Discussion

### Knowledge building practices

#### Online contribution patterns

The overall online activity and performance in this community is shown in Table 2. Throughout the whole semester, the participants contributed a total number of 625 notes with a mean number of 26.04 (SD=6.69) notes being generated per person. In addition, Table 2 also shows other related online knowledge-building measures recorded in this community, including number of note revisions, number of keywords in notes, and number of build-on notes generated, and number of rise-above notes created. Overall, the online activities were substantive as compared with our previous study (see, Hong & Lin, accepted; Chai & Khine, 2006). Nevertheless, while these behavioral measures gave a general picture of how participants worked online in this database, they do not tell much about how participants actually interacted with one another. To better understand the social dynamics in the community, a social network analysis (SNA) focusing on network density was conducted.

Table 2. Descriptive analysis on individual online knowledge-building activities

| Online activity | Mean | SD |
|---|---|---|
| No. of notes created | 26.04 | 6.69 |
| No. of note revisions | 8.5 | 7.0 |
| No. of keywords in notes | 6.6 | 4.21 |
| No. of build-on notes created | 10.2 | 4.45 |
| No. of Rise-above notes created | 1.1 | 0.81 |

#### Online interaction patterns

SNA was conducted to investigate interaction patterns in the community by using the automatic assessment tools embedded in the Knowledge Forum. Table 3 shows the overall interactive and collaborative patterns in the community throughout the whole semester, using two indicators that are available in the Knowledge Forum: passive "note-reading" and active "note-linking" (including build-on notes, references, and annotations). It also shows detailed results of participants' interactions in two knowledge-building stages (using the mid-term exam as a point of seperation). In this particular analysis, density is defined as the proportion of connections in a network relative to the total number possible. The higher the number of the density is, the stronger the social dynamics of a community is implied. An intention of adopting the knowledge-building practice in this course was to transform the traditional knowledge-transmission mode of learning into a knowledge-construction mode to engage these students in collective problem-solving and knowledge work. Therefore, it was expected that the students should collaborate more as they progress. As can be seen, there was an increasing trend of social interactions as reflected by the measures of density recorded online for this community from the early to the later knowledge building stages, especially in terms of note-linking (which inlcude build-on, reference, and annotation). Lipponen Rahikainen, Lallimo, and Hakkarainen (2003) regarded a social network density of .39 for students building-on each other online messages as adequate. In this study, the social network density for building-on at the end of course is 44.2%. The findings indicate a satisfactory level of social interaction in this community.

To further understand the quality of learning in this community, we content-analyzed students' notes. In so doing, we illustrate the processes of how they actually learn and deepen their understanding towards the pre-determined teaching goal, which was to better understand the relationships between theories and practices in teaching.

Table 3. Social network analysis (SNA) of interactivity in this community

| Network density | Early KB stage | Later KB stage | Whole semester |
|---|---|---|---|
| Note reading | 223 (80.79%) | 223 (80.79%) | 276 (100%) |
| Note linking | 47 (17.02%) | 130 (47.1%) | 143 (51.81%) |
| Build-on | 35 (12.68%) | 109 (39.49%) | 122 (44.2%) |
| Reference | 16 (5.79%) | 15 (5.43%) | 30(10.86%) |

| | | | |
|---|---|---|---|
| Annotation | 17 (6.15%) | 57 (20.65%) | 71(25.72%) |

### Reflective patterns

Table 4 shows how the focus of students' discourse with regard to teachers' cognitive activity/responsibility changed over time from the early to the later knowledge building stages. A Chi-Square test showed a significant difference between the two stages ($\chi^2 = 19.78$, df = 1, $p < .001$). As it shows, at the early KB stage before the midterm, students' online discourse tended to focus more on lower-level cognitive responsibility of teachers, highlighting that teachers only need to understand and appreciate teaching theories, and apply them accordingly in practice. As an example (translated from Chinese), below is a student's online reflection after she read an article about corporal punishment; in her reflection, she basically views theories as authoritative sources for knowledge application:

> The teacher [in the reading materials] expressed her opinions on "education of love" and "corporal punishment". I have no teaching experience, in reality, and therefore am not able to judge which strategy works better. I, however, very much agree with her ideas. "Education of love" certainly could cultivate more independence and autonomy in students, but I also doubt its effectiveness. For those students who appreciate the teacher's encouragement, "education of love" might work well; however, for those who do not care about the teacher's encouragement, "corporal punishment" might not be a bad thing…Nevertheless, I believe that the approach of "education of love" has more benefits than drawbacks…If the teacher can apply the right strategy at the right situation, students will be able to trust him/her.

At the later KB stage, students' online discourse began to focus more on the higher-level cognitive responsibility of teachers, emphasizing that teachers need to improve and even generate their own teaching theories. For example, below is another excerpt from the same student drawn from a note composed at the later knowledge building stage:

> Thank you, those who replied to my note. I am glad to see that we are gradually linking our ideas together. I believe we all think that "a theory needs to be shaped again and again." This is a process and also a procedureof strengthening a theoretical statement. By referring to classmate Hsu's idea, I think theory itself is a conceptual sketch. No matter how it is challenged or shaped by the practice,the sketch will be modified and refined in a better way.

Table 4. Changes in students' understanding of the relationships between theories and practices in teaching

| | Lower-level cognitive activity | Higher-level cognitive activity |
|---|---|---|
| Early knowledge-building stage | 42 | 9 |
| Later knowledge-building stage | 25 | 36 |

The above findings suggest that engaging students in knowledge building practice is helpful to gradually promote more reflective discourse among participants and deepen their understanding of the relationship between theory and practice in teaching. Below we examine whether engaging students in knowledge building practice also has any effects on their views about knowledge building theory and practice.

## Students' views about knowledge building

### Changes in students' perceived importance and feasibility of knowledge building

To further understand if engaging students in knowledge building practice also has impact on their views about the importance and feasbility of knoweldge building, t-tests were conducted. First, in terms of the pre-test, it was found that the teacher-education students tended to consider knowledge building to be both important (M=4.38, SD=0.41) and feasible (M=3.35, SD=0.49) as their means were both higher than the average mean value (M=3.0). To explore futher, however, a paired-sample t-test showed a significant difference between the importance and feasibility of knowledge building (M=1.03; SD=0.68; t=7.41, df=23, p <.01), suggesting a perceived discrepancy among the participants (see Table 5). In terms of the post-test, a paired-sample t-test continued to show that there was a significant perceived discrepancy (M=0.79; SD=0.49) between the importance (M=4.23, SD=0.54) and feasibility (M=3.44, SD=0.44) of knowledge building (t=7.88, df=23, p <.01) at the end of the semester. These findings, however, were quite expected as the participants were teacher-education students who had no prior teaching experience at the time of this study; thus it was natural that they inclined to rate the feasbility lower than the importance, both in terms of pre-test and post-test. Nevertheless, what is more important to know is whether the discrepancy was reduced after engaging students in knoweldge-building practice for a semester. Further t-test indicated there was a marginally significant difference (M=0.24, SD=0.57) between pre-post tests (t=2.02, df=23, p =.055), suggesting that engaging students in knoweldge-building practice did help reduce their perceived discrepancy to some extent.

Table 5. Students' perceived discrepancy between the importance and feasibility of knowledge building

| | Difference | | t-value | p-value |
|---|---|---|---|---|
| | M | SD | | |
| Importance-feasibility discrepancy in pre-test | 1.028 | 0.679 | 7.410 | 0.000** |
| Importance-feasibility discrepancy in post-test | 0.792 | 0.492 | 7.881 | 0.000** |
| Reduced discrepancy between pre-post tests | 0.236 | 0.573 | 2.017 | 0.055* |

* < .10 ** <.01

## Perceived barriers to knowledge building

As the above finding suggests, students' perceived feasibility was relatively low as compared with their perceived importance of knowledge building. With this in mind, a relevant question to ask is what might be the barriers to students perceiving knowledge building as feasible? Making these barriers explict is an essential step to addressing them. Our follow-up interviews indicated concerns regarding the aforementioned three knoweldge building entitites (agency, ideas, and community).

Views on student agency. The interview data first revealed teacher-education students' distrust of children as epistemic agents capable of constructing their own knowledge. For exmaple, as one participant commented, "I think it [knowledge building] is less feasible because of age differences. Age differences must be considered. This is especially true for young students. I believe that if they plan their own learning, they will focus on playing." Apparently, this interviewee tends to believe that children are too young to plan and regulate their own learning as an independent knowledge agent. Such beliefs, however, are contrary to previous research findings that suggest knowledge building is possible even among young children such as grade five students (Hong, Scardamalia, Messina, & Teo, 2008; Zhang, Scardamalia, Lamon, Messina, & Reeve, 2007). Unfortunately, such disbelief in children's knowledge building capacity does align with conventionally held eudcational beliefs which hold that learning must always come first (e.g., during K-12 schooling), before one can really produce new knowledge (e.g., during graduate study) (cf. Hong & Sullivan, 2009). Under this view, maximizing one's individual knowledge (i.e., seeing knowledge as a psychological state confined within Popper's second World) seems an important criterion in judging whether instruction is effective or not, leaving little room for knowledge-building.

Views on idea-centered learning. The interviewed students were also less in favor of idea-centered learning that highlights the importance of sustained production and improvement of ideas. Instead, they tended to emphasize the importance of accumulating basic knowledge in order to pass exams. As an interviewee commented, "…it [knowledge building] is less feasible because what is taught in school in order to help students pass exams is often not related to the real ideas or authentic problems in life." As another commented, "It is not practical to teach more than one solution to a math problem. For example, in learning math, more than one solution [as opposed to idea diversity] may lead students to confusion, especially when the instructional goal is to help students pass the test." As mentioned above, conventional classroom work tends to be defined by pre-specified procedures, clear scripts and rules, and highly-structured learning activities in order to help learners acquire pre-specified knowledge efficiently and then pass exams. As such, establishing a broader knowledge base becomes much more important as an instructional goal than encouraging students to work innovatively with knowledge and engage in sustained idea production and improvement.

Views on community knowledge. The interview data also showed the future teachers' concern about group equity and social harmony in relation to building community knowledge. For example, a participant commented, "I think people can work together in a group but there will never be equal contribution in a group." As another commented, "You can not make sure everyone will have the same value and share the same responsibility, as each one has his or her own individual learning goal." In other words, they still tend to treat knowledge as individual, rather than public, property. They were also less inclined to accept the concept that to give knowledge is to get knowledge in a knoweldge community. For example, one said, "some members never give/share knowledge, but just take from others. To maintain a good social relationship is a key factor that should be taken into consideration." Perhaps, this is because their past schooling and test-related experiences tend to emphasize individual learning rather than group knowledge work. Clearly, how to help transform these teacher-education students' individualistic learning view into a view that also appreciates the social aspects of learning remains an important challenge.

## Summary and Conclusion

In this exploratory research study, we reported the process of knowledge building among a group of teacher-education students and investigated the effects of this knoweldge building process on their views about knowledge building theory and practice. In summary, it was found that engaging students in knowledge building is helpful to (1) promote gradually more interactive and reflective online knowledge building activities; and (2) to somewhat reduce their perceived discrepancy between the importance and feasibility of knowledge building as a theory of knowing and as a way to transform conventional teaching practice. In addition, a major challenge of implementing knowledge building identified through in-depth interviews among participants who especially rated knowledge building as less feasible was that participants' prior schooling experience and socio-cultural expectations tended to strongly influence how they might interpret and value the feasibility of knowledge building. Overall, these participants' prior epistemic views are still largely confined within Popper's world 2 epistemology which sees knoweldge as psychological entity (as opposed to the concept that sees ideas as public artifacts) and learning as individualistic activities (as opposed to the concept that sees learning as a communal acivity) and as accumulation of authorative knowledge (as opposed to the concept that values self-initiated and self-directed knowledge construction). To help students develop more informed and practical views of knowledge building theory and practice thus implies helping them to develop a world 3 knowledge view that sees knowledge as public conceptual artifacts and learning as a social process (Hong, Scardamalia, & Zhang, 2007).

The instructional goal of the present research was (1) to help better prepare teacher-education students to attain a deeper understanding of the relationships between theory and practice in teaching, and (2) to help them develop more informed views about knowledge building. To further this end, we conjecture that a possible strategy is to make teacher-education students' own pedagogical, epistemological, and socio-cultural views about learning and knowledge-building more visible to themselves. Accordingly, an effective instructional design may be to engage them to discuss more explicitly in class their own views about knowledge-building, while at the same time engaging them in actual knowledge-building practices. It is posited that doing so would further help students clarify their conceptual discrepancies between theories and practices in teaching, and gradually achieve World-3 oriented views and thus be able to see knowledge building as more feasible in reality. It is futher conjectured that after being immersed as a knowledge builder in the teacher education program, it may be beneficial to engage teacher-education students in facilitating knowledge-building communities during their practicum experiences under the guidance of experienced knowledge building teachers (See Chai & Tan, 2009). Given the deeply rooted nature of beliefs highlighted above, it seems clear that a single stand-alone course on knowledge building is unlikely to counter the effects of existing beliefs and views on one's own teaching and learning. These claims, however, remains to be further examined by future research.

The preparation of this paper was supported in part by the National Science Council, Taiwan, grants NSC96-2524-S-008-001 and NSC97-2511-S-004-001-MY2. We extend special thanks to the students and teacher for their participation and for the research opportunities enabled by them. Our special thanks also go to Florence R. Sullivan for editing the manuscript.

# Design-based knowledge building practices in mathematics teaching

Huang-Yao Hong & Yu-Han Chang
National Chengchi University, Taiwan
Email: Hyhong@nccu.edu.tw, 97152010@nccu.edu.tw

**Abstract:** This study investigates the impact of engaging teacher-education students in sustained design and knowledge building practices in mathematics teaching on their views of mathematics and mathematics teaching. Participants were nine teacher-education students who took a university course titled "Middle School Mathematics Teaching." Data primarily came from student discourse recorded in a Knowledge Forum database, peer evaluation and video analysis on student teaching practices, and an open-ended mathematics belief survey. Preliminary results suggest that teacher-education students became progressively more adaptive in their teaching practice. More importantly, their views of mathematics became more constructivist-oriented, and in the meantime, their views of mathematics teaching also became more student-centered.

## Introduction

The purpose of this study is to introduce knowledge building practices into a teacher-education course and to investigate if such practices have any impacts on teacher-education students' views of mathematics and mathematics teaching. According to Paul Ernest (1991), there are two general epistemological stances in terms of views of mathematics, one often referred to as foundationalists and absolutists, the other fallibilists, humanists, relativists and constructivists (see also Handal, 2003). The fundamental argument of the former is that mathematics knowledge is certain, cumulative and unaffected by social interests or personal value. On the other hand, the latter is inclined to believe that mathematics knowledge is through historical, social and cultural, and that there are limitations to its claims of certainty and absoluteness (Ernest, 1991). While the two views are opposing to each other, it is accepted that people's epistemological views in general tend to progress slowly from one that sees knowledge as certain and absolute, to a more relativistic stance that emphasizes knowledge as uncertain and constructed by individuals (Chai, Hong, & Teo, 2009; Magolda, 2004; King & Kitchner, 1994).

As for views of mathematics teaching, they may be broadly classified under the knowledge transmission category or the knowledge construction category (Entwistle, Skinner, Entwistle & Orr, 2000; Handal, 2003; Samuelowicz & Bain, 2001). The former category is characterized as teacher-centered, content-based didactic teaching practice that emphasizes on passive reception of knowledge by students; and the later as student-centered, learning-oriented constructivist instruction that encourages students to actively make sense of their experiences.

Previous research indicates that epistemological views are closely in relation to learning in various ways and have implications for teaching (Pajares, 1992; Richardson, Anders, Tidwell & Lloyd, 1991; Schommer, 1994; Wilson, 1990). Yet, such views are often neglected, or not properly addressed, within teacher education programs (Nespor, 1987). Despite studies in general suggest that it is possible to change pre-service teachers' epistemological views (e.g., see Brownlee, Purdie & Boulton-Lewis, 2001; Gill, Ashton & Algina, 2004; Howard, McGee, Schwartz & Puecell, 2000), there is no consensus as to what represents a most effective way.

One way to help teacher-education students develop more constructivist-oriented epistemological and pedagogical views is perhaps to directly engage them in knowledge building practices (Chai & Tan, 2009; Hargreaves, 1999; Hong, Zhang, Teo, Scardamalia, 2009). Knowledge-building is a social process focused on the production and continual improvement of ideas of value to a community (Bereiter & Scardamalia, 2003) and is supplemented by the use of a software program called Knowledge Forum. Previous research on in-service teachers who have been practicing knowledge building pedagogy for years suggests that it may stimulate epistemological growth among teachers (Chai, Wong & Bopry, 2009; Chai & Tan, 2009; Hong, Zhang, Teo, Scardamalia, 2009). Therefore, it is posited that engaging teacher-education students in collaborative knowledge building practices should also have effects on their views about the subject matter they are to teach and about their teaching methods. Yet, such assumption remains to be examined, especially for the subject of mathematics. The purpose of the present study is to investigate this claim and our main research questions focus on: How do knowledge-building practices affect students' learning processes and outcomes? Specifically, in terms of processes, we looked into participants' online contribution pattern, social interaction patterns, and patterns in their teaching practices throughout the semester; and in terms of outcomes, we looked into changes in their views of mathematics and mathematics teaching.

## Method

### Context and participants

The present research was conducted in a university course titled "Middle School Mathematics Teaching" in Taiwan. The course was offered by the university's Center of Teacher Education to students who plan to become a mathematics teacher at the middle school level. The university is ranked as one of the best universities in the nation and the students enrolled in the subject university are all academically high-achievers and are overall considered by the society as the best prospective teachers in the nation. Participants in this study were four female and five male teacher-education students and their age ranged from 19 to 23 years (M = 21; SD=1.59).

### Instructional approach

We employed an instructional approach that features design-based knowledge building practices (Hong, Zhang, Teo, & Scardamalia, 2009). The main purpose of engaging teacher-education students in such practices is threefold: (1) to help them understand the nature of teaching as creative and adaptive (Sawyer, 2004), rather than routine and script-oriented, (2) to help them avoid viewing teaching as merely pursuing best practices of certain model teachers by means of mastering pre-defined teaching skills; and (3) to enable them to go beyond "best practices" and assume the role of designer and knowledge-builder in continual improvement of their own teaching practices.

To implement, the course was divided into the following four related phases: (1) Initial Design: First, participants were guided to work on their initial design in order to implement their first teaching practice; accordingly, they prepared lesson plans, and learning materials and learning sheet, etc.; (2) First teaching practice: Then, based on their initial design, they performed their first teaching practices in class, with the other classmates serving as the audience. The whole process of each student's teaching practice was video-taped, and, at the end of each teaching practice, a peer evaluation was conducted to assess the quality of teaching for future improvement; (3) Re-design: During this phase, participants collectively worked online in Knowledge Forum to provide feedback and suggestions to the target student who already performed his (or her) teaching practice. Then he (or she) further reflected on these suggestions, analyzed the recorded video of his (or her) own teaching practice, and collaborated with other peers to improve his (or her) initial design by co-designing next lesson; and (4) Second teaching practice: Finally, based on the new instructional design, each participant performed their second teaching practice; the whole teaching process again was video-taped, and then a second peer evaluation on the quality of teaching was conducted again.

In addition, the course also employed other complementary instructional activities, mainly whole-class and small-group discussion after each teacher-education student's teaching practice, in order to engage them to frequently reflect on how to improve their own and others' teaching practices. Some questions being discussed in class were, for example: what have you learned from others' teaching practices; if you were to teach this lesson again, what would you do differently, and why? There were no fixed or pre-defined answers to most questions. The instructor served as a facilitator in guiding students to explore, discuss and reflect on all questions emerged in class in order to help them construct their own views of mathematics and mathematics teaching. Knowledge Forum were only used after class and it played an important role as an online space for students to record all key points generated from class discussion and personal reflection.

### Knowledge Forum environment

The learning environments adopted in the present study is Knowledge Forum (KF). It is an online platform that runs on a multimedia database. KF allows users to simultaneously create and post their ideas in the form of note into the database, read others' postings, reply to others' notes, search and retrieve records, and organize notes into more complex knowledge representation. KF runs on both a text-based and graphics-based mode. In the graphics mode, it shows linkages of postings as a way to represent the interconnectivity and dialogical nature of knowledge. As such, it also enables the development of ideas to be traced. Figure 1 shows an example of a KF view (i.e., an open space designed for collaborative problem-solving), within which users are guided to work as a community by posting their problem of interest, producing initial ideas for problem-solving, sharing and connecting ideas, synthesizing their ideas, and deepening their collective understanding of problems at issue. Specifically for this study, the main problem of interest is concerned with understanding of the nature of mathematics and mathematics teaching, and in the beginning of the course students generated and shared their best ideas (e.g., "What is mathematics?"); then they designed and practiced their mathematics teaching according to their initial ideas and try to improve their initial ideas about mathematics teaching through frequent discussion, reflection, and co-design in Knowledge Forum.

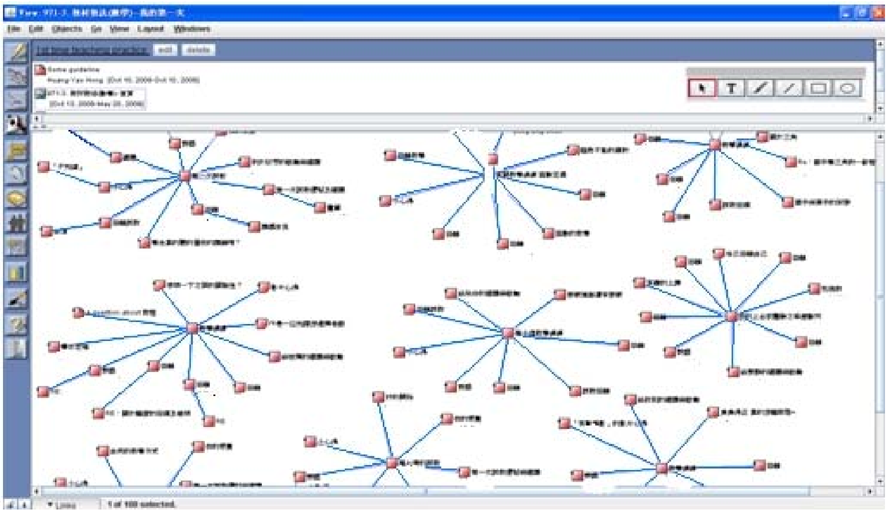

Figure 1. A Knowledge Forum view

## Data Source and Analysis

Data source mainly came from student online discourse, two teaching practices, and a belief survey. First, in terms of student online discourse, it was recorded in a Knowledge Forum database and we analyzed student participation patterns (e.g., note creation and reading) and interaction patterns by employing descriptive analysis and social network analysis. In addition, we also looked into patterns of group feedback and personal reflection, in terms of each participant's own teaching practices.

The second set of data came from peer evaluation and video analysis on students' two teaching practices. In the beginning of the course, students collectively constructed an evaluation form focusing on the following five categories: objective (one item), learning materials (five items), instructional methods (six items), activities (six items), and presentation (three items). All items employed a 5-point Likert scale (5=excellent performance, 1=poor performance). In addition, both teaching practices of each participant were videotaped and then content-analyzed based on a pre-determined coding scheme highlighting the following three general types of learning activity: passive, active, and interactive (see Collins, 1996). To analyze, we examined percentage of time spent in each type of activity during each teaching practice.

The third set of data came from a belief survey, which was designed based on Handal's (2003) conceptualization of mathematics beliefs concerning the nature of mathematics and that of mathematics teaching. Accordingly, we asked the following eight open-ended questions: (1) What is mathematics? (2) What does "doing mathematics" mean? (3) What is an ideal way to teach mathematics? (4) What are some key factors for successful mathematics teaching? (5) What makes an ideal mathematics teacher? (6) What is an ideal way to learn mathematics? (7) What are some key factors for successful mathematics learning? (8) What does an ideal mathematics learning environment mean to you? Of all questions, questions 1 and 2 concern the nature of mathematics; and questions 3 to 8 concern the nature of mathematics instruction. To analyze, we employed an open coding procedure (Strauss & Corbin, 1990). Six codes emerged from this coding process (see table 1). Pair-sampled t-tests were conducted to examine if there were any pre-post differences.

Table 1: Coding scheme for students' views of mathematics and mathematics teaching

| Categories | Code | Example of students' statements (Translated from Chinese) |
|---|---|---|
| Nature of mathematics | A science of quantity and calculation applied in life | Math is a science about calculating numbers.<br>What we see, do and make in our daily life all needs math. |
| | A science of patterns and orders | To do mathematics is to seek for the patterns or rules by means of certain given conditions, using symbols and numbers to predict, estimate, or conjecture possible outcomes. |
| Nature of mathematics teaching | To let students practice again and again | Practice makes perfect. |
| | To let students understand basic concepts and procedures | To understand what each mathematical formulas means and to get the gist of a math problem and know how to solve it. |
| | To train logical thinking skills | The most important thing is to train students' problem-solving and thinking abilities. |

| | | |
|---|---|---|
| | To help students develop and explore their own way of mathematics learning | Students have to explore and find their own way of math learning and develop their own learning styles. |

## Results and discussion

### Online contribution patterns

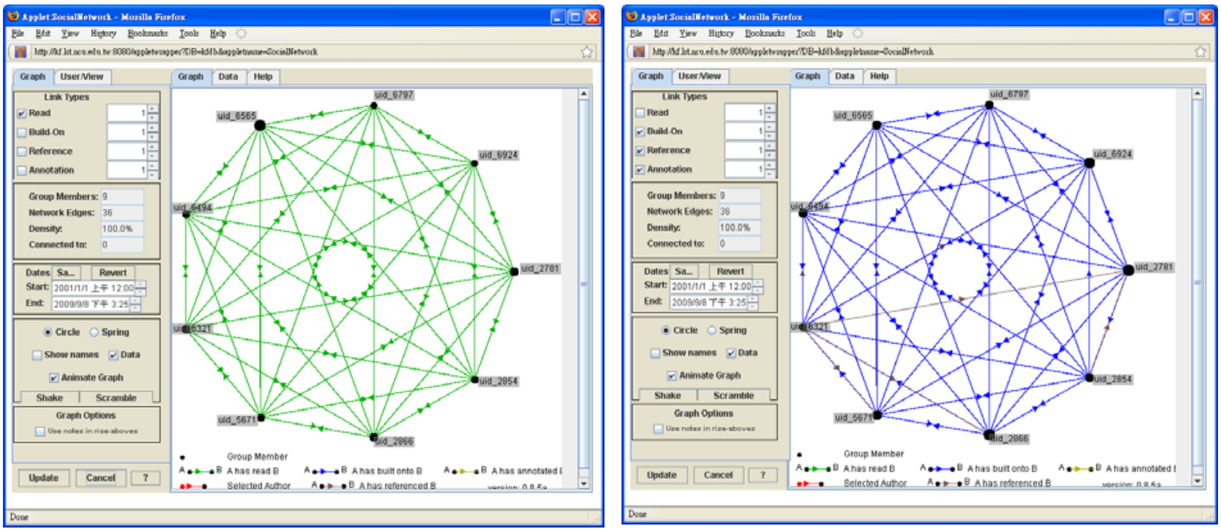
The overall online activity and performance in this community is shown in Table 2. Throughout the whole semester, participants contributed a total number of 171 notes with a mean number of 17.8 (SD=4.29) notes per person. In addition, other complementary online knowledge-building measures recorded in this community include number of note read, percentage of note read, number of annotation, number of note revisions, number of build-on notes, and percentage of notes linked. Overall, the online activities were substantive as compared with previous research using subjects with similar background (Hong & Lin, accepted). Nevertheless, while these behavioral measures gave a general picture of how participants worked online in this database, they do not tell much about how participants actually interacted with one another. To better understand the social dynamics in the community, a social network analysis (SNA) focusing on network density was conducted.

Table 2. Descriptive analysis on individual online knowledge-building activities

| | Mean | SD |
|---|---|---|
| No. of notes created | 17.8 | 4.29 |
| No. of notes read | 140.2 | 32.94 |
| Percentage of notes read | 82% | 19.26% |
| No. of annotations | 21.2 | 12.26 |
| No. of note revisions | 8.2 | 3.29 |
| No. of build-on notes created | 11.3 | 2.49 |
| Percentage of notes linked | 64.3% | 6.17% |

SNA was conducted using the automatic assessment tools embedded in the Knowledge Forum. Figure 2 shows the overall interactive and collaborative patterns in the community throughout the whole semester, using two indicators that are available in the Knowledge Forum: "note reading" (which indicates community awareness of contributions made by other peers) and "note building-on" (which indicates complementary contributions by the effort to build on to others' work and ideas). Table 3 shows detailed results of participants' interactions in two knowledge-building stages (using mid-term exam as a point of separation). In this particular analysis, we used an indicator, called "network density", which is defined as the proportion of connections in a network relative to the total number possible. The higher the number of the density is, the stronger the social dynamics a community is implied. An intention of adopting knowledge-building practices in this course is to transform the traditional way of knowledge-transmission mode of learning into a knowledge-construction mode that engages these students in collective problem-solving and knowledge work. Therefore, it was expected that students should progressively work more collaboratively in Knowledge Forum. As expected, there was an increasing trend of social interactions as reflected by the measures of density recorded online for this community from the early to the later knowledge building stages. Lipponen Rahikainen, Lallimo, and Hakkarainen (2003) regarded a social network density of .39 for students building-on each other online messages as adequate. In the present study, the density level is at .94, which indicates a highly satisfactory social dynamics of this community. The SNA findings alone, however, did not tell us much about the quality of interaction in the community. So, we further content-analyzed students' notes to illustrate what they actually did to help each other improve their teaching practices.

Table 4 shows the total numbers of group feedback and personal reflection made after the first and before the second teaching practice in terms of three dimensions: instructional design, learning materials, and presentation skills. There were in total 106 suggestions/comments and 43 times of personal reflections being made. On average each student received 13.25 suggestions from others and made 4.78 times of personal reflection between the first and the second teaching practices. This suggests that participants' online interaction were both quite purposeful and practical. The next question to ask is how online interaction, group feedback, and personal reflection contribute to the improvement of student actual teaching practices.



a. Note reading b. Note linking

Figure 2. Interaction patterns in the community throughout the whole semester

Table 3. Social network analysis (SNA) of interactivity in the community

| Network density | Early KB stage | Later KB stage | Whole semester |
|---|---|---|---|
| Note reading | 100% | 100% | 100% |
| Note building-on | 72.22% | 94.44% | 100% |

Table 4. Group feedback and personal reflection made between the first and the second teaching practices

| Category | Dimension | Frequency |
|---|---|---|
| Group feedback | 1. Instructional design | 44 |
| | 2. Learning materials | 28 |
| | 3. Presentation skills | 34 |
| Personal Reflection | 1. Instructional design | 16 |
| | 2. Learning materials | 14 |
| | 3. Presentation skills | 13 |

## Patterns in teaching practices

Table 5 shows students' peer evaluation results. It was found that the ratings in the second teaching practice were significant higher than the first teaching practice in 20 (out of the total 24) aspects of teaching practice. This suggests that there were significant improvement in students' second teaching practice. While the findings showed no significant improvement in four aspects—"Clarity of instructional goal" (M=4.49), "Appropriateness of learning materials" (M=3.98), "knowledge of the learning content" (M=4.38), and "Time management" (M=4.19)—this could be due to ceiling effects as their initial ratings were already very high (i.e., closer to or beyond point 4, out of the maximum points of five in a Likert scale). One thing worth noting is that the biggest improvement mainly came from the "Instructional methods" category which in particular highlights adaptive teaching (e.g., Uses innovative instructional approaches) and student-centered learning (e.g., Promots creative, critical and higher-level thinking), rather than conventional step-by-step and scripted teaching methods. These changes are important indicators of adaptive teaching as a central goal of employing design-based knowledge building practices in the present study was to help participants achieve a more flexible and innovative teaching approaches.

Table 5. Peer evaluation on one another's teaching practices

| Category | Aspect | 1st practice | | 2nd practice | | t-value |
|---|---|---|---|---|---|---|
| | | M | SD | M | SD | |
| Objective | Establishes clear purpose or objective of lesson | 4.49 | 0.13 | 4.58 | 0.15 | -1.31 |
| Materials | Materials are purposeful and interesting | 3.72 | 0.32 | 3.88 | 0.29 | -3.04* |
| | Materials are age-appropriate | 3.98 | 0.32 | 4.22 | 0.16 | -2.29 |

Video analysis was further conducted as a form of data triangulation. Table 6 shows analysis results in terms of percentage of time spent in three different instructional activities during the two teaching practices. It was found that there was a significant decrease in the percentage of time spent in passive learning activities, from the first practice (72.1%) to the second practice (46.9%) (t=5.04, df=8, p<.01). In contrast, there was a significant increase in the percentage of time spent in active learning activities, from the first practice (17.9%) to the second practice (36.4%) (t=-3.79, df=8, p<.01), and a slight increase in the percentage of time spent in interactive learning activities (t=-2.15, df=8, p=.064). Overall, our video analysis confirmed that participants' teaching practice was shifting from a more teacher-centered approach to a more student-centered approach.

Table 6. Percentage of time spent in different instructional activities in two teaching practices

| Activity | First practice | Second practice |
|---|---|---|
| Passive learning | 72.1% | 46.9% |
| Active learning | 17.9% | 36.4% |
| Interactive learning | 10.0% | 16.7% |
| Total | 100.0% | 100.0% |

## Views of mathematics and mathematics teaching

Finally, we looked into whether engaging students in design-based knowledge building practices also have effects on their views of mathematics and mathematics teaching. As shown in Table 7, in terms of views of mathematics, there was a significant drop in scores in the view that emphasizes mathematics as a science of quantity and calculation (M = 3.67 in the pre-survey and M = 1.67 in the post- survey). In contrast, there is a significant increase in scores in the view that highlights mathematics as a science of patterns and orders between the two measurements (M = 0 in the pre-measurement and M = 2.33 in the post- measurement). In sum, the findings suggest that in the beginning of the semester, teacher-education students tended to think that mathematics was all about number calculation or was something that is useful and can be applied to our daily life. Accordingly, it was assumed that a teacher should focus his or her instructional goal on helping students do appropriate mathematics calculation or develop related math abilities. However, such routine mathematics practices and training may only help students be familiar with and able to acquire some conceptual and procedural mathematics knowledge efficiently. It may not necessarily help students to use mathematics in a more creative way. But, after a semester, it was found that the teacher-education students were able to gradually view mathematics from a more constructive and creative manner. They began to appreciate mathematics as a science of finding patterns and orders, or as a tool for more constructive learning and problem-solving.

Accordingly, they also changed their views of mathematics teaching. As shown in the bottom part of

6

Table 7, there was a desirable (although insignificant) drop in scores in terms of the first three views of mathematics teaching, which regard mathematics teaching as a way "to let students practice again and again" (M = 2.11 in the pre-test and M = 0.44 in the post-test), or a way "to let students understand basic concepts and procedures" (M = 2.56 for the pre-test and M = 1.33 for the post-test), or a way "to train students' logical thinking ability" ( M = 4 for the pre-test and M = 3.11 for the post-test). In contrast, there is a significant increase in scores between the pre-measurement (M = 0.22) and the post-measurement (M = 3.56) in terms of the last view of mathematics teaching, which highlights mathematics teaching as a way "to help students develop and explore their own way of math learning". Overall, it was found that in the beginning of the semester, teacher-education students' views of mathematics teaching is more teacher-led, whereas after engaging in design-based knowledge building practices for a semester, their views of mathematics became more student-centered.

Table 7: Students' views on the nature of mathematics and that of math teaching

| Views of mathematics and mathematics teaching | Pre-survey | | Post-survey | | *t-value* |
|---|---|---|---|---|---|
| | M | SD | M | SD | |
| Nature of Mathematics | | | | | |
| A science of quantity and calculation applied in life | 3.67 | 1.87 | 1.67 | 1.41 | 4.00** |
| A science of patterns and orders | 0 | 0 | 2.33 | 1.80 | -3.88** |
| Nature of mathematics teaching | | | | | |
| To let students practice again and again | 2.11 | 2.21 | 0.44 | 0.73 | 2.041 |
| To let students understand basic concepts and procedures | 2.56 | 3.05 | 1.33 | 1.80 | 0.854 |
| To train students' logical thinking ability | 4.00 | 2.50 | 3.11 | 3.52 | 0.567 |
| To help students develop/explore their own way of learning | 0.22 | 0.44 | 3.56 | 2.19 | -4.588** |

**p<.01

## Summary and implication

In this study, we reported an instructional approach of design-based knowledge building practices among a group of teacher-education students and investigated the effects of such instructional approach on their views of mathematics and mathematics teaching. The instructional approach was design-based as participants were engaged in sustained design, re-design, and co-design activities when planning and practicing their mathematics teaching. The instructional approach was knowledge building oriented as it highlighted continual production and improvement of ideas in pursuit of deeper understanding of the nature of mathematics and mathematics teaching. In summary, it was found that design-based knowledge building practices as an instructional approach was helpful to promote more interactive and reflective online activities. Moreover, it was found that at the end of the course, teacher-education students changed their views of mathematics to become more relativist-oriented and they also changed their views of mathematics teaching to become more student-centered. Arguably, while cultivating teachers' pedagogical content knowledge is important and should always be included as part of overall teaching training in a teacher-education program, our study suggests that it is equally important to help teacher-education students develop more informed and sophisticated mathematical beliefs. And to enable such belief change, it will be crucial for teacher education programs to avoid traditional didactic ways of teacher training, and adopt more constructivist-oriented instructional approaches in order to cultivate more future teachers who view mathematics teaching as creative and adaptive, rather than routine and ritualistic, practices.

# Centering a Professional Learning Community on a Learning Progression for Natural Selection: Transforming Community, Language, and Instructional Practice

Erin Marie Furtak, Deborah Morrison, and Kathleen Henson
University of Colorado at Boulder, School of Education, UCB 249, Boulder, CO 80309
erin.furtak@colorado.edu, deb.morrison@colorado.edu, kathleen.henson@colorado.edu

In this study we examine the development of a professional learning community (PLC) centered on the practice of understanding student learning of natural selection. Eight biology teachers engaged with researchers to use an educative learning progression (LP) empirically developed from student work as a tool for exploring prior ideas and sharing potential instructional strategies to move students towards scientific understandings of natural selection. The PLC involved iterative cycles of development and reflection of the LP, formative assessments and feedback strategies. Three primary results are reported in this paper with respect to the PLC's development associated with the LP: transformation of interactions within the PLC, changes in the language teachers used to describe student thinking, and modifications in the ways instructional practices were shared. These changes demonstrate the potential for a PLC when used in conjunction with a LP to encourage meaningful changes in classroom practice.

## Theoretical Background

The *National Science Education Standards [NSES]* (National Research Council, 1996) defined the knowledge and practices students are expected to learn, but were never intended as a 'how-to' document for teachers (Collins, 1998). To supplement the NSES, science education researchers are currently creating Learning Progressions (LPs), which are empirically-based sequences of conceptual understandings and scientific skills intended as guides for teaching and learning. LPs map "the successively more sophisticated ways of thinking about a topic that can follow and build on one another as children learn about and investigate a topic over a broad span of time" (National Research Council, 2007, p. 213).

At least two approaches have emerged for the construction of LPs. The first approach consists of a progression of *correct* ideas based on standards documents or consultations with scientists, articulated across grade spans (American Association for the Advancement of Science, 2001; Catley, Lehrer, & Reiser, 2005). This kind of LP tends to be created by exhaustive conceptual analyses of how scientifically accurate student ideas should develop during instruction; examples have been created in the domain of evolution (Catley et al., 2005) and modern genetics (Duncan, Rogat, & Yarden, 2009). These LPs are being developed as guides for curriculum and large-scale assessments. A second approach to LPs entails the creation of maps of concepts anchored on one end by naïve ideas about the natural world and on the other end by scientifically accepted explanations. The middle is occupied by increasingly sophisticated intermediate understandings. A key feature of this second type of learning progression is that they are anchored at the lower end by students' common prior ideas and misunderstandings (Briggs, Alonzo, Schwab, & Wilson, 2006; Wilson, 2005).

### Toward Learning Progressions as Teacher Development Tools

Given the aforementioned challenges presented by previous studies employing LPs in the classroom, it follows that LPs could be complimented with additional information to make them not only maps of how student knowledge develops through instruction, but also maps of the instructional strategies that will help teachers more effectively teach a given concept. Knowing the means by which students learn concepts is important, but without the tools to help teachers recognize and act upon those ideas, the means by which the information LPs contain will be translated into practice is unclear. LPs need to be developed that will scaffold the development of the knowledge and practices that teachers need for effective science instruction.

The science education community, after several years of developing LPs, is now emphasizing the need for empirical explorations of the impact of LPs on teacher practice and student learning (Shavelson, 2009). According to the Center on Continuous Instructional Improvement's recent report on LPs, the field needs "continuing effort, and funding, to refine and test the progressions that now are under development, including making a concerted effort to demonstrate the effects on instruction and improved student outcomes when teaching and assessment are aligned with well tested progressions - to provide a kind of "existence proof" that further investment in developing progressions would be justified." (Corcoran et al., 2009, p. 9).

## Educative Learning Progressions

Although the primary purpose of LPs as currently conceived is to sequentially map the knowledge and practices students are expected to learn, LPs have great potential to be invaluable tools for teacher development. LPs could serve as the foundation for what Davis & Krajcik (2005) called 'educative curriculum materials' with the dual potential of scaffolding not only student learning, but also teacher learning in a conceptual domain. This kind of LP – which will henceforth be referred to as an educative LP - contains information regarding knowledge of common student ideas and alternative conceptions, suggestions for strategies or actions to help students learn, and a model for teacher development in relation to the LP. An educative LP is thus a suite of tools that may work synergistically to support improvement in teacher practice and student learning.

In the inquiry-based learning environments currently emphasized in science education reforms (National Research Council, 1996, 2001, 2007) the ideas that students develop are often undifferentiated, poorly stated, and inconsistent with standards-style statements of idealized student understanding (e.g. Driver, Guesne, & Tiberghien, 1985). In order for teachers to navigate these ideas and move students toward learning goals, they must have deep content knowledge, as well as knowledge of students' understandings and misconceptions (Duschl, 2003; Gess-Newsome, 1999; Shulman, 1986). Since teachers' content knowledge is not always interconnected or easily translated into reform-based classroom practice, the ideas students present in inquiry-based activities pose a particular challenge (Luft & Roehrig, 2007; Windschitl, 2004).

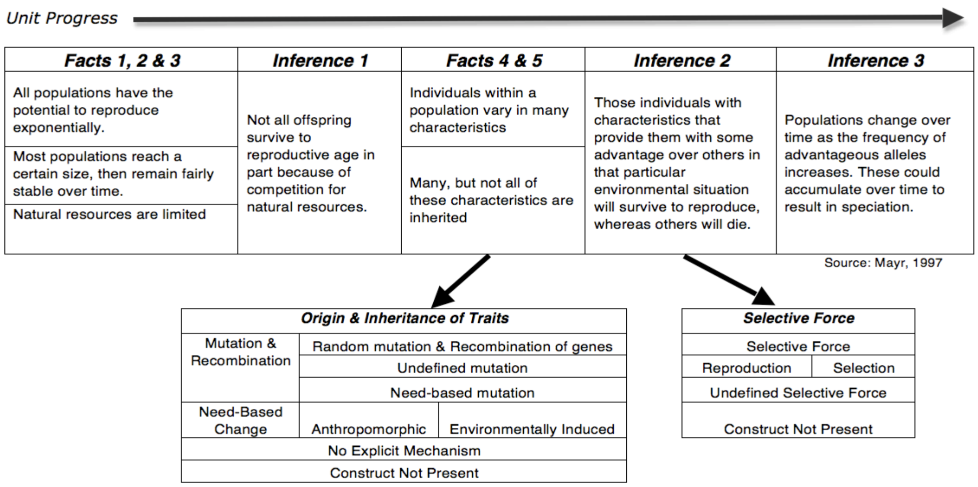
Educative LPs could serve as scaffolds for teachers in inquiry-based settings by helping them to anticipate not only the ideas students might share, but also to suggest instructional strategies tailored to these ideas. In order to serve that purpose, however, LPs need to include examples of student responses for each level, as well as instructional strategies, feedback suggestions to help students proceed up the LP, and professional development to support changes in practice. Educative LPs should thus contain the preceding five elements; the first four are features of the educative LP itself, and the fifth emphasizes the importance of sustained professional development within a community of practice to support teachers' adoption of new instructional strategies based on the educative LP (Lave & Wenger, 1991). Sustained professional development centered on an educative LP and its accompanying tools could help teachers learn the structure and relationship of students' understandings about a particular concept, teaching strategies to elicit student thinking, likely student responses, and targeted feedback for students. In this way, educative LPs can act as a guide for teachers, showing them potential steps to take in order to help students move along the learning progression, thereby meeting increasingly challenging learning goals (Sadler, 1989) and positively impacting student learning (Black, 1998). To explore the potential influence of an educative LP on a PLC, this paper responds to the following research question: How does sustained, ongoing professional development in a PLC centered on the LP transform the community, language and practice?

## Context: Natural Selection and the Daphne Project

Charles Darwin's theory of evolution through the process of natural selection is the unifying framework for Biology (Dobzhansky, 1973); nevertheless, students often have a difficult time understanding it (Bishop & Anderson, 1990; Ferrari & Chi, 1998). Studies indicate evolution instruction in high school has been "absent, cursory, or fraught with misinformation" (Rutledge & Mitchell, 2002, p. 21), and students commonly have misconceptions about how populations change over time (Anderson, Fisher, & Norman, 2002; Rudolph & Stewart, 1998; Shtulman, 2006).

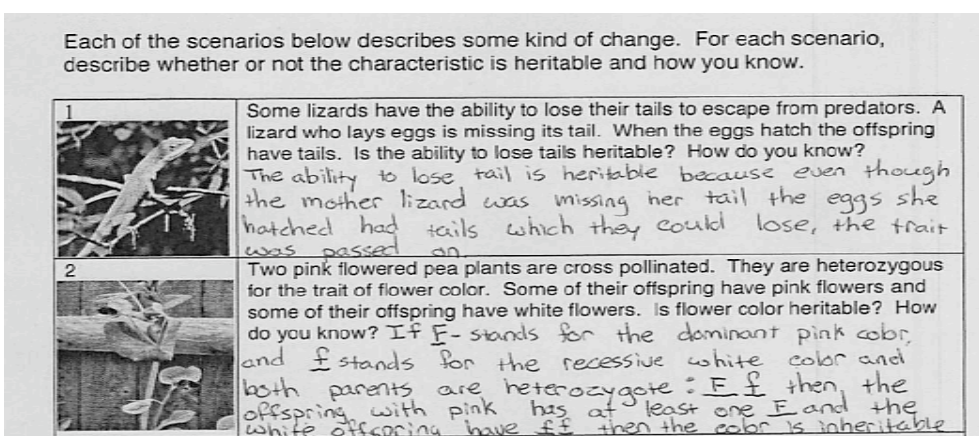
The Daphne Project is a design-based research study located at the intersection of the new theory of LPs and classroom practice (Brown, 1992; Sandoval & Bell, 2004; Sloan 2009). The goal of the Daphne Project was to collaborate with a department of biology teachers to explore and refine a hypothesized LP. It was hypothesized at the outset of the study that engaging in the process of developing this LP would help teachers be better prepared to recognize and act upon student thinking, which in turn would impact student learning by closing what has been called a 'feedback loop' in the formative assessment process (Black & Wiliam, 1998; National Research Council, 2001).

The educative LP created in the Daphne Project combines features of LPs designed as frameworks for curriculum with lower anchors serving as foundational *correct* understandings (Catley et al., 2005) and those anchored by students' common prior ideas as suggested by Shepard (2009) and Wilson (2009). In this way, the LP has as its foundation both an overarching framework to inform scope and sequence as well as information mapping students' complex thinking that can often obfuscate the path forward for teachers. The educative LP is not a curriculum in itself, but is intended as a framework to guide teachers' enactment of a curriculum by representing a sequence of correct ideas as well as a categorization of the common misunderstandings students may have regarding those ideas. The educative LP is shown in Figure 1; the horizontal sequence of correct ideas is taken directly from Mayr (1997), and the two vertical sequences (*Origin and Inheritance of Traits* and *Selective Force* constructs) were identified through analyses of student responses to the assessments in the Daphne Project. The educative LP is paired with accompanying tools intended to scaffold instruction, as well as a professional development model to support teachers in changing their practice. The educative LP for natural selection includes a set of formative assessment prompts designed to be embedded in the curriculum to provide opportunities for teachers to elicit student thinking and map it to the progression. It also includes common student responses to each assessment at each level and suggested feedback strategies for students with different ideas.



<u>Figure 1.</u> Learning Progression for Natural Selection

A suite of tools including a series of formative assessment prompts, sample student responses, and feedback ideas were developed and piloted across the three years of the Daphne Project. The result was a set of formative assessments that targeted different ideas on the *Origin of New Traits* and *Selective Force* constructs, including a constructed-response prompt of "How do species change over time?", a multiple-choice plus-justification prompt, an evaluation of Peter and Rosemary Grant's data on Darwin's finches in the Galapagos Islands, and interpretation of real-life scenarios (Figure 2). and analysis of these prompts being implemented led to collection of student responses for each level of the LP, as well as suggested feedback strategies (Table 1).



*<u>Figure 2</u>*. Sample formative assessment activity

*Table 1*. Sample student responses, and feedback strategies linked to the need-based conceptions on the *Origin and Inheritance of Traits* construct.

| Description | Example Student Responses | Suggested Feedback |
|---|---|---|
| *Anthropomorphic*: Changes arise from deliberate acts by the parent organism or the species as a whole | "The moths become darker because of bark." "The moths would change their color to a darker color to blend in with the dark bark." | Examine evidence collected in class activities and focus upon where variation originated. Explore Lamarck's idea of descent with modification, and compare to modern ideas about genetic inheritance |
| *Environmentally Induced*: Changes emerge because of environmental conditions; i.e., the environment causes changes in organisms to occur | "When food and other resources become scarce, the finches develop over a period of time different beaks to eat the hard seeds that seem to be abundant." "Animals mutate to fit in with their natural surroundings. So becoming darker helps to keep them in camouflage." | Explore differences between mutations in an individual and population changes. Discuss instances in which individuals change in response to the environment (e.g. arctic hares), and how this differs from changes in the proportion of genes in a population |

### Sustained Professional Development

Since the LP and the tools themselves do not represent a sufficient intervention to help teachers develop their own practices, a central component of the Daphne Project was the development of a PLC consisting of the authors and seven biology teacher participants, with a biologist providing content-specific guidance when necessary. These multiple stakeholders brought myriad perspectives to the PLC, allowing for the active exchange of ideas based on the participants' diverse expertise. The PLC met monthly during the school year for the duration of years two and three of the project. According to DuFour (2004), three components of successful PLCs in schools are (1) a focus on student learning, (2) a culture of collaboration and (3) a focus on results. Each of these components was undertaken within the Daphne Project work as the activities of the PLC were modeled on problem-solving and assessment development cycles from mathematics education (Borko, 2004; Webb, Romberg, Burrill, & Ford, 2005) to facilitate teachers' reflection on their current practices and adoption of new practices supported by the educative LP.

The Daphne Project PLC is modeled on an iterative four-step process. At each step in this process student learning was central in teachers' collaboration around specific instruction and feedback necessary to move students with specific prior ideas forward to correct understandings. The first step is for teachers to **Reflect** upon their current practice, sharing instructional strategies and materials with each other and discussing their advantages and disadvantages (Loughran, Mulhall, & Berry, 2004). In the second step, teachers **Explore** student thinking in their classes and compare those ideas with the LP. In this step, a particular focus is placed upon deepening teachers' content knowledge, as well as understanding students' common misunderstandings and alternative conceptions and the sources of those ideas. In the third step, teachers **Practice** using the associated tools and formative assessments, categorizing samples of student work, anticipating feedback, and discussing video cases. At this stage, encouraging teachers to discuss not only the identification of student ideas is essential, but also anticipating the kinds of feedback students within each category of student thinking would need. The fourth step has the teachers **Enact** their natural selection units with the tools contained in the educative LP, after which the teachers continue the cycle by reflecting upon their enactment and **Revising** their plans for next time.

## Method

### Participants

Eight biology teachers at Springfield High School participated. Springfield, considered among the top high schools in the state, is an ethnically and socioeconomically diverse school near a large city in the western US. The teachers represented a wide range of backgrounds and experience, ranging from a second-career student teacher to a 29-year veteran Biology teacher. Students in the participating teachers' classes were enrolled in four levels of biology: 9th grade pre-International Baccalaureate Biology, 10th grade General Biology, 10th grade English Language Learner (ELL) Biology, and 11th grade Advanced Placement Biology.

## Learning Progression and Professional Learning Community

On the basis of the student ideas about natural selection identified above, a draft LP was developed, piloted, and revised based upon analyses of student work (Furtak, 2009). By organizing students' ideas in a linear fashion, progressing from simple to complex, moving away from the ideas of Lamarck toward those of Darwin. As described above, the LP was accompanied by formative assessments designed to elicit student thinking, along with sample student responses and feedback strategies that were updated and extended by the reseachers and teachers through the course of the study.

Prior to the beginning of the study, the biology teachers at Springfield High did not have common planning time, and other than using the same textbook at each level of biology instruction, did not have a common curriculum. The teachers and the lead researcher participated in meetings every two to three weeks during the 2008-2009. Sessions involved discussing approaches to teaching evolution, predicting and exploring students' ideas about natural selection, categorizing student work, and discussing different instructional approaches given student ideas represented in the LPs.

## Sources of Data

Videotapes made of PLC meetings spanning the 2008-2009 and 2009-2010 academic years are the primary source of data for this study. Complimenting these videotapes are field notes kept by the authors of the study during each meeting, reflective notes made immediately followign each meeting, artifacts from the meetings, and content logs made of each videotape.

## Data Analysis

Through the course of the study, the authors kept ongoing notes based upond emergent themes they noticed during the PLC meetings. Reflection and discussion of these notes within research group meetings revealed converging themes centered on three shifts that occurred across the course of the academic year: shifts in the community interactions, shifts in the language teachers used to characterize student thinking, and shifts in practice.

The authors independently viewed videos supplemented by the artifacts described above and noted instances of interest in the PLC videos related to these three themes. Observations were categorized according to their relationship to the three elements of focus in this study: community, language, and instrucitonal practice. Then propositions were made on the basis of what each researcher viewed as the nature of the interactions in that video. The three researchers then met and came to a consensus about the nature of the three categories in each video. Longitudinal comparisons were then made across the set of PLC videos.

Table 2: Sample categories

| Categories | Questions to frame analysis |
|---|---|
| Community | How do teachers interact within the PLC community? Who allies with whom? What are the issues of status that arise? Who is speaking, and who is listening? How do they listen to and respond to each other? |
| Language | How do teachers characterize student ideas? What kinds of ideas do they mention, and what words are they using to describe them? How do these relate/not to the learning progression? Issues of creationism and intelligent design versus misconceptions? |
| Instructional Practices | What kinds of instructional practices are discussed? What are the rationales for using these teaching practices? How are learning experiences sequenced? How do these teaching practices relate to those represented in the learning progression? |

# Results

Results of our analyses of the multiple sources of data collected around the PLC meetings indicate that the PLC became more empathetic and communicative, respecting and exchanging ideas in a way that did not happen at the beginning of the study. In addition, teachers moved away from describing student beliefs in general terms and migrated toward description of the student ideas represented in the learning progression, using the common language present in the LP to describe and label these ideas. Finally, teachers' discussion of their instructional practices moved away from simple discussion of what their favorite activites were to more targeted description of which practices were better suited to the ideas represented in the LP. In the full paper, we will describe and illustrate how these changes occurred over the course of the study, describing in detail important events in this transformation process; however, for the purposes of the proposal, we summarize our results briefly below.

### Shifts in Community Dynamics

Early in the study, teachers took oppositional stances about practices in individual classrooms, without strong sense of a need for collaboration. For example, In the first PLC meeting, Lisa stated that that she was not trying to change student beliefs about evolution while Rachel stated that she didn't feel like she needed to respect non-scientific student ideas. Over time, however, the conversation in the PLC shifted almost completely away from oppositional stances and toward teachers expressing mutual respect for each other's arpproaches to teaching the strategies common to the LP, sharing strategies and their effectiveness at addressing particular student ideas, and taking up each other's ideas. For example, Rachel moved away from her oppositional stance later in the study, responding to a video of a colleague teaching with the statement, "I just really like that last bit of questioning she did…who would be the only predator…what would happen? So she, like, took it to be predictive and extended the idea." This comment highlights the development of mutual respect within the group. In addition, the balance of contribution to the PLC shifted away from its initial status, in which Rachel and Chris, the teachers most confident in their content knowledge, dominated the discussion at the expense of other teachers who were less confident, toward a more even balance of contribution. We argue that this shift took place not only because the previously dominant teachers gained a new respect for the practices of their colleagues, but also because the previously non-dominant teachers gained confidence in content knowledge through the PLC and therefore had more to contribute.

### Shifts in Language to Describe Student Ideas

Early in the study, teachers were not able to differentiate between different kinds of student ideas about natural selection. In early meetings, they spoke extensively either about students' rejection of evolution and natural selection or, when pushed to speak about common student understandings, teachers stated their impression of student ideas in general terms. This general stance is reflected in a statement by Alison, who said, "I just feel like yeah they're confused about all parts of natural selection so I'll just go from there." Later in the study, conversation about evolution all but disappeared in favor of explicit description of student ideas using the categories from the LP; for example, distinguishing between various categories of what we came to call 'need-based change' in the forms of students arguing that the environment induces changes in organisms, or that organisms mutate to fit their surroundings. In addition, teachers cited Mayr's facts and inferences when talking about the 'big ideas' students were expected to come to know. In fact, Chris and Lisa - teachers who previously had not worked collaboratively - met independently of the scheduled PLC meetings and categorized preassessments according to the categories in the LP.

### Shifts in Descriptions of Instructional Practices

We found that early in the study, teachers described which activities they liked to use to teach particular concepts, but did not have common activities that would facilitate their sharing of strategies across the group. Much of early discussion in the PLC was therefore focused on the teachers coming to an understanding of exactly what they were doing in their classrooms. However, as the study progressed, teachers agreed to use a common set of formative assessments in all of their classrooms as a basis for a discussion about their relative effectiveness in eliciting student ideas along the LP. In addition, teachers' conversations about the source of common student misunderstandings served as an impetus to create new formative assessments to which each teacher contributed, and which each teacher then used in her or her own classroom. In addition to these common activities that were a part of the educative LP, teachers came to discuss more explicitly which of the student ideas represented on the LP necessitated use of different activities in the classroom. Early in the development of the PLC teachers expressed hesitation to solicit student ideas about evolution. This hesitation appeared to be driven by a fear of creating conflict in the classroom. Later, this hesitation disappeared and teachers not only were interested in soliciting student ideas but also the sources of those ideas. We suggest that the confidence to tackle student ideas grew out of the stronger content knowledge and instructional strategies developed in the PLC.

In addition to these common formative assessments, teachers also came to share the different variations of common class activities that they were using in their natural selection units. For example, several teachers used some version of the Biological Sciences Curriculum Study's (2006) activity in which students pick up colored dots from patterend cloth, discovering over multiple iteractions of the activity that the harder-to-see dots were less likely to be picked up from the cloth. During the course of the study, all teachers decided to use some form of this activity, some using physical materials and others using an online applet to model the same phenomenon. Teachers then came together later in the study and discussed the relative effectiveness of the activity, weighing trade-offs such as time spent on the activity and depth of student understanding.

Another change in the discussion of instructional practices within the PLC was a change in focus from talking about activities to specifically identifying and addressing student misconceptions, and targeting which instructional examples, analogies, and activities would best address them. In addition, teachers reflected on the fact that students reverted back to their naïve ideas when presented with novel scenarios in class. This highlights the fact that these teachers, in addition to developing more advance strategies for eliciting and identifying student ideas, are also reflecting upon the process of conceptual change in a more sophisticated manner than at the beginning of the study (Smith, diSessa, & Roschelle, 1993).

.

## Educational Importance

Thte preceding data indicate that the PLC centered on the educative LP provided teachers an opportunity to reconnect and develop a common language around a single conceptual domain, enriching their own content knowledge while they simultaneously built a new community in their department. We found that repeated meetings centered on the educative LP helped to refocus teachers from defensive stances regarding the teaching of evolution to the smaller instrucitonal issue of natural selection, to enrich teachers' common language regarding student ideas, and inform their discussion and selection of instructional strategies targeted at student thinking.

The present research also illustrates the importance of involving the 'user' audience in the development of LPs and their accompanying tools.

Given the current level of interest in the development and study of LPs in science education, the present analysis is of critical importance to inform educational researchers and professional developers of the utility of these tools not only in guiding assessment and curriculum development, but also in developing the content knowledge of practicing science teachers and building community around a common content area.

# Measuring Transformative Modeling: A Framework of Formatively Assessing Students' Deep Conceptual Understanding in Physical Sciences

Ji Shen, University of Georgia, Mathematics and Science Education, Athens, GA, jishen@uga.edu

**Abstract:** Measuring students' conceptual understanding can provide important information for learning and teaching. Many formative assessment approaches elicit students' prior knowledge without identifying the sources of their misconceptions. This proposal presents a framework that guides the development of formative assessment to measure student understanding of physical science topics using three types of connections. Particularly, we assess how students link physical states, processes and mechanism, integrate different scientific models, and connect scientific knowledge to everyday experience. Based on this framework, we construct sample items on sinking and floating and piloted the items with 18 preservice middle grades science teachers. Analyses of student responses to these sample items provide evidence of the effectiveness of the framework in extracting information valuable to improve learning and instruction. Criteria and implications of using this formative assessment framework in science classrooms are then discussed.

## Introduction

Many national and state-level science tests fail to measure deep understanding (Hyde et al. 2008; Liu, Lee, Hoftstetter, & Linn, 2008). As a result, American students continue to languish on international science assessments (OECD, 2006). To reverse this trend and promote science achievement in the U.S., it is critical to design formative assessments that can effectively capture students' prior experience and measure deep understanding (Shen, Gibbons, Wiegers, & McMahon, 2007).

The challenge of capturing students' deep understanding through formative assessment is manifold. The complicated dimensions of science learning create challenges in both assessment design and utility of the information extracted from the assessment. For instance, many science assessments targeting conceptual understanding are designed to measure a single aspect of the correctness of science content. However, science learning is such an integrated and dynamic system that multidimensional abilities should be considered in the assessment (Anderson & Krathwohl, 2001). The assessment should capture student ability in integrating understanding and justifying explanations as well as their mastery of content knowledge. Most importantly, to take advantage of the assessment results, teachers should understand how students apply textbook knowledge in a new learning context.

To address these challenges, many science education researchers have developed frameworks to capture the multiple dimensions of science learning that shifted away from only focusing on content correctness (Linn et al. 2006; Yin et al. 2005). Science educators are also interested in understanding how students develop competences such as inquiry and modeling abilities to conduct science experiments (e.g., Gotwals & Songer, 2006). Acknowledging the multiple dimensions of science learning, we expand the dimension of conceptual understanding to capture students' modeling and inquiry abilities in this study. Particularly, we present a framework that guides the development of formative assessment to measure students' understanding of abstract and complex topics in physical sciences in three types of connections: linking physical processes and states with underlying mechanism, integrating multiple explanatory models, and connecting their science knowledge to natural observations and everyday experiences (National Research Council [NRC], 2000; Shen & Linn, 2010).

We focus on formative assessments that help teachers identify students' weaknesses in order to learn science concepts more effectively. Our framework can be enacted in multiple formats, e.g., paper and pencil quizzes, computerized word problems, oral interviews, or group-discussion questions. In the following section, we first discuss some exemplar assessment approaches in science education on which our framework is built. We then present the rationale and mechanism of our framework. Finally we elaborate on the framework with sample student responses on an item in sinking and floating.

## Measuring Deep Conceptual Understanding

Effective assessment practices in science education are aligned with distinctive learning theories (NRC, 2001; Wilson, 2005). Here we elaborate on three examples that influenced the development of our framework.

### Measuring Integrated Understanding Using Knowledge Integration

Many students gain fragmented knowledge. Linn and colleagues have developed a knowledge integration (KI) framework that emphasizes student abilities in establishing connections among ideas (Linn & Eylon, 2006; Linn et. al., 2006; Liu et al. 2008). The KI framework emphasizes the repertoire of ideas that students build as they interact with the world. Students add varied ideas as they experience science in daily life. The KI framework calls for taking advantage of the reasoning that students employ to formulate these views. The framework promotes coherent understanding by encouraging students to add new ideas, distinguish new and existing ideas, develop scientific criteria to reconcile ideas, and build coherent connections. The KI framework is realized through technology-enhanced learning environments that present complex and usually unseen science topics through computer visualization programs. The KI assessment framework features multiple assessment formats (e.g., pre/post tests, annual assessment, embedded assessment) for both formative and summative evaluation purposes. The KI scoring rubric rewards student reasoning and ability to articulate scientific evidence as well as content mastery. The KI assessment framework has been tested with large-scale empirical studies and has demonstrated satisfactory psychometric properties (Lee, Liu, & Linn, in press; Liu et al. 2008).

The KI framework states that there are different types of connections (Linn & Eylon, 2006) but does not distinguish these types in scoring (Linn et al. 2006). Building on this framework, we further detail and speculate that three types of connections are extremely important (will be discussed momentarily) in helping students gain deep conceptual understanding across science disciplines. Our assessment framework is aimed at identifying these different types of connections, which in turn can inform instructions.

## Measuring Understanding of Scientific Models

Modeling-based instruction in science classrooms is a constructivist approach that encourages students to develop, use, and evaluate models to describe, explain, and predict scientific phenomena (Chinn & Samarapungavan, 2008; Clement, 2000; Lehrer & Schauble, 2006; Schwarz & White, 2005). For example, through the MoDeLS project, Schwarz et al. (2009) developed a learning progression framework based on modeling for upper elementary and middle grade students. They defined a scientific model as "as a representation that abstracts and simplifies a system by focusing on key features to explain and predict scientific phenomena" (Schwarz et al. 2009, p.633). They considered two dimensions of the practice of modeling. One dimension addressed scientific models as tools for prediction and explanation; the other dimension considered the change of models when understanding improves. They built a construct for assessing students' progress in each dimension.

The works by Schwarz et al. (2009) and others provide important insights in how to teach and measure modeling in science classrooms. Our work focuses primarily on how deeply students understand scientific models and how well students are able to connect scientific models to natural phenomena. We believe that robust understanding of existing models can help students compare, evaluate, and revise models. We agree with Schwarz et al. (2009, p.635) in that "it is crucial to involve learners in the construction of models." However, we argue that it is equally important that students firmly grasp provided models because these models provide the solid foundations from which students can construct their own ones (Shen & Confrey, 2007). When students learn more advanced models in higher grades, they need to build on and integrate the simplified ones they have learned earlier on. Therefore, one important component in our framework is to assess how students integrate different scientific models they have learned.

## Measuring Complex Reasoning in Scientific Inquiry

Science education researchers also look at students' complex reasoning in inquiry. Principled Assessment Designs for Inquiry (PADI) is an assessment framework that focuses on providing design patterns and structures to measure students' inquiry skills and science knowledge. For example, Gotwals and Songer (2006) created a content-inquiry matrix that laid out different levels of science inquiry and science content required in assessment tasks. They used the matrix to highlight the interplay between inquiry abilities and science knowledge as students performed inquiry tasks or took inquiry assessments. The matrix had three levels of science content knowledge and three steps of science inquiry processes. The simple level of science content knowledge meant that the task or assessment provided sufficient content; the moderate level required students to demonstrate solid understanding of science concepts; the complex level required students to connect among multiple concepts. For the three steps of science inquiry the authors indicated that the steps might differ depending on the aspects of inquiry being targeted, such as generating scientific explanations or constructing representations using data.

While the content-inquiry matrix is used to help assess how students develop science knowledge and inquiry skills at different levels of complexity over time, our framework focuses on laying out important aspects of conceptual understanding that students need to explain complex phenomena specifically in physical sciences. Similar to the PADI framework, our framework assesses complex reasoning closely related to inquiry such as explaining phenomena in light of its underlying mechanism, or connecting between multiple explanatory models. The difference is that our framework can be used in a variety of teaching and learning contexts that may or may not necessarily measure the full scale of inquiry.

We propose a new assessment framework on conceptual learning to address the limitations that we see in the existing approaches. Built upon the existing literature, our work is an ongoing contribution to advance the formative assessment of students' deep understanding in science classrooms. We envision such a framework as a useful tool for instructors to revamp instruction based on the information extracted from the assessment responses.

## Theoretical Framework

Our framework is informed by the instructional theory of transformative modeling (TM) (Shen & Confrey, 2007, 2010). It is a theoretical framework used to describe, analyze, and inform learning processes. TM delineates learning and teaching as a process of modeling the natural world through chains of operations on materials. At the center of the operations are a set of transformations that alter the nature of physical or symbolic objects by adding or suppressing information. The transformed materials, as well as the operations on these materials, render potential for future learning. Examples include transforming detailed observations into numerical records to ground scientific understanding of measurement uncertainty, transforming data and graphs into mathematical formula to enrich abstract conception of motion, transforming between the geocentric model and the heliocentric model to better comprehend the solar system.

In this framework, conceptual learning is defined as the process of gaining ability to transform materials in both physical and abstract forms. Specifically, the consistency among the transformed materials perceived by a cognizing agent defines the depth of the comprehension of the concept. The variety of transformation types and forms determines the broadness of the construed concept. For the depth of comprehension, an example is the common misconception that many students hold about the cause of the seasons (Harvard-Smithsonian Centre for Astrophysics & Schneps, 1988). Many students reason that it is hot in the summer because the sun is closer and it is cold in the winter because the sun is farther away (the distance model). This reasoning draws upon everyday experience (e.g., sitting besides a fireplace) that one feels warmer when sitting closer to a heat source. In the TM theory, we interpret this explanation as being able to transform everyday experience to explaining the seasons to a certain degree, even though it is not compatible with the scientific model. People later learn that the northern hemisphere and the southern hemisphere have opposite seasons, and that in fact in summer the earth is farther away from the sun. The distance explanatory model then becomes conflicting to the new information, which calls for a deeper understanding of the cause of the seasons. For the broadness of conceptual understanding, the TM framework advocates the incorporation of multiple representations in learning science to ensure coherent understanding. For instance, when students learn kinematics, constant transformation among graphic representations can help them summarize many observations and physics principles (Shen, 2009). Students need to acquire a rich set of graphs (e.g., position-time graph, velocity-time graph, free-body diagram) to broaden their understanding of Newtonian mechanics.

Based on the TM instructional theory and previous analyses of students' responses to questions on electrostatics (Shen & Linn, 2010), we identify three most important aspects in knowledge transformations: (a) linking scientific mechanism with both states and processes of the target domain; (b) integrating multiple explanatory models, and (c) connecting scientific models with everyday observations. In the following we elaborate on these three important transformations.

### Linking Physical States, Processes, and Underlying Mechanism

The idea of integrating mechanism with states and processes comes from the fact that much scientific understanding originates from transforming observations of natural changes into data, inscriptions, and digital records. During such an observation, the states and the processes need to be accurately described. The scientific records of the initial, transitional, and final states help students identify the interacting agents and the relevant variables that constitute the key properties of the target system. A physical process of a system consists of changing states over time. Many of these processes lead to a physical equilibrium (e.g., thermal equilibrium) in which the state of the system does not change anymore. A mechanism is defined as an explanation (e.g, mathematical formalism, causal inference) one draws to theorize the patterns of how the key states emerge and change. Oftentimes, the mechanism introduces abstract concepts (e.g., force) or microscopic entities (e.g., electron).

Here are two examples in physical sciences that illustrate how students need to integrate mechanism with states and processes to gain deep understanding. An electrical *state* of an object may be positively charged, negatively charged, or neutral. For example, an object is initially positively charged. Then, it is discharged after touching one's hand, and eventually, the object becomes neutral. Students may only pay attention to the initial state (positively charged) and the final state (neutral) of the object without thinking about the in-between *process* when the change takes place. The understanding of the charging/discharging processes provides a trajectory of the observed changes and trends of the electrical states. Therefore, a better understanding includes the process where the negative charges are transferred from the hand to the object to neutralize it. The understanding is further enhanced by learning the *mechanism* of why charges move: like charges repel and opposite charges attract. That is, the forces between charges drive the motion of the charges. Likewise, deep understanding of the state of thermal equilibrium involves explaining the heat transfer processes. A thermal state of an object (hot, warm, or cold) can be measured by its temperature. Consider a hot object in touch with a cold object. The initial thermal states of the two objects are measured in different temperatures. Many students learn that, eventually, the two objects will reach the same temperature. They need to know how this happens by learning the processes and mechanism. When envisioning that heat is transferred from the hot object to the cold object, one is considering the process. A mechanism states that temperature difference drives heat to transfer from an object with higher temperature to another object in touch until they reach the same temperature (thermal equilibrium).

### Integrating Multiple Explanatory Models

One may build different models to explain the same phenomenon since there are different aspects of the phenomenon one chooses to model (Shen & Confrey, 2010). Some of the models are consistent with the accepted scientific models; others conflict with accepted understanding. Students typically start with simple and concrete models, and then advance to more abstract and general ones in learning complex science topics (Lehrer & Schauble, 2006). We argue that when learning more advanced models, students need to integrate the earlier models they have learned. For instance, to explain and predict how the planets move in the solar system (kinematics only), students may start with a geocentric model since that is what one sees from the earth. Then students may move to learn the heliocentric model used to explain the geocentric model. A higher-level understanding indeed incorporates the two models and helps students go back and forth between the two models depending on the context.

For the discharging example, one may employ a charge-based model as discussed in the previous section. One may also use a particle-based model: initially, the object has less electrons (which carry negative charges) than a neutral state (the final state). During the discharging process, electrons from human hand move to the object. The movement of electrons is driven by the interactions (forces) among the particles. The connection between the two models lies in the fact that types of charges are properties of certain particles (e.g., electrons are negatively charged). For thermal equilibrium, the heat transfer process may be attributed to a substance carrying heat that flows from one object to another, which may be considered as a misconception. Alternatively, one may consider a particle model. In this model, temperature of an object is a measure of the average kinetic energy of the particles, which corresponds to the average speed of the particles. That is, an object with a higher temperature has particles vibrating faster on average than an object with a lower temperature. In the heat transfer process, collisions between particles drive the transfer of the kinetic energy from one object to the other.

### Connecting Science Knowledge to Physical Observations and Everyday Experience

Physical sciences study the patterns of the physical world and students experience the physical world every day. It is expected that students learn science more effectively and meaningfully if their learning is built upon and tied back to their everyday experience (Linn, 2006). Unfortunately, many teachers do not use students' experience as resources for teaching. As a result, students often build models in the learning context but rarely connect to their learning experiences in other contexts or to everyday experiences (Kozma, 2003). Being able to connect scientific models to other learning contexts or everyday experiences is an indicator of the degree to which students develop integrated understanding of the represented concept.

Many examples of everyday experience are related to discharging: e.g., grabbing a metal doorknob and getting shocked, touching the metal part of a car before refueling, spraying water to prevent fluffy hair. Deep understanding of electrostatics requires students to make sense of these phenomena outside of classrooms. Similarly, when learning heat and temperature, students should reflect on everyday experiences such as determining a better material to keep things warm.

## Constructing Assessment Items on Sinking and Floating

Sinking and floating are interesting phenomena for students to investigate. It involves different explanatory models and everyday experience. Abundant previous research was devoted to identify students' understanding of sinking and floating (e.g., Dentici et. al. 1984; Halford, Brown, & Thompson, 1986; Mullet & Montcouuiol, 1988; Rowell & Dawson, 1977; Yin, Tomita, & Shavelson, 2008). In the following section, we first introduce the physics behind the phenomena of sinking and floating. We then present three sample items to illustrate how we apply the TM framework to build assessments that help students identify the connections among key states and processes, link multiple explanatory models, and apply to the physical world. Finally we present sample student responses and demonstrate how the responses can be analyzed using our framework.

## Physics of Sinking and Floating

To determine if an object is either a sinker or a floater without putting it in a fluid, one can compare its average density with the density of the fluid - the density model. If the average density of the object is greater than the fluid, then the object will sink when put in the fluid. If it is smaller, the object will float. If the average density of the object is equal to the fluid, then the object will suspend in the fluid. Alternatively, one may also compare the weight of the object with its buoyancy - the force model. Buoyancy on an object is defined as the net force exerted by the surrounding fluid. [(1)] One may simply predict that an object will sink when put in the fluid if the buoyant force on the object is smaller than its weight. But the opposite is only partially true: the object will *start to* float if its buoyancy is greater than its weight. This only applies for an object completely submerged under water. It may lead to the misconception that the buoyancy is greater than weight when an object floats on water. Having learned the density model, one may think that the force model is redundant. In fact, the force model is able to explain the processes of sinking and floating in much more details. [(2)]

A deep understanding needs students to be able to integrate the density model and the force model. To compare the buoyancy and the weight of an object completely submerged under a fluid, one may compare its weight with the weight of the fluid displaced since the buoyancy of an object is equal to the weight of the fluid displaced (Archimedean principle). Also since the object is immersed in the fluid, the volume of the object is the same as the volume of the fluid displaced. Hence, it is equivalent to compare the density (mass/volume) of the object with the density of the fluid.

## Instruments Used to Assess Understanding of Sinking and Floating

Figure 1 shows a sample item in an instrument used to identify students' misconceptions developed by Yin, Tomita, and Shavelson (2008). This item does a nice job in revealing students' misconception, i.e., "Big/heavy things sink, small/light things float." Some students may predict the two blocks will "sink" when stacked together (or subsurface float) because the bundle of blocks A and B is heavier than each individual block.

Block A and Block B both float in water. Suppose that we glue them firmly together and place them in water; together they will: ____________.

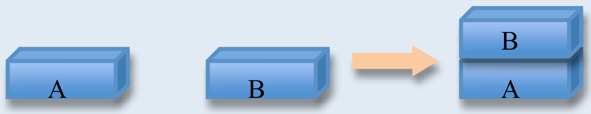

Figure 1. A sample item on sinking and floating from Yin et al. (2008).

However, this kind of items does not inform the teacher of the possible origins of these misconceptions. Using our TM framework, a possible explanation for the misconception is that the students may not distinguish density (mass over volume) from weight (a force). This explanation is also consistent with our experiences of teaching the topics on sinking and floating. In everyday language, the term heaviness often refers to the two terms interchangeably. [(3)] One can explain the phenomenon of sinking and floating using the density model or the force model (detailed explanation is provided in the next section). But these explanatory models may be taught in a fragmented fashion, and students are not able to connect these models. Moreover, this kind of items does not inform the teacher if students are able to connect the knowledge of sinking and floating to observations. We may infer that the incorrect answer entails that the student cannot connect to everyday experience, e.g., if one bundles two pieces of wood together, the bundle still floats.

## A Sample Item on Sinking and Floating Using the TM Framework

*Participants.* We created an instrument on sinking and floating using the TM framework and piloted with 18 undergraduate students working towards middle grades science teaching certificates (17 female, 1 male). These students had weak science background based on the results of a survey measuring general physics knowledge (25% correct). The items on sinking and floating were administered in a quiz after they had two lessons on sinking and floating (4 hours in a total) including a lab confirming Archimedean Principle. The quiz has six constructed-response items. It took the students half to one hour to finish. Here we provide an example.

*Item Two Balls* [**due to space limit, here we only present one sample item and students' responses**]
The item Two Balls (see Figure 2) asks students to predict and explain what will happen to two balls (one floater and one sinker) in water when salt is added. A physical demonstration can also be set up. Students can use either the density model or the force model to explain the observations as in the previous item. The key points are summarized in Table 1.

Ball A and ball B have the same volume. A is floating on water, B is sitting at the bottom of the water tank.
(1) Which ball has the greater buoyancy? Explain.
(2) Which ball has the greater density? Explain.
(3) Sam adds some amount of salt in water and let them dissolve. What happens to the buoyancy of the two balls? Explain.
(4) What changes would you expect after Sam has added salt in the water?
[A physical demonstration can be shown when students respond to this problem].

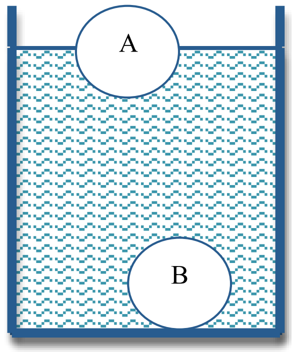

Figure 2. Item "Two Balls" on sinking and floating.

Table 1: The density and force models used to explain the item Two Balls.

| | Density Model | Force Model |
|---|---|---|
| State | • Ball A is floating initially. Part of ball A is submerged under water.<br>• Ball B is sitting at the bottom initially. All of ball B is submerged under water.<br>• After adding salt, ball A still floats. Ball B may sink or float depending on the amount of salt added in.<br>• After adding salt, the density of the water increases. | • Ball A is floating initially. Part of all A is submerged under water.<br>• Ball B is sitting at the bottom initially. All of ball B is submerged under water.<br>• After adding salt, ball A still floats. Ball B may sink or float depending on the amount of salt added in.<br>• After adding salt, the weight of the water of the same volume increases. |
| Process | • When the salt is added, more part of ball A comes out of water.<br>• When salt is added, ball B may still sit at the bottom. It may also move up and becomes a floater. | • When the salt is added, more part of the ball A comes out of water.<br>• When salt is added, ball B may still sit at the bottom. It may also move up and becomes a floater. |
| Mechanism | • An object less dense than water tends to float. An object denser than water tends to sink. An object having the same density as water suspends in water.<br>• For a floater, the proportion of the volume of the object that is submerged under water over its whole volume equals the proportion of the density of the object over the density of the fluid (relative density). | • An object accelerates if the net force acting on it is non-zero (Newton's second law). An object is at rest or moves at a constant velocity if the net force acting on it is zero (Newton's first law).<br>• There are two forces acting on an object floating on water: weight and buoyancy.<br>• There are three forces acting on an object sitting at the bottom of a water tank: weight, buoyancy, and normal force by the tank.<br>• Buoyancy is equal to the weight of fluid displaced (Archimedean Principle). |

The detailed explanation follows. Since ball A displaces less volume of water than ball B, it has a smaller buoyancy than B. For a floater, its density is less than the density of water; for a sinker, its density is greater than the density of water. So the density of ball A is smaller than that of ball B. When salt is added, the density of the salt water is increased. Therefore, ball A keeps floating. For any floater, the buoyancy equals its weight, so the weight of ball A does not change. This means that the buoyancy of ball A does not change. To maintain constant buoyancy, ball A has to rise up a bit to displace less volume of salt water. For ball B, it may still rest at the bottom, but exerting less force on the bottom of the water tank. It may also move up if the amount of salt dissolved leads to a greater density of the salt water than ball B. If that is the case, Ball B will go all the way to the top until a part of it comes out of the salt water.

*Students' Responses and Implications for Instruction*

All students stated that ball B has a greater density in sub-question #2. This indicates that all the students are able to use the density model to explain the final states of sinking and floating at this stage. However, students' responses to sub-questions #1, #3 and #4 revealed that most of them did not integrate the buoyancy model to explain and predict the phenomenon of sinking and floating.

Students may confuse the sinking and floating states with the underlying mechanism of competing forces. Buoyancy is a variable (force) that influences the sinking or floating of an object. However, students often think that buoyancy refers to the state of floating (i.e., floating higher indicates a greater buoyancy), and may think that buoyancy is a property of an object. In the pilot test, 10 out of 18 students thought that ball A had a greater buoyancy in sub-question #1. A typical response stated that "Ball A has the greater buoyancy because it is floating on the water." Another student wrote, "Ball A has a greater buoyancy because it has a density that is less than water and is floating, (therefore) buoyant forces acting on it are greater." It was very likely that this student had a concept of "relative buoyancy" in mind. This student might equate buoyancy to the relative magnitude of buoyancy and its weight, corresponding to the relative density of the object compared with the density of the water. Students often ignore associated changes when one change is introduced to a physical system (Shen et al. 2007). For sub-question #3, all students responded that both balls changed in the same manner: the two balls either had a greater buoyancy, smaller buoyancy, or the same buoyancy. Similarly, for sub-question #4, 12 out of 18 students responded that both balls floated "better" or "higher." All of them recognized the change that when salt was added, the density of the fluid was increased. However, most of them didn't distinguish the two balls as two different cases, as one student reasoned, "the two balls will float better in the salt water, since the difference between the densities of the balls and salt water is greater, both balls will float higher than they did in plain water."

Analyses of these responses provide many insights on how to help students gain deep understanding of sinking and floating in future instruction. These items create the need and the instructional means for students to integrate different models they have learned, as they may realize through class discussion or instructors' feedback that their explanatory models conflict with each other. Follow-up questions that target detailed changing processes of sinking and floating may help students to connect these models. Sample questions may include "how does ball A 'know' how much to rise up when salt is added? How does ball B 'know' when to go up? What happens to its buoyancy when ball B moves up? When ball B comes out of water, does it stop right away?" These questions also call for more careful observations that help the students link the states and processes of sinking and floating. Students' alternative conceptions and prior experience can serve as knowledge resources for bridging different explanatory models. For instance, conceivably, students' understanding of "relative buoyancy" as the ratio of buoyancy over its weight may lead to the scientific understanding: for an object less dense than water, it has a greater ratio of buoyancy over weight.

## Conclusion and Implication

In this study we present an assessment framework that focuses on three aspects of conceptual understanding: linking physical states and processes with underlying scientific mechanism, integrating multiple explanatory models, and connecting scientific models with everyday experience or natural observations. We illustrate with students' responses to items on sinking and floating. Careful analyses show that these aspects are imperative for students to learn science. Specifically, the proposed framework has potential to help instructors identify the important links that students often miss among multiple explanatory models. With information provided by the framework instructors can effectively observe the detailed processes that students need to explain certain science phenomena, and help students integrate prior knowledge or experience to new science concepts.

## Endnotes

(1) From a microscopic view, the net effect of buoyancy is due to the collisions of numerous fluid particles -- the particle model, which is not discussed in this paper.

(2) Considering an object completely submerged under a fluid. If its buoyancy is greater than its weight, then the object starts to move up in acceleration until it floats above the fluid. When the object moves out of water, it displaces less water, hence experiences less buoyancy. When the object displaces the right amount of water so that its buoyancy equals its weight, the object does not stop immediately. It has acquired momentum, so it keeps moving out of water. Then the weight takes over and the object is pulled back towards the water. After some oscillations at the surface of the water, it stops eventually and its buoyancy and weight are balanced. This force model connects to Newtonian mechanics (force corresponding to acceleration) and links process (moving up and down) and with initial and final states (floating or sinking). The density model also connects to the mathematical construct of ratio, which has many implications.

(3) Most of them are also not able to distinguish mass and weight, which is relevant, but probably not critical here.

# Using changes in framing to account for differences in a teacher's classroom behavior

Jennifer Evarts Lineback, Fred Goldberg, San Diego State University, 5500 Campanile Drive, San Diego, CA 92182
lineback@sciences.sdsu.edu, fgoldber@sciences.sdsu.edu

**Abstract:** In this paper we account for how a 5th grade teacher changes in how she attends and responds to student thinking in terms of differences in her framing of the instructional situation. Coordinating verbal (i.e. speech, voice inflection, and word emphasis) and non-verbal (i.e. body orientation, eye gaze, and gesturing) behavioral data, we characterize three patterns that reappeared with stability throughout a fourteen-day, inquiry-based instructional module on the water cycle. We argue that each of these behavior patterns suggests a distinctive way the teacher frames her instruction. We label these frames as: (A) moving towards content objectives; (B) promoting a student-centered discussion; and (C) making sense of students' ideas. The episodic manner in which these frame shifts occur in the classroom suggests a way of conceptualizing a learning progression in teachers' ability to attend and respond to student thinking.

## Introduction

The following transcripts document two brief exchanges between a fifth grade teacher and her students that took place on successive days during a fourteen-day, inquiry-based, science unit on the water cycle. Exchange #1 is part of a classroom discussion where the teacher and students are trying to understand an idea for an experiment suggested by a student (Jasper). Exchange #2 is part of a classroom discussion where the teacher (Mrs. Miller) is trying to get students to come up with specific ideas about precipitation. Words in italics indicate words emphasized by the speaker. Non-verbal behaviors that coincide with talk are indicated in brackets.

Exchange #1: Day 13

**Jasper:** If you did that with a *different* drink, that would work.
**Mrs. Miller:** Now *why* would you want to use a different drink? Other than water?
**Jasper:** 'Cause then you have no clue if it's leaking or not. I mean *that* could be water from a leak or water from the condensation.
**Mrs. Miller:** Like, what would you want to freeze?
**Jasper:** You could use, like … like soda or something, and then water appeared in the *bag*, you know it's- And you, like, *drank* it and you found out it wasn't like, soda or something-
**Jamil:** Oh yeah. I get what you're trying to say-
**Mrs. Miller:** OK. Alright. Go ahead. Go ahead. Finish what you're saying. (…)
**Jamil:** I get what Jasper's saying. Like, if you use, like, a different *drink*, like let's say, *orange juice* or something or *soda*, um- If it was *leaking*, … if you thought it was leaking *water*, you would know if it was from the *condensation*, because the orange juice is *yellow*, it's not all like clear like *water*.

Exchange #2: Day 14

**Mrs. Miller:** What s*teps*- notice that word right there- [points to the word "steps" written on the easel] What steps might be involved in making each type of precipitation? … And does somebody have a thought? Cam? (…)
**Cam:** First, rain is collected by the ocean, and the cloud carries it until it can't carry it anymore. So, it drops- so it- so when it can't carry it anymore, it drops it. It holds it until it's completely- it- it completely can't hold it anymore, at all. And, then it just falls.
**Mrs. Miller:** So, (…) does that define precipitation? Does what you say really tell me what *these* four [points to the types of precipitation] are? Or does it tell me what *that* [points to the word "precipitation"] is? What do you guys think? Is Cam telling me what *this* is, or is he telling me what *these* are?
**Jack:** He's telling you what rain is.
**Mrs. Miller:** *Really*?

Although the context for both teacher/student exchanges is the same (i.e. the water cycle), the verbal information gleaned from the transcripts suggests that the interactions taking place on these two days are substantively different. If these transcripts are analyzed along with the co-occurring extra-verbal behavior, such as the participants' body orientation, eye gaze, and gestures, the case is strengthened that something dramatically different is taking place in these exchanges. How can researchers best make sense of this shift in the dynamics of the classroom, particularly with respect to the teacher's practice? We propose that the construct of *framing* is a potentially useful framework to help answer this question.

## Framing as a Framework

Educational researchers have adopted the theoretical construct of framing in recent years to help account for the dynamic nature of students' and teachers' reasoning during instruction. A concept that originated in the disciplines of anthropology, sociology, and linguistics, framing refers to an interpretation of how an individual makes sense of "What's going on here?" (Bateson, 1972; Goffman, 1986; Hammer, Elby, Scherr, & Redish, 2005; Tannen, 1993). Framing is considered to be a mechanistic, cognitive process, serving to activate sets of locally coherent epistemological, conceptual, and social resources and enabling individuals to effectively navigate their current situation (Hammer et. al, 2005; Redish, 2004). An individual's frame, and the resources that are thereby activated, informs the set of expectations that he or she has about a situation, which is necessarily grounded in his or her previous experience with similar types of situations.

In the context of education, framing influences both what individuals attend to within instructional situations and how they think to respond in the moment. For example, a teacher's framing of instruction influences how and to what she attends in the classroom, as well as how she thinks to respond (Levin, Hammer, & Coffey, 2009). How students frame instructional activities helps determine the ways they interact with one another, their teacher, and the available learning materials (Hammer et. al, 2005; Scherr & Hammer, 2009). In an empirical study, Scherr and Hammer (2009) characterized distinct sets of co-occurring behavioral clusters that suggested that college students were framing their group activities in different ways at different points in time. Shifts *between* these frames were observed within single physics sessions, indicating that students did not maintain one consistent way of making sense of and approaching their learning activities. By considering frames as a theoretical framework, researchers may be able to better make sense of changes in students' and teachers' behaviors and posit *why* they behave as they do.

It has been previously suggested that when teachers attend and respond to the substance of students' ideas, the students are more likely to genuinely engage with the material under investigation and advance in their learning (Black and Wiliam, 1998; NRC, 2001). With respect to developing students' inquiry practices, a teacher's focused attention and response can, therefore, help students refine and develop their questions, investigations, and explanations surrounding specific natural phenomena (Levin, 2008; NRC, 2000). If attending and responding is a key component of promoting student inquiry, then it is critical for researchers to be able to account for how and why teachers attend and respond to the things that they do. Framing provides a vehicle for us to do just that. Characterizing the ways a teacher frames instruction enables us to make sense of how she attends and responds to students in the moment and explore how her attention and responses change longitudinally.

The objective of this paper is to present behavioral evidence that suggests different ways a single teacher frames her inquiry-based instruction within a unit on the water cycle. This work lays the foundation for research that investigates the frequency by which she shifts between frames, how this frequency changes over time, and how such changes may indicate progress in learning to attend and respond to student thinking. Furthermore, this research enables us to determine whether similar frames and shifting patterns are observed in additional teachers.

## Methods

The setting for this study was a fifth grade teacher's classroom during her implementation of a fourteen-day "module" on the water cycle. The module represented one of several developed by our research group designed to provide teachers with a context with which to explore and promote student inquiry practices (1). To accomplish the goal of encouraging practices such as making-sense of and reasoning about scientific phenomena, proposing plausible, mechanistic explanations of those phenomena, and collecting evidence to support or refute these explanations, the water module begins with the teacher posing an open-ended question to her students:

> Suppose that one night it rains. When you arrive at school, you notice that there are puddles of rainwater in the parking lot. When you go home, you notice that the puddles are gone. What happened to the rainwater?

The students are encouraged to suggest possible answers and consider reasons *why* these answers are plausible. While the minimal curricular materials provide teachers with potential student responses and possible ideas for follow-up discussion topics, the teachers are encouraged to base their future instructional moves solely on the nature of the students' ideas as they emerge during the discussion itself. Hence, the teacher may choose to go in a variety of different directions in this and subsequent class sessions depending on the responses of the students.

A single teacher, Mrs. Miller, was observed in her classroom throughout the duration of the water module in the spring of the 2008-9 academic year. Mrs. Miller is a national-board certified teacher and has taught elementary school for over twenty-five years. She has served as a mentor teacher for novices and has identified herself as a teacher comfortable with teaching science. Prior to the module implementation, Mrs. Miller participated in inquiry-based professional development (PD) activities organized by our research group for just under one year. Our PD sessions provide opportunities for in-service elementary and middle school teachers to practice attending and responding to student thinking, with the explicit intent of helping them develop their ability to promote rich student scientific inquiry in the classroom.

Mrs. Miller's class sessions during the module were video recorded in entirety. This video served as the primary source of data for analysis, supplemented by field notes taken by the first author both during class and during debriefing interviews with the teacher that occurred shortly after each instructional session. Since the focus of the research was on *teacher* framing, portions of the classes that centered on student group work and experimentation, which tended to involve minimal teacher participation and to which we had less access, were excluded from the data analyses. Methods of analysis were modeled after those used by Scherr and Hammer (2009), in that video data was evaluated for patterns that displayed specific sets of Mrs. Miller's verbal (i.e. speech, voice inflection, and word emphasis) and non-verbal (i.e. body orientation, eye gaze, and gesturing) behavior that seemed to consistently co-occur. Once such behavioral pattern sets were tentatively characterized, they were compared with additional segments of class video to determine whether they occurred with relative frequency and stability. From those that were established to be regularly occurring patterns, inferences were drawn regarding how these patterns might reflect Mrs. Miller's framing of the instructional session.

## Results

Three distinct and coherent patterns of Mrs. Miller's verbal and nonverbal behaviors seemed to emerge from the data, which we are calling patterns (A) "focusing on content," (B) "focusing on generating student interaction and discussion," and (C) "focusing on making sense of student ideas." These patterns seemed to occur with some regularity throughout the module, with some occurring more frequently and lasting for a longer duration than others. Interestingly, these patterns did not seem to appear in a specific chronology. For instance, pattern (A) was not only observed in the earliest class sessions of the module, nor was pattern (C) detected only in the final sessions. The data also indicated that Mrs. Miller's students were actively engaged in discussion throughout the module, no matter the pattern of behavior exhibited by Mrs. Miller. The types of interactions in which they engaged and the substance of the discussion that took place, however, did appear to shift in coordination with Mrs. Miller's behavior.

In the sections below, each of Mrs. Miller's three behavioral patterns is described in detail. Supporting evidence for these patterns is provided via portions of classroom transcript, digital stills taken from video, and field notes taken from the debrief interviews. These data provide the basis for inferences drawn regarding how Mrs. Miller was framing her instruction. The emerging behavioral patterns were considered to be stable in that they were consistent for *at least* several exchanges between discussion participants. It is worth noting that while there were occasions where a single behavioral pattern seemed to last for the entire class session, there were several occasions where Mrs. Miller shifted between different sets of behavior(s) at different points during a single session.

### Pattern (A): Focusing on content

Behavior associated with pattern (A) was observed regularly throughout the module and often lasted for large portions of the class session. Throughout these segments, Mrs. Miller regularly employed gestures emphasizing and/or enacting specific words or phrases, seemingly to help her students focus on particular concepts. These gestures often involved pointing out important terms or characters selectively inscribed on an easel (Fig. 1b) and/or drawing attention to specific content terms she employed in her verbal questioning. For example, in Figure 1c, Mrs. Miller held her hand up above her hand at a horizontal angle, emphasizing the idea of cloud height to her students.

With respect to teacher talk, Mrs. Miller tended to initiate these discussions by asking pointed questions in a direct, clear voice (e.g. line 1-2 in Exchange #2 shown in the introduction). These questions were often prefaced with "what is/are" and repeated at various intervals throughout the session to keep the students following a particular line of thinking. Her intonation during her speech, like her gestures, tended to emphasize content specific terms and phrases. Mrs. Miller seemed to pay close attention to students' terminology, as reflected in her repeating or emphasizing a particular term or phrase volunteered by a student and/or asking a student follow up questions regarding a term or phrase he or she used. Furthermore, Mrs. Miller selected certain pieces of her students' talk for display on the easel, seemingly choosing those phrases that advanced the discussion towards content goals.

Teacher/student interactions throughout these discussions tended to follow the traditional initiation, response, evaluation (IRE) format (Mehan, 1979).

Figure 1: Examples of Mrs. Miller's body orientation and gestural movements consistent with behavioral pattern (A): (a) Mrs. Miller creates a summary table that her students are to fill out; (b) Mrs. Miller gestures across her easel, directing their attention to the "steps" she is looking for; (c) Mrs. Miller emphasizes a particular descriptor she is looking for in her students' responses.

The following section of transcript displays an interaction between Mrs. Miller and her students taken from Day 2 of the module. The discussion illustrates behavior typical of pattern (A) and centers on the different types and locations of clouds.

**Tommy**: When you're at the, like the, um, *ocean*? To the *west*, in *early*- you get dark clouds. Usually, it would be *marine* layer, and it- um, most of it would be moving in, and then when it gets in enough, it will just come *into* a cloud. I don't know- [Mrs. Miller writes: "West early, dark clouds moving in."]

**Mrs. Miller**: But, ah- wh- are they *high* [moves hand horizontally above head, indicating "high"] or *low*? What's the *altitude*, I guess is what I'm asking. What's the *altitude* of the clouds?

**Tommy**: Well, when they're by the ocean, they're gonna be low. And then, when- When they're going on land, they're just going to drift a little higher and higher. [Mrs. Miller writes: "low" and "higher."]

**Mrs. Miller**: 'K, so they're gonna get *higher*. *Is* there someway we can connect how high they are with what they *look* like? (…)

**Cam**: Um, like, maybe when, like, there's storm rainy clouds, *way* high, maybe that means it just gonna drizzle or something. But, when they're *lower*, they're gonna- it's gonna, like, pour and rain really hard.

**Mrs. Miller**: Lower. Clouds. *Heavy* rain. *Higher* clouds. Drizzle. [Mrs. Miller writes on a new sheet of paper: "Lower clouds, heavy rain. Higher clouds, drizzle."] What does anyone else think about that? About *clouds* and their *altitude* as to how they look?

Notice in lines 1-4 that Tommy does not refer to the height of the clouds. Nevertheless, Mrs. Miller introduces the concept of altitude (line 6) and then goes on to emphasize specific terms in her own talk and in that of her students (e.g. *high*, *low,* and *altitude* in lines 5-6 and *higher* in line 9). She appears to be trying to get her students to recognize a relationship between clouds' appearance and their altitude. This is reinforced by Mrs. Miller inscribing what she identifies as the most pertinent words and phrases (e.g. "Lower clouds, heavy rain. Higher clouds, drizzle." in line 14) on the easel and repeatedly asking questions about a relationship between clouds and their location (e.g. "*Is* there someway we can connect how high they are with what they *look* like?" in lines 9-10). During her debriefing interview, Mrs. Miller's focus centered on the fact that her students' thoughts "were really scattered" during the discussion and they weren't "getting it." She seemed disappointed that they hadn't reached specific conclusions.

This pattern of behavior, exemplified by Mrs. Miller in both this segment and Exchange #2 in the introduction, suggests that she is framing her instruction in these types of discussions as *moving toward content objectives*, which we shall refer to as "frame (A)." Her direct line of questioning, reiteration of questions, emphasis on terminology and phrasing, and her later description of students "not getting it," all appear to be consistent with maintaining this type of content-driven frame. Rarely during these types of interactions would Mrs. Miller allow herself or her students to veer onto trains of thought that differed from this singular agenda.

### Pattern (B): Focusing on promoting student interaction and discussion

Similar to pattern (A), behavior associated with pattern (B) was observed throughout the module and lasted for large portions of the class session. In these discussions, Mrs. Miller neither directed her students' attention to an easel nor to her notes, as was commonly observed in pattern (A). In fact, she did not seem to direct the students' attention to herself at all. Rather, Mrs. Miller seemed to position herself, both verbally and non-verbally, as a discussion facilitator and "traffic cop," deciding who speaks next and who must wait. Her gestures seemed to be less emphatic or enactive than those observed in pattern (A) and were usually limited to pointing out the sequence of students next in line to contribute to the discussion (see Figure 2).

With respect to teacher talk, Mrs. Miller would generally initiate discussions with an open-ended question about some type of phenomenon (e.g. "Which clouds cause lightening?"). Subsequent to this initial question, however, her verbal contributions were generally limited to brief, non-committal "mmm hmmm's," and/or to call out the names of the students next in line to participate. Occasionally, she would insert a brief comment indicating that one student's contribution added to or responded in some way to a comment made earlier by a different student. She rarely evaluated or probed the students' ideas. Instead, Mrs. Miller seemed to expect that the students would comment on and/or ask questions about *each other's* contributions. These segments did not follow a single conceptual strand or delve particularly deeply into a single explanation or observation. Rather, students seemed to pursue several different trains of thought, dependent upon which ideas they decided to take up in the moment.

Figure 2: Examples of Mrs. Miller's body orientation and movements consistent with behavioral pattern (B): (a & b) Mrs. Miller points to the next student to speak; (c) Mrs. Miller faces a student as he contributes to the discussion.

The following transcript, taken from Day 3 of the module, is typical of interactions consistent with pattern (B). The focus of this session was on the causes and consequences of lightening. It is worth mentioning here that Mrs. Miller's behavior varied little during this entire sixty-minute session, reinforcing the idea that pattern (B) behavior is often stable for long segments of class time.

**Jack**: If you cut down *every* tree in the world, which isn't possible, but if you *did*, and you had nothing attracting lightening, it wouldn't be able to- um, um, some place twice. (4 sec pause.)
**Mrs. Miller:** Alright. [Points to Tommy.]
**Tommy**: Well, I was thinking that, if- if- *lightening* comes, is it just how much h- heat or electricity it gets? To touch the ground? Like, how many *volts* it collects? [Mrs. Miller writes in her notebook and looks back up at Tommy.] Or, (…) if a cloud has power, how much power does it get, compared to a *smaller* cloud, you know? If a *big* thundercloud, it might have a lot of it, and always strike the ground…
**Mrs. Miller**: Mmmm. Sam?
**Sam**: If you're in a *submarine* (…) Ah, not that that deep down, um, and lightening, um, went *down*, would it be able to, um, shock the submarine from underwater? [Mrs. Miller looks down at her notebook and up at Sam.]
**Harry**: If it hit the water [Mrs. Miller looks at Harry.], it would probably be able to send an electric current through it (…)
**Mrs. Miller**: Danny and then Len.

In this dialogue, Mrs. Miller's words are limited to non-committal responses or calling out students' names (e.g. line 9 "Mmmm. Sam?"), and her gestures are constrained to pointing to students. The student ideas are on display and tend to dominate the conversation. This segment also shows that, as commonly observed in pattern (B), multiple student ideas are available at any one time, many of which are never taken up by other participants in the class (e.g. Jack's ideas in lines 1-2 and Tommy's ideas in lines 4-8). In the debriefing interview that followed the class session, Mrs. Miller commented on the large number of students participating in the discussion and the frequency of that participation. While she was able to point out a few emergent student ideas when prompted, her focus was more on the participatory nature of the discussion, rather than on the richness of the expressed ideas.

Mrs Miller's pattern of behavior during these segments of instruction appeared to sharply contrast to that of pattern (A), which tended to be much more teacher-directed. The verbal and non-verbal behaviors of Mrs. Miller depicted in pattern (B) interactions suggest that she is framing the instructional sessions (or portions thereof) as "making room for students to share ideas and reach their own conclusions about phenomena with minimal interference from the teacher," or *promoting a student-centered discussion* for short. We will refer to this as, "frame (B)." Mrs. Miller's limited talk and her propensity for calling out the names of students seems consistent with eliciting student ideas and encouraging student participation. Mrs. Miller seemed to be intent on making room for her students to express their thoughts and allowing the students' ideas to take the floor. Rarely did she try to control and/or direct the trajectory of the students' ideas. Her focus on participation during her debrief interview, rather than the substance of her students' ideas, seems to reinforce this interpretation.

## Pattern (C): Focusing on making-sense of student ideas

The set of behaviors associated with pattern (C) was observed less frequently and for shorter duration (usually less than 15 minutes) than those associated with patterns (A) and (B). Similar to that which was observed in pattern (B), Mrs. Miller's behavior made room for student ideas and allowed them to be objects of discussion. A substantive difference between (B) and (C), however, was Mrs. Miller's active role *during* that discussion. In these sessions, Mrs. Miller seemed to concentrate intently on the substance of the students' ideas, leaning towards the student as he or she spoke. She also actively employed gestures during these interactions, seemingly to enact the situation that the student was describing (see Figure 3a). On one occasion, she even spontaneously constructed a simple demonstration to further enact the student's idea being described (see Figure 3b). These non-verbal gestures are in contrast to those associated with pattern (A), where she tended to use hand and body movements to emphasize specific content terms or phrases in her own talk rather than those of her students.

**a**

**b**

Figure 3: Examples of Mrs. Miller's body orientation and gestural movements consistent with behavioral pattern (C): (a) Mrs. Miller uses arm gestures to enact a particular idea posited by a student (see line 14 in transcript below for co-occurring talk); (b) Mrs. Miller constructs a demonstration enacting a student's experimental design.

Similar to what was observed in behavioral pattern (A), Mrs. Miller tended to be more engaged verbally during these discussions. A major difference, however, is her engagement with the students' ideas, rather than her own. During these sessions, she actively asked questions of her students, emphasizing their words and probing more fully into their thoughts about the phenomena under discussion (e.g. "Now why would you want to use a different drink? Other than water?" line 2 in Exchange #1 listed in the introduction). In these discussions, Mrs. Miller seemed to act as a participant, similar to the other members of the class, working with the ideas the students proposed. At times, she attempted to repeat the students' ideas back to them, following such comments with inquiries as to whether she had "got it" or if she "was putting words in [their] mouth." Such questions indicate that she was checking in with her students to determine if she fully understood their ideas.

The following is a transcript that reflects an interaction typical of behavioral pattern (C). It was taken from a discussion that occurred on Day 12 of the module, which centered on a question posed by a student (Tommy) concerning a phenomenon that he had witnessed.

**Danny**: I just *know* I've seen it before. On the car windows-
**Mrs. Miller**: So more on a *car* window, though. [Looks at Tommy.] Is it the same idea as a car window? Or is it *different*? Are you thinking something different?
**Tommy**: It's almost the same concept except- except *that* is sideways, and I'm talking about, ah- up- you- ah- up, like, so as a straight area, so it doesn't have any *tilt*. You know? You have a window that's *this* way [Tommy tilts his right hand downward], you know the drop of water's gonna come *down* [Tommy indicates drops sliding down with his left hand]. And if it's *this* way [Tommy holds his right hand horizontally], it'll come toge- I don't know why, it just comes together, like, you know.
**Mrs. Miller**: So, you're *asking* if it's on the ceil- First, how's it get on the ceiling?
**Tommy**: Well, ah- a- I don't know, it was just thinking maybe if you splash water or something.
**Mrs. Miller**: Oh. If you splash water or something?
**Tommy**: Ah- ah- yeah.

**Mrs. Miller**: So, it [looks up at her hands, which are raised to the ceiling] comes together- [moves her hands together]
**Tommy**: And then it makes one drop of water and falls.
**Mrs. Miller**: Instead of coming just straight down. [brings both hands downward]
**Tommy**: Yeah- like, why does the water *move*? It doesn't have [Mrs. Miller looks up at right hand.] any reason to. [Mrs. Miller drops hand downward.]

Mrs. Miller's interactions with Tommy in this transcript clearly indicate that she is trying to understand the phenomenon that Tommy is trying to describe. She asks several pointed questions (e.g. "Is it the same idea as a car window? Or is it different?" in lines 2-3 and "How's it get on the ceiling?" in line 9) and employs gestures throughout the exchange. This use of gestures seems to serve two objectives: (1) to help herself visualize the phenomenon better, and (2) to ask Tommy if she has grasped his idea correctly. In total, the verbal and non-verbal behaviors of Mrs. Miller displayed during pattern C suggest that she is framing this portion of the instructional session as *making sense of student ideas*, which we refer to as, "frame (C)." Her active participation, probing questions, and use of gestures seems consistent with trying to understand her students' thoughts and further the development of these thoughts. Overall, these appeared to be richer discussions than those that occurred when Mrs. Miller employed frames (A) and (B) in that these conversations tended to extend and develop a single student's idea to its conclusion rather than following a series of different ideas superficially.

## Discussion

Mrs. Miller is a teacher who has historically taught science by focusing on reaching content objectives. Data collected from Mrs. Miller's classroom early in the 2008-9 academic year (not reported here) showed a clear tendency for Mrs. Miller to focus her attention on institutionalized content standards. After participating in PD sessions focused on attending to student thinking for one year, however, Mrs. Miller's verbal and non-verbal behavior in the classroom indicated that she no longer framed her instruction solely in terms of reaching content objectives. Instead, our findings show that while Mrs. Miller did demonstrate behavior that indicated that she was framing instruction as *reaching content objectives* in some situations, she also demonstrated that she framed her instruction as *promoting a student-centered discussion* and *making sense of students' ideas.* The employment of different frames, rather than a single frame, suggests that she is shifting in her approach to teaching science and facilitating scientific inquiry.

It might be expected that an experienced teacher, such as Mrs. Miller, would move between frames in a stable, predictable manner. This was certainly not the case. She did not appear to shift from one instructional frame to another sequentially, such as framing the initial module sessions as *reaching content objectives* (A), framing subsequent sessions as *promoting a student-centered discussion* (B), and framing the final module sessions as *making sense of students' ideas* (C). Nor did she seem to shift between frames in a cyclic fashion, moving from frame (A) to (B) to (C) rapidly, only to instantiate a similar cycle in later instructional sessions. Instead, Mrs. Miller tended to shift between frames sporadically, framing instruction differently on successive days and occasionally appearing to shift between frames within single instructional sessions. For example, Exchange #1 took place on Day 13 and provided behavioral evidence that Mrs. Miller was framing instruction as *making sense of students' ideas.* Exchange #2 took place the very next day (Day 14) and provided behavioral evidence that Mrs. Miller was framing instruction as *reaching content objectives*. Furthermore, Mrs. Miller displayed behavioral evidence (although not included here) that she was framing instruction as *promoting a student-centered discussion* just twenty minutes prior to the Exchange #2 segment.

Mrs. Miller once again participated in our research project during the 2009-10 academic year. Her second implementation of the water module provided us with the opportunity to explore how her framing of instruction may have changed from her first implementation. Preliminary behavioral analysis indicates that Mrs. Miller employs frame (A) considerably less frequently, whereas evidence of frames (B) and (C) seems to be more prevalent than was observed during her first implementation. Furthermore, while instances of frame (C) continue to be fewer in number and of shorter duration than those of frame (B), Mrs. Miller does appear to be shifting between these two frames more frequently *within* session than was observed during her first implementation of the module. Although these data are admittedly tentative, fewer instances of (A) (e.g. focusing on content only) and shifting from (B) to (C) more regularly (e.g. engaging with student ideas *in-the-moment* during student discussions) suggests that Mrs. Miller is progressing with respect to attending and responding to the substance of her students' thinking. Her debrief interviews from this fall seem to corroborate this interpretation, for her comments seem to be focused primarily on her students' ideas and how these ideas can promote additional explanation and discussion about phenomena. This focus contrasts with last year, when she tended to comment on whether her students did or did not achieve content goals and/or to what degree her students were participating in discussion.

Part of the broader scope of our research project is to begin to conceptualize a teacher learning progression in the promotion of scientific inquiry. We expect that such a learning progression necessarily involves a dimension in how teachers attend and respond to the substance of their students' ideas. Linear descriptions of learning progressions tend to characterize learning as happening in stable, plateau-like stages representing the increasing degrees of sophistication (e.g. Thompson, Braaten, & Windschitl, 2009). The dynamic, episodic nature of Mrs. Miller's observed behavioral patterns, however, suggests that it might be less meaningful to describe longitudinal progress in terms of successive stages or levels. While it is arguable that frame (C) is more sophisticated than frame (A) regarding a teacher's consideration of the substance of her students' thinking, it is questionable as to whether it is desirable (or feasible) for a teacher to only frame instruction this manner. Allowing students to first share their ideas and reasoning in a student-centered discussion might be a necessary foundation for engaging, probing, and working with their ideas. Characterizing *how* a teacher shifts in her framing of instruction, as well as the *frequency* in which she shifts between frames, might serve to be a more productive way to think about a learning progression in attending to and responding to student thinking. Hence, a learning progression in this dimension might consider the degree to which a teacher is able to move flexibility between frames *in-the-moment* as different students' ideas emerge through discussion.

From a research perspective, framing appears to be a useful construct to help make sense of the ways Mrs. Miller attends and responds to her students thinking. Such a construct allows us to move from just describing observable classroom activity to positing reasons for *why* she might be attending and responding in specific ways at different times during instruction. Furthermore, thinking of framing in terms of activation of specific resources provides a means to consider the possible explanatory mechanisms underlying that activity.

# Explaining across contrasting cases for deep understanding in science: An example using interactive simulations

Catherine C. Chase[1], Jonathan T. Shemwell, and Daniel L. Schwartz
Stanford University School of Education, 485 Lasuen Mall, Stanford, CA, 94305
cchase@stanford.edu, jshemwell@stanford.edu, danls@stanford.edu

Undergraduate students used a simulation to learn about electromagnetic flux. They were provided with three simulated cases that illustrate how changes in flux induce current in a coil. In the POE condition, students predicted, observed, and explained the outcome of each case, treating each case separately. In the GE condition, students were asked to produce a general explanation that would work for all three cases. A second factor crossed whether students had access to a numerical measurement tool. Effects of the measurement tool were less conclusive, but there was a strong effect of instructional method. Compared to POE students, GE students were better able to induce an underlying principle of electromagnetic flux during instruction and were better able to apply this principle to novel problems at post-test. Moreover, prior achievement predicted learning in the POE group, while students of all academic levels benefited equally from the GE condition.

Science education has learning goals that range from basic lab skills to beliefs about the sources of scientific knowledge. One enduring goal is for students to develop a deep understanding of phenomena so they can engage in the structure of scientific explanation. One way to characterize deep understanding is the capability and disposition to perceive and explain natural phenomena in terms of general principles. In this study, we show that deep understanding can depend critically on the way in which multiple instances of phenomena are presented to students and how students are instructed to explain those instances. The research is done in the context of undergraduate physics students learning about magnetic flux with a computer simulation.

It is common in science instruction to ask students to solve or conceptually explain a series of problems. One version of this approach is the Predict-Observe-Explain (POE) cycle (White & Gunstone, 1992). Students receive the set-up of an experiment and predict what will happen. They then observe the outcome and develop an explanation for why their prediction did or did not match the expected outcome. For POE and other sequenced formats, a series of questions or examples is carefully selected to help students instantiate a given core principle in multiple contexts, so that they develop a deeper, more abstract sense of the principle and learn the kinds of situations to which it applies. Formats such as POE are considered to be effective in part because they foster deep and often extended engagement with each new question or problem that students consider.

A risk of presenting students with a series of instances of a given principle is that students may treat each instance as unique and not grasp the underlying structure that links them together. Novices often have difficulty finding the underlying structure across instances that differ on the surface. In a classic study contrasting physics experts and novices, the experts categorized problems by their underlying concepts, such as energy conservation, whereas novices categorized them by their devices, such as springs or inclined planes (Chi, Feltovich, & Glaser, 1981). This encoding of surface instead of deep features would seem a likely pitfall of any pedagogy that engages students intensively with many instances of phenomena presented in series. For example, students doing POE might focus on the manipulation of a particular experiment, not noticing that it shares properties with a seemingly different manipulation. As a simple thought experiment, if a person adds a red solution to a beaker in one POE cycle to see what happens, and then adds a purple solution in the next cycle, it would be natural to treat red and purple as distinct manipulations, even though they are both cases of adding a color that contains red.

An alternative to instructional methods that have students work intensively with separate instances of phenomena is to have students explicitly consider multiple instances jointly. Contrasts among multiple, juxtaposed cases are known to support the induction of underlying structure if they differ on a few key dimensions (Beiderman & Shiffrar, 1987; Gibson & Gibson, 1955; Marton & Booth, 1997). Much like wine tasting, the process of comparing across cases helps people discern critical differentiating features that they might otherwise overlook (Bransford, Franks, Vye, & Sherwood, 1989). When students come to recognize invariant structure among cases with different surface features, they can schematize this invariant and more readily transfer this more general knowledge to new situations (Gick & Holyoak, 1980). Approaches to instruction that optimize contrasts have been successful in teaching statistics (Schwartz & Martin, 2004) and psychology (Schwartz & Bransford, 1998). O'kuma, Maloney & Hieggelke (2000) provide an example of this type instruction in science, wherein students are asked students to discover, apply, and explicitly state an underlying principle induced from a series of related cases.

However, merely engaging with contrasting cases does not automatically produce deep understanding. Our hypothesis was that *how* students were instructed to process multiple, related cases would be critical for determining whether they would notice and encode the underlying structure. In particular, without explicit prompting, students would be likely to treat each problem separately and miss the common underlying structure. This hypothesis is supported by research in the domain of analogical reasoning. For example, Loewenstein, Thompson, & Gentner, (1999) showed that simply asking students to process two cases presented together was not nearly as effective for schema abstraction as explicitly prompting them to compare the cases and describe their similarities. Likewise, Catrambone & Holyoak (1989) found that transfer of underlying principles was improved when students were explicitly asked to identify the deep features that were common to two analogs. In the current study, we furnished all students with a set of contrasting cases embodying a single underlying principle. We asked one group of students to provide a general explanation (GE condition) for all the cases, whereas the other group followed the more typical approach of predicting, observing, and explaining each case in turn (POE condition). Our hypothesis was that the GE approach would lead students to induce the underlying principle during the activities, which in turn, would lead to better understanding at post-test.

Scientific principles that explain natural phenomena often involve complex relationships that are difficult to conceptualize using everyday language. Mathematics can provide crucial vocabulary and syntax to support students' conceptual reasoning in the face of complexity. For example, researchers (Schwartz, Martin & Pfaffman, 2005) had younger students use POE with the balance scale (i.e., will the scale tip or stay balanced given weights on pegs at various distances from the fulcrum). They found that encouraging students to "invent math" to predict and explain the results led to much greater learning than encouraging students to explain in "words." Representing distances and weights as numbers enabled students to test possible relationships (i.e. the multiplicative relationship of weight and distance that balanced the scale) and make precise comparisons that were difficult to make using words.

The simulation used in the current study features a measurement tool that mathematizes the concept of magnetic field by expressing field intensity as numerical values separated into their vector components. We gave half of the students in the study access to this measurement tool and encouraged its use on the presumption that it would help them identify and reason more precisely about the contrasts and similarities across the three configurations.

In the current study, undergraduates in an introductory physics course learned about magnetic flux in the context of an interactive computer simulation. Simulations offer exciting new possibilities for science learning (de Jong, 2006;), but pedagogies for their use are new and evolving. Instructional design has focused on providing embedded scaffolds to support student inquiry in relatively open-ended tasks, so students produce optimal experimental runs of a simulation (e.g., de Jong, 2006). Rather than focus on inquiry, we took advantage of simulations' affordances for engaging students with a set of contrasting cases. To do this, we asked students to generate conceptual explanations from a series of three scenarios within a simulation. We expected that using the common POE model of instruction, which encourages intensive processing of individual cases, would lead students to see different scenarios in the simulation as unique, unrelated instances, like the red and purple solutions in our thought experiment. Therefore, we wanted to determine if the simple switch of asking students to find a general explanation for all the cases could overcome this likely problem and produce superior learning outcomes.

Thus, the design of the study was a 2 x 2, crossing the factors of General Explanation (GE) v. Predict, Observe, Explain (POE) by Measurement Tool (MT) v. No Measurement Tool (No-MT). We expected the GE group to gain a deeper understanding of magnetic flux because in comparing across cases, they would be more likely to induce the general principle. We also predicted that the GE-With Measurement Tool (GE-MT) condition would perform the best of all on our learning assessments, because the precision of mathematical representation would help them identify and reason about relevant contrasts.

## Methods

### Participants

Participants were 103 undergraduates in an introductory physics course on electricity and magnetism at a highly selective university. The study took place during one of the 50-min recitation sections associated with the course. Because many students needed to leave before the end of the section (often to get to another class), 23 students did not complete at least one of the four questions on the post-test, leaving us with complete data for only 80 students.

### Design

Sections were assigned intact but at random to the four treatments: GE-MT (n=20; 3 sections), GE-No-MT (n=25; 3 sections), POE-MT (n=20; 3 sections), and POE-No-MT (n=15; 2 sections). The unequal numbers of students in each condition were due to variations in section size (6-15 students) and the odd number of sections. The eleven different sections were taught by six different teaching assistants, and all but one of the teaching assistants taught two sections. To compensate for teacher effects, each teaching assistant taught one GE and one POE section. Both sections for a given teaching assistant were then randomly assigned to either the MT or No-MT condition.

## Procedure and Materials

During the lesson, students completed worksheets, which directed them to use the simulation to learn about magnetic flux in the context of electromagnetic induction (Faraday's Law). Students worked in groups of two to three with one laptop computer. All groups spent 25-30 minutes on the worksheets. Throughout the class, the teaching assistants moved from group to group, answering student questions. Teaching assistants were unaware of the study's hypotheses. At the end of class, students completed a brief post-test to assess learning outcomes.

The simulation (Figure 1) was a PhET interactive simulation (Wieman, Adams, & Perkins, 2008; available at http://phet.colorado.edu/simulations). This simulation allows students to move a magnet around the screen to light a bulb attached to a conducting coil. According to Faraday's Law, a changing magnetic flux in the coil will induce a voltage and light the bulb. The simulation represents the magnetic field as a sea of tiny test compass needles. Changes in field direction and strength are depicted by rotation of the needles and changes in their brightness.

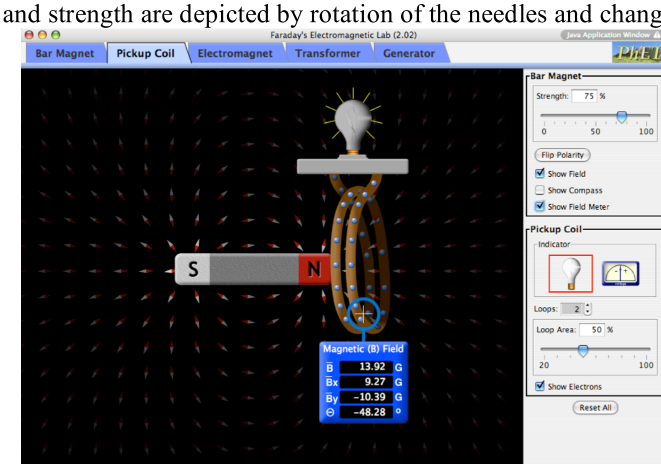

Figure 1. Phet Simulation. The magnet can be moved around the screen at varying speeds and positions to demonstrate how voltage is induced from magnetic field changes. The "field meter" measures field strength.

The worksheets presented all students with the same set of three cases (Figure 2). Two of the cases vary the magnet's position and one flips the magnet's polarity. A comparison of these cases reveals the invariant cause of voltage induction – a change in the component of the field within and perpendicular to the face of the coil. This translates to a change in the magnetic flux. The cases were designed to demonstrate three different manifestations of this underlying principle. Case A shows that a change in overall field strength can produce a voltage. Case C shows that a change in the field's direction can produce voltage. Case B illustrates that a change in field in the vertical direction does not produce voltage. Taken individually, it can appear that different kinds of changes are causing the voltage in each case. In Case A, the strength is changing; in Case C the direction is changing; in Case B there is almost no change in direction, and the change in strength is not particularly salient. Thus, a change in the field's strength or direction would seem sufficient to induce a voltage. But taken as a group, it is possible to induce the deep principle – that only a change in strength of the horizontal component of the field qualifies as a change in magnetic flux, which produces voltage.

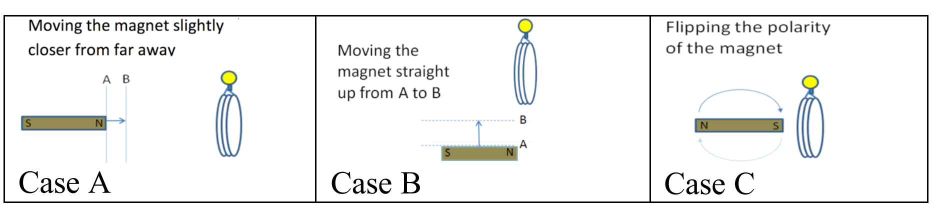

Figure 2. Cases. Students recreated these cases in the simulation and observed their effects.

## Description of Conditions

In the POE condition, for each of the three cases, students made predictions, observed what happened, and explained why. In the predict phase, the worksheets instructed students to make predictions for each of the three cases in Figure 2. Specifically, they had to predict what the light bulb would do in each situation and draw expected changes to the magnetic field. In the observe and explain phase, students used the simulation to test their predictions by recreating each of the three cases. For each case, there was a space on the worksheet for students to record "what the light did," describe the light's brightness, draw the changes that happened to the magnetic field, and "explain the change in the magnetic field that caused the bulb to light." Thus, the POE condition was unlike many POE cycles in that students worked with all three cases at the same time. This was done so that the POE condition would be comparable to the GE condition, which also worked with the three cases simultaneously.

The GE worksheets did not contain a prediction phase. Instead, GE students were told whether the bulb would light brightly or dimly, after which they observed the cases and worked to generate a single, unifying explanation that would work across them all. The worksheet contained an example general explanation for how three cases of objects of varying masses and volumes would sink to varying depths of a liquid (the example general explanation described density as a ratio of mass to volume, which determines sink "depth"). After looking over this example, students were instructed to open the simulation, produce each of the cases, draw and record observations of the magnetic field, and then write "a single general explanation that will address what the magnetic field must do for the bulb to light or not light in any given case."

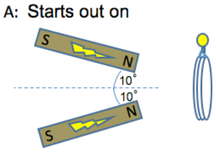
The field meter, an optional feature of the simulation (depicted in Figure 1) allowed users to take numerical measurements of the magnetic field. The field meter measured horizontal and vertical components of the field, the angle between the field vector and the vertical, and the overall magnetic field strength. Groups in the MT condition were given access to the field meter and told to use it to record horizontal and vertical components of field strength inside the coil. Studentsin the No-MT condition were told not to use the meter.

## Dependent Measures and Coding

During the last 10 minutes of the lesson, students individually completed a six-item test assessing their understanding of the vector (perpendicular component) contribution to changes in magnetic flux in the context of Faraday's Law. Two of the items were dropped from our analyses because they proved to be unreliable measures of student understanding of magnetic flux. Figure 3 shows an example post-test item.

Electric magnets A and B generate the same magnetic field as a regular bar magnet, but they can be switched on and off.

**Case 3**: Switch electric magnet A off at the same instant that you switch electric magnet B on. The field quickly fades from A and quickly builds up from B, so that the overall amount of field is held constant, but the direction of the field is changed.



Will the bulb light and if so, when? Why? Your explanation should discuss what happens to the magnetic field inside the coil.

*Answer: No, because even though the field changes direction, the amount of field perpendicular to the coil stays the same.*

Figure 3. Sample post-test item.

Post-test responses were coded for whether or not the deep structure (the vector component nature of flux) was discussed, using a 1-0 coding scheme. An answer with a score of 1 applied the principle that changes in magnetic flux depend on changes in the component of magnetic field perpendicular to the coil. We further subdivided the non-deep answers into two categories: shallow and vague. Shallow answers depended on surface features by referring to a change in the strength or direction of the magnetic field as the causal agent. Vague answers referred to a general change in magnetic field as the causal agent, without further specifying the type of change. In this shallow-vague coding scheme, shallow answers earned a score of 1, while vague answers earned a score of 0. Worksheet explanations were also coded along these two dimensions: deep structure and shallow-vague. All questions were coded by two primary coders. For each question, a random sample (20%) of the data was double-coded to achieve inter-rater reliability. Percent coder agreement ranged from 80-100% across questions.

# Results

## Equivalence of Groups

To check the equivalence of students across experimental conditions, we compared groups on prior achievement as measured by students' course midterm scores and found no significant differences. A factorial ANOVA on midterm scores crossed instructional method (GE or POE) with measurement tool (MT or No-MT). There were no differences in scores by instructional method, $M_{GE} = 27.3$, $SE_{GE} = 1.3$, $M_{POE} = 26.5$, $SE_{POE} = 1.5$, $F(1,73) = 0.17$, $p = .68$, nor was there an interaction of instructional method with measurement tool, $F(1,73) = 0.02$, $p = .90$. There was a near main effect of measurement tool, as the MT group had lower scores than the No-MT group, $M_{MT} = 25.3$, $SE_{MT} = 1.4$, $M_{No\text{-}MT} = 28.7$, $SE_{No\text{-}MT} = 1.4$, $F(1,73) = 3.30$, $p = .07$. However, this difference was in the opposite direction of experimental effects (described below).

## Post-Test Performance

Post-test measures revealed that the GE students developed a deeper understanding of the vector component nature of magnetic flux than POE students. There was a near-significant trend for MT students to outperform No-MT students, which suggests that using the field meter might also have helped students arrive at a deep understanding. Figure 4 depicts these patterns.

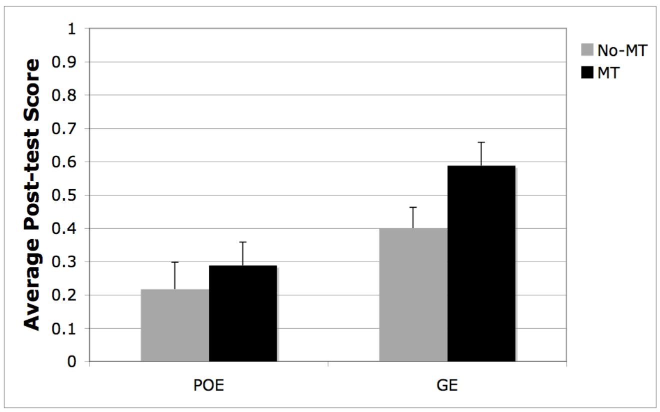


Figure 4. Average deep structure score across all post-test items, broken out by condition.

To test the effects of treatment on learning outcomes, a factorial ANOVA crossed method of instruction with measurement tool, using students' average deep structure score across all post-test items as the dependent variable. The ANOVA yielded a main effect for GE instruction, $F(1, 76) = 11.57$, $p = .001$, $d = 0.39$. There was also a near main effect of measurement tool, $F(1, 76) = 3.30$, $p = .07$. The interaction effect was not significant, $F(1, 76) = 0.67$, $p = .41$, though descriptively, the difference between MT and No-MT conditions was larger in the GE group.

## Effects of Prior Achievement

Pre-existing achievement levels predicted learning outcomes, but only for the POE condition. Correlations between post-test and course midterm scores were non-significant for the GE group, $r = 0.03$, $p = .83$, but moderate and significant for the POE group, $r = 0.39$, $p = .03$. Both MT, $r = 0.28$, $p = .09$, and No-MT, $r = 0.12$, $p = .46$, students' post-test scores were uncorrelated with achievement. The low correlations between post-test and midterm for the GE groups suggest that the positive effect of GE instruction acted independently of students' prior achievement levels. The opposite occurred in POE instruction, where high achievers learn more from the instruction.

## Worksheet Explanations

While working with the simulation, students in the GE condition wrote deep explanations on worksheets at a much higher rate than POE students (Table 1). This effect was pronounced. For the 80 students completing the experiment, only 1 out of 35 (2.9%) in the POE condition wrote a deep explanation compared with 14 out of 45 (31.1%) in the GE condition, $\chi^2$ (1, N = 80) = 1.03, $p = .001$. Measurement tool, in contrast, did not significantly affect worksheet performance, $\chi^2$ (1, N = 80) = 0.08, $p = .78$. So GE students were far more likely to induce the deep structure during the worksheet activity than POE students.

Table 1. Percentages of students who wrote deep explanations on worksheets (n deep/n total), by condition.

| | No-MT | MT | Total |
|---|---|---|---|
| **POE** | 0/15 (0.0%) | 1/20 (5.0%) | 1/35 (2.9%) |
| **GE** | 7/25 (28.0%) | 7/20 (35.0%) | 14/45 (31.1%) |
| **Total** | 7/40 (17.5%) | 8/40 (20.0%) | 15/80 (18.8%) |

## Relating Worksheet Explanations and Post-Test Performance

How students performed on worksheets predicted how they performed at post-test. A one-way ANOVA used worksheet explanation (deep or non-deep) as the independent variable and post-test score as the dependent measure. There was a substantial main effect of worksheet explanation, $F$ (1, 78) = 30.08, $p < .001$, $d = .62$. Students who noticed the deep structure during instruction (and wrote about it in their explanations) were far more likely to apply the deep structure to novel problem situations on the post-test. Only one POE student discussed the deep structure of the worksheet, so it is impossible to determine whether worksheet performance predicts performance equally for both instructional conditions. Nonetheless, the findings are clear. Worksheet performance strongly predicted post-test performance, and students in the GE group were far more likely to perform well on the worksheet.

## Descriptive Trends in Non-Deep Worksheet and Post-Test Responses

What were students' worksheet explanations and test responses, if not deep? Figure 5 shows the percentages of student worksheet explanations and post-test responses that were deep, shallow, and vague, broken out by condition. Overall, students across all four conditions gave similar proportions of vague responses, meaning that POE students did not simply neglect the task, at least not more than the GE students. However, the POE group had a higher percentage of shallow responses on both the worksheet and post-test, indicating that POE students tended to focus on locally salient aspects of the three cases (i.e. the field changed strength, or it changed direction). In comparison to MT students, No-MT students wrote a higher proportion of shallow explanations at test, though this pattern was far less prominent on worksheet performance. As is evident from the data already presented, the GE group generated a higher percentage of deep responses on both worksheets and tests.

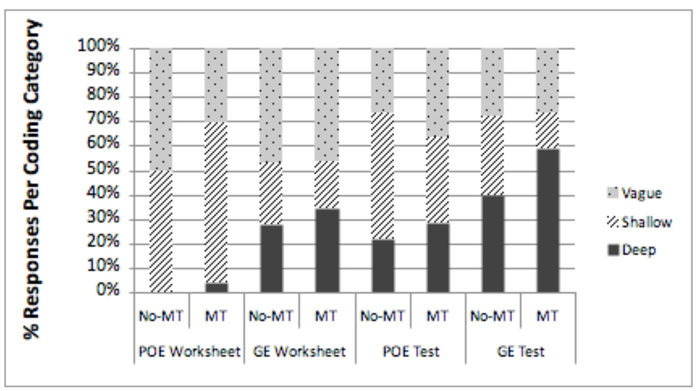

Figure 5. Percentages of deep, shallow, and vague responses on worksheets and post-tests.

## Mortality Threat

As described in the methods section, 23 students did not complete one or more of the assessment items because they left the experiment during the assessment phase. These students' worksheet and partial test performances are omitted from the analyses described above. To check for mortality effects, we calculated the percentage of students who answered in terms of deep structure for each post-test question and on worksheets, including all student data (Table 2). Importantly, the pattern of worksheet performance including all 103 students is identical to the pattern for the 80 students who completed all post-test items. At post-test, GE students gave deep responses at a higher rate than POE students on all four items. Also, with the exception of Item 3, MT students gave deep responses at a higher rate than No-MT students. In a final check, we examined differences in prior achievement by comparing leaving and remaining students' midterm scores. Scores in the two groups did not differ, $M_{leave} = 26.8$, $SE_{leave} = 1.5$, $M_{remain} = 27.0$, $SE_{remain} = 1.0$, $t(1,97) = 0.09$, $p = .93$, nor did they differ by condition. Given the equivalent prior achievement and the results shown in Table 2, and especially considering the strong relationship between worksheet and test performance, it is unlikely that results described above were caused by attrition.

Table 2. Percentages of students with deep worksheet explanations and post-test responses, broken out by condition and item. Includes all student data.

| | | **Worksheet** (N = 103) | **Item 1** (N = 102) | **Item 2** (N = 101) | **Item 3** (N = 90) | **Item 4** (N = 82) |
|---|---|---|---|---|---|---|
| **POE** | No MT | 0.0% | 0.0% | 5.6% | 55.6% | 22.2% |
| | MT | 4.4% | 13.0% | 17.4% | 47.8% | 26.1% |
| **GE** | No MT | 27.8% | 16.7% | 33.3% | 58.3% | 27.8% |
| | MT | 34.6% | 46.2% | 57.7% | 69.2% | 38.5% |

## Discussion

Three strands of evidence show the superiority of working to create single, unified explanations of several simulated cases of a phenomenon (GE condition) over predicting and explaining those cases separately (POE condition). First, GE students had higher post test scores, showing their deeper understanding of the vector component nature of magnetic flux. Second, better worksheet performance in the GE group strongly linked this deeper understanding to the process of constructing a single explanation that satisfied all cases. Finally, in contrast to post-test scores for POE, post-test scores for GE were uncorrelated with prior achievement, indicating that this pathway to deeper understanding was open to students of all levels.

It is worth emphasizing that the students in all the conditions were engineering students at a selective enrollment university who had received instruction on magnetic flux in their main lecture class, many of whom had extensive prior experience with procedural basics including vector decomposition. Therefore, the lesson we taught was far from an introduction to the topic but rather an opportunity for students to rediscover "old" ideas in a new context. These special conditions suggest caution when generalizing our findings to contexts where students know less about the topic beforehand. Nevertheless, the non-correlation of test scores with midterm scores indicates that GE-type instruction could be beneficial for students with a broad range of prior knowledge. Here we note that many students in the study "forgot" about the component nature flux when working with the simulation despite their exposure to this topic in their course. Apparently, recitation activities that drive students to the task of "rediscovering" what they have been told in lecture is a valuable – perhaps indispensable – addition to student learning.

How did producing a general explanation help students develop a deeper understanding? Our favored interpretation is that when students search for a single explanation that applies to all cases, they are seeking and inducing the invariant under transformation. They are asking, "What is it about the three simulated experiments that are the same?" When successful, they induce an invariant relation that gives a principled account of different surface transformations. By contrast, students who work on cases in isolation, as the POE students did, are more apt to notice and think in terms of surface features that differ in each case. Of course, simply seeking a general explanation is insufficient if the data one collects are poor. The three simulation scenarios were designed *a priori* to include optimal contrasts that would help highlight the invariant structure. The GE students took greater advantage of these optimal contrasts than the POE students.

In addition to treating the cases either separately or together, there were other differences between the GE and POE conditions. Students in the POE condition predicted and observed the outcome of each case while those in the GE condition observed each case but were told the outcome. We cannot rule out these other differences as potential causes of the learning effects. However, given the nature of students' worksheet explanations, the "cross-case vs. within-case" explanation seems most plausible.

These results do not warrant a negative judgment on POE or similar pedagogies (such as sequential problem solving) because our implementation was not meant to represent optimal use of POE. Rather, the results show that asking students to induce a general explanation across a set of cases has the important consequence of facilitating a deeper understanding. Moreover, the results show that it can be risky to expect that students will generalize across multiple cases when they are asked to give a separate answer or explanation for each one.

In addition to the GE effect, the data included a trend in which the measurement tool helped both GE and POE students learn the underlying principle, according to post-test data. However, MT students did not have better worksheet explanations than No-MT students. We conclude from the worksheet data that, in opposition to our prediction, the reasoning afforded by this additional mathematical representation did not help students induce the underlying structure of magnetic flux from the three cases. Assuming that mathematical representations can facilitate students' conceptual reasoning, it seems that those we made available to students via the measurement tool were not appropriate, or were not appropriately structured, for the task of inducing a general explanation. Additionally, it is puzzling that MT students came near to outperforming No-MT students at post-test even though their worksheet explanations were not different. One explanation for this disparity is that the post-test contained stronger cues for students' prior knowledge of the vector component nature of flux than the worksheet activity. These cues would likely have been of greater help to MT students as a result of their having worked explicitly with vectors via the measurement tool.

Pending further research, the current study provides two suggestions. One is for the design of simulations and another is for the design of instruction. Currently, the design of simulations suggests running multiple experiments, each with a single condition. This design pulls for something like a series of cases using a POE pedagogy, where students set parameters, make a prediction, observe, and explain. This makes it difficult to compare across multiple conditions, which is what real world experimenters often do. Perhaps simulations should allow the presentation of multiple cases simultaneously on the screen. This would permit the production of optimal contrasts, and with proper orientation, students could be guided to generate general explanations. A second learning from this study, confirming prior research and extending it to the context of conceptual learning in science, is that when students are presented with several instances of a phenomenon, they will not automatically search for the common structure that exists across them. Rather, students need to be pushed to do this. Science instruction that compels students to generate explanations that work for several different experiments or situations can help students construct deep understandings of general principles and the conditions to which they apply.

# Conceptual Confusion in the History Classroom

Chava Shane-Sagiv, The Hebrew University of Jerusalem, chava.shane-sagiv@mail.huji.ac.il

**Abstract**: This paper addresses the inherent difficulties of learning concepts in the history classroom—inherent, because unlike disciplines that use a specialized vocabulary for concepts, history draws on the linguistic resources of everyday life, and uses the same concepts in different historical contexts. Relying on an eight-month classroom ethnography in a Jerusalem high school, I show how seemingly straightforward concepts such as "anti-Semitism" and "Nationalism" become, in the transaction of classroom life, a site of confusion reflecting the complexity of 'school history': learning about the past while struggling to find a common ground between disciplinary terms, on the one hand, and student knowledge and interests on the other. A close investigation of this confusion calls attention to how the disciplinary—everyday life and schooling—may be at cross purposes, and how we can become more astute in how to deal with this.

## Major issue addressed

In this paper I explore the challenges students face when learning concepts in the history classroom. Learning concepts and conceptual change have been dominant topics in science and math education for the past few decades but are rarely discussed in history education (Hallden, 1997). While biology concepts such as photosynthesis have clear definitions within the discipline and such concepts are generally used only in a biology context and not daily life (excluding metaphors) questions like "What is a historical concept?" or "What is the definition of a concept used in history such as 'fascism'?" seem less clear. Certainly many definitions of fascism can be found in textbooks and elsewhere, but understanding that twentieth-century fascism in Italy is not the same as a Texas congressman calling his President a "fascist dictator" (July 17, 2009 [LPAC]) is a challenge unique to the discipline of history.

The whole notion of generalizing in history, which lies at the core of conceptualizing, is viewed by some philosophers as ahistorical (Mink, 1987). Seen through this approach, history is about the concrete and particular rather than something abstract and general. But while the use of concepts in history may at times cloud more than it clarifies, teachers and students are discussing history concepts, both directly and indirectly, in classrooms around the world, and textbooks and tests are addressing them more frequently. This paper explores the confusion caused by such concepts as anti-Semitism and nationalism in a high school history classroom, and argues that while the use of concepts in the classroom is unavoidable, it presents difficulties for understanding both the history topics being discussed and the concepts themselves.

Consider the following excerpt from a high school history classroom in Jerusalem:

Ms. Stern: Today we will be talking about the Jews in Russia in the nineteenth century —In previous lessons we talked about the Jews in Western Europe and their acceptance and rejection, and we called this rejection anti-Semitism, but we didn't explain the term. What is anti-Semitism?
A few Students: Anti--?
Ms. Stern: "Anti" means against, and "Semitism"--?
Same students: Uh . . .
Ms. Stern: Shem was one of Noah's sons. What's the connection between him and the Jews?
Moti: The Jews came from Shem.
Ms. Stern: The Semites were a group of nations that originated from "Shem," including the Jews, Arabs, Aramaeans, and nations from all over the Middle East that had a common biological origin.
Tamar: So it's not just a term for the Jews?
Ms. Stern: No, it doesn't just refer to the Jews, but it eventually became a term that only applies to Jews.
Male student: What do you mean by "Semitic Nations?"
Ms Stern: The Semitic nations are a group of nations that originated from Shem.---
Shimi: So how can Arabs be anti-Semites?
Ms. Stern: Because of a lot of different things that happened over a long period of time. Basically we understand that the term today refers to the Jews, even though "the Semitic nations" include the Arabs as well.
Male Student: Shem?
Ms. Stern: *[slightly impatient]* Yes, from "Shem"--

There are clearly communicative aspects in this discussion that I will address; however, I would like to focus on the attempts to transact disciplinary knowledge. In five minutes of discussion, the following topics were mentioned: Jews, Russia, the nineteenth century, Western Europe, anti-Semitism, Semitic nations, Shem, Noah, Middle East, Arabs. We move from Eastern Europe to Western Europe to the Middle East, and from the nineteenth century to the time of the Bible in seconds, as the teacher tries to define anti-Semitism. She wants her students to acquire a basic definition of the concept and learn what it means etymologically while at the same time how to use it in the context of their history curriculum. While for the teacher the literal definition of the term is important as part of understanding the narrative presented in class (actually a multilevel narrative involving different kinds of hatred against Jews as well as a specific narrative of Jews in nineteenth- century Europe), the students when presented with this literal definition seem lost. The definition takes them far from the narratives the teacher would like to discuss, and they "cling" to the parts they don't understand or find intriguing, like the word "Semites," which makes no sense to some of them or the reference to Arabs, which they find confusing given the context.

The discussion quoted above exhibits communicative aspects across different disciplines, aspects that have been examined in research on classroom life (Jackson, 1968), classroom strategies (Holt, 1967), and classroom discourse (Cazden, 2001), for example, the teacher hoping her students would grasp what she's trying to say so that she can move on to another topic; the students trying to take clear notes in class so that they can do their homework and pass a test. While all of these aspects represent at once ways of passing along knowledge and power struggles in the classroom (Lemke, 1990), reasoning within the field of history has unique aspects which this paper will explore.

The teacher's attempt to give a general definition of the term "anti-Semitism" runs counter to several major forces at work in teaching and learning history. The first is students' experience with the concept in their own lives; the second is how different historical events, and the detailed narratives that form them, are unique, as opposed to generalizing them across time and space. In other words, students growing up in Jewish-Israeli culture are quite familiar with the term "anti-Semitism"; they bring into the classroom their own understanding of a modern "hatred of the Jews based on their Jewishness" which is so often mentioned in the news and in their education. Their own understanding is challenged by past historical events that share the same conceptual term but come from a period unknown to them, as well as by the term's literal definition, which some students have never before considered.

The confusion these students face when learning about a term like anti-Semitism (which is considered a concept in the curriculum) cannot be viewed as just the result of poor teaching or bad curriculum (though these can always be improved). Rather, it calls attention to the multiple linguistic layers and clashes between professional discipline, school goals, and student experience and interests, aspects which are apparent in every history classroom. While historians have tried to define anti-Semitism and filled countless books with their struggle to do so (Langmuir, 1990), the term's definition occupies only a few lines in a textbook and a few minutes of class time. This is not likely to change; the real question is how to manage it.

Learning history involves complex cognitive processes (Leinhardt, Stainton, & Virji, 1994). Some scholars have even argued that it is unnatural to think historically (Wineburg, 2001). Understanding the past can become even more complicated and charged in the classroom, given curricula and textbooks that all have a say in which topics to cover (or not) (Nash, Crabtree, & Dunn, 1997), in terminology that doesn't always explain topics well (McKeown & Beck, 1990), and where teachers and students bring to bear different historical knowledge and aims (Hallden, 1994 ). All of these factors play out in learning concepts in the history classroom. One of my goals is to show how the difficulties that arise in using concepts in the history classroom reflect the challenges of 'schooling history'—or any discipline, for that matter—challenges that must be resolved before they can be incorporated them into history studies.

This study investigates the challenges that concepts bring to the history classroom while addressing the following questions:

- What are 'concepts' in the history classroom?
- How do cognitive aspects involved in learning about the past (Lee & Ashby, 2000; Shemilt, 1983) and sociocultural aspects of studying culturally charged (Barton & McCully, 2005) and identity-charged (Seixas, 1994) historical topics in school play out in the learning of concepts?
- What kind of changes can be found in students' explanations of concepts once they have encountered them?

## Potential significance of the work

This work claims that, first and foremost, we need to recognize the disjunction between how concepts are used in everyday life and in disciplinary history, and then understand the fundamental problem of generalizing within the discipline of history. This may be researched not only through experimental work but in daily classroom exchanges. It asks us to explore the epistemological and linguistic landscape of disciplinary reasoning in today's classroom. Second, it points out that the remedy occasionally cited in research on disciplinary reasoning in the classroom, that difficulties in disciplinary understanding can be solved by changing the words used by textbooks or teachers, is too simplistic. Challenges such as learning historical concepts cannot be easily overcome; oftentimes the best that a teacher can do is manage them.

## Theoretical and methodological approaches pursued

Data for this paper were drawn from a larger research program of a tenth-grade history classroom in Jerusalem, Israel. This research was done in the tradition of classroom ethnography (Schweber, 2004) focusing on disciplinary understanding (Wineburg & Wilson, 1988) and more specifically on the "transaction of subject matter in speech" in a history classroom with 'typical instruction.' During the course of an academic school year I observed and took notes and audio recorded all 42 history lessons across eight months of instruction. Recognizing that many forces are present in classroom life that can regulate as well as silence certain voices, the research was enhanced by the use of a questionnaire, interviews, and other methods not traditionally associated with linguistic ethnographies in the classroom. This was a single-site case study (Yin, 1994) and as such, not intended to be generalized to other populations, but rather meant to illuminate and theorize phenomena that occur in other settings.

Mixed methods were used both in collecting data and in analyzing them. I collected multiple sources of data that could shed light on how students learned the history content presented in class.

1."Pre" and "Post" Knowledge Questionnaire: A questionnaire was handed out to all the students in the class before instruction began, asking about the topics in the curriculum. The same questionnaire was given at the end of the school year.

2. Ethnography Observations: Over the course of the school year I observed the history class twice a week. I digitally tape-recorded all lessons while taking notes on student talk.

3. Semi-Structured Interviews: During the school year I conducted bimonthly interviews with a focus group of selected students whom I asked questions about the classroom discussions.

4.“Artifacts of practice”: I collected materials used by the teacher and students in class (what Ball and Cohen call "artifacts of practice" [(Ball & Cohen, 1999)] including the textbook, handouts, notebooks and tests.

The first stage of data analysis took place while collecting the data. Protocols of lessons and interviews were transcribed based on my notes and class recordings, and preliminary codes were generated, focusing on students' line of reasoning in the classroom discussions (Hallden, 1994b). All the students' questions and in-class remarks were analyzed, looking for patterns of responses to content knowledge, i.e., difficulty in understanding, engagement, personal identification, etc. The second stage of analyzing these patterns meant examining them in light of discourse theories on learning knowledge in classrooms, focusing on moment-to-moment interactions between the teacher and students and the students themselves (Lemke, 1990; Wortham, 2006), and drawing on theories of group and classroom argumentation, adapted to the exigencies of the history classroom (Pontecorvo, 1993; Schwarz, 2009).

## Major findings, conclusions, and implications

Another example of confusion that arose in defining and discussing a concept in the history classroom involved the term "nationalism." Consider this excerpt from a class discussion:

Ms. Stern: What is nationalism? We’re starting a new topic: nationalism. Please write this down [*as she writes on the board she is speaking slowly]*. Nationalism developed out of the French Revolution, which emphasized nationality—the nation, or the people—as the basis of the state and the regime *[finishes writing on the board]*. Before the French Revolution, who owned the country?

Students *[in unison]*: The king.

Ms. Stern: The king. The French Revolution basically highlights the idea that the basis for the state is not the king, but the state, the citizens of the state… What is this thing we call nationalism? Nationalism is a strong sense of belonging to the national group, the common denominator for all members of the nation and a political aspiration for independence of the nation. . . . Okay, let’s try to understand. Finish copying, and let’s try to understand what this nationalism thing is all about *[reads from the board the definition she just gave the students]:* A strong sense of belonging to the nation--what is the word that recurs?

Students *[in unison]*: Nation.

Ms. Stern: Nation. What is this thing called a nation? What is this group that people feel a part of?

Natan: A state.

Ms. Stern: No, the state relates to the ruler. What is a nation?

Shimi: A group of people.

Ms. Stern: A group of people who what?

Student: Who have something in common.

Ms. Stern: Something in common such as what? Let’s try to take this apart: A nation, a group of people. But there are many groups of people. We’re a group of people in this class. Are we a nation?

Students: Uh . . .

This excerpt illuminates aspects that surround the confusion caused by studying concepts in the history classroom. Unlike the case of anti-Semitism, here the teacher is trying to explain an abstract concept that is new and unfamiliar to the students. She tries to explain nationalism by walking them through a definition of the concept she has just given for the first time, drawing on their own knowledge and experience. Analyzed from the perspective of a transaction of content knowledge and ideas, and not as a criticism of her teaching methods, this example shows how students fail to follow the teacher's "line of reasoning" because they don't share her context or knowledge. More specifically, it shows how the attempt to explain a concept by exploring the students' experience (i.e., "We're a group of people in this class. Are we a nation?") doesn't help, because the notion of nationalism is too foreign and complicated—foreign in its origin, since most of the students were born and raised in the nation-state of Israel, making it difficult to imagine what it would be like to live in a pre-existing world, and extremely complicated because the country they live in is a nation state that doesn't exactly conform to the definition of nation and nationalism they are learning about (data not presented here shows how the latter caused a lot of confusion). This can be seen as an example of how cognitive challenges (grasping an abstract concept) intertwine with socio-cultural challenges of learning a concept in the history class (Jews in Israel can define their nationality as Jewish, Israeli or both)

Comparing pre- and post- student questionnaires in terms of concepts like anti-Semitism and nationalism showed that while students did learn new information, the concepts themselves remained fairly blurry ahistorical ideas. These findings reflect the other processes connected to learning history in school that are addressed in this work: students' prior knowledge, beliefs, and ideas about the concepts discussed in class, which can represent a clash between "official and unofficial history" (Tulviste & Wertsch, 1994), and the difference between schematic and specific narratives about the past (Wertsch, 2002). These students tended to stick to schematic narratives, which resemble ahistorical concepts (anti-Semitism equals hatred of the Jews); while mentioning the specific narratives they learned (as a modern phenomenon anti-Semitism differs from religious hatred, or that practiced in nineteenth-century Russia or France), they were not clear on how to connect the two.

This work suggests three major sources for the confusion caused by discussions of concepts in the history classroom: (1) the clash between professional and everyday meanings as used in history; (2) the clash between history as a discipline of the unique and the notion of generalization that underlies the social science disciplines; and (3) the clash between the endless and opened structure of historical narratives and the time-limited/stressful/test-oriented structure of classroom life.

Given the push toward using concepts in teaching history in Israel and around the world (especially with the rise of standard testing), a better understanding of the many factors involved in understanding general concepts in the historical context is crucial. These days little classroom time is spent learning historical narratives in detail; as a short version of complicated narratives, using concepts may seem an ideal solution. The problem comes when this kind of shortcut creates confusion both in the class and in the narratives students take away. This work examines this confusion and argues that it reflects the complex processes that are involved in both trying to understand the past and the teaching of it. As such, it cannot be solved either through teaching strategies or changing words in a textbook; rather, this is a challenge that can be managed only through careful attention and a concerted effort within the field of history education.

# "Let the Players Play!" & Other Earnest Remarks about Videogame Authorship

**Abstract:** This exploratory case study describes how middle school youth authored videogames at an urban summer camp using Kodu, a visual programming language and game creation tool. The study details how the youth took on authorship and gave and withdrew agency to their intended game players through a process of continuous revision. Connections to traditional literacy are made and future research on the transfer of literacy practices between informal and formal learning environments are suggested.

## Introduction—Youth as Producers

Youth production of videogames and other media has been largely ignored by researchers (Peppler & Kafai, 2007a), and despite calls by educational scholars for further research in this area (e.g., Alvermann, 2008), very little is known about how multimodal production overlaps with traditional literacy practices. Our exploratory case study begins to fill the gap in the literature by looking at how middle school youth used Kodu (2008), a free tile-based, animation and videogame-making tool, during an inner city summer program. It also attempts to link the worlds of traditional academic literacy with the unique world of videogame authorship through a constructionist environment.

There is over 25 years of research on constructionist tools (Papert, 1969; DiSessa & Abelson, 1986; Sykes, 2007; Resnick, Kafai & Maeda, 2003) and youth videogame making (Kafai, 1993; Habgood, Ainsworth, & Benford, 2005; Perciles, 2007; Kelleher & Pausch, 2006; Howland, Good & Robertson, 2006; Robertson & Howells, 2008; Burn, 2008). The videogame studies have illustrated how production has a motivational effect, boosts self-esteem, engages participants in storytelling, and provides a gateway into early programming. Additionally, the research on constructionist tools has focused on learning and teaching practices, e.g., youth collaborative and creative processes (Peppler & Kafai, 2007a, 2007c), technology literacy and fluency (Cooper, Dann & Pausch, 2003; Resnick, Kafai & Maeda 2003), media literacy (Peppler & Kafai, 2007b), and instructional approaches (Moskal, Lurie & Cooper, 2000; Rusk, Resnick, Berg & Pezalla-Granland, 2008). Resnick and Silverman (2005) have also suggested that interactions with programming languages through constructionist tools "provides [users] with experience in using and manipulating formal systems" which may be transferred to "many other domains (from mathematics to grammar to law)." Other researchers have echoed such sentiments (see Gee, 2003; Ito, Horst, boyd, Her-Stephenson, Lang, Pascoe & Robinson, 2008). The shape of this transfer between subject area domains, however, has remained unexplored and unformulated.

Tackling the issue of transfer between domains, this exploratory case study devised simple research questions for an open and fruitful investigation of Kodu, a tile-based programming environment based on When/Do statements. These questions were: How did the youth engage with Kodu? And how did this engagement intersect with traditional generative literacy practices?

## Methods

An inner city community center in the Pacific Northwest was chosen for the study based on its geographic accessibility, computer lab availability, compatibility of the computers with Kodu specifications, and willingness of staff to support the program. Camp Kodu met three days a week over three weeks for 2.5 hours each session for a total of 22.5 hours of Kodu exposure. The youth, who attended Camp Kodu, might best be described as "geeking out" according to Ito's (2008) "genres of participation" since they wanted to be in Camp Kodu to build a project as they learned technology by interacting with adults and receiving feedback from peers. They were self-selected and learned about the program through signs around the community and word of mouth at the community center and at other institutions serving low income, urban and minority youth. In all, eleven youth between 6th and 8th grade signed up for the class. Six of the eleven had regular attendance and were able to complete a final project for the program. These youth emerged as the focus of the study (Patton, 2002). Of the six core attendees, three were African American (Ky, Zeb, and Thomas), one was white (Eli), one was second generation Chinese (Dale) and one was second generation Ethiopian (Ahmed). (All names are pseudonyms.) We acted as participant observer as researchers and instructional support for the youth. Since the unit of analysis for the study focused on the youths' game making and literacy practices and activities rather than on the interactions between the instructor/ researcher and the youth, we felt that we could interact with students freely as we followed their actions, but making sure not to direct their end products.

## Data Gathering and Coding

Observations were recorded and tagged for four areas: acts of collaboration, problem-solving, programming focus and storyline generation. Often tagging categories overlapped, e.g., collaboration and problem solving might both be tagged for an observational unit. Informal interviews during observation were also common.

These exchanges were recorded, parsed by thought unit, and coded by the same system as above. Ten to twenty minute think aloud protocols were also used as students were encouraged to talk while they composed with Kodu. The traditional think aloud format proved difficult for the youth given their task. Consequently, cognitive interviewing (Willis, 1999) was used to probe students in situ about why they made choices during programming. These sessions were parsed and coded by the same system as described previously. To round out our qualitative analysis, we analyzed the youths' games for code sophistication, clarity and simplicity. After the first round of coding was completed and reviewed, the theme of audience emerged prominently in the data, and subsequently, we added a theory driven coding structure based on Hammer's (2008) concepts of authority and agency, as it became clear these were of growing importance to the youth. We recognized that student uptake and use of the concepts would vary, perhaps because of the type of game they wanted to design or because of their comfort with Kodu or programming.

## Results and Analysis

The concepts of authorship proved fruitful for contextualizing our findings and illuminating the degree to which the youth crafted games with an eye toward audience. Traditional writing research has shown that revision and audience awareness are key components to an expert writer's compositional repertoire of skills (Bereiter & Scardamalia, 1987; Fitzgerald, 1987; Flower, Hayes, Carey, Shriver & Stratman, 1986; McCuthen, 1994, 1997). In this respect, authorship in videogame making is similar to traditional modes of writing; however, videogame authoring is murkier in its structure and more layered, as other New Literacies research has illustrated (see Hammer, 2008; Knobel & Lankshear, 2008; Miller, 2005). Consequently, our frame for analysis was most applicable theory to Hammer's concept of first, second, and third authorship in multiplayer role-playing gaming (2008). She theorized that "The primary text is that which outlines the rules and settings of the game in general. The secondary text uses material to create a specific situation, and the tertiary text is created as the characters encounter the situation in play" (p. 70). From an authorial standpoint, the first author develops the world, sets the rules, systems, and settings. They are considered the world builder who creates the sets and costumes. The second author, according to Hammer, constructs specific fictional situations (the scripts) within a pre-established imaginary world. The third author is the player who brings the story to life.

### 1st to 2nd Author

According to the above framework, the youth in Kodu occupied a space between the first and second author, suggesting that in constructionist environments authorship is more aptly described as degrees on a spectrum, which are influenced by the toolset established by the first author (in this case, the Kodu developers). Although Kodu has preset characters that are controlled through a series of preset tiles, the settings produce a myriad of environments, game genres, and character attributes. Such affordances fall more on the side of first authorship than second, but the degree to which these affordances are utilized is influenced by the user, as well as the genre the user is evoking. While the dynamics between what the first authors (Kodu makers) allow and what the second author (the youth) utilize is not the focus here, it should be noted that the youth were able to still be creative given the confines of the program by adjusting the settings of the world (gravitational pull, environmental colors/brightness, firing speed, etc.) and the settings of the characters (movement speed, level of springiness, etc.).

Additionally, the youth were also creative in their use of tiles (thus pressing on their abilities to evoke the first author through a problem scenario, not just via the tools that allowed setting changes). To demonstrate this, I challenged the youth to create a storm within a Kodu environment. There are no storm tiles within Kodu, but a number of tiles in combination can make a storm-like effect. This was an exercise in bricolage. For instance, one could clone a number of clouds that were colored gray or black and then add a yellow or orange glow to some, along with downward aimed wisps to illustrate the act of lightening. After this request, two students asked where to find the storm or rain tile while several others simply looked for the tile. I informed them that such tiles did not exist, and they had to figure out how to use the tool to create the effect. One student was overheard saying, "Oh, a storm. First I take a cloud and color it black to make it a storm," and Thomas went further and programmed the cloud to rain rocks when precipitation tiles were not found. These instances might be considered as the youth finding the bounds of their secondary authorship in connection to the first which constrained them to a degree.

As Hammer (2008) defined it, authorship is partially an issue of agency. Each author has agency, but the degree to which it is available is determined by the author above it. Unlike traditional texts which remain fixed in form but malleable in interpretation, secondary authors have the complicated task of formulating a fluid game-story. However, according to Hammer (2008), in order to compose they need to have various types of agency in certain amounts. Types of agency include: textual (freedom text code), narrative (ability to create one's own storyline), psychological (the feeling of authorial control) and cultural (others recognizing one's authorial control).

While in role-playing games, all these areas need to be activated in order for the secondary author to do her job, this may not be the case in Kodu, where it is likely that these areas of agency again run along a spectrum (as in authorship). For instance, cultural agency may not play as large a role in individual game-making as it does in the socially bound arena of role-playing. These points aside, however, it is important to point out that "Agency is not simply 'free-will' or 'being able to do anything,'" as Wardrip-Fruin argued (2009). "It is interacting with a system that suggests possibilities through the representation of a fictional world and the presentation of a set of materials for action." The notion of agency acting in a bounded system is sourced in the work of Mateas (2001) and reverberates in the work of Gee (2007), who positioned it as a key component of educating and one reason why videogames hold so much promise for learning.

## 2nd to 3rd Author

So this begs the question of how the youth acted as secondary authors in relation to their tertiary authors (their audience). What affordances of agency did they allow their game players and what were their contours of agency design?

In the bounded domain of game genre, some of the most potent examples of second-to-third author agency came to the foreground. The youth continually called upon a game genre on which to hang their hats—mostly racing and action. Although a variety of seed story games were available to the youth, they gravitated to the genres they played at home according to the surveys. Similar findings surfaced in Burn's research (2008) in which authorship emerged within the "proto-critical discourse" of gaming in general, Eli created a game called Left 3 Dead, a play off the zombie game genre in general, Left 4 Dead (2008) specifically. Interestingly, the original game served as a stencil of sorts by which to formulate a story, and Eli crafted a hybridized, remixed game (Knobel & Lankshear, 2008) using the DNA of Kodu with the game story of Left 4 Dead. Consequently, the genre and storyline not only deeply affected what he created, but also how the game was perceived and played by others. The general dynamics of this game were clear-cut for the player, and references to the original were deep.

In the original game, players controlled the four survivors of a zombie apocalypse, but Eli's game was transformed to three players, hence the name change. Zoey, Bill, and Francis were all taken from the original and used as characters in his version—though with a Kodu skin. Besides character names, however, Eli incorporated similar features and narrative plot lines to his game that were noticeable to his peers who were familiar with the game. Consider Eli's brief description of one part of the game he is creating, "They think everybody turned into zombies. And their friend is in this house and they have to rescue em. And then, that is how you win the game without dying because those zombies are trying to kill you by hitting you." Reflexively, these connections to the original game (which acted as another first author) bound the agency for the second and third author through replication of storyline and rules of game.

Dale used a similar strategy, designing a game around the Tower Defense genre, but he ran up against the player and genre expectation while creating his game, demonstrating how third author agency was violated. Dale had created a wonderful landscape—a maze made of steep canyons filled with water in which white and black Kodus started on opposite sides and tried to destroy each other's home base—a castle and factory respectively. We interviewed him about his game during the think aloud. After he showed in detail how his game worked, we probed for the role of the user.

| | |
|---|---|
| Researcher: | So what is the user controlling in this game? |
| Dale: | Ah, he is just watching. |
| Researcher: | Oh, he is just watching it so far? |
| Dale: | Yeah. |
| Researcher: | Is he going to be playing anything? |
| Dale: | No. |
| Researcher: | No? [long pause] Will he be playing anything? |
| Dale: | I don't think so. |

The exchange with the student surprised us a bit given the narrative foundation on which the student was building his game; Tower Defense definitely had an active user. We closely observed the student as he continued to develop the game and share it with others. At one point during the session, we had the campers play each other's games and give feedback. Zeb was particularly blunt in his assessment of Dale's game. He simply wrote, "Let the players play!" Clearly, he was feeling as if he had no agency and that his colleague (the second author) was impinging on his ability to actually be an active participant in the game. The player expectations rubbed too roughly against the player affordances, and Dale began to realize he was violating user expectation. He sat in his seat before making revisions, and stared blankly, "My game sucks." His game design was more attuned to an animated story, but in subsequent drafts, he created an environment that better aligned with player expectations—including player control. It is perhaps interesting to note that Dale scored well on standardized writing measures and did not define himself as a game player. These two factors suggest perhaps that during the initial stages of game development, he was connecting with more traditional, closed lines of authorship to express himself virtually and forgetting to leave a space for the third author to move.

These examples demonstrate how genre, knowledge of narrative history, and canonical pull impact the agency of the second and third author. These limits are not necessarily bad things, as stated earlier, since they serve as a function of coherency. As Nickerson suggested (1999) participants within an environment need structure in order to support their actions. However, it is when a second author limits the agency of the third in an unexpected way we see conflict. Participant agency is a balance between being bound and having freedom, which is not necessarily located in the powers of characters, but through them. This allows the third author to feel as if they have freedom without a sense of anomie. This idea is also reflected in game authoring literature. Wardrip-Fruin (2009) posited that "players come to games with assumption about the domain of play. To play successfully they must transition from their initial assumptions about this domain…to understand, often largely implicit, of how it is supported by the software model." If the transition is too sharp, novel or illogical according to the users past experience—for instance, not even allowing game play—the user will react.

Despite Dale's foibles with giving agency to the third author, there was a growing concern and attention given to the user by all the youth as they progressed through the camp. As with programming in general, they constantly pedaled between the Kodu program interface and the experience they were trying to create for the user. At first this act was the perpetual testing of the code without much thought about the player—perhaps acting as testers versus players. During the second of half of camp, however, and with more time devoted to sharing work, the youth became more interested in how and to what success their game was being played. For example, Ky was particularly attuned to audience and at first took pride in the fact that no one could win his game. With time and player feedback, however, he adjusted code to make the experience player friendly. He did this so much so that he would adjust the code and settings of his game depending on which camp peer was playing his game. When Ahmed won Ky's game on the first try, Ky increased the difficulty whenever Ahmed played his game—even if the first try was a fluke as they seemed to all agree. Such intense preoccupation with revising became a common practice for Ky and Eli. These two also spent the most time polishing their games in accordance with audience and what they considered to be challenging play.

Part of this revision included enhancement to the player's controller. Most of the youth began with long lines of code that allowed the user to control their characters in certain ways. However, Ahmed, Ky and Eli supplied the user with more than just movement and shooting ability. Ky for instance, gave the player the ability to glow blue, which was supposed to "blind" the enemies that were after him. Such a defensive tactic was not only clever, but also was in response to others suggesting that his game may be too difficult, hence also allowing the user greater agency to move within an environment without being destroyed.

As another example, Eli supplied the user with an array of options to act with agency. Although longer programming strands do not necessarily make for better programming, just as longer sentences don't make for better writing (consider the works of Hemmingway or Vonnegut), Eli's code set was telling, reflecting the type of creativity that was elicited from the storm-prompt. As an example, he used a programming feature (reloading) in a way that it was not explicitly intended. Additionally, his code offered a myriad of actions for the user through the game controller (some might think overuse), signaling his reaching out to the third author. First, he gave the player the ability to communicate status information (reloading) to the other two players in the game, as well as express emotions through text (DIE!!!). Interestingly, he also automated the calling of another character within the game (e.g., "Bill!!!") perhaps launching the story into narrative action. This may be considered an attribute assigned to user experience (the affect of the game) over third author agency (the ability to move within the game) since the player was not in control of this feature.

Additionally, Ahmed used text to communicate within his game, too. In contrast, however, he programmed text to appear when the lead character was moving on certain land types. "Careful! Oh Yeah! Keep Going! Stay on target! Heating Up!" The message acted both as a warning and as an encouragement, perhaps educating the third author of the constraints Ahmed had put within the game to make the play more challenging. This text might be considered an informative note to the third author suggesting the parameters of their agency.

The creation and adjustment of landscape was another way that the youth balanced agency for the third author. While considerably different from the broad scope of Hammer's (2008) definition of "framework agency" as it relates to role playing games, the crafting of landscape proved to afford players with degrees of agency in relation to the virtual physical world. The youth's continuous revision of the landscape signaled its importance as a game-play element. Thomas, for instance, spent several class sessions developing a racing game in which the landscape consisted of jagged mountains with steep valleys, but the landscape the path rested on was too extreme for his players to navigate without falling off and getting stuck. This was a real drag on agency for both characters, one of which was controlled by the player and other of which was automated. During one 20-minute think aloud (which was part of a much longer observation), we watched Thomas continually revise the path, rather than adjusting the characters' settings (such as speed). The session consisted of widening the path, changing the steepness of the path somewhat, adjusting the angle of the turn, raising the turns, and swapping path types. Between each change he ran the program to see if the characters would fall off, and they fell repeatedly. At one point, he said, “Poor little cycle.” This episode illustrated how the youth tried to give agency by tempering the effects of steep terrain, as he measured the game’s challenge level.

While Thomas attempted to tame the force of landscape as he retained its aesthetic, Ahmed totally revised his landscape to tame it for character and participant movement, “making it a little more even for both the enemy and the player,” and Ky used the landscape as part of strategic play. While discussing his landscape, Ky had a mind toward the player continuously.

| | |
|---|---|
| Ky: | It makes it look like it’s more intense because of all these rock spaces and stuff. It is going to make the player feel like he is in an enclosed area so when he runs this, [directs the players character] so like when he goes this way, he is going to be trapped when he turns around there is going to be a dead end with all the zombie Kodu. |
| Researcher: | So the landscape is influencing the story you are telling? |
| Ky: | Oh yeah, and I forgot there is a safe space. |
| Researcher: | Oh really? |
| Ky: | Right here, this is going to be a little safe spot and they won’t know where I [meaning player] hide and so you [the player] can plan out what you are going to do next. And so when you are through, and you come out, they won’t be able to see you because there is a wall right here. So you can sneak around and stuff, but once you get here you have to go really fast because when they see you they are going to go after you. |

The above dialogue captured Ky’s intense interest on the user experience and the degree of agency he gave the third author. Most interesting perhaps is his inclusion of a safe space for the player to collect his or her thoughts. The creation of this element took forethought about potential users and how they may be feeling during game play. Ky established a dramatic stage on which the game-narrative played out, giving the third author the agency to rest and decide actions.

Additionally, Ky’s shifting of pronouns was perhaps interesting as well, reflecting the continual volley between second and third authorship he performed during coding third author agency into the game. While the lexical mistake might be considered random, the confusion might also be sourced in the dual roles the youth had to embody as they shifted back and forth from player to programmer. The player turns from “he” to “I” to “you” within the above dialogue. Such role acrobatics are not trivial and signal the complexity of authoring.

Connecting to the ever shifting nature of composing from multiple perspectives, all the youth had to also balance a “them” in the development of character and participant agency. *Them* refers to the degree to which allies and enemies were programmed to confine or assist the player’s action. Interestingly, some of the youth moved from being particularly unforgiving in the virility of their antagonists to developing allies to assist the player in the world. Zeb, for instance, went from making a game in which the player was blown away within the first few seconds of play to distributing the antagonists along a linear path that supplied the player with a more refined experience and actual agency to survive within the world for an extended period of time. Ky also introduced a character, the last surviving flying fish, to assist the user during play by attacking the flying fish that had turned into zombies. And finally, Ahmed created a deep structure of alliances and enemies that afforded help and constraint on play. He strategically positioned them on the terrain and in the air to make the play “fair for both side.” He spoke of the characters as if they were not attached to a player, though he considered how the player might be alerted to behaviors of alliance characters.

| Ahmed: | I am going to add more characters to this side of the field and program this blimp thing |
| Researcher: | What are you going to program it to do?<br>[Ahmed starts programming the balloon] |
| Ahmed: | When see cycles they glow to like warn the Kodus and the jet that they [the cycles] are coming to protect them. |

Although these illustrations are partly attributed to building an interesting story for the third author, they are also related to giving the characters and objects in the field of play agency either by adjusting behaviors or establishing relationships in opposition or in alliance. As Wardrip-Fruin (2009) suggested, “Designing experiences toward the satisfactions of agency involves balancing the dramatic probabilities of the world with the action it supports. In other words, the design task is to entice players to desires the game can satisfy” (p. 13). In this case, Ahmed was anticipating his players’ needs within the drama of the game. Satisfying the desire of an unknown player is a complex task in game making, where the interactions between the characters, the characters and landscape, and characters and user all need to be taken into account. The shifting of perspectives the youth underwent in the development of their games was complex. Considering character and participant agency was a key component in the making of a plot that was driven by character behaviors and landscape constraints and affordances, and not traditional plot lines. Since this compositional task was so complex, one is left to wonder how these strategies related (or not) with traditional academic domains, particularly writing. How is authorship with an Xbox controller and Kodu different from a pencil and paper or keyboard and screen? Despite obvious differences, there may be conceptual, complementary compositional underpinnings.

## Discussion and Educational Implications

Many educational researchers have presented descriptions on youth who are disengaged with learning traditional language arts curriculum but motivated by informal new literacy practices like videogames (Goodman, 2003; McGinnis, 2007; Ranker, 2008; Sarroub, Pernicek & Sweeney, 2007). Outside these depictions of the motivating and identity forming effects of New Literacies, however, there is little data on how engagement with various media domains intersects with what is defined as academic literacy.

Often times, traditional and New Literacies are considered "dueling discourses" (Alvermann, 2008), but in truth, while digital compositional spaces are unique, they also intersect with the goals of traditional writing instruction. Consider how the findings of Camp Kodu are connected to traditional literacy. Students crafted game-worlds in which they scripted character and player behaviors, motivations, weaknesses and strengths. They also produced settings that positively and negatively influenced character and player actions, and plot arcs were highly influenced by how the characters, players and settings were coded and designed. Additionally, the youth engaged and seemingly learned from the expectations associated with a genre and narrative plots, sometimes transforming both in interesting ways, much in the same vein as literary canons are built over time. They were also cognizant of audience expectations and afforded their users with agency through various controls of movement and expression. The students also demonstrated the importance of setting not just for mood and tone, but also as a space for user constraint and assistance. They developed characters that were interconnected and influenced each other's behaviors, and they continually inhabited the roles of author, users, and characters in order to create game-worlds that were appealing to an audience. Finally, the students constantly revised game text according to perceived audience wants and skill levels.

Centrality of audience, the roll of revision, and positioning one's authorship were essential to the students' creations and were motivated by the very academic goal of gaining and sustaining the attention of readers and viewers over time. During this authorship, the complex ways youth process information was largely implicit in the activity of game making. This processing overlaps with various literacy domains perhaps signaling a conceptual move away from learning as an explicit collection of knowledge to be acquired for mastery and a movement toward a framework based on the connections between knowledge, skills, and practices across authored spaced. Such a shift operates, according to Knobel and Lankshear (2008), on the vast and broad plane of encoding, not "letteracy," as literacy is often played out in schools, and it presses on idea of transliteracy (Thomas, Joseph, Laccetti, Mason, Mills & Perril, 2007).

Interestingly, learning transfer, as outlined by Schwartz, Bransford, & Sears (2005) suggested that multiple contexts and exposures to tasks underlie these implicit learning concepts. Extending their theories and findings to New Literacies and to programs like Kodu, it might be argued that compositional practices and skills are enriched by authoring in multiple modes of communication—generating an adaptive, compositional expertise that operates to some degree successfully across domains. For instance, by learning how composition operates across modes of communication, youth may build upon, learn new, and leave behind composing strategies as they discern what compositionally works from what does not across domains.

Consequently, future research in videogame making with Kodu might further unpack the relationship between authoring videogames and student reading and writing in traditional areas, looking at what transfers in and out of the practices associated these generative/creative activities across various modes and genres. Cross domain studies are needed in literacy education, and they suggest that videogame making through constructionist tools have merit outside of just teaching youth early programming concepts. As this small study itself demonstrated, students enlisted compositional strategies that were unique to game making, but also broadly related to authoring across compositional areas. Of course, dynamics of agency with Kodu seem uniquely situated in game making, though perhaps not without import to other compositional practices.

# A Closer Look at the Split Attention Effect: Integrated Presentation Formats for Troubleshooting Tasks

Markus Huff, Vera Bauhoff, Stephan Schwan,
Knowledge Media Research Center Tübingen, Konrad-Adenauer-Str. 40, 72072 Tübingen

**Abstract:** According to the spatial contiguity principle of multimedia, learning interrelated information should be presented in an integrated instead of in a disconnected way. In this experimental study (80 participants), we examined performance with a troubleshooting task preventing such an integrated design. Instead, we used a display technology enabling a so-called "vexing image presentation", where there is no need for two foci of visual attention. Compared to a classic split screen setup in which participants have to shift their visual focus frequently, troubleshooting performance was superior in the "vexing image" mode. Hence, not the separation of external representations but processes of re-orientation after switching the visual focus seem to be responsible for split attention effects.

## Theoretical Background

As a well-established principle in multimedia design, the "spatial contiguity principle" is concerned with the spatial arrangement of different sources of information, for example a picture and an accompanying text description. Basically, the principle assumes that inter-related information (e.g., a geometric sketch and its related mathematical formula; Tarmizi & Sweller, 1988) should be presented in an integrated format in order to help the learners to mentally connect corresponding elements of the content (Ginns, 2006; Mayer, 1997). In contrast, if inter-related information is presented in a disconnected way (at locally distinct locations), learners have to search for corresponding pieces of information. This process wastes cognitive resources that are then missing for processes of elaboration and transfer into long-term memory (Mayer & Moreno, 2002). Another relevant example of the split attention effect is troubleshooting. Here learners have to find an error in a mechanical device and – if there is one – judge if this is critical for the proper functioning of the system. This is usually done by visually comparing a real device (or its depiction) with a reference device, be it another real device or a picture in a manual. Again, one finds the typical characteristics of split attention, namely, the necessity to switch the focus of attention frequently between two representations in order to mentally connect its corresponding elements in a time-consuming and error-prone manner.

However, although for combinations of text and pictures integrated presentations that avoid split attention are abundant (e.g., Scheiter, Gerjets, & Schuh, in press; Schnotz, 2002), until recently, similar solutions for combinations of real devices and pictures, or pairs of pictures, have been scarce. Accordingly, there have been few empirical studies to date that have examined split attention effects for learning tasks which require the comparison and mental integration of two pictures (Lee, Plass, & Homer, 2006; Huff & Schwan, subm.). But current digital technologies, such as augmented reality or auto-stereoscopic displays, offer new design possibilities for the problem of split attention. In particular, auto-stereoscopic displays allow for the realization of vexing images, that is, the presentation of two pictures in a way that enables participants to switch between them just by moving their head without a need for saccades (Huff & Schwan, subm.). Hence, one major goal of the present study was to examine the suitability of digital vexing images to substantially reduce the split attention effect for troubleshooting tasks that require extensive comparison of pairs of pictures.

Further, if one takes a closer look at the troubleshooting process, one can decompose it into at least two (distinct) sub-tasks, namely, a stage that can be termed as "comparative visual search" (Hardiess, Gillner, & Mallot, 2008) that is followed by a second stage which can be termed as "decision by mental animation".

During the first stage of troubleshooting, the learners have to identify one or more elements in the depiction of the target device that deviate from the respective parts of the correct reference depiction. In order to do this, correspondences between the elements of both pictures have to be established and for each corresponding pair, its similarity or dissimilarity has to be determined. This requires extensive visual search processes that are accompanied by frequent eye saccades and therewith shifts of the visual focus (Hardiess et al., 2008). Saccading alters the projection on the retina and consequently disrupts visual input. This in turn leads to a disruption of the visual working memory because the so-called "transsaccadic memory" store has a limited capacity and maintains visual characteristics of the learning material for only a brief time after stimulus offset (Phillips, 1974). If it would be possible to switch between different external representations without saccades, knowledge acquisition strategies could be based on the iconic memory store of high capacity (Irwin, 1991, 1992; Philips, 1974). In the present study, it is assumed that presenting the picture pairs as a vexing image via an auto-stereoscopic display might substantially reduce the need for shifts of visual focus and therewith the frequency and amplitude of saccades that are necessary to process the relevant information.

Once one or more possible problematic elements have been identified, the learner has to decide for each element whether or not it causes a malfunctioning. During this second stage, a promising strategy for diagnosing a breakdown could be to consider the identified element as part of a causal chain of events, and to simulate this chain of events by mental animation (Hegarty, Kriz, & Cate, 2003). Typically, mental animation is a process that poses high demands on cognitive resources. By reducing cognitive load during the first stage, more cognitive resources should be available for the second, decisional stage. Additionally, if participants can switch between two pictorial representations without moving their visual focus, the causal chain of events should also be easier to trace. Therefore, the second stage of processing should profit from an integrated presentation via vexing image, too.

Finally, an additional consideration concerns the kind of differences between a target device and its correct reference depiction. Here a distinction can be made between differences that are critical for the proper functioning of the target device (e.g., a missing gear in a clockwork) and differences that are not critical (e.g., a differentially colored part). Compared to functioning devices, the causal chain of events should be distorted and shorter for non-functioning devices. Therefore, identifying malfunctioning devices should be more accurate and faster than identifying a different but functioning clockwork. Hence, in sum, a second major goal of the study was to develop a more differentiated account of the cognitive processes that contribute to the split-attention effect.

### Hypotheses and Design

In the present study, participants were asked to solve a troubleshooting task by comparing two depictions of a mechanical pendulum clock and deciding whether one of the clocks was malfunctioning. After a learning phase in which the participants learned the basic principles of mechanical clockworks, picture pairs were presented either side by side in a classic split screen presentation mode (Split) or via an auto-stereoscopic display as a "vexing-image" in an integrated mode of presentation (Vex). While one of the pictures showed a functioning pendulum clock as the correct reference device, the second picture showed either the same (functioning) clock, or a different, but also functioning clock, or a different malfunctioning clock. The task was two-fold: First, learners had to visually search the picture pairs for differences and to state whether the two clocks were identical. If the two clocks differed, a second phase followed in which the learners had to decide whether or not the target clock was a functioning one.

We expected troubleshooting performance to be superior in the Vex condition for both the search and the decision sub-task. More specifically, visual search should be more accurate and faster in the Vex mode as there is no need to make a saccade when switching between the two external representations. This in turn should free some resources for the subsequent decision phase, again providing an advantage for the Vex mode. Further, we expected task performance to be superior for malfunctioning target clocks in the decision task, because in this case the causal chain of events is disrupted, which in turn should lead to faster and more accurate decisions.

Compared to the Split mode, where the two external representations were presented on two displays standing next to each other, in the Vex mode, the representations were presented on an auto-stereoscopic display. With such a display, participants could easily switch between two representations without shifting their visual focus. Instead, they just had to move their head. First participants, who were trained on the physical characteristics of a mechanical pendulum clock, had to accomplish a troubleshooting task. Second, they were asked to judge whether both clocks function properly. For this to work, we constructed three kinds of clockwork sets, namely, pairs of identical clockworks, and functioning and nonfunctioning pairs of non-identical clockworks. In the visual search sub-task, participants just needed to search for the respective identical and non-identical clockworks.

## Method

### Participants and Design

80 students of the University of Tübingen, Germany participated in the study. They received compensation for their participation and were randomly assigned to one of two cells of the between-subjects factor "presentation mode", which described whether information was presented in the Vex or in the Split mode.

### Materials and Apparatus

For each participant, the materials consisted of a computer-based learning environment that also included the troubleshooting tasks and a set of questionnaires, including one questionnaire for demographic information and a post-test containing transfer questions. Further we measured self-assessed cognitive load with a German adaptation of the NASA-TLX (Hart & Staveland, 1988), participants´ spatial abilities with the Mental Rotation

Test (MRT, Vandenberg & Kuse, 1978), and the Spatial Orientation Task (Hegarty & Waller, 2004). Visual span was measured with the Visual Patterns Test (VPT, Della Sala, Gray, Baddeley, & Wilson, 1997) and verbal span was assessed via the "Zahlen Merken" (digit span) scale from the Wilde Intelligence Test (Jäger & Althoff, 1983).

The computer-based learning environment was three-tiled. It took approximately 50 minutes to complete. First, participants were asked to learn the basic physical principles of a mechanic pendulum clock that were displayed on 7 HTML-pages using static images and short descriptive texts. More specifically, participants had to learn the functionalities of the weight as energy source, the escapement as central time base, and the different gears with the hands for indicating the time. The second part of this learning environment was a comprehension test that assessed participant's knowledge of pendulum clocks with 5 multiple-choice questions. For each question, three answers were displayed of which one was correct. (e.g., "Which statement is true?" (a) The ticking sound of a mechanical pendulum clock is generated by the pendulum. (b) The escapement is causal for the movement of the gears. (c) The weight is the energy source of the mechanical pendulum clock. Finally, the third part of this learning environment was the troubleshooting task. Participants were presented with two stills of a mechanic pendulum clock that were created using blender3D (http://www.blender.org). The two pictures either depicted exactly the same or different clockworks (see Figure 1). The "same" pictures showed clockworks that were exactly the same (including colors and the indicated time). This could be either two functioning clockworks or two malfunctioning clockworks. There were two kinds of "different" picture pairs. The functioning pairs showed different clockworks that both function properly but where one surface feature was different (e.g., the clocks indicated different times). In contrast, the malfunctioning pairs showed one functioning clockwork and one malfunctioning clockwork (e.g., a clockwork with a missing gear). Additionally, we varied the color of the clockworks presented pairwise across participants. Altogether, the troubleshooting task consisted of 40 pairwise clockworks (20 identical and 20 non-identical clockworks pairs). A training phase at the beginning of the troubleshooting task consisted of 8 clockwork pairs. These trials were excluded from further analysis.

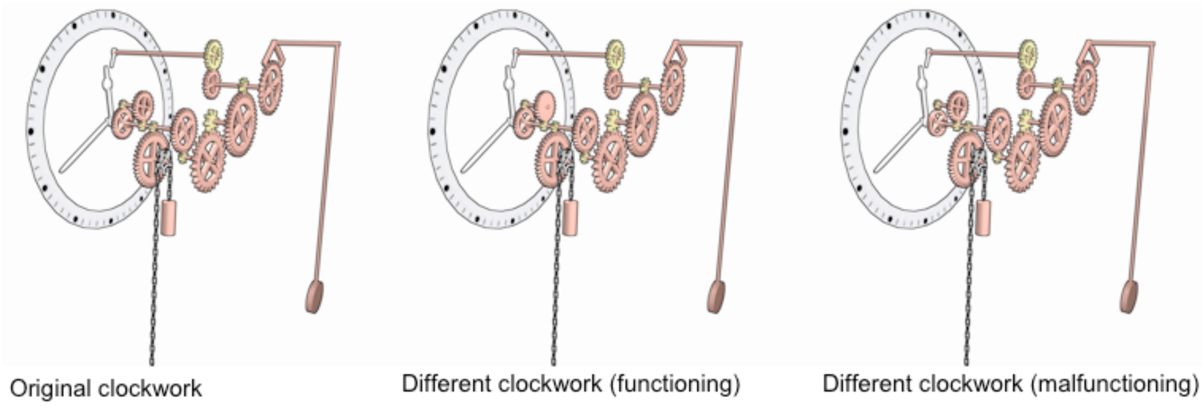

Figure 1. Examples of the stimulus material. In each trial, participants were presented with a combination of an original clockwork with a different clockwork (either functioning with a filled gear or malfunctioning with a gear without cogs).

There were two presentation modes: In the Split mode, the pictures were presented side by side on two displays standing next to each other. In contrast, in the Vex mode we used an auto-stereoscopic display that presented the two pictures such that participant were able to alternate between them simply by shifting their head. In this condition it is not necessary to shift the visual focus (see Figure 2; Huff & Schwan, subm.).

The experimental procedures were controlled by a PC and programmed using custom software programmed with python (http://www.python.org/). In both presentation modes, the first part of the learning environment was presented on a 24" display. The third part of the learning environment (troubleshooting task) was either presented on two 24" displays that were placed next to each other (Split mode) or on a single auto-stereoscopic display (Vex mode). In all presentation modes, the visual angles of the stills were comparable.

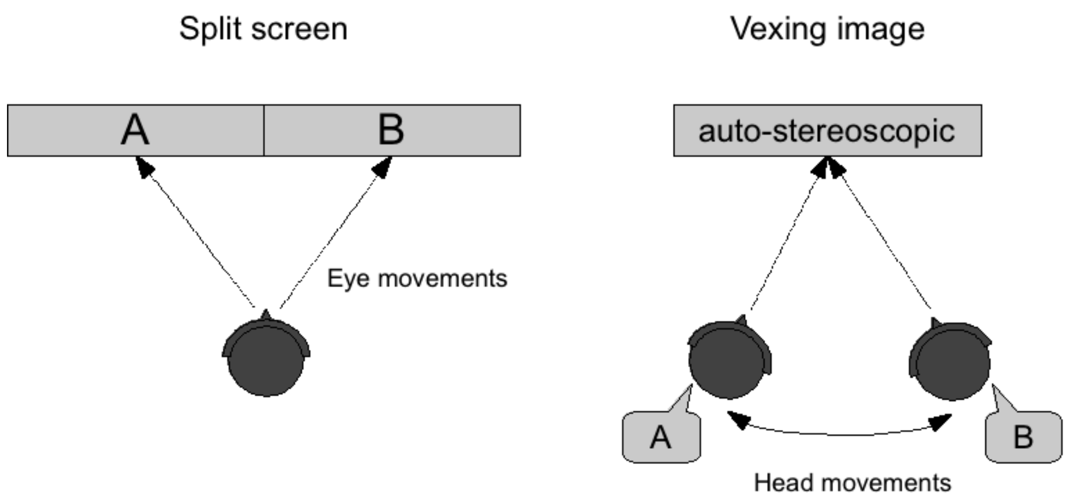

Figure 2. Split screen (left) and vexing image (right) presentation modes both presenting two pictorial representations ("A" and "B"). Whereas participants had to shift their visual focus in the Split mode, participants in the Vex mode just needed to move their head in order to see the second representation.

### Procedure

All participants were tested individually and received instructions via the computer monitor. At the beginning, participants completed the first two parts of the learning environment (learning phase and comprehension test). In the third part (troubleshooting task), participants were presented with 48 sets of clockwork pairs. Learners' task was two-fold. After the stills appeared on the screen, the participant had to visually compare the two clockworks and to answer the question whether both clockworks were identical by pressing the key "J" for "Yes" and "N" for "No, the clockworks are different.". Second, if the participant correctly detected that the two clockworks were different she/he had to decide whether both clockworks function properly or if one clockwork was defective. Again, the participant had to press the corresponding key in order to answer the question "Do both clockworks function properly?" ("J" for "Yes" and "N" for "No"). Half of the 40 experimental sets contained functioning and the other half non-functioning clockworks (see Table 1); the serial order and the left/right position of the original clockwork were chosen at random. The first 8 trials were for exercise purposes and were excluded from analysis.

Finally, the post-test, the mental-rotation test, the spatial orientation test, the visual patterns test, the test for the verbal memory span, and the cognitive load assessment questionnaire were filled out by the participants.

## Results

### Pre-Test

After the first part of the learning environment in which the participants worked through a description of the basic principles of clockworks, they received five multiple-choice questions about pendulum clocks in order to check their knowledge level. Each question had three possible responses of which one was true. Each correctly answered question was scored with one point. A total number of 5 points was possible. Three participants who obtained less than 3 points in this test were excluded from further analysis because they did not learn the relevant principles of a mechanical pendulum clock.

### Troubleshooting task

The troubleshooting task consisted of two components. In the comparison task, the participants had to decide whether the two depicted clockworks were identical or not. If the participants had detected a difference between the two clockworks, they were given a second task. In this task, they were required to decide whether the target clockwork was a functioning or a malfunctioning one.

#### Comparison task

Comparison task performance was measured with the sensitivity measure from the signal detection theory (Green & Swets, 1966) and search times to correctly identified sets of two original clockworks.
Mean hit rate (correct answers to target items – the clockworks were identical) and to false alarm rates (wrong answers to differing picture pairs – although the clockworks were different, participants answered "yes", both

for functioning and malfunctioning differing target clocks) were calculated for each participant in both conditions (Split vs. Vex). Next, two corresponding A' measures (Pollack & Norman, 1964) as sensitivity measure were calculated and submitted to a 2 (presentation mode; between-subjects) x 2 (target clock functionality; within-subjects) mixed factor ANOVA (see Table 1). Participants' performance was significantly influenced by both presentation mode and target clock functionality as the significant interaction of these factors showed, $F$ (1, 75) = 15.88, $p < .001$, $\eta_p^2 = .17$. A Bonferroni correction with $\alpha = 0.008$ was used to correct for the 6 multiple comparisons in this experiment. Performance in the "vexing image" mode was not affected by the kind of target clock type (functioning or malfunctioning, $p = .996$). In contrast, in the split screen mode, search performance was higher for malfunctioning target clocks than for functioning target clocks ($p < .001$). The main effect for "presentation mode" indicates higher performance in the Vex mode and the main effect for "target clock functionality" higher performance with malfunctioning clockworks, $F$ (1, 75) = 22.13, $p < .001$, $\eta_p^2 = .22$ and $F$ (1, 75) = 15.52, $p < .001$, $\eta_p^2 = .17$, respectively.

Table 1: Sensitivity measures of the comparison task (Question 1). Arithmetic means and standard deviations in parentheses.

| Presentation mode | Clock functionality | |
|---|---|---|
| | Functioning | Malfunctioning |
| Vexing image | .79 (.07) | .79 (.09) |
| Split screen | .69 (.06) | .74 (.05) |

The time from stimulus onset until the decision regarding the similarity of the clockworks was calculated for each participant in each condition (see Table 2). Data as presented in Table 2 were submitted to a mixed-factor ANOVA including the within-subject factor "clockwork type" (search times for identical, non-identical functional, and non-identical malfunctioning clockworks) and the between-subjects factor "presentation mode" (Vex, Split). Participants' search times were faster in the Vex mode as the main effect for presentation mode shows, $F$ (1, 68) = 38.03, $p < .001$, $\eta_p^2 = .36$. Further, clockwork type influenced search times too, $F$ (2, 136) = 6.14, $p = .003$, $\eta_p^2 = .08$. A Bonferroni correction with $\alpha = 0.024$ was used to correct for the 2 multiple comparisons in this experiment. Whereas there was no difference between the two non-identical clockwork types functioning ($M$ = 15.71 sec., collapsed over "presentation mode") and malfunctioning ($M$ = 15.95 sec., collapsed over "presentation mode"), $t < 1$, $p = .62$, search times for non-identical clockworks were faster than search times for identical clockworks ($M$ = 17.19 sec., collapsed over "presentation mode"), $t$s > 2.62, $p$s < .011. However, the interaction of clockwork type and presentation mode did not reach the level of significance, $F$ (2, 136) = 2.23, $p = .112$, $\eta_p^2 = .03$.

Table 2: Search times of the comparison task in seconds (Question 1). Arithmetic means and standard deviations in parentheses.

| Presentation mode | Clockwork type | | |
|---|---|---|---|
| | Identical | Functioning | Malfunctioning |
| Vexing image | 11.52 (6.08) | 10.83 (5.56) | 11.27 (7.79) |
| Split screen | 21.97 (7.01) | 19.81 (6.85) | 19.90 (6.55) |
| Mean (collapsed over "presentation mode") | 17.19 (8.40) | 15.71 (7.71) | 15.95 (8.31) |

## Decision task

If participants were presented with a pair of non-identical clockworks (with the target clock either functioning or malfunctioning) and they had correctly classified them as "not identical" in the comparison task, they were asked to state whether both clocks function properly. Again, we analyzed the data with the signal detection theory measure, sensitivity A', and reaction times for both correctly identified pairs of functioning clockworks and for correctly identified malfunctioning clockworks. Note, this task uses a two alternative forced choice paradigm. That is, the sensitivity measure as plotted in Table 3 reflects the participants' ability to distinguish between functioning and malfunctioning clockworks in the different presentation modes. Hence, it is not necessary to include this factor in the analysis.

Data as displayed in Table 3 were submitted to a t-test with the independent variable presentation mode for the sensitivity and to a mixed factor ANOVA with the between-subjects factor "presentation mode" and the within-subjects-factor “functionality” for the search times. Neither the sensitivity measure A', *t* (54.40) = 1.52, *p* = .134, nor the search times were influenced by the presentation mode *F*s < 2.65, *p*s > .11.

Taken together, both sensitivity and search time indicate that participants in the Vex mode outperformed participants in the Split mode. The superiority of the Vex condition is based on higher performances in the comparison task. In contrast, performance measures in the decision task were comparable across presentation modes.

Table 3: Results of the identification task (Question 2). Arithmetic means and standard deviations in parentheses.

| Presentation mode | Sensitivity (A') | Search time (seconds) | |
|---|---|---|---|
| | | Functioning clockworks | Malfunctioning clockworks |
| Vexing image | .78 (.07) | 4.99 (4.24) | 5.77 (7.82) |
| Split screen | .74 (.14) | 4.99 (4.34) | 6.64 (5.00) |

### Transfer test

In the final phase of the experiment, participants were asked to answer 6 multiple-choice questions that each described one malfunctioning clockwork (e.g., “The hour hand stands still, all other hands move correctly.”). Participants were presented with 3 alternative solutions (e.g., “The axis for the hour hand transmission is missing.”) of which one was true. Each correct answered question was coded with 1; maximum score was 6. Mean performance was 4.43 (*SD* = 1.14), there were no significant differences between presentation modes, *t* (74.90) < 1, *p* = .591.

### Cognitive load and learner related factors

Cognitive load was assessed with a German adaptation of the NASA-TLX (Hart & Staveland, 1988). The six questions were analyzed separately with a t-test including the independent variable presentation mode. Questions 1 (mental activity), 3 (time pressure), and 4 (effort) showed no significant differences between presentation modes (*t*s < 1.58, *p*s >.12). However, compared to the Split presentation mode, participants in the Vex mode reported a higher amount of physical activity (Question 2), *t*(64.45) = 2.51, *p* = .01, were more confident in scaling their own performance (Question 5), *t*(65.40) = 3.39, *p* = .001, and were less frustrated (Question 6), *t*(71.92) = -3.12, *p* = .003.

The experimental groups were checked for a-priori differences on the two learner-related factors spatial abilities (assessed with MRT and SO), visual memory span (VPT), and verbal memory span (assessed with ZM). We conducted a t-test for each of the tests separately with the independent variable presentation mode (Vex vs. Split presentation mode). There were no significant differences between groups with regard to spatial ability. Neither MRT, *t*(74.68) < 1, *p* = .996, nor VPT, *t* (74.99) = 1.31, *p* = .19, and SO, *t* (66.58) < 1, *p* = .874 reached level of significance. The same was true for working memory span, *t*(74.74) = 1.08, *p* = .28.

## Discussion

Although the spatial contiguity principle is well established in research on multimedia learning (Ginns, 2006; Mayer, 2001, 2006), few attempts have been made to extend the principle from picture-text combinations to picture-picture combinations. Hence, the present study attempted to develop an integrated format for the presentation of picture pairs in the context of a troubleshooting task and to compare it experimentally to a non-integrated split-screen presentation. Also, the troubleshooting task was decomposed into a two distinct phases, namely a “comparative visual search” phase (Hardiess et al., 2008), and a “decision by mental animation” phase.

We observed troubleshooting performance to be superior with a new display technology that allows for the integrated presentation of two pictures, compared to a traditional split-screen condition. The integrated presentation was realized by a vexing image which was presented via an auto-stereoscopic display. Here, it is not necessary to change the location of the visual focus in order to switch between the pictures. Instead, learners just had to move their head (see Figure 2). Hence, processes of reorientation were reduced to a minimum. In contrast to the split screen condition, visually comparing the two clockworks in the vexing image condition was both twice as fast and significantly more accurate. This finding suggests that error-prone processes of reorientation are one major reason for lower performance scores in learning environments with low spatial contiguity. In addition, participants were more confident in scaling their own performance and were less frustrated. If the split screen presentation mode can be characterized by frequent shifts of the visual focus and – as a consequence – frequent re-orientation processes, we can conclude that the split attention effect is reduced in the vexing image mode, which seems to be an adequate presentation mode for pairs of pictorial representations.

An interesting finding was that the functioning or malfunctioning of the non-identical clockworks did influence troubleshooting performance in the Split mode but not in the Vex mode. Because viewers in the vexing image mode could keep their visual focus at the critical position while switching between the representations, one can assume that the comparison task can be solved primarily by means of perceptual pattern matching. In contrast, in the Split mode participants cannot rely on perceptual information alone. Switching between representations requires also memory based processing. Participants have to encode parts of one representation and compare this mental representation with the corresponding part of the second representation. Such memory-based processes might involve mental animating of the static clockworks (Hegarty et al., 2003). A central part of mental animation as described by Hegarty et al. (2003) is the identification of the causal chain of events. Learners have to identify the energy source and the transmitting gears. This causal chain is disrupted in malfunctioning clockworks. As participants were instructed in the mechanical principles of pendulum clocks at the beginning of the experiment, this might have helped them during troubleshooting.

Surprisingly, we observed all these effects in the first phase when participants were asked to visually search for differences between the clockworks. Originally, we hypothesized that such processes take place in the decision phase and not – as observed in this study - during the visual search phase. One reason for this might be that participants intermixed the tasks of comparing the clocks and deciding whether the clocks work properly. If this is true, the decision about the proper functioning of the clockworks might have been finished before the decision task began and participants used the decision phase just to verify their decision. For a clearer distinction between those two phases, measures of process related variables such as gaze behavior could be employed. Further research should include eye gaze as dependent measure in order to gain deeper insights in the cognitive processing of separated information.

Finally, we measured participants transfer knowledge in a verbal-based transfer test. As there was no need for costly re-orientation processes in the Vex mode, we hypothesized that participants should be able to encode a more elaborate and more precise mental representation of the mechanical clockwork. As a consequence, compared to participants in the Split mode, transfer test performance should be higher. However, transfer test performance was comparable across the two presentation modes. Faster search times in the Vex mode indicate that learners did not use the free mental resources to encode an elaborated mental model. Instead, they used the free capacity to speed up their responses.

## Conclusions

In conclusion, we were able to show that the process of troubleshooting as employed in this study is highly dependant on visual search processes. Shifting the visual focus frequently involves costly processes of re-orientation. The subsequent decision, whether or not the identified difference between two mechanical devices is critical for its proper functioning, is independent of the presentation mode. Solving this task does not require any shifts of visual attention. Instead, learners can solve it by mentally animating both clockworks in a row. They are finished if they find an error or if they successfully animated both clockworks. An integrated design not only reduces the number of shifts of visual focus but also leads to lower frustration scores and higher confidence ratings. Hence, multimedia design reducing costly re-orientation processes is beneficial for the troubleshooting task as a whole. This finding has also consequences for our understanding of multimedia learning. Whereas previous research focused mainly on the combination of pictorial and verbal information, this study showed that common principles of multimedia learning also apply to purely pictorial material. Finally, this study also demonstrated that new display technology is helpful in designing new kinds of learning environments and, in turn, in gaining new insights in cognitive processes involved in learning from multiple external representations.

**Abstract:** The laboratory course is an inferential curriculum designed to foster science inquiry ability in science education. However, in the universities of Taiwan, laboratory courses often last only a limited time and explore only a single topic of inquiry. Students' individual ideas and experiences are not well represented in the group inquiry process. Therefore, this study attempts to provide an organizing tool on PDAs to help student groups regulate their inquiry processes and engage in reflective inquiry activities.By gathering data from 56 students (17 groups) participating in the laboratory course, this study utilizes handheld devices as an observational tool for peer interactions in collaborative inquiry activities. A total of 360 minutes of activity log was analyzed for details of peer interaction in order to understand how handheld devices can influence group regulation when students are provided with group regulation functions on PDAs. Students demonstrated six main types of interaction when formulating group inquiry plans via PDAs. This study makes distinction between four patterns of cooperative PDA use. Such distinction could assist teachers and system designers in facilitating group activities by avoiding unfavorable interaction patterns. The results show that unperceived conflicts concealed in individual devices impede peer interaction. This finding suggests that designers of learning environments should consider the importance of reinforcement mechanisms applied in Mobile Computer Supported Collaborative Learning (MCSCL) to maintain shared understanding.

**Keywords:** Laboratory courses, group regulation, handheld devices, peer interaction analysis

## 1. Introduction

The laboratory course follows an inferential curriculum designed to foster science inquiry ability in science education (Hinrichsen & Jarrett, 1999; Hollingworth & McLoughlin, 2001). Students in laboratory courses learn how to pursue scientific knowledge through inquiry and experience the process of constructing such knowledge (Edelson, Gordin, & Pea, 1999). Within the inquiry process, students formulate testable hypotheses, measure variables, and design experiments. However, in current practice, the design and implementation of laboratory courses is based on an instructional rather than hands-on approach (Mayer 2004; Kirschner, Sweller , & Clark, 2006), i.e., students complete experiments step by step according to the textbook or an instructional manual provided by the teacher. Such an approach deprives students of the opportunity to experiencethe reflective inquiry process and to learn how to acquire knowledge through that inquiry process in laboratory courses and settings.

Collaborative inquiry has recently come to be considered an effective mode of reflective scientific inquiry. Students can actively develop problem solving and knowledge construction activities during peer discussion and interaction (Blumenfeld, Marx, Soloway, & Krajcik, 1996; Littleton & Hakkinen, 1999). Peer discussion and interaction can facilitate social construction of knowledge (Jonassen, 1994) that cannot easily be attained through individual inquiry learning. However, laboratory courses often last onlya limited amount of time and explore only a single inquiry topic. For example, laboratorycourses in the universities of Taiwan consist only of weekly 3-hour classes covering a single topic. Students' individual ideas and experiences are not well represented in the group inquiry process due to time limitations. Thus, students may fail to get the opportunity to exchange ideas and experiences with peers. Furthermore, previous studies have confirmed that students still have difficulty formulating testable hypotheses, designing conclusive experiments, and compiling compatible data (Manlove, Lazonder, & De Jong, 2006). In order to achieve effective reflective scientific inquiry, student groups need regulative support in collaboratively forming inquiry strategies. Therefore, it is necessary for laboratory courses to provide an organizing tool to help student groups regulate their inquiry processes and conduct reflective inquiry activities.

Prior to this study, researchers (Manlove, Lazonder, & De Jong, 2006) had developed some regulative learning tools on handhelds designed to help students with collaborative development of inquiry strategies; handhelds had become increasingly affordable in classrooms over the course of recent years (Roschelle, 2003; Zurita & Nussbaum, 2004; Liu et al., 2006; Fry & Hin, 2006; Liu & Kao, 2007), and increased student participation and collaboration in classrooms had been experimentally facilitated by means of handheld devices. However, although students could use handhelds as regulative tools in their pursuit of knowledge, they had difficulty generating a complete group experience in the limited time available. They could not easily exchange experiences with peers due to lack of individual inquiry experience. Therefore,this study designed an inquiry learning activity which integrated in-class discussion of inquiry planning using PDAs with pre-class regulation of inquiry planing. Students could organize individual exploration plans on the web to build individual inquiry experience in advance. At the laboratory, handhelds were adopted as a group regulation tool to help students organize and discuss their group inquiry plans based on their individual inquiry plans. This study attempts to bridge the gap between individual and collaborative construction of knowledge in order to promote efficiency and effectiveness in science laboratory courses.

This study attempts to understand how handheld devices can influence group regulation when students are provided with group regulation functions on PDAs. Recent research methodologies in Computer Supported Collaborative Learning (CSCL) have put significant emphasis on the micro analysis of peer interaction, through which improvement of learning may take place (Stahl, Koschmann, & Suthers, 2006). This study not only takes into consideration the performance gain resulting from technologies but also attempts to uncover the reason why the technology improves the interactions that lead to meaningful learning (Liu et al, in press). Accordingly, this study uses micro analysis to explore the interaction demonstrated by student groups using the group regulation functions of PDAs. Furthermore, to provide a comprehensive understanding of how the PDAs and regulation functions influence group inquiry achievement in laboratory courses, this study also analyzes the relationship between group inquiry achievement and interaction patterns as revealed by micro analysis. By gathering and analyzing the system usage logs of 56 college students in a laboratory course in National Central University, this study attempts to answer the following research questions based on peer interaction analysis:

- How do the students in a group interact with each other through PDAs with group regulation functions when using pre-regulated inquiry plans to form a group plan?
- What kind of peer interaction patterns can be observed when students develop regulative strategies using PDAs that have group regulation functions?
- How do the peer interaction patterns facilitated by the PDAs influence group inquiry achievement?

## 2. Group inquiry planning via handhelds

The laboratory course involved in this study included a pre-class inquiry regulation activity and an in-class collaborative inquiry regulation activity. The pre-class inquiry activity required students to build individual inquiry plans based on a given science topic. Students were thereby able to learn the procedure and objectives of an inquiry activity. In the in-class inquiry regulation activity, students were required to work with their partners to generate a group plan based on the pre-generated plans. This study developed a pre-class inquiry regulation tool on the web. Using this tool, students could make an inquiry plan. An inquiry plan consists of six main items: (1) purposes of the inquiry, (2) related theories of the inquiry, (3) instruments, (4) hypothesis, (5) measurement variables, and (6) procedures.

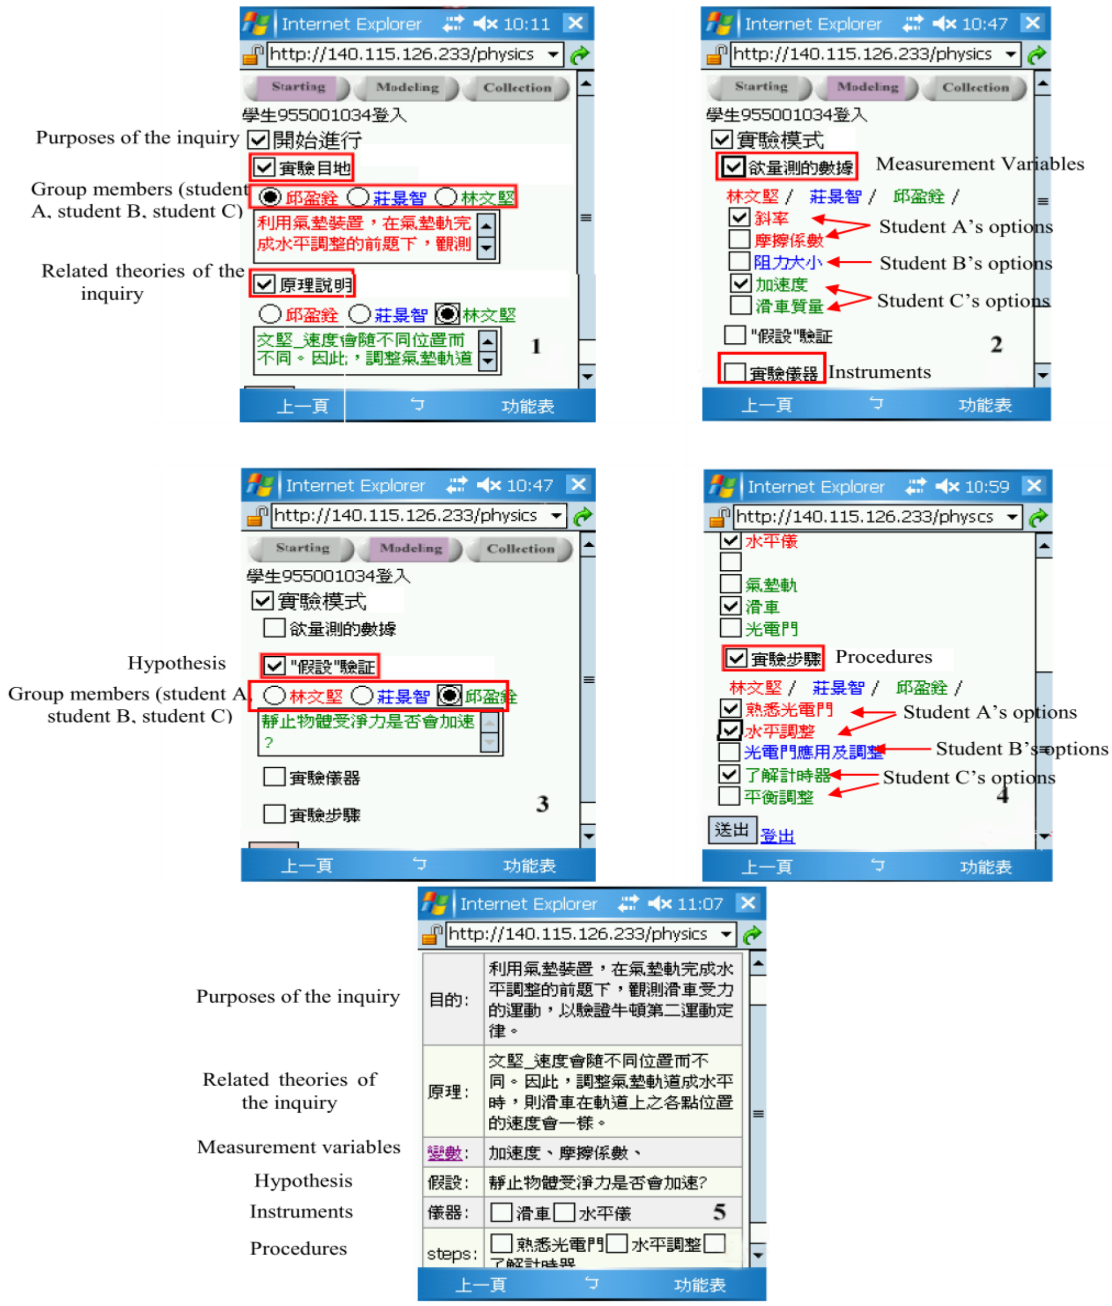

Figure 1. The regulative tool for group inquiry planning on PDAs

In the laboratory, the teacher would outline the purposes of inquiry, and then student groups would start to regulate their group inquiry plan, which would contain the same six main items found in the individual inquiry plans. In order to formulate testable hypotheses and design conclusive experiments, students were asked to collaboratively revise and discuss the individual inquiry plans they had generated on the course website to reach a unified group plan. The handhelds were used as an organizing tool to combine students' individual plans into a group inquiry plan. Using the PDAs, students could review their own inquiry plans and compare them with those developed by their partners while deciding on a unified group plan. An application on the PDAs could generate a summary of the group inquiry plan based on the decisions the students made in class. Students could then proceed to the inquiry activity and gather data based on the unified group plan. This whole process is interactive, because students were able to modify the group plan during the inquiry if necessary. After collecting all the data necessitated by the group inquiry plan, students would discuss and develop a final report according to the inquiry plan summary generated by the PDAs. Finally, the teacher would evaluate the inquiry achievement of the student groups based on the final reports.

This study develops a regulative tool for group inquiry planning on PDAs intended to support group members in comparing, reviewing, and generating unified inquiry plans (Fig. 1). The regulation tool enables students to use PDAs to refer to each others' pre-designed individual inquiry plans. During class activities, the individual inquiry plans students made before class became options that all students could choose from when selecting the six main items for their group inquiry plans. Students could review and check the provided options for the main items on the PDAs. In order to generate a summary of an inquiry, firstly students needed to decide on the purposes and related theories of the inquiry. Individuals' plans regarding the above main items were shown as options in different colors (Step 1 in fig. 1). Students could distinguish between and compare the different options provided by the group members by color. Secondly, students needed to decide which of the measurement variables proposed by group members should be included in the group inquiry plan Students were able to do this using the PDAs by checking boxes next to the variables (Step 2 in fig. 1). Thirdly, students needed to select a hypothesis for the inquiry from among the hypotheses proposed by the group members (Step 3 in fig. 1). Fourthly, students needed to decide on an executable procedure for the inquiry from the list of procedures proposed by the group members (Step 4 in fig. 1). After students had finished the group regulation activities, the tool would generate a summary of their inquiry plan on the PDAs (Step 5 in fig. 1). These interactions were recorded on the PDAs along with details of the peer interactions that took place during the group regulation and inquiry activity. Students' activities on the PDAs were archived for later analysis of peer interaction so that the effect of the PDAs' group regulation tool on learning experience in laboratory courses could be confirmed.

## 3. Method

The primary purpose of this study is to explore the effects of handheld devices with the above mentioned regulation functions by analyzing the peer interactions involved in collaborative inquiry activities. The participants were 56 freshman students enrolled in a physics laboratory course at National Central University (Taiwan). Students were divided into 17 groups, whose size ranged from three to four students. This study analyzes student interactions over the course of two 3-hour sessions of a weekly laboratory class, during which they performed experiments focused on Newton's second law of motion and the law of conservation of angular momentum. Students were able to make their inquiry plans on the course website provided by the study. During the laboratory class, students modified their inquiry plans, referred to options presented in other group members' inquiry plans, and regulated a unified group plan using the PDAs provided by this study. All of the students' interactions were recorded by the PDAs while the students regulated their group inquiry plan. After the class, the teacher evaluated the inquiry reports.

Figure 2 shows the collaborative inquiry behavior found in two threads as recorded by the PDAs. For instance, if student 1 (s1) checks item 1, this behavior is denoted as s1 (1). Likewise, if student 1 checks the second option of item 3, this is denoted as s1 (3_2). All regulation activities of individuals, such as modifying options, choosing options presented by other group members, and reviewing/comparing options provided by group members, were logged in the PDAs. The activity log helps demonstrate the students' regulation behaviors and development of regulative strategies as aided by PDA-based tools. This study analyzes peer interactions to determine what peer interaction patterns students can engage in through PDAs and to confirm the influence of the regulation functions provided by PDAs on the effectiveness of inquiry activities.

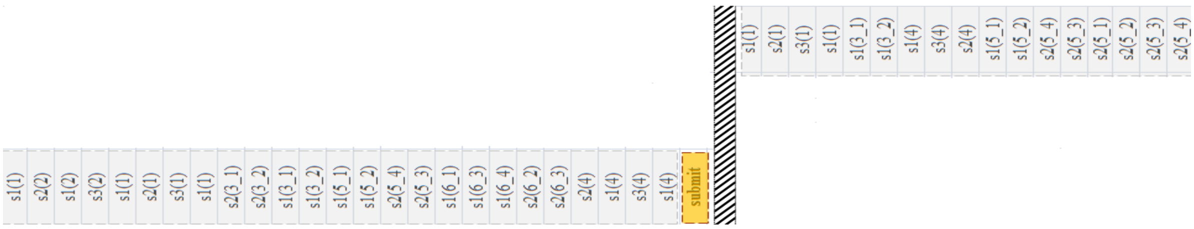

Figure 2. The activity log

As students performed collaborative regulation activities in the laboratory, data were collected and recorded by the PDAs. This study analyzes a total of 360 minutes of activity log. All analyses of peer interactions were performed by two independent researchers (coders). The analyses included the identification of peer interaction activities, e.g. comparison, conflict, and resolution, as well as the classification of peer interaction patterns. The inter-coder reliability (agreement) for each analysis was at least 85%, indicating that the analysis is sufficiently reliable. Researchers resolved disagreements in analysis and categorization through discussion.

## 4. Results and discussion

The results of the analysis are categorized to address the following questions. (1) What types of peer interaction can PDAs facilitate in order to help students to regulate their plans? (2) What general patterns of peer interactions can be observed in students using PDAs? (3) How do the general patterns of peer interaction affect student achievement in the context of the inquiry activities required by the laboratory course?

### Peer interactions through PDAs

The activity logs were analyzed in detail to explore the peer interactions that occur during group regulation activity. Upon analysis of the activity log, six main types of interaction were identified within the group regulation activities. These types are as follows:

- Comparison: Students often compared their own individual inquiry plans with those of others by switching the options of some items. In general, they performed such activities in a short period of time in order to understand the inquiry plans of others.
- Perceived conflict (change of options): Such interaction occurred when one student chose a different option from that which was chosen by another group member. This behavior indicates that the student has noticed a difference of opinion between himself/herself and others regarding the group inquiry plan. For instance, if student A chooses the hypothesis proposed by student B as the hypothesis of the group inquiry plan, student C might modify the group inquiry plan by choosing another hypothesis proposed by himself/herself, creating a perceived conflict between student A and student C.
- Perceived agreement: Such an interaction occurs when a student reviews the group plan and agrees on the group inquiry plan as proposed by others.
- Resolution of conflict: While regulating a group plan, student A might switch to the option that student B chose after detecting the conflict between B and himself/herself (perceived conflict) regarding that item in the plan. Students A and B would then have reached a resolution regarding this item.
- Unperceived conflict: The PDAs are personal devices that allow individuals to modify inquiry plans. There generally exists a time lag between personal modification of the application server and acknowledgment of the modification on other members' PDAs. For example, one student might modify the group inquiry plan with his/her PDA and thus cause a conflict with the group plan proposed by others. If other students cannot detect the conflict before this inquiry plan is sent off to others, this is unperceived conflict. Since the inquiry plans were concealed in the PDAs, other students sometimes could not detect the conflicts between themselves regarding the inquiry plan.

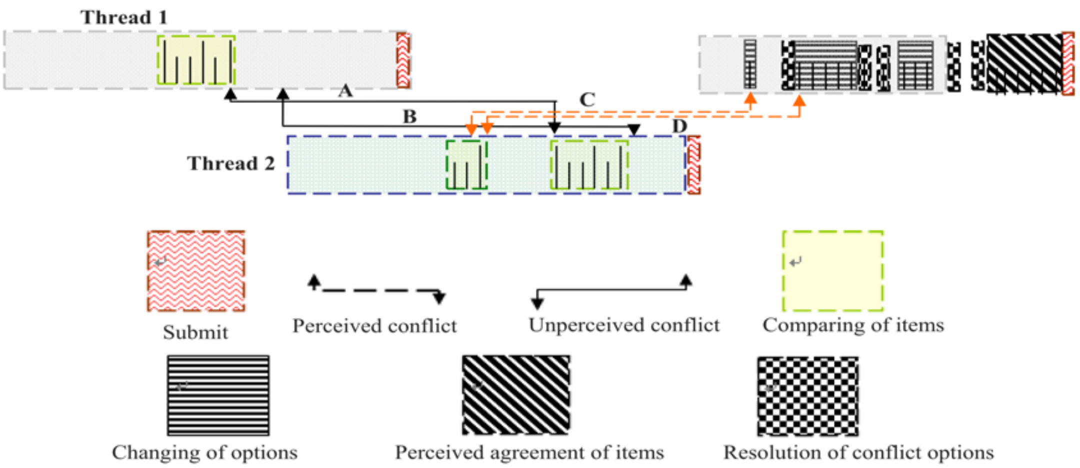

Figure 3. Group dynamic chart

In order to depict peer interaction explicitly, this study codifies and represents students' interactions based on the aforementioned peer interaction events in a group dynamic chart (Fig. 3). Each bar in a row represents a thread of student regulation activity in the PDA. Each dotted arrow from one thread to another in the chart denotes a perceived conflict. For example, Fig. 3 shows two threads that proceeded concurrently after the student in thread 2 submitted his plan. The other student in thread 1 checked a different option for an item and noticed the conflict between his inquiry plan and those of others (e.g.: line C and line D). Therefore, there is a dotted arrow between the two threads to represent the perceived conflict. In addition, each thick arrow between threads in the chart denotes an unperceived conflict. For instance, the arrow between threads 1 and 2 in the first chart of Fig. 3 reveals that a student had not noticed another student's inquiry plan and did not perceive the difference between that plan and his/her own (e.g.: line A and line B), because the student in thread 1 had not submitted his/her plan. A rectangle with vertical lines represents a student comparing his/her plan with those of others. Each long vertical line indicates a student checking his/her own plan, while a short line indicates him/her checking the plans of others. A rectangle with a horizontal line shadow denotes conflict and modification. A rectangle with a diagonal line shadow denotes conflict resolution. Perceived agreement is indicated by a rectangle with a dotted shadow. The group dynamic chart of each group was analyzed to determine what interaction patterns occurred during the collaborative inquiry activities.

Analysis of the group dynamic chart reflects the frequency of different peer interaction activities. Table 1 lists the frequency of each type of peer interaction. Table 1 reveals that PDAs helped students obtain a global view of each individual's inquiry plan. Students frequently performed comparison activities using the PDAs. In total, students performed such comparisons on 152 items in the different individual inquiry plans. In addition, the PDAs also helped students to express agreement with their group members. While comparing different options, students showed perceived agreement in 94 items of the group inquiry plans. In addition, students detected perceived conflicts in 75 items and chose 169 options which differed from those chosen by their peers. Of the changes of option selection in the group inquiry plans, 65 options were ultimately determined to be consistent among group members. Thus, there were still many conflicts that remained unresolved. Interestingly, unperceived conflicts occurred with high frequency. The log generated by the PDAs shows that there were conflicts between members over 79 items. This indicates that conflicts among students are often concealed when PDAs are used to mediate the formation of group plans. When using such a mechanism, students still have difficulties solving conflicts when attempting to create a unified group plan.

Table 1. Frequency of peer interaction in collaborative inquiry regulation activity

| Interaction types | Frequency |
|---|---|
| Comparing of items | 152 items |
| Perceived agreement | 94 item |
| Perceived conflict (changing of options) | 75 item (169 options) |
| Resolution of conflict | 65 (options) |
| Unperceived conflict | 79 items |

## Peer interaction patterns through PDAs

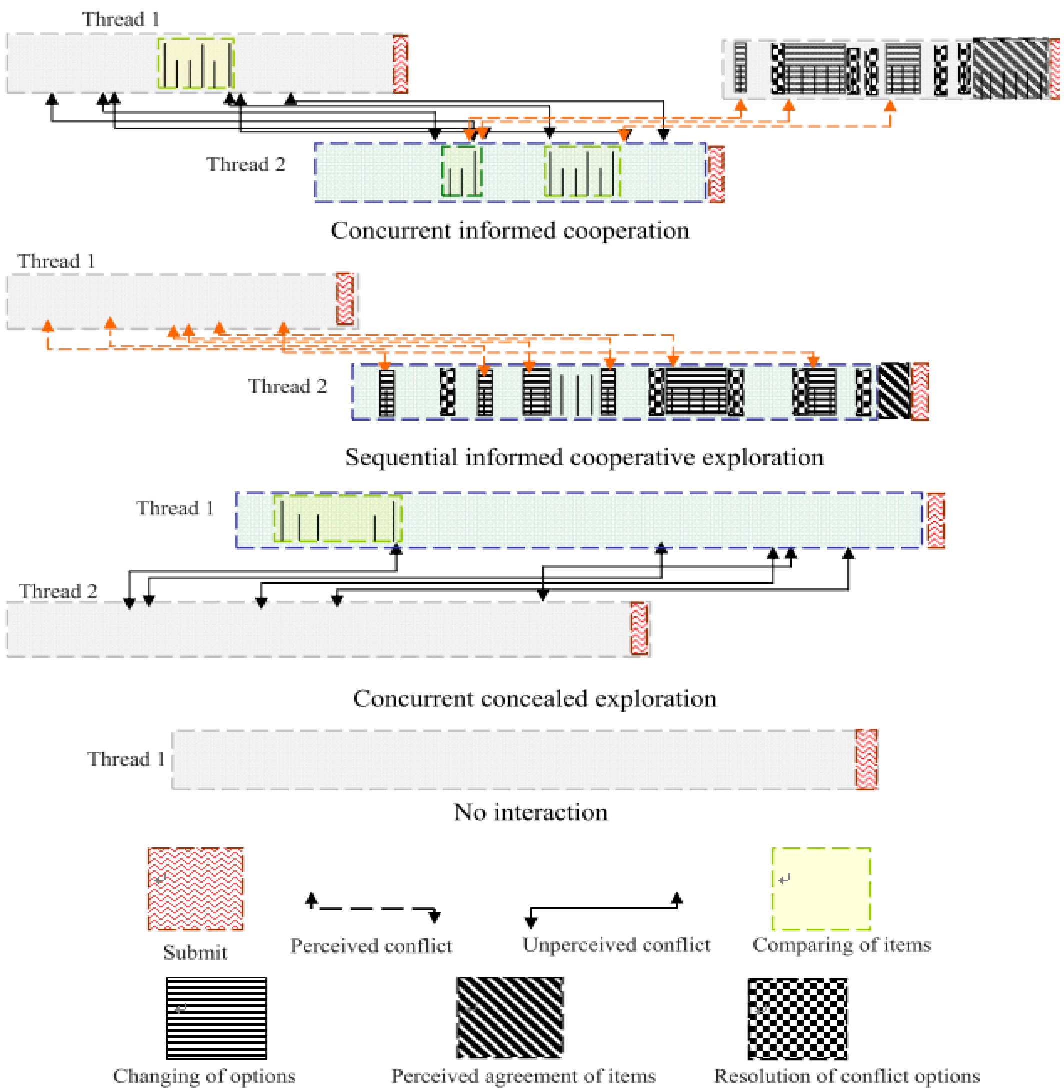

Figure 4. The group dynamic chart of four peer interaction patterns

Analysis of the group dynamic charts identifies four distinct interaction patterns (Fig. 4) occurring during the collaborative inquiry activities observed in this study. These patterns are as follows:

- *Concurrent informed cooperation*: This pattern takes the form of two concurrent threads and occurs when students begin by working independently and then jointly revise each other's plans to form the final plan. At the beginning of this pattern of interaction, individuals do not inform each other of the work they are doing, but instead each organizes a group plan individually. This behavior allows for frequent occurrences of unperceived conflicts at the beginning due to the concurrent nature of the participation. At the later stage of the pattern, students revise their group plans based on the individuals' results. Perceived conflicts are detected and resolved only at this stage. Therefore, the main characteristic of this pattern is the initially independent organization of group plans, upon which students then jointly base further revision of their group plan.

- *Sequential informed cooperation:* This interaction pattern occurs when students organize their plans sequentially, i.e., one student initiates a new thread and modifies the group plan, and then another student further revises the group plan based on these modifications. Unlike concurrent informed cooperation, this pattern only allows for perceived conflicts. There are no unperceived conflicts between the two threads.
- *Concurrent concealed cooperation:* Students following this pattern organize their plans concurrently and independently. They do not notice the difference between their own inquiry plans and those of others. The conflicts between their inquiry plans are concealed, and thus many unperceived conflicts occur in this pattern. Consequently, students who exhibited this pattern did not demonstrate any conflict resolution.
- *No interaction:* This pattern occurs when students do not interact with each other to make their group plans.

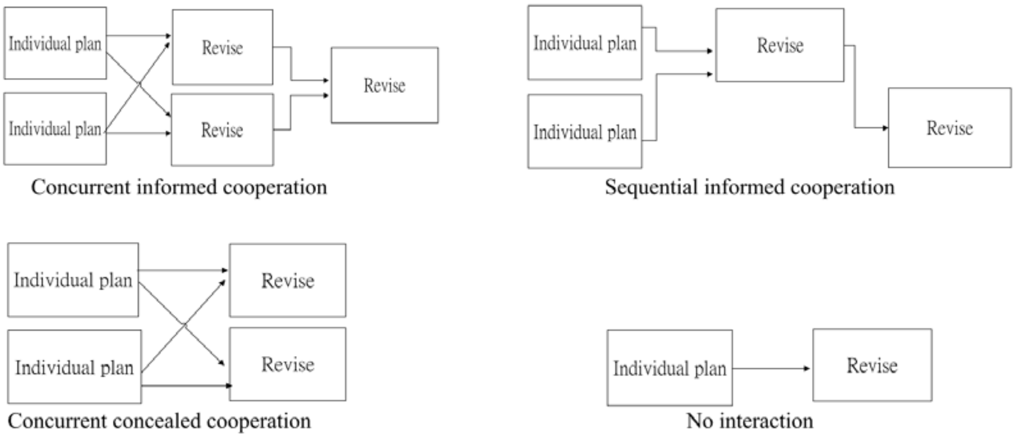

Figure 5. Peer cooperation patterns of the four interaction patterns

The four interaction patterns defined by this study demonstrate how students work together to organize their group plans using PDAs. Figure 5 presents the four peer cooperation patterns in a comprehensive manner. In concurrent informed cooperation, students generated group plans based on all individual inquiry plans and then revised the plan collaboratively. Students exhibiting sequential informed cooperation generated a group inquiry plan and then each revised the plan one after another. Less productively, using the concurrent concealed cooperation pattern, some students generated group plans based only on their individual plans without any cooperation. Even more disconcertingly, some students did not interact with each other at all when formatting their group plans, in accordance with the no interaction pattern.

This study categorizes the interaction patterns of each group based on the group dynamic charts. The distribution of interaction patterns is represented in Table 2. Only five groups demonstrated concurrent informed cooperation while thirteen groups exhibited the pattern of sequential informed cooperation. Surprisingly, there were ten groups working in the pattern of concurrent concealed cooperation and six groups working in the no interaction pattern; that is, students in these groups worked independently even when the regulation tools of the PDAs were provided to facilitate group regulation of plans.

Table 2. Group achievement distribution among different interaction patterns and interaction behaviors mediated by PDAs

| Group | Type of cooperation | Planning time | Score | Comparison of items | Change of options | Unperceived conflict | Perceived agreement of items | Resolution of conflict options | Resolution ratio |
|---|---|---|---|---|---|---|---|---|---|
| 6 | Concurrent informed cooperation | 00:22:43 | A+ | 5 | 7 | 4 | 6 | 3 | 43% |
| 1 | | 00:25:36 | A | 5 | 5 | 6 | 9 | 4 | 80% |
| 20 | | 00:21:49 | A | 12 | 9 | 6 | 6 | 5 | 56% |
| 2 | | 00:30:29 | A- | 6 | 4 | 5 | 10 | 3 | 75% |
| 18 | | 01:45:50 | A- | 7 | 10 | 6 | 6 | 5 | 50% |
| 23 | Sequential informed cooperation | 00:20:40 | A+ | 5 | 9 | 0 | 4 | 4 | 44% |
| 3 | | 00:21:23 | A- | 5 | 5 | 0 | 6 | 2 | 40% |
| 22 | | 00:22:40 | A- | 5 | 13 | 0 | 3 | 5 | 38% |
| 5 | | 00:23:52 | A- | 0 | 13 | 0 | 3 | 5 | 38% |
| 7 | | 00:15:31 | B+ | 0 | 8 | 0 | 8 | 3 | 38% |
| 29 | | 00:14:04 | B+ | 6 | 11 | 0 | 2 | 5 | 45% |
| 31 | | 00:13:26 | B+ | 0 | 15 | 0 | 1 | 7 | 47% |
| 11 | | 00:18:39 | B+ | 0 | 10 | 0 | 5 | 3 | 30% |
| 12 | | 00:16:28 | B+ | 5 | 11 | 0 | 6 | 3 | 27% |
| 14 | | 00:13:41 | B+ | 5 | 10 | 0 | 3 | 2 | 20% |
| 16 | | 00:16:32 | B+ | 0 | 9 | 0 | 7 | 0 | 0% |
| 19 | | 00:17:48 | B | 6 | 6 | 0 | 9 | 2 | 33% |
| 21 | | 00:12:17 | B | 5 | 14 | 0 | 0 | 5 | 36% |

| | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|

| 33 | | 00:03:59 | B- | 6 | 0 | 0 | 0 | 0 | 0% |

### *The interplay between interaction patterns and inquiry achievement*

Student interaction and interaction patterns were analyzed to reveal how different patterns of interaction affect inquiry achievement in the laboratory course. This study thus analyzes group interaction patterns: group performance as it relates to the five interaction types, time used to regulate group plans, and the ratio of conflict resolution to demonstrate how the students used PDAs in the laboratory classes to affect their achievement in the course. Because the PDAs were used to help students resolve conflicts and create shared inquiry plans, this study measures the resolution ratio within each group by formula (1). The formula can also be used to determine how different peer interaction patterns affect group inquiry achievement.

$$\text{Resolution ratio} = \frac{\text{Total number of resolution of options by group members}}{\text{Total number of changing of options}} \quad (1)$$

Table 2 shows the analysis of inquiry achievement and planning time in terms of peer interaction patterns and interaction activities. Students displayed different characteristics with regard to interaction patterns and interaction activities. Obviously, students required more planning time in concurrent informed cooperation and sequential informed cooperation than in concurrent concealed cooperation, because the former two patterns require time for students tounderstand each other' s opinions and to resolve conflicts. The average planning time for concurrent informed cooperative exploration and sequential informed cooperative exploration were 41 and 17 minutes respectively. In contrast, the average planning time of concurrent concealed cooperation was only 10 minutes.

Furthermore, groups whose interactions were classifiable as thesequential informed cooperation pattern showeda higher frequency of perceived conflicts than those demonstrating concurrent informed cooperation. Groups exhibiting concurrent informed cooperation also had a higher conflict resolution ratio than that of groups following the sequential informed cooperation pattern, probably because each student following the concurrent informed cooperation pattern, after independently revising the group plan, had acquired richer experience organizing group plans and thus was better prepared to establish agreement in later activity. Conversely, student groups adhering to the pattern of sequential informed cooperation, despite ultimately demonstrating high perceived agreement, were unable to achieve conflict resolution ratios as high as those of concurrent informed cooperation groups, possibly because students following other students' work when revising group plans lack personal experience in group plan development.

In the teacher' s evaluation of the final inquiry reports, the concurrent informed cooperation groups obtained the highest overall scores (ranging from A- to A+) of all interaction patterns. The groups using sequential informed cooperation achieved the second highest scores (ranging from B to A+). Table 2 shows that planning time and resolution ratio may each play an important role in affecting group inquiry performance. When using the patterns of concurrent informed cooperation and sequential informed cooperation, students spent more time planning and achieved higher conflict resolution ratios.

These patterns were defined on the basis of the various types of interaction engaged in by the groups. By comparing the differences and similarities of the 34 groups, some basic rules to categorize their interaction patterns could by developed:

- Concurrent informed cooperative exploration: Students spend a great deal of time planning their inquiry (41 minutes on average). Groups following this pattern demonstrated a high conflict resolution ratio (on average 61%) and high perceived agreement (7.4 on average). Student groups following this pattern achieved the highest overall scores (ranging from A- to A+) in the teacher's evaluation of the inquiry reports.
- Sequential informed cooperative exploration: Groups following this pattern showed a high frequency of perceived conflicts (10.3 on average). Students could perceive conflicts amongthemselves but did not reach a high conflict resolution ratio. Student groups following this pattern achieved the second highest overall scores (ranging from B to A+) in the teacher's evaluation of the inquiry reports.
- Concurrent concealed exploration: Students work independently with only limited interaction. Some conflicts go unperceived. Neither conflict nor agreement is perceived by students. Student groups following this pattern achieved the second lowest overall scores (B) in the teacher's evaluation of the inquiry reports.
- No interaction: There is no perceived conflict nor resolution. Student groups following this pattern achieved the lowest overall scores (ranging from B- to B) in the teacher's evaluation of the inquiry reports.

## 5. Conclusions

Because of the difficulties students encounter with inquiry in laboratory courses, this study attempts to provide students with regulative tools on PDAs to aid in regulating and interacting with peers. Analysis of student interaction through PDAs found five main types of peer interaction, i.e.comparison, perceived conflict, perceived agreement, conflict resolution, and unperceived conflict, when student cooperation is mediated by PDAs. The benefits of using PDAs in cooperative planning activities include the ability of PDAs to provide each student with free access to the artifacts (individual inquiry plans) produced by every group member and thus to negotiate directly with peers regarding those artifacts in order to produce group work. The four main interaction types (comparison, perceived conflict, perceived agreement, and conflict resolution) that students demonstrated through PDAs are important negotiation activities. This result reflects the effect PDAs have in facilitating the negotiation of group work.

However, unperceived conflicts were frequently observed because of the client-server nature of PDA software. The implementation of the regulation tools on the PDAs in this study did not enforce simultaneous synchronization among the PDAs of group members. In other words, the changes to the group plan made by one member were not immediately displayed on the PDAs of other members. Students were able to obtain the most recent state of the group work only by reloading after all members had submitted their latest group plans. This facet of the design resulted in the frequent occurrence of unperceived conflicts.Unperceived conflicts may lessen the ability of students to share their learning experiences with each other.Technological devices, PDAs in the case of this study, can record and reflect students' current ideas and states, but unperceived conflicts may still be concealed in the individual devices. Further investigation into the possibility of an effective status awareness mechanism to synchronize the work of individuals in PDAs may be required to alleviate the problem of unperceived conflict. For example, the reinforcement mechanism applied in MCSCL to maintain shared understanding among group members may be applied to establish mutual understanding.

This study also identifies four interaction patterns that are indicative of the different styles of interaction afforded by PDAs. The four interaction patterns are: concurrent informed cooperation, sequential informed cooperation, concurrent concealed cooperation, and no interaction. Teachers and system designers should take note of the advantages and disadvantages of using PDAs in facilitating group activities and use this information to avoid unfavorable interaction patterns such as concurrent concealed cooperation. Different interaction patterns may have different advantages and disadvantages. For instance, although students in groups using sequential informed cooperation could perceive the current status of members, they still could not easily resolve their conflicts. Such difficulties may result from the lack of prior experience in learning. On the other hand, student groups using concurrent informed cooperation could easily resolve conflicts but had problems with time constraints and some unperceived conflicts. However, the best way to help students efficiently negotiate and avoid unperceived conflicts still requires further investigation.

Students engaging in different interaction patterns showed different levels of inquiry achievement. Generally, the amount of time used to regulate group plans and the ratio of conflict resolution seems to affect student achievement significantly. A high conflict resolution ratio helps students achieve high scores in the final inquiry report. The study results confirm the importance of shared agreement in negotiation activities. This result is consistent with the current principle of collaborative learning, which states that students have to express and discuss divergent ideas in order to construct and share knowledge collaboratively (Puntambekar, 2006). Therefore, educators using PDAs in classrooms and the designers of groupware on PDAs should not only support students in expressing personal ideas but should also build a mechanism or a protocol, such as the display of different personal ideas as in this study or the MCSCL mechanism (Zurita & Nussbaum, 2004), to mediate the negotiation process and help establish shared agreement.

# Examining Preservice Teachers' Ability to Attend and Respond to Student Thinking

Vicky Pilitsis and Ravit Golan Duncan, Rutgers University, New Brunswick, NJ 08901
Email: pilitsisv2@yahoo.com, rgduncan@rci.rutgers.edu

**Abstract:** In order to effectively implement inquiry practices in science, teachers must be able to attend to student thinking and adjust their lessons to build on and respond to student ideas. Research on experienced teachers suggests that their understandings of learners influence their instructional decision-making. However, the research on teacher education has mixed results about preservice teachers' ability to attend to students' ideas (Davis et al, 2006). Although preservice teachers may recognize that learners have prior knowledge they usually do not take into account students' ideas in their teaching practices (Friedrichsen et al, 2009). In this paper, we report on preservice teachers' ability to notice students' ideas (as manifested in written models) and respond to these ideas in subsequent instructional planning. Our data is drawn from clinical interviews conducted with 15 preservice teachers at the end of each of four consecutive methods courses (total of 60 interviews) in a two-year certification program.

## Introduction

Standards documents and recent policy reports have called for a nationwide emphasis not only on the content and processes of science but also on the epistemology and the practices of scientific inquiry (AAAS, 1993; NRC, 1996; Duschl, Schweingruber, & Shouse, 2007). Inquiry based instruction entails a student-centered classroom in which teachers attend to and work with students' ideas to develop models and explanations of natural phenomena. A key factor in implementing inquiry-based practices is the ability to attend to and interpret student ideas and to use that interpretation to guide instructional design (Hammer, 2000; van Zee & Minstrell, 1997; NRC, 1996; AAAS, 1993). Researchers have found that when teachers attend to student understanding and adjust instructional practices this can help minimize the gap between desired student performance and observed student performance (Bell & Cowie, 2001; Black & William, 1998). Davis, Petish, & Smithey (2006) conclude that although experienced teachers' understanding of learners influences their instructional decision making, the research on preservice teachers does not have any conclusive findings.

Some studies report that preservice teachers foresee few student learning difficulties when planning lessons (De Jong & van Driel, 2001; Simmons, 1999; Geddis, Onslow, Beynon, & Oesch, 1993). Other studies have found that preservice teachers do acknowledge the significance of students' ideas about science (Davis et al, 2006; Russell & Martin, 2007; Van Driel, De Jong, & Verloop, 2002). However, even when preservice teachers recognize that learners have prior knowledge they usually do not take into account students' ideas extensively in their teaching practices (Friedrichsen, Abell, Pareja, Brown, Lankford, & Volkmann, 2009). In a 1999 study, Tabachnik and Zeichner found that preservice teachers were interested in uncovering their students' understandings of particular concepts in science, but they did not take this information into consideration when designing their lessons. Moreover, Davis et al (2006) concluded that new teachers do not have very clear ideas about what to do with regard to students' ideas once they have surfaced them.

van Es and Sherin (2002) argue that reform based practices call for a new understanding of teaching and learning which requires teachers to develop new ways of interpreting the classroom. Furthermore, they claim that current teacher education programs do not focus on helping teachers to interpret interactions that take place in the classroom. In our research, we investigate the development of preservice teachers' ability to notice student ideas in written work, as well as the ways in which they subsequently respond to student ideas in their instructional plans.

## Theoretical Framework

According to van Es and Sherin (2002) the skill of noticing for teaching consisted of three aspects: (a) identifying what is important in a teaching situation, (b) making connections between specific events and broader principles for teaching and learning, and (c) using what one knows about the context to reason about the situation. The aspect of identifying what is important in a teaching situation refers to the ability of the teacher to select what they will attend and respond to in the class. Because there are so many different things going on in a classroom at any given point, the teacher must decide what is important and use this information to guide their instruction. Leinhardt, Putnam, Stein, and Baxter (1991) found that experienced teachers have "check points" and use these "check points" to judge how the lesson is going and decide how to proceed. Therefore, experienced teachers are more capable of recognizing and attending to what is important in the lesson (van Es & Sherin, 2002).

The next aspect of noticing, making connections between specific events and broader principles for teaching and learning, refers to the ability of the teacher to make connections between events that occur in the classroom and the broader ideas that they represent (van Es & Sherin, 2002). Similarly to the first aspect of noticing, as a teacher becomes more experienced, he or she will be able to determine how specific events relate to the process of teaching and learning. However, given the same situation, preservice teachers tend to only describe literal events that take place and miss making the connections to the bigger picture (van Es & Sherin, 2002). The last component of noticing, using what one knows about the context to reason about the situation, entails being able to take their knowledge of the subject and knowledge of how students think and apply it in the classroom. In our case its identifying relevant aspects of students' models, like accuracy of explanation or representation, explanatory power, use of evidence, and justification. The preservice teachers then evaluate these identified components to determine the students' understanding. Once the preservice teachers have evaluated the components in regards to student thinking than they determine what course of action is necessary, such as a class discussion or experiment, to clarify any misunderstandings.

In addition to learning how to notice, it is important for teachers to be able to take what is noticed and adjust their instructional practices. The activities that teachers undertake during instruction in order to produce information that can facilitate adaptation to on-going instruction are known as formative assessments (Sadler, 1989). Formative assessment can take many forms such as asking probing questions or class discussions, but it always includes a component of attending to and assessing student ideas in relation to the learning objectives and then adjusting instruction. In 1998, Black and Williams concluded that formative assessments improved student learning, especially for those students who were having difficulty with the content being taught. Formative assessment helps to prevent persistent student misunderstanding because the teacher is looking for evidence of student learning and adjusting instruction as needed (Erickson, 2007). Friedrichsen et. al (2009) found that teaching experience influenced the types and timing of assessments and that novice teachers did not readily implement formative assessments. For example, more experienced teachers tended to enact informal questioning throughout the lesson to check for understanding, while novice teachers waited to grade worksheets and only then revised subsequent lessons. Similar to the development of noticing, the ability to implement formative assessments are difficult and novice teachers struggle with making the connections between what students do not understand and what types of activities would promote student learning. In our study we are trying to help preservice teachers develop the competencies they would need to engage in the complex practice of formative assessment. The competencies they need to have are the ability to notice student thinking in written work and to design instruction that adequately responds to these interpretations.

A way to promote the development of noticing student thinking and designing instructional plans that correspond to these interpretations is through the analysis of student artifacts. The uses of artifacts of practice, such as video and student work have received a lot of attention in teacher education research (e.g. Kazemi & Franke, 2004). Several studies have advocated the use of student work as a tool for professional growth (e.g. Ball & Cohen, 1999; Little, 2002). Using student work has the potential to engage teachers in a cycle of experimentation and reflection and to shift teachers' focus from general pedagogy to one that is connected to their own students (Kazemi & Franke, 2004). However, empirical research on this topic is very limited (Kazemi & Franke, 2004).

In this paper, we hope to expand the research on the use of student work by examining the development of teachers' ability to notice and attend to student thinking as manifested in written artifacts. During clinical interviews, preservice teachers were given a task in which they were asked to analyze student models. We examined the development of teachers' ability to notice and interpret and respond (through instructional planning alone) to students' ideas in these student models. Specifically, our research questions are: (a) What do preservice teachers notice about student thinking as manifesting in student artifacts? (b) In what ways do preservice teachers attend to student thinking in their instructional design?

## Methods

### Study Context

This study was conducted in the context of a two-year Ed.M. certification program for secondary biology teachers at a large public university in the North East. The program included four life science specific methods courses that were taken in sequence. These courses were geared towards helping preservice teachers develop the knowledge and practices of inquiry-based teaching. The first course, *Methods I,* focused on the nature of scientific research and theory building. *Methods II,* the second course was essentially a design course in which the teachers worked in groups to design an extended inquiry based unit. *Methods III*, which accompanied the teaching internship, focused on the implementation of inquiry based lessons and on assessment strategies. Finally, the fourth course, *Methods IV,* engaged teachers in action research and the analysis of data collected during the teaching internship. All courses, especially the last two, included an emphasis on student thinking (including analysis of student work) and the importance of attending and responding to students' ideas. There were 15 preservice teachers who were enrolled in the program and completed all four courses in sequence.

## Data Collection and Analysis

At the end of each of the four courses we conducted clinical interviews with all the teachers. A faculty member and trained graduate students conducted the interviews. Although somewhat different protocols were used in each set of clinical interviews, there was a common student-model critique task, which is the data source analyzed for this paper. In this task the teachers were presented with three student models explaining how a cut heals (cellular division) or why ice floats (density); two versions were used for counterbalancing purposes. We created the student models to closely mimic student thinking and representations. The models consisted of a drawing with an explanation written underneath. Models varied in terms of level of details, scientific accuracy of explanation, use of evidence (from students' prior knowledge) and justification of how the evidence relates to the explanation provided by the model. The teachers were then asked to identify (a) good aspects of the models; (b) problematic aspects of the model; (c) description of their next instructional move if these were naïve models (done at the beginning of a unit); and (d) description of their next instructional move if these were revised final models (done at the end of a unit). Interviews lasted 30-45 minutes and were videotaped and later transcribed verbatim and blinded for analysis.

We conducted a content analysis and through an iterative process of constant comparison we developed a coding scheme to capture four emergent themes of the models the teachers critiqued. The four themes were: (a) model representation (e.g. labeling); (b) mechanism in model (e.g. model shows a before and after or progression); (c) use of evidence or justification in models (e.g. student supports belief with data); and (d) accuracy of ideas of the models. To capture the quality of the preservice teachers' critiques of the models, we focused on two aspects of the critique: (a) the specificity of information they provided and (b) the noticing aspect- what themes were noted by each teacher. In terms of specificity, the preservice teachers' responses were coded as one of three categories: (a) identification; (b) description; or (c) interpretation of student thinking. A statement was coded as identification if the teacher stated what was good or problematic about the model without providing any additional details about why that aspect of the model was good or problematic (e.g. "the explanation is good"). A comment was coded as a description if it involved both identifying an aspect of the model and describing what was positive or negative about this aspect (e.g. "the explanation is good because it contains some empirical evidence") . Finally, an interpretation comment involved identifying, describing, and interpreting a certain aspect of the model in regards to student understanding. A statement such as "the explanation is lacking because cells do not stretch in the healing process; the student is missing the concept of cellular division" would be coded as interpretation since the preservice teacher identified an aspect of the model (explanation), described the problem (cells do not stretch), and interpreted what this means in terms of the student's understanding (missing concept of cellular division). We also counted how many of the themes described above were discussed in the critique to obtain a value for the noticing aspect of our analysis. At the end of the analysis for the critique part of the model, each interview had a two part code (specificity code and a count of themes mentioned).

We then analyzed the last two parts of the interview task, in which the teachers were asked about their next instructional move given two conditions: students models were naïve or students models were final models. We developed a coding scheme that captured three aspects of these revisions: (a) attention to student ideas, (b) specificity of instructional moves, and (c) alignment with model based inquiry. The first aspect, attention to student ideas was coded as: (a) no mention of student ideas which was coded as a "1"; (b) mentioned specific students ideas in regard to a particular model which was coded as a "2"; and (c) mentioned specific student ideas and provided an instructional move that addresses these ideas which was coded as a "3" (e.g. "model #1 did not understand molecules so I would have the students draw out the molecular structure of water to show the polar bonds of water"). The second aspect, specificity of instructional moves, was coded as: (a) stated general activity with no further example which was coded as a "1"; (b) stated a specific activity which was coded as a "2"; and (c) stated a specific activity that has a logical progression in attaining the lesson objectives which was coded as a "3" (e.g. I would give the students data and have them work in groups to make a group model from this data and then present these models to the class and come up with a class model so that all the students are on the same page). The third aspect, alignment with model based inquiry, was coded as: (a) no alignment which was coded as a "1" (e.g. lecture, teacher centered questioning); (b) slight alignment which was coded as a "2" (e.g. demonstration, cookbook lab); (c) alignment which was coded as a "3" (e.g. collaboration with peers, argumentation).

## Results and Discussion

### What Preservice Teachers Notice in Students' Models

Our analysis of the teachers' critique of the student models, allowed us to determine what teachers noticed in students' work and in what ways they could interpret the models in relation to students' understanding. In terms of the aspects of students' work teachers attended to, we found that their comments pertained mostly to the mechanism and explanatory nature of the model (e.g. "model has no explanation"; "model shows wrong grain size"; "model has a before and after"). Comments that pertained to model representation were statements about the components that made up the model (e.g. labeling) and were the second most frequent theme. Finally, statements about the use of evidence and justification (e.g. "model is supported by data"; "student justifies their model") and accuracy of ideas in terms of the thoughts expressed in the models (e.g. "student's thinking about cells stretching is incorrect"; "student understands the concept of density") were less frequently noted (see Table 1).

We then examined how many different themes teachers noted in analysis of students' models. On average, we found that there were approximately 2.3 themes noted per interview; thus teachers, on average, discussed two such aspects of students' models. We found no difference in terms of whether their comments were on positive (e.g. "it is good that all the students know that ice does float") versus the negative aspect of students' work (e.g. "model #1 doesn't explain what happens to a molecule which is what the question is asking"). Although there was only slightly more themes mentioned in *Methods III*, overall the number of themes mentioned by teachers at the end of each course was the same. The preservice teachers tended to focus more on representational aspects of the models (e.g. labeling) in the first methods course and did not attend to the accuracy of the ideas or the use of evidence and justification. However, after *Methods II*, the teachers began to focus more on accuracy of ideas and use of evidence and justification.

Table 1: Frequency count of themes noticed in the students models by methods course

| Themes | Methods I | Methods II | Methods III | Methods IV |
|---|---|---|---|---|
| Mechanism in Model | 15 | 12 | 14 | 14 |
| Model Representation | 12 | 4 | 7 | 7 |
| Accuracy of Ideas | 0 | 9 | 8 | 7 |
| Use of Evidence and Justification | 4 | 6 | 8 | 7 |

Aside from analyzing what teachers noticed we also wanted to understand how teachers discussed what they noticed. Specifically, did they merely identify a problem (or leverage) in student thinking, or were they able to reason about, or explain, how what they noticed relates to student learning (for example, explaining what exactly the student confused about based on their model). We found that most of the teachers' comments were of the identification and description type (91 comments out of a total of 120) and that there were far fewer comments in which they elaborated upon and explained student thinking (29 comments out of a total of 120). Thus, the preservice teachers seemed to be more facile with describing what is problematic about a specific model, but were less able to explain what this means in terms of the student's state of understanding. However, it is the latter capability that is crucial to designing lessons that address students' ideas.

We also looked at whether teachers tended to provide more elaborate comments about positive or negative aspects of student models. We wanted to explore this to see if there was a significant difference between the good versus the problematic components noticed. There was a small, but consistent, difference between the number of identification comments made about positive versus negative aspects of the models (21 positive vs. 25 negative) and the interpretive comments made about the positive and negative aspects of the models (13 positive vs. 16 negative). However, we noticed that there were many more descriptions of positive aspects of the models provided by the teachers than descriptions about negative aspects (32 positive vs. 13 negative). Therefore, it seems that the preservice teachers were able to describe the positive aspects of the models more readily than the negative aspects, even though they generally did not notice many more positive aspects.

Our findings reveal that preservice teachers tended to focus on identifying and describing components of the student models rather than interpreting the models in regard to student understanding. In reference to van Es and Sherin 's (2002) components on the aspects of noticing, it seems that the preservice teachers are not making the connections between the specific events, or ideas, in the models and how that relates to the broader principles of teaching in learning. Our teachers did not seem to be attending to written responses as evidence of specific cognitive obstacles (or leverages) in student learning, rather many of them tended to analyze the models in a very literal and contextual manner. Additionally, it was evident that the teachers struggled to interpret what they saw in the models in relation to student understandings of the phenomenon. For example, one of the teachers realized that the model did not portray the phenomenon at the correct grain size, but was unable to see this was potentially due to a lack of knowledge about molecular structures. A plausible explanation for this trend was that the teachers may not have had strong subject matter knowledge about the modeled phenomenon (e.g. density and cellular division).

## Attending to Student Thinking in the Instructional Design

We next focused on whether and how the preservice teachers took into account and addressed student thinking in their instructional plans. In order to answer this question, we focused on the last part of the interview task in which the teachers were asked what they would do the next day in the classroom if the student models presented were (a) typical naïve models (created prior to formal instruction) and (b) typical final models (created after formal instruction). We analyzed three aspects of teachers' instructional designs: (a) attention to student ideas; (b) specificity of activities suggested; and (c) alignment with the model based inquiry pedagogical approach.

In regards to attention to student ideas, we gave each teacher a score, from 1-3, to reflect the extent to which they took into account student ideas in their plans. We found that, for the most part, teachers did not attend much to student thinking and that they did not substantially improve, in this regard, over time. The average scores for each course (for both naïve and final model questions) had only a slight difference (1.25-1.8). For example, during *Methods III* Sean was presented with the student models about why ice floats. He commented that the students were not using the correct grain size to represent the phenomenon that ice is less dense than water. When asked what he would do in class the next day if these were naïve models, he stated "I think the first thing I would do is ask them to collaborate with each other. Some have better ideas than others and after that perhaps the groups can do experiments themselves". While Sean felt that a major problem with students' models was that they were not at the molecular structure of ice and water (and hence their models were not at the correct grain size); his instructional move does not relate to this analysis in any specific way. The instructional move he suggested is a viable one (and we suspect that such a move may result in some discussion of molecular structures in some groups); however, it is a rather generic move and it doesn't take into account what he noticed about students' thinking.

In contrast, during *Methods II,* Catherine evaluated student models that focused on the healing of a cut. She commented that all the models had explanations but that some were incorrect. Catherine described her next instructional move as stemming from her interpretation of students' understandings: "Model #1 may understand that cells are involved [based on the written part of the model] but didn't incorporate it in the model. It is important that they know cells are involved so that is where I would start off". Catherine identified "cells" as the missing piece of the puzzle, and thus noted that her next instructional move would address the role of cells in the phenomenon. Unlike Sean, Catherine used her interpretation of students' understanding based on the models to inform her next instructional move, this sort of response was infrequent in our data set. Table 2 shows the teachers that received at least one score of "3" in regards to taking into account student thinking (a score of 3 corresponds to comments that mentioned specific student ideas and provided an instructional move that addresses these ideas). Out of the fifteen teachers, only eight of them received at least one score of 3. In comparing the different courses, the lowest average score (1.25) was during *Methods I* and the highest average (1.8) during *Methods IV.* We then calculated the overall average for all four courses for the instructional move after being presented with the naïve model and the instructional move after being presented with the final model, and found that the teachers took students' ideas into consideration slightly more when the plan was for the naïve versus final models (1.65 vs. 1.48). However, overall the teachers did not readily take into account student thinking when planning their next move in the classroom. This mirrors findings by Friedrichsen et al (2009) and Tabachnik & Zeichner (1999).

Table 2: Selected teachers that did attend to student thinking in their instructional design

| Teachers | Methods I | | Methods II | | Methods III | | Methods IV | |
|---|---|---|---|---|---|---|---|---|
| (pseudonyms) | Naïve | Revised | Naïve | Revised | Naïve | Revised | Naïve | Revised |
| Catherine | 2 | 2 | 3 | 1 | 3 | 1 | 2 | 2 |
| Anna | 1 | 2 | 3 | 1 | 3 | 2 | 1 | 2 |
| Ava | 1 | 1 | 1 | 3 | 1 | 2 | 1 | 3 |
| Patrick | 1 | 2 | 1 | 1 | 1 | 3 | 1 | 1 |

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Jackie | 1 | 1 | 3 | 1 | 3 | 1 | 1 | 1 |
| Nina | 1 | 1 | 1 | 3 | 1 | 1 | 2 | 1 |
| Jack | 1 | 2 | 3 | 1 | 3 | 3 | 3 | 2 |
| Claire | 2 | 2 | 1 | 1 | 1 | 1 | 2 | 3 |

We next analyzed the specificity of their next instructional move; that is, how clear and specific were they about what they planned to do. We found that the last two methods courses had higher average specificity scores compared to the first two, with the highest average score of 2.07 for the instructional plan for final models in *Methods IV.* For example, after being presented with the student models about why ice floats during *Methods IV*, Bani discussed her next instructional plan for these naïve models as: "I would give them more data" a rather unspecified move; Bani didn't explain: (a) what type of data or (b) what she would have the students do with that data. However, Sean, after critiquing student models during *Methods III*, was much more specific with his instructional design. He stated that "I would have the kids get in small groups and share their models in small groups. I would then have the group create a consensus model and share them in front of the room and we would argue them". Sean's description of his next instructional move included information about the specific activities that would be performed in the classroom and these activities followed a logical progression.

We expected that the teachers may tend to be more specific about what they planned when confronted with "final models" because had the teachers attended to student thinking the specifics of the instructional designs would probably have related to specific challenges students' demonstrated in their models. Therefore, the activities being described in their next instructional move would be specific to the misunderstandings in the student model. For example, if the teacher critiques the models for not being the correct grain size, an activity that would be coded as a "3" for specificity would outline how doing X would improve student's understanding of grain size. However, there were very small differences (1.85 vs. 1.80) in terms of the specificity with which teachers described their next instruction in the context of the naive versus final models. This could be because the teachers did not readily attend to student thinking or understanding, and therefore, the specificity of the activities did not change during moves for the naïve versus final models because the teachers were not evaluating the models in regards to student understanding. Thus, the activities that the teachers described were most likely common activities, for that content, that they had implemented successfully before.

The last aspects of teachers' next-instructional-moves we examined were the alignment of these plans to the model-based inquiry approach which is the focus pedagogy of the teacher education program. This method entails a student centered classroom in which teachers attend to and work with students' ideas to develop models and explanations of natural phenomena. When looking at each of the four methods courses in turn, we found that during the first course the teachers' plans were not aligned with inquiry-based practices but were mostly teacher centered in nature (e.g. lecture). During the second and last course, the instructional plans were much better aligned with model-based inquiry practices (2.85 and 2.57 respectively). For example, during *Methods I,* Ava described her next instructional move as "I would talk about how a scab forms so that they [students] understand that the scab isn't doing the healing". Ava's practices are teacher centered and showed no connection to model based practices. However, the teachers' lessons began to align more with model based inquiry during *Methods II* and *Methods IV.* Patrick, during *Methods II,* stated that, "The best thing to do is have the students explain their models to the rest of the class and justify them. The class could work out the rest of the problems and allow them [students] to argue and allow other students to argue why that model would be incorrect". Patrick's solution of collaboration and argumentation are consistent with the principles put forth in the heuristic for progressive disciplinary discourse (HPDD) framework that aims to foster learners' participation in material and discursive activities characterizing the work of scientists (Windschitl, Thompson, and Braaten, 2008).

Comparison of the overall averages for the naïve-models instructional move and final-models instructional move, revealed that the teachers' plans were slightly more aligned with model-based inquiry practices for the naïve-models condition (2.36 average) versus the final-models condition (2 average). Thus the preservice teachers tended to suggest more model based inquiry practices when they were designing lesson activities assuming their students were just beginning to study the topic. For example, Molly discussed her instruction after the naïve models during *Methods I* as:

> "I would have a class discussion and everyone shares their naïve models to get everything out and then after the discussion we would do some sort of introduction or look at some kind of experiment. We will draw the raw models, discuss it, and then change the models after the class discussion and then have them [students] do some sort of experiment."

Implementing practices that Molly has outlined above, such as peer collaboration and interpreting data, are part of model-based inquiry instruction. However, for her instructional move given the final model, Molly stated "I would need to go back. I feel that I should go back and do some kind of activity or discussion with them even if it is a five to ten minute lecture". Molly, who previously advocated for student centered activities, now changed the focus of her instruction to lecturing." Molly's responses are not unique and in fact many of the teachers reverted back to teacher-centered activities after they assumed that an initial constructivist approach did not work. Grossman, Wilson, and Shulman (1989) concluded that teachers may revert back to the way they were taught if they are uncomfortable or uncertain of their abilities. Therefore, many of the teachers, including Molly, were unsure of other constructivist approaches to implement; thereby, reverting back to their comfort zone, teacher centered approaches.

In summary, our analyses suggest that the preservice teachers tended not to take students thinking into account when designing their next instructional practice, which could be due to a lack of content knowledge and/or pedagogical content knowledge. Without such knowledge, the teachers may not recognize problematic ideas expressed in the models, and they would not know what types of activities could help address the misconceptions they did identify in the student models. Erickson (2007) contends that teachers fail to make formative use of assessment data because the teachers do not know how to interpret the information to pinpoint alternative pedagogical "moves." Additionally, Davis and Smithey (2009) argue that further support is needed to help preservice teachers consider the factors that contribute to students' ideas or the resilience of those ideas, as well as to connect student ideas to instructional experiences. This resonates with our findings in this study. We did notice a slight increase in attention to student ideas during *Methods IV* which may be attributed to the action research activities teachers engaged with during this course. As part of their research projects teachers analyzed student artifacts from their class and had to relate their analyses back to their research questions and learning theories.

The instructional practices discussed by the teachers were often well aligned with model based inquiry practices. One important aspect to note is that after *Methods III,* the alignment to inquiry practices slightly decreased in comparison to *Methods II* and *Methods IV.* It was during *Methods III* that the preservice teachers were completing their student teaching practicum. Through several class discussions it was apparent that many mentor teachers did not implement these inquiry practices in their class and some were overtly against their use. It could be that some of the preservice teachers were influenced by this and may have begun to mimic the practices of their cooperating teacher. Therefore, this drop in inquiry practices could be contributed to the experiences they were facing during their student teaching, and perhaps a shift in their philosophical stance regarding effective pedagogy. Overall, during *Methods IV* showed improvements in all three categories- attention to student thinking; specificity of activities; and alignment with inquiry based practices. Although the improvement was small, it does show promise that action research projects do promote changes in preservice teachers' attention to student thinking in instructional design.

## Conclusions and Implications

Research has shown that beginning teachers typically focus on themselves as teachers, often at the expense of paying close attention to student learning (Meskill et al, 2002). Our findings support this assertion and illustrate the ways in which preservice teachers may begin to develop this skill. We believe that teacher education programs can encourage the shift from teacher (self) to student learning by engaging teachers in the practice of looking for evidence of student understanding in written artifacts as well as classroom discourse. In our methods courses we provide opportunities for teachers to evaluate student work and student discourse. However, our findings suggest that these opportunities were either not substantive or not frequent enough to engender the kind of evidence-based approach to instructional design we had hoped teachers would develop.

It seems that the single most influential course on teachers' ability to attend and respond to student thinking was the last methods course with its action-research focus. During this course, teachers analyzed various student artifacts for student understanding that they had collected during their student teaching internship the previous semester. In follow up studies, we would like to engage the teachers in analysis of student work and help them develop more robust strategies for looking at evidence of student understanding and relating such interpretations to potential instructional strategies.

# Changes in Teachers' Ability to Design Inquiry-Based Lessons During a Two-Year Preparation Program

Augusto Z. Macalalag Jr., Ravit Golan Duncan, Rutgers University, New Brunswick, N.J.
Email: azmjr@eden.rutgers.edu, ravit.duncan@gse.rutgers.edu

**Abstract:** Current reforms require teachers to design effective inquiry-based lessons. This is a challenging task particularly for preservice teachers who may not have experienced inquiry learning, and who do not posses a large repertoire of teaching strategies, or knowledge of student thinking in the domain. Here we report on the development of preservice teachers' lesson designs in the context of a two-year certification program with four consecutive methods courses. These courses included multiple opportunities to plan and implement inquiry-based lessons and units. We analyzed the lesson-designs of 15 preservice teachers. These lessons were generated as part of clinical interview conducted at the end of each course. Analysis of lessons revealed growth in the teachers' ability to: (a) craft appropriate questions to gather students' preconceptions and drive inquiry lesson, (b) anticipate students' prior knowledge and attend to the broader context of the curriculum, and (c) create more relevant investigations.

## Introduction

Current reforms advocate teaching scientific inquiry, which "refers to the diverse ways in which scientists study the natural world and propose explanations based on evidence derived from their work" (National Research Council, 2000, p.1). Teaching science through inquiry is congruent with constructivist perspectives of a more student-centered approach that promotes the learning of both science content and practices in a social setting (Anderson, 2007). However, over the past several decades, science educators and researchers have used and defined inquiry differently in their classrooms, curricula, and research projects. Historical definitions of inquiry in the classroom have ranged from traditional hands-on laboratories to open ended student-driven investigations (Windschitl, 2004). In this study we define model-based inquiry teaching as a form of inquiry that emphasizes the role of models in scientific practice, in particular, the use of models to build, revise and argue about scientific knowledge. Successful teaching of inquiry, model-based or otherwise, is challenging for most teachers particularly preservice teachers (Schwarz & Gwekwerere, 2007; Windschitl & Thompson, 2006). In a study of preservice elementary teachers, Hayes (2002) found that preservice teachers struggled in their new roles as teachers of inquiry. Specifically, he uncovered three major difficulties: letting go, going with students' interests, and asking the right questions. It was challenging for the teachers to let go of the didactic approach to teaching and move toward more student-centered instruction.

Teaching is a complex process that involves conceptualization of the teacher's intent and then the execution of the plan in the context of the classroom given the particulars of student ideas and responses to the plan. Lesson plans reflect teachers' thinking and the multiple decisions that teachers make before actual instruction begins (Duschl & Wright, 1989). While lessons plans do not usually reflect the nuances and complexities of implementation, they can provide a reasonable picture of the ways in which knowledge of inquiry is applied to instructional design. In this paper, we examine the ways in which preservice teachers' ability to plan (but not implement) inquiry-based lesson designs changes over the course of four consecutive science Methods courses in a two-year preparation program.

## Theoretical Framework

Lesson planning and design are windows to teaching practices. Planning refers to teachers' conceptualization and formulation of courses of action in a lesson, which has a profound influence in teachers' classroom behavior and students' learning (Shavelson, 1987). In planning and preparation, teachers demonstrate their knowledge of content and pedagogy, knowledge of students, selection of instructional goals, knowledge of resources, design of coherent instruction, and assessment of student learning (Danielson, 1996).

Several studies have explored aspects of experienced teachers' lesson planning process. Peterson, Marx, & Clark (1978) investigated the relationship between teacher planning, teacher behavior, and student achievement. The study focused on 12 experienced teachers who taught social studies lessons to three groups of high school students. Findings from the analysis of planning statements of the teachers indicated that the largest portion of planning focused on the content and selecting activities to be taught. A comparably small number of planning statements concerned the materials and the learner, and a very small number of planning statements mentioned lesson objectives. Brown (1988) conducted a case study of 12 middle-school teachers' yearly, unit, weekly, and daily planning. Analysis of written plans, think-aloud, and a questionnaire, indicated that the common factors that affect teachers' planning included student ability (very often), district curriculum guides, orderly transition between activities, student attention, standardized tests, and undergraduate training (rarely). Brown (1993) conducted a longitudinal study of two novice secondary teachers' instructional planning. In this study, she saw that cooperating teachers' planning practices, university professors' classes, textbooks, and curriculum guides influenced lesson planning. Duschl and Wright (1989) investigated the teachers' decision making models for planning and teaching of science of 13 high school teachers. They found that selection, planning, and designing of instructional tasks were dominated by considerations about student development, objectives set by the curriculum, and accountability pressures. However, teachers paid little attention to the scientific theories involved. These studies pertain to in-service teachers and highlight the complexity of the lesson design task and the different factors that influence teacher decision-making and planning.

The state of affairs regarding preservice teachers' lesson planning is similarly complex. Several research efforts to develop preservice teachers' ability to design lessons, specifically inquiry-based, have met with mixed success (Friedrichsen, et. al., 2009; Schwarz & Gwekwerere, 2007). Friedrichsen, et.al, (2009) analyzed the lessons developed by four teachers in a certification program: two interns and two full time (alternative route) teachers, to investigate differences between the two groups. Their analysis of the lessons revealed that both groups relied primarily on their subject matter knowledge and general pedagogical knowledge to plan the lessons. Both groups of teachers lacked topic specific knowledge about learners, instruction, curriculum, and assessment. Friedrichsen and colleagues found that a typical lesson for both groups began with the teacher asking questions, followed by a lecture and guided practice designed to memorize and practice the lecture material; these lessons were mostly teacher centered. Their research suggests that preservice teachers, in either route, do not tend to take students' prior knowledge and curriculum into account when designing lessons, nor do they have the necessary pedagogical content knowledge to address specific ideas that students may have about the content.

On the other hand, research by Schwarz and Gwekwerere (2007) suggests that by using highly scaffolded frameworks for instructional design, preservice teachers can begin to develop lessons that are more reform oriented. Schwarz and Gwekwerere (2007) used a guided inquiry and modeling instructional framework (termed EIMA) to support K-8 preservice science teachers in developing lesson plans and units. The preservice teachers learned and used the EIMA framework for their instructional activities and lesson planning in one science method course. Their findings suggest the framework was successful in helping teachers increase the use of different models to engage students, and move toward a more reformed based approach to teaching (i.e. conceptual change, inquiry, and guided inquiry). However, at the end of the semester, these researchers found that the preservice teachers still struggled with the concepts of scientific models and modeling.

In a different study, Windschitl, Thompson, and Braaten (2008) used the Heuristics for Progressive Disciplinary Discourse (HPDD) framework to improve preservice teachers' epistemic discourses in science. Their research showed that while most preservice teachers improved their knowledge of the function and nature of models, they failed to incorporate it into their inquiry lessons. Windschitl et al., (2008) thus showed that with appropriate scaffolding preservice teachers could improve their concepts of scientific models, concepts that Duschl and Wright (1989) had previously found to be challenging for teachers. These studies highlight the challenges that preservice teachers face when trying to use inquiry approaches in their instructional design.

In our Methods courses, preservice teachers engaged in designing, revising, and implementing inquiry based lessons in four consecutive courses. The intensive focus on lesson design was part of Methods II and Methods III, which are described in the next section. We anticipated that our preservice teachers would increase their attention to students' learning, curricula, and scientific models in their lesson plan and design over the four courses. More specifically, we hypothesized that the initial lesson designs would focus on the selection of activities from curricula and textbooks in ways that are similar to what Peterson, Marx, & Clark (1978) found in their study. Given the findings from the studies by Brown (1988) and Duschl and Wright (1989), we predicted that lessons would begin to focus on students' learning and development. Focusing on student ideas is challenging for teachers to do but is central to the constructivist approach. In contrast to Duschl and Wright's (1989) findings, however, we hypothesized that our preservice teachers might be better at focusing on scientific knowledge building (models and theories); ideas that are at the core of scientific inquiry.

## Methods

### Study Context

A qualitative approach was used to understand the extent to which the preservice teachers' ability to design lessons change over time. The participants are fifteen (4 male and 11 female) preservice teachers enrolled in a two-year biological science teacher education/certification program in a large university in the north east of the U.S. All preservice teachers have at least 30 credit hours in Biological Sciences before entering the program. Specifically, one teacher has a PhD in Biology, four have Bachelors of Science in Biology, and ten are in their forth year of a five-year Biological Sciences or related (e.g. Animal Sciences, Ecology and Natural Resources, and Environmental Science) programs. Moreover, two teachers have extensive research experiences, one as a senior scientist and the other as a researcher/laboratory manager, in commercial laboratories and another two worked as research assistants at the college during their undergraduate programs. As part of the certification program, students completed four subject-specific Methods courses in consecutive semesters. All courses were taught by one professor, the second author of this paper. In the first method course, Methods I, preservice teachers were engaged in science inquiry activities, readings, and discourse that promoted their understanding of scientific inquiry and theory development. During this course, the teachers, as a class, developed a framework for model-based inquiry that was to inform their lesson development in the subsequent course. The second course, Methods II, was a design-based course in which the teachers, in small groups, developed extended model-based inquiry units about selected topics in biology. In this course, teachers were introduced to several design frameworks including Learning for Use (Edelson, 2001) and Backwards Design (Wiggins and McTighe, 1999). At the end of this course they developed and implemented a single model-based inquiry lesson in their observation placement classrooms. The third course, Methods III, was a weekly seminar associated with their 15-week student teaching internship. Teachers were placed in local middle and high schools with teachers who may or may not have been familiar with reform-oriented science teaching. In this course, the teachers planned and implemented numerous lessons. They were required to extensively reflect on two short inquiry based units that they developed and implanted in their student teaching placements. In the final course, Methods IV, teachers conducted action-research projects aimed to develop their skills as reflective practitioners. Teachers used data collected during their student teaching to answer practical questions related to the use of the model-based inquiry approach in the science classroom.

## Data Sources and Analysis

We conducted clinical interviews with each teacher at the end of each of the four Methods courses. The interview protocol had four tasks that included defining model-based inquiry, critiquing a lesson, designing a lesson, and evaluating students' written work examples. In this report we focused on the analysis of the third task: the lesson design. We created two comparable versions of this task for counterbalancing purposes and each version was alternated across the four end-of-course interviews. Version A had three objectives for the topic of photosynthesis, while version B had similar objectives for the topic of cellular respiration. The teachers were given the objectives, asked to plan a lesson or short set of lessons that would address the objectives given to them, and then prompted to explain their lesson. This design task lasted for about 5-10 minutes.

Data analysis for this task began with the identification of essential features of inquiry-based lessons (e.g. hook, procedures, investigations, and assessment) and the systematic description of interrelationships among these features (Wolcott, 1994). The development of our coding schemes proceeded through an iterative process of application to the data set and refinement of the codes to capture relevant emerging themes in the data (Corbin & Strauss, 2008; Merriam, 1998). The first coding pass gave us a list of the different activities in the lesson (e.g. questions, investigations, student modeling, etc.) that teachers described in their interviews. We then examined these to identify patterns of change.

Through recurrent comparison of transcripts from interviews at different points in time we were able to identify shifts in the nature and quality of teachers' lesson designs with regard to several dimensions: (a) specificity and suitability of teacher *questions*, (b) *student-centeredness* of lesson*,* and (c) development of *investigations.* We will describe these dimensions in detail in the next section. Within the first dimension, we counted the specificity and suitability of the question to drive the need to know and students' prior knowledge in the lesson. For example, the following questions were constructed by teachers to drive a lesson on photosynthesis: (1) "how do plants grow, what do they need, what are they made up of, what are they made from" and (2) "I pose a question to the students on how do plants and humans work together in order to survive." In the first question, the teacher proposed specific questions to gather students' preconceptions about photosynthesis using plants' growth, sources of energy, and its composition. On the other hand, the second question was too broad and less suited to drive the lesson on photosynthesis. Students will most likely mention plants as a source of food and shelter to answer the question, which are correct but beyond the topic of the lesson. Moreover, the question did not clearly reflect the teacher's intention of using the question to deliver concepts such as human consumption of oxygen from plants and plant use of carbon dioxide from humans.

Within the second dimension, we coded the number of lessons that were procedural or activity oriented. These lessons have a set of activities that were predetermined by teachers, have no indication whether students' preconceptions will change the lesson, and reflected teacher-centered approach of teaching. We also coded the number of lessons in which teachers' voiced students' ideas, for example, Nadia mentioned during her planning that "[students] understand [energy being stored] and in carbohydrates, not only do they get how the molecule is being synthesized but they also get why for the energy and this energy is stored in molecular bonds," which indicated her sensitivity to students' knowledge. Furthermore, within the first dimension, we coded the number of lessons in which there was attention to the broader context of curriculum and to students' prior knowledge. These lessons contained careful sequencing of activities with respect to science content and scaffolding of students' knowledge.

Lastly, within the *investigations* dimension we counted how many investigations were open *or unstructured* (e.g. investigations that asked students to create their own experiments with minimal directions from the teacher). We counted how many of the lessons had investigations that provided specific data to the students, this included investigations using experimental data from a published science experiment or purposeful teacher constructed data.

## Results

### Specificity and suitability of Teachers' Questions

Most teachers mentioned *questioning* as one of the essential parts of a science lesson. These questions were often posed to students in the beginning of the lesson to serve as a motivator or hook, to guide the activities in the lesson, and to ascertain students' preconceptions about the topic. In analyzing the questions that the teachers created for their lessons, we found that lesson questions from the interviews of the third and fourth Methods courses were more specific and suitable for the topic than the questions generated from the interviews in the first and second Methods courses. In other words, teachers' seemed better able to form more specific and more suitable questions as the courses progressed (see Figure 1).

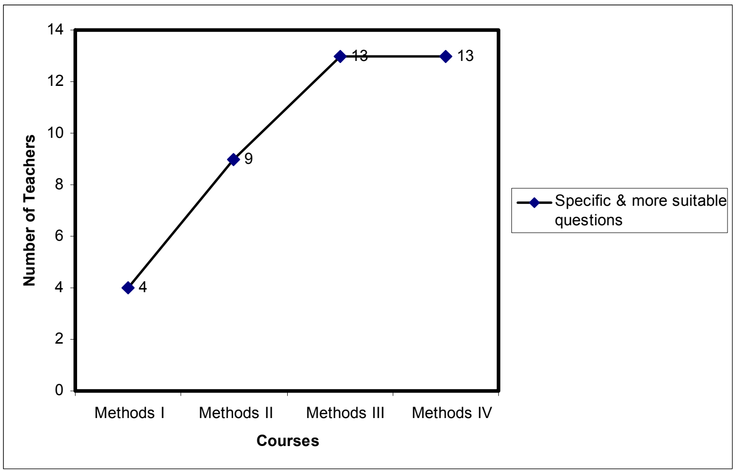

Figure 1. Specificity and suitability of Teacher Questions

Clare's questions from the second and fourth Methods courses are provided below as illustrative examples. In both cases Clare was designing a lesson on photosynthesis and her questions were posed at the beginning of the lesson.

> First, have a discussion with the class and maybe a hand-out about the purpose of photosynthesis and maybe what the students think what the purpose is and umm call out students to write on the board the main ideas and the key players in this process (Clare, Methods II)
>
> [Ask students] how plants get their energy and see what generates from that. (Clare, Methods IV)

Clare's question in Methods II is problematic in that it requires that students know the term photosynthesis and the idea of a biological process as having a purpose is somewhat teleological. It is unlikely that such a question would yield substantive participation from students; nor would it reveal relevant prior conceptions that, while incorrect, may be suitable building blocks (as students may not associate these ideas with the scientific name for the process). Her second question is couched in terms that students are likely familiar with (energy) and is more likely to enlist broader class participation and useful insights about students' prior knowledge. While the first question involves a more specific term (photosynthesis), it is the second question that specifically deals with the objectives of the lesson, namely, understanding the process by which plants get their energy.

### Student-Centeredness of Lessons

We also found shifts in the extent to which the designed lessons were student-centered. These changes included a decrease in the number of procedural or activity-focused lessons, an increase in voicing students' ideas in the lessons, and an increase in attending to broader context of the curriculum and prior knowledge of students (see Figure 2).

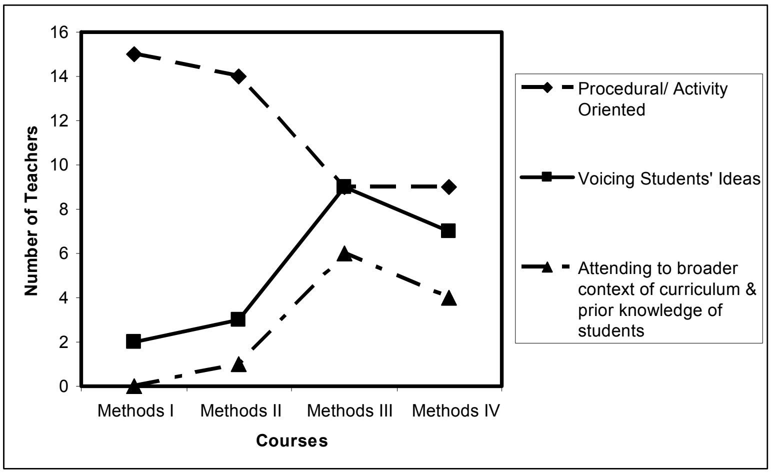

Figure 2. Student-Centeredness of Lessons

Specifically, almost all the lessons (93% to 100%) that the teachers created in the first two courses were procedural or activity-driven. For instance, Jackie's lesson about cellular respiration was primarily teacher-driven with students engaging in some inquiry practices, like model building, but, even then, they work with existing literature.

> Well, I think I would start with just a brief introduction of what cellular respiration is. And then I would have the students make a naïve model based on this pathway, like the overview that I give them of cellular respiration. And, in the model, I would want them to explain…[pause] from there I would probably give them literature. So then I would have them make – revise their naïve model based on that information. They will have to read about it, they will talk about it in small groups, possibly of two to three individuals in a group… discuss it, and make up a new model. (Jackie, Methods I)

Although Jackie included models and modeling in her lesson, there was no indication of how the students' naïve models or revised models will influence the course of instruction or the sequence of activities in the lesson. The majority of lessons in interviews from Methods I and II were similarly teacher-centered. In many cases, the lesson was an amalgam of activities that the teacher was familiar with (often from their own experiences as learners) without a clear connection to the lesson objectives and without any reference to students' expected level of understanding or the broader curriculum context. In addition, while the teachers described activities and practices that were inquiry-oriented, there was little consideration of students' prior knowledge or how the students' models/explanation could influence the lesson.

However, in the lessons designed during the interviews of Methods III and IV, 46% to 60% of teachers voiced-out students' ideas in the lesson and they began to attend to broader context of the curriculum in terms of what students might have already learned (and what prior knowledge they may have as a result). By "voicing-out" students' ideas, we mean that the teachers would speculate what sorts of responses they may get from students, often acting out student talk. Teachers also paid greater attention to potential difficulties that students may have in an activity. Christine's lesson exemplified this case. She mentioned possible conceptions or ideas that her students may have regarding where plants get their food.

> I would start by asking how plants get their food if they don't get it by eating things. The kids are going to be like "Venus flytrap eats flies" but that is the exception to the rule. So kind of get kids to think about how plants are stationary so how are they able to get food. See if anyone knows that plants make their own food, so ask them to explain a little more along those lines. But I am pretty sure that kids in high school don't have a grasp on photosynthesis so umm after that, say let's take a look at things that plants do have access to, like sunlight, air, nutrients, soil, water and then, from there, break down air because it is a mix of gases. Get them to kind of isolate carbon dioxide plants make oxygen. (Christine, Methods III)

Christine's lesson is more student-centered compared to Jackie's lecture-based lesson and she actually voiced out what students might say in response to her questions (Venus flytrap eats flies), and what knowledge they may have that she can build on. In another example, Catherine viewed her line of questioning as contingent on students' conceptions.

> First, I would have them do an initial model of, "how do animals get their energy?" And that would just be so they can get their ideas out there, and I can also see what they're thinking about this. I'm hoping that one of them would say, "food," because then, maybe I, with enough questions, I could pull out of them, "glucose." I'm assuming they've already learned about plants, with photosynthesis. And, so maybe I'd give them a data sheet, with information about …. [pause] or maybe my line of questioning might be, well, "what do chloroplasts store?" and try to get them along that line of thinking so maybe I can get them to come around and say, like, "oh, I guess maybe humans or other animals need glucose for energy." (Catherine, Methods III)

Like Catherine and Christine, teachers became not only cognizant of the students' prior knowledge and experiences but also willing to change the lesson based on what students brought to the lesson. Lastly, a number of teachers (26% to 40%) began to attend to the broader context of curriculum. This included consideration of the sequence of topics in a unit (or over a semester) and references to prerequisite knowledge that students must have prior to the lesson. In the following example, Nadia mentioned the concepts that her students learned before the lesson, the knowledge that they have to contribute in the lesson.

> Of course how I start it depends on what they learned before that. And I just took an example that I had in school. We learned carbohydrates before that and I actually did that on purpose. I did the bio-molecules before and I would do that again because it is a nice flow. Throughout the bio-molecules, they get the idea about the energy being stored… So they have this previous knowledge already and they know plants do that at least high school, they know plants do photosynthesis and build sugars and they mostly know that, at least in high school that is the case. So it is not hard to ask the connection. (Nadia, Methods III)

Nadia's teaching experiences in Methods III helped her reflect on the sequence of topics and what students are expected to know based on that sequence.

## Nature of Investigations

Another dimension of change was the teachers' ability to design *investigations* for their students. These changes included a decrease in open or unstructured activities, and an increase in providing data to students (see Figure 3).

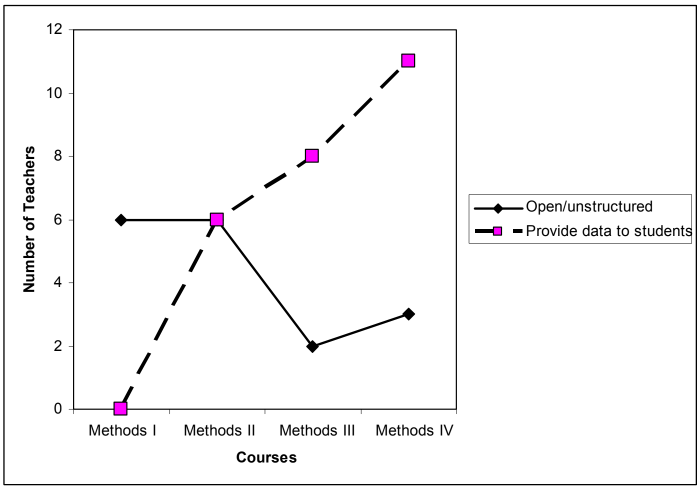

Figure 3. Development of Investigations

Less than half (40%) of teachers in Methods I and II proposed investigations that were open-ended or ill-structured. For example, Jake proposed a discovery-type of investigation in which the students, rather than him, would design and execute relevant experiments.

> I am trying to think of something more specific [investigation] but I can't think of it. I mean in general I would have them do that [experiments with carbon dioxide and oxygen] and it wouldn't necessarily be something that I designed. But I mean I would definitely give them the tools and let them play around with it and see to see what they were able to come up with. (Jake, Methods I)

Interestingly, we noticed a decline in open-ended investigations in the interviews from the last two courses. We believe that this may be due to teachers' realization (from to their experiences during their student teaching internship) of how challenging it is to implement open or unstructured investigations in the classroom. Instead of open-ended investigations, teachers tended to suggest investigations where teacher provides data to students or teacher-guided investigations.

In terms of providing data to students, we found that after Methods II, more than half of the teachers (60%) suggested investigations that involve providing data to students. Jake in Methods III, chose to provide data to his students, instead of giving them an open-ended problem, to address the same concept of energy in photosynthesis. Jason mentioned the data he would provide, the purpose of activities and the target concepts of the lesson. He also used an authentic problem context and data to motivate students to learn the material (the fertilizer runoff problem).

> Then I would give them some data that when there is fertilizer runoff, the amount of algae in the lake increase and the fish are still alive. But as the amount of algae kept going up and the fish are still there… but as the algae increased some more, fish eventually drops off. And I would have them revise their model based on this and I would anticipate that the first one will say something about the fertilizer and the second one will be the algae that somehow killed them. And I would have them either ask them to do an experiment that when you put a plant in the light and one in the dark and put a pH indicator and blow in it, using bromothyl blue in it, and the light will filter back to blue cause it took the $CO_2$ out and the dark it will turn the same or yellow to show that there is more $CO_2$. (Jake, Methods III)

Providing data to students or finding data for students to look at allowed teachers to focus on concepts that they wanted their students to learn, reduce open-ended or ill-structured activities, and promote other scientific practices such as analyzing data and modeling.

## Conclusion and Implications

The purpose of this study was to examine the changes of teachers' ability to design lessons as they progressed through a teacher certification program. Based on our analyses of the lesson design task in their end-of-course interviews, we characterized several dimensions along which there seemed to be shifts in teachers' abilities. The first was an increase in their ability to craft specific and better suited questions to gather students' preconceptions and drive the inquiry activities in their lessons. In the initial interviews, teachers' questions were typically too broad, which mirrors findings of Friedrichsen, et.al. (2009). However, the teachers in our study, given its longer duration, developed more specific and more suited driving questions in the last two Methods courses.

We also identified a trend of increased attention to student thinking and the boarder curriculum, and the use of more student-centered instructional approaches. In the first and second Methods courses, our teachers developed lessons based on selected activities similar to what Paterson, Marx, and Clark (1978) saw in study of their twelve experienced teachers. However, in Methods III and IV, our preservice teachers started to attend to students' prior knowledge and larger curricular context in designing their lessons. They started to voice-out students' ideas in the lesson and they began to attend to broader context of the curriculum in terms of what students might have already learned. This was similar to what Duschl and Wright (1989) found in high school science teachers' attention to student development in their lesson planning and instructional decision making, and what Brown (1988) found in the lesson planning of middle school teachers. Moreover, the progression to a more student-centered lesson and increased attention to the broader context of the curriculum suggests an increase in teachers' knowledge of learners, knowledge of context, and pedagogical content knowledge (Abell, 2007; Friedrichsen, et.al, 2009). The last dimension of changes was found in the teacher-developed investigations. These changes included a decrease in open or unstructured activities and an increase in providing data to students. We believe that the decrease of unstructured activities was due to the teachers' realization of how challenging it is to implement his kind activity. The shift of providing data to students allowed teachers to focus on concepts that they wanted their students to learn and on other scientific practices (e.g. modeling and data analysis).

In terms of scientific inquiry in the lessons, we saw that preservice teachers used the strategy of having students create naïve models (prior to any formal instruction) to gather their pre-conceptions about the question and designed investigations based on student learning. The model-based inquiry practices were congruent with the efforts of Schwarz and Wright (1989) and Windschitl, Thompson, and Braaten (2008). Analysis of Methods courses showed that after Methods II, which focused on instructional design, we noted increases in specificity and suitability of teachers' questions, and an increase in the number of lessons in which teachers provided students with data to analyze. After Methods III and IV we observed increases in student-centeredness of lessons (voicing of students' ideas and attending to broader context of the curriculum). Lastly, after Methods II, we saw a decrease in unstructured activities and an increase in providing data to students as part of investigations. We believe that changes in Methods II were due to the extensive focus on instructional design and multiple design frameworks in this course and the changes in Methods III occurred due to teachers' teaching experiences, interaction with students, and analysis of students' works. This latter development is congruent with the shift in focus from self (perceptions of one's capabilities as a teacher) to a focus on students and learning (Darling-Hammond & Baratz-Snowden, 2005).

# Effects of On-line Collaborative Argumentation Processes on Justifications

Jingyan Lu, The University of Hong Kong, Pokfulam Road. HK, Jingyan@hkucc.hku.hk
Ming Ming Chiu, SUNY – Buffalo, mingmingchiu@gmail.com
Nancy Law, The University of Hong Kong, Pokfulam Road. HK, nlaw@hku.hk

**Abstract**: Justifications (through evidence or explanations) are central to productive argumentation. This study examines how the participant structures and discourse moves of students engaged in collaborative learning affect their justifications. Forty students working on Knowledge Forum, an on-line collaborative learning environment, posted 136 messages, which were coded and analyzed with an ordered logit, vector autoregression, system of equations. When students disagreed or made claims, they were more likely to use evidence. After a student made an alternative claim, the next student posting a message was less likely to use evidence. When students made claims, disagreed, disagreed with other's justifications, or read more notes, they were more likely to use explanations. Boys made more claims than girls did, but otherwise, they did not differ significantly in their likelihood of using justification. Together, these results suggest that participant structures and discourse moves are linked to justifications.

## Introduction

During argumentation, students can construct knowledge through their use of justifications to support their claims and evaluations (Lipponen, 2000; Saab, van Joolingen, & van Hout-Wolters, 2005; van Amelsvoort, Andriessen, & Kanselaar, 2007). The quality of their justifications depends on their evidence, their explanations (Clark & Sampson, 2008; Hakkarainen, 2003; Weinberger & Fischer, 2006), and the complexity of their reasoning (Hmelo-Silver & Barrows, 2008). Since justification is a critical activity while constructing knowledge, the way in which individual learners use justifications to construct claims is an important issue (Kuhn, 2001). This is especially true in online environments (Weinberger & Fischer, 2006) which can facilitate the construction of justified claims by providing learners with more time to formulate arguments (Marttunen & Laurinen, 2001); in contrast, learners rarely constructed justified claims on their own in individual argumentation due to time limitations (Kuhn, 1991).

This study focuses on messages posted on an electronic forum by students in a secondary school geography class. The students were discussing possible solutions to problems associated with global warming. The study investigated how the discourse moves of the students and the resulting participant structures affected the justifications they made during the online discussion.

## Theoretical framework

### Collaborative Argumentation and Knowledge Construction

Traditional theories of argumentation have often focused exclusively on the various stages of argumentation (Kuhn, 2001; Toulmin, 1958). Overly restrictive, they regard arguments as essentially a means to winning, overlooking its highly interactive nature. When students participate in collaborative learning, however, they typically argue to learn rather than to win. More recent approaches to argumentation have introduced the idea of *interactive argumentation*, which is defined as a social and collaborative process directed at articulating informal reasoning (Perkins, Farady, & Bushey, 1991) and constructing and advancing knowledge (Duschl & Osborne, 2002), rather than only justifying or refuting particular points of view (Van Eemeren, Grootendorst, & Snoeck Henkemans, 2002)

As a collaborative learning format, knowledge construction has shown that learners can engage in diverse forms of interactive argumentation to advance shared understandings (van Boxtel, van der Linden, & Kanselaar, 2000). The activities involved in constructing knowledge include sharing, shaping, modifying, restructuring and abandoning knowledge; all of which are both cognitive and socio-cultural. Thus, learners need environments in which they can discuss, share, evaluate, justify, and debate.

Researchers have found that learners use evidence and explanation during argumentation differently (Brem & Rips, 2000; Kuhn, 2001). For instance, Kuhn (2001) found that young children failed to differentiate between evidence and explanations, but their ability to do so increased as they grew older. Brem and Rips (Brem & Rips, 2000) found that learners could differentiate between explanations and evidence but still preferred explanations over evidence due to social and pragmatic factors. What determines the preference for explanation or evidence during argumentation? One view is that it is determined by "personal characteristics, or a person's epistemological beliefs concerning the way knowledge may be justified, and the different roles of evidence and theoretical explanation in the construction of knowledge" (Glassner, Weinstoc, & Neuman, 2005, p. 107). Moreover, the availability and strength of evidence also determines how students use it to justify arguments (Brem & Rips, 2000; Kuhn, 2001). During argumentation, if students are provided with evidence, they tend to use it. Otherwise, they tend to use explanations (Brem & Rips, 2000).

Although many studies have shown that giving evidence and explanations to justify arguments is involved in constructing knowledge, most have focused on individual rather than collaborative argumentation. Do discourse moves, such as questions, claims, and evaluations influence types of justification? Do the characteristics of learners influence the types of justification they use? The next section focuses on discourse perspectives on interactive argumentation and their relation to discourse quality.

## Discourse Moves, Participant Structures and Justifications

To examine how collaborative construction of knowledge occurs through constructive argumentation, consider two central elements: discourse moves and participant structure (Hmelo-Silver & Barrows, 2008).

Discourse moves are used here as units of analysis for investigating the socio-cultural contexts in which the cognitive processes of argumentation, such as justifications, are embedded. Discourse moves, whether written or spoken, typically involve one participant addressing one or more participants and are characterized by their communicative functions (Tapper, 1996). For instance, Hmelo-Silver and Barrows (2008) identify questions, statements, and regulations as three important discourse moves in knowledge building discourse. Thus, the discourse moves that online learners use to justify arguments often elicit further discourse moves by other students.

Question types are related to the use of evidence and explanations during collaborative knowledge construction. The presence and nature of questions in the online discourse have been used as indicators for the level of knowledge construction. Hakkarainen (1998) classified questions into factual-oriented and explanation-oriented questions, specifying that the former should yield evidence, while the latter should yield explanations (Kuhn & Pearsall, 2000). Making claims and evaluating different points of view are important discourse moves in argumentative discourse and are essential in the productive construction of knowledge. Participants make claims and evaluations to express and examine diverse perspectives, and to negotiate shared understandings in light of prior knowledge and new information (Andriessen, Baker, & Suthers, 2003; Teasley & Roschelle, 1993; Veerman, 2003).

Evaluations include full agreements, full disagreements and partial disagreements. To minimize conflicts, students typically express disagreements diplomatically through polite disagreements (Holtgraves, 1997) or unstated partial agreements and partial disagreements (Pomerantz, 1984). Based on research on face-to-face conversations, Pomerantz (1984) found that very often, agreements are preferred during conversation. Consequently, respondents usually preface a disagreement with an agreement ("Yes, … but…"). This type of partial agree/disagreement organization is often used to disagree. We will explore how evaluations affect justification in online discourse in this study.

Few studies have examined the relationship between discourse moves and types of justification. A preliminary descriptive study showed that in a collaborative learning environment, learners tend to present evidence and explanations when responding to disagreements while they tend to present more explanations when supporting claims (Clark & Sampson, 2008). However, researchers have not systematically tested explanatory models of how discourse moves or participant structures predict subsequent justifications (explanation or evidence).

The rise of collaborative learning has deepened awareness that the cognitive processes of learning are rooted in and grow out of socio-cultural processes. These include complex structures of participation by which learners constitute and are in turn constituted by communities of practice (Lave & Wenger, 1991). The notion of participant structure was originally characterized as the ways in which teachers arrange "verbal interactions with students, for communicating different types of educational material, and for providing variation in the presentation of the same material" (Phillips, 1972, p. 377).

2

The definition of participant structure focuses mainly on students' involvement or engagement, which was usually qualitatively defined or described. Participant structures in computer-supported collaborative knowledge building discourse can be represented by means of social network analysis (SNA) which can measure both reading and writing behavior (Zhang, Scardamalia, Reeve, & Messina, in press). SNA represents social networks in the form of directed graphs composed of nodes representing people, and links representing people reading or responding to the messages of other participants. Online participants may write messages that build on the messages of other participants or read messages of other participants. The positions of participants social network are based on their connections to other network participants. Researchers have also suggested that the use of evidence or explanations are also affected by learning contexts and learner characteristics (Brem & Rips, 2000). We will also explore them in this study.

This study explores the use of discourse moves and participant structures to predict two kinds of justification (giving evidence and explanations) in online argumentative discussions. Specifically, it focuses on the following four questions: 1. Are general features, such as participants' gender, age, and topics related to types of justification? 2. Are participant structures related to types of justification? Specifically, do participants with different importance to the network tend to produce different justifications? 3. Are discourse moves related to types of justification? E.g., will participants generally use more explanations when making claims or giving evaluation? Do different forms of disagreement involve different types of justification? 4. Can discourse moves predict types of justification of subsequent notes? E.g., can questions, claims and disagreements in earlier messages be used to predict types of justification in later messages?

## Methodology

### Data Sources

This study analyzes the online discourse of students in a secondary school in Hong Kong. For one semester, 40 Form Three students in the humanities course used Knowledge Forum (KF$^{TM}$) (Scardamalis, 2004), an online learning environment to support discussions. The teacher had students discuss energy problems from a number of perspectives. Two topics that had provoked sustained discussion were selected for study. One topic, "The Energy Crisis," elicited 82 postings and the other topic, "There are More Advantages than Disadvantages for China Developing Nuclear Energy," garnered 54 postings.

### Coding Schema

Utterances were coded separately for discourse moves and types of justifications. Difference levels of coding are applied for discourse moves. First, utterances are coded as claims, evaluations, questions, and information. Claims, evaluations, and information are exclusive codes. Questions are coded separately. Thus, an utterance coded as a claim, evaluation, or information may also be coded as a question. Claims may be new claims or alternative claims. Evaluation may be agreement, disagreement, agreement plus justification or disagreement plus justification. Questions may be fact-oriented and explanation-oriented.

This study examined quality of argumentation by focusing on types of justification: evidence and explanation in order to identify the extent to which students use them as warrants for claims or evaluations on others' message. Explanations involve reasoning in justification but have no empirical data, personal experience, or references to an authority, e.g., "I don't agree with your opinion because I think wind and hydro power are more environmental than coal and oil resources". Evidence involves empirical data, personal experience, or references to an authority, e.g., "I don't agree with you that there is no danger of nuclear power. The Chernobyl Nuclear Power explosion at Ukrainian in 1989 is an example". Notes that only have evidence are assigned 1 for evidence, and 0 for explanation. Notes that only have explanation are assigned 0 for evidence, and 1 for explanation. Notes that include both evidence and explanation are assigned 1s for both evidence and explanation, and notes with neither evidence nor explanation are assigned 0s for both evidence and explanation. Coding was first done by the first author and then recoded blindly by a research assistant. The inter-rater reliability, measured via agreement percentage ranged from a low of 79% (claim) to a high of 94% (question).

Various indicators were used to examine the participant structures of social networks (centrality, density) and the positions of members (frequent responders with high outdegrees vs. popular members with high indegrees, betweenness) in networks. Betweenness measured the extent of brokers' importance between two actors connected with him. Participants with high betweenness have more control over conversations.

## Analysis

Statistical analyses of group processes at the speaker turn level must overcome three difficulties. First, the outcome variable is discrete, not continuous. Second, events are often similar to recent events in time-series data (serial correlation). Third, modeling justifications requires modeling multiple outcome variables (explanation and evidence). We addressed these difficulties by using an ordered logit, vector autoregression (VAR, Kennedy, 2004), seemingly unrelated regression (SUR) systems of equations (Goldstein, 1995). We entered the variables according to time constraints, expected causal relationships, and likely importance.

$$\pi_{iy} = P(Y_{iy} = 1) = 1 / \{1 + \exp[-(\beta_{0y} + e_{iy})]\} \quad (1)$$

$\beta_{0y}$ are the grand mean intercepts $Y_{iy}$, of speaker turn $i$ for each outcome variable $y$ (Evidence and Explanation). The residuals are $e_{iy}$.

$$\pi_{iy} = 1 / \{1 + \exp[-(\beta_{0y} + e_{iy} + \beta_{vy}\mathbf{V}_{iy} + \beta_{wy}\mathbf{W}_{iy} + \beta_{xy}\mathbf{X}_{iy} + \beta_{zy}\mathbf{Z}_{iy})]\} \quad (2)$$

First, we entered a vector of $v$ speaker background variables: topic, age, gender, total number of messages, SNA aspects, such as degreeness, closeness, and betweenness of reading and building on others' notes ($\mathbf{V}$). A nested hypothesis test ($\chi^2$ log likelihood) indicated whether each set of explanatory variables was significant (Kennedy, 2004). Non-significant variables were removed. Then, we entered a vector of turn property variables: disagree, polite disagree, disagree against justification, a claim, extended claim, question, interpret question ($\mathbf{W}$). Next, we tested for the property of the previous turns. We entered lag 1 – lag 4 variables of the above turn property variables ($\mathbf{X}$). To test for moderation effects, we added interactions among significant variables ($\mathbf{Z}$).
An alpha level of .05 was used.

## Results

### Test and Summary Statistics

Of the 136 messages, 134 were coded using our coding scheme. Of the two remaining notes, one was blank, which we assumed was a system error. The other was an off-task comment and since it was the only one in the data set, we ignored it. Among the 134 notes, three were composed by the teacher, and 115 notes were coded as evaluations or claims. 16% of them were coded as having neither evidence nor explanation, 40% as having explanations only, 17% as having evidence only, and 27% as having both. 51% of the messages were posed by girls. Disagreements occurred in 25% of the messages. Also, justifications occurred more often during disagreements than during agreements. During both agreements and disagreements, explanations occurred more often than evidence use. People also used justifications more when making a claim than when evaluating a claim. Please refer Figure 1 about the effects of discourse moves and participant structure variables on evidence and explanation.

### Explanatory model

#### Predict Evidence

Boys were 33% more likely to express their ideas with evidence than girls. Girls were 13% less likely to make claims (Sobel $z = -1.97$). Taking into account the likelihood of making new claims, girls' and boys' use of evidence do not differ significantly.

When learners disagreed, they were more likely to invite evidence. A disagreement in the current turn was 39% more likely to have evidence. When learners made a claim, they preferred to use evidence. Controlling for claims in current turns, the gender effect on evidence was reduced by 30%.

Alternative claims in the previous turn yielded 8% less evidence in the current turn. When a previous learner Made an alternative claim, the next learner was 41% less likely to use evidence. The gender effect on evidence no longer significantly controlled for alternative claims in previous turns. Other variables were not significant (e.g., discussion topic).

#### Predict Explanation

Those who read more notes by other people were more likely to use explanations when expressing their ideas.

4

Disagreements in current turns were 78% more likely to have explanation. Current turns' disagreements against justification were 78% more likely to have explanation. Moreover, claims in current turns were 61% more likely to have explanation. Other variables were not significant (e.g., discussion topic).

## Discussion

This study found that gender, disagreements, claims, and alternative claims can predict the use of evidence. Claims, disagreements, disagreements against justification, and students' reading frequencies are linked to the use of explanations. Messages with alternative claims yielded subsequent notes with fewer explanations.

Boys tended to use more evidence than girls in justification because they made more new claims than girls did. Taking into account the number of claims, the likelihood of evidence use did not differ significantly among boys and girls. Previous studies found that males engaged in more and longer online discussions than females, and that males tended to engage in greater levels of social exchange than females (Barrett & Lally, 1999). Females were also found to make fewer qualified arguments than males (Meyers, Brashers, Winston, & Grob, 1997). However, past studies of gender differences did not differentiate evidence vs. explanations in argumentation. Girls preferred to evaluate the opinions of others or to add their own opinions to new claims. Encouraging girls to make new claims or to state new opinions might lead to their greater use of evidence.

Participants who read more messages by others were more likely to produce explanations, possibly because they acquired more information from others to use for their explanations. In addition, reading messages from others might also help them recognize the potent impact of justifications (e.g., to persuade others to agree, e.g. Chiu, & Khoo, 2003). In contrast, participant centrality (brokerage positions) did not correlate with types of justification. The fact that brokerage positions were not related to disourse moves may indicate that such positions in online social networks do not function as they do in face-to-face social networks. Because learners in higher brokerage positions neither control nor have more access to resources, they did not perform differently from learners in non-brokerage positions.

When people make claims, they typically provide evidence and explanations to support them (Figure 3). For instance, when learners make claims, they might anticipate disagreements and provide justifications preemptively, and thereby be more persuasive (Chiu & Khoo, 2003). Disagreements are also often accompanied by evidence and explanations (especially compared with agreements) because when learners challenge each others' ideas, they are more likely to provide evidence or explanations for persuasion than when they agree with them. This finding is consistent with Clark and Sampson's (2008) study of online discussions of science issues. Furthermore, when learners challenge the validity of evidence or explanations offered for claims or evaluations, they are much more likely to use explanations than when they challenge theses (Clark & Sampson, 2008; Erduran, Simon, & Osborne, 2004). This differs from disagreeing with theses that do not attack the evidence or explanations. Learners

5

use their own explanations to undermine the beliefs of other and to justify their own opinions. The preference for explanations over evidence is consistent with previous claims that learners tend to use explanations in arguments (Kuhn, 2001) and is sensitive to goals(Glassner, et al., 2005; Schwarz & Glassner, 2003)which in this case involves disagreeing with something rather than proving it.

Alternative claims provide new interpretations of problematic phenomena. They are claims that differ from earlier claims but do not disagree with a specific aspect of the earlier claim. Unlike notes disagreeing with justifications or with claims, notes containing alternative claims do not contain suchexplicit discrepancies. The example in the results section shows that after student B's first alternative claim, student C provided a second alternative claim without evidence. It could be that people do not recognize the conflict between original and alternative claims, and without the conflict, people are less likely to use evidence after alternative claims. It could also be that because there was no strong connection between the alternative claim and the preceding message, student C was unable to follow the argument and thus was unable to provide a simple agreement or another alternative claim.

This study has theoretical, methodological and practical implications for researchers and practitioners. Theoretically, it suggests that discourse moves and participant structure might influence the use of justifications. It provides evidence that cognitive and social communicative processes are closely related and integrated in the online discourse activities. Methodologically, this study used quantitative methods to analyze messages in an online forum, traditionally viewed as qualitative discourse data. It usedordered logit, vector autoregression, systems of equations to analyze relationships among the multiple dimensions of online discourse thus modeling the discrete outcome variables and the relationships among the messages. More practically, the findings provide teachers with information for understanding and managing online discussions. Teachers usually have difficulty examining students' online discussions in detail and providing them with useful feedback. If these results are validated in future studies, then teachers can encourage students to read each others' notes to collect information and develop their skills in providing justifications.

# Dispositions, disciplines, and marble runs: a case study of resourcefulness

**Abstract:** In this paper, three researchers and two teachers have zoomed in on three 'mid-level' episodes of learning in a childcare centre and analyzed them using two lenses: a dispositional lens and a disciplinary (science) practices lens. We wonder how these two perspectives could be combined, in order to provide a coherent and illuminating analysis of the learning and to have something to say about the transactional and progressive processes towards 'being a competent learner' and 'being a scientist' that might be at work here. We have found the notion of 'resourcefulness' to be a useful boundary object; it works differently in the different lenses, but has core features in common. We look back across three documented learning episodes and teacher reflections from an early childhood centre, and consider ways in which 'resourcefulness' can provide a boundary-crossing concept that has value for discussions about learning across educational sectors.

## Introduction

Traditionally, outcomes to do with attitudes towards learning, or dispositions, have been fore-grounded in early childhood curriculum discussions, while subject- or discipline-based concerns with knowledge have been fore-grounded in secondary curriculum discussions. Two of the authors of this paper are early childhood teachers, one of the university researchers has a background in early childhood teaching, and the other two have backgrounds in secondary school teaching of science and mathematics. We are all interested in zooming in on particular episodes of learning and teaching in classrooms and early childhood centres, and then zooming out to develop ideas about the ways in which learning trajectories or learning journeys might have been set in motion or strengthened, and what learning opportunities appear to be particularly affording, inviting and engaging for this educational purpose. We all enjoy seeing rich details and the broad patterns within which the details fit: hoping to become both 'tree-wise and forest-wise' (Moss, Phillips, Erickson, Floden, Lather, & Schneider, 2009 p. 504). The university researchers had two lenses on this - learning dispositions and disciplinary practices (in this case of science). This paper focuses firstly on learning dispositions and we investigate troublesome notions such as transfer and authoring. Secondly, a lens of disciplinary practices highlights relationships between children and teachers and artifacts of the environment. We were interested that the early childhood teacher authors appeared to shift easily from one lens to another and, in this paper, we are seeking some common ideas across these two lenses, for analyzing the learning in ways that enrich our ideas about learning journeys and learning pathways.

*Learning dispositions* as a concept usefully starts with Perkins, Jay & Tishman's (1993) triad of elements for a 'thinking' disposition: inclination, sensitivity to occasion, and ability. Using the triad, dispositions can be summarized as being ready (inclined) willing (sensitive to occasion) and able (having the ability or the knowledge) (Claxton & Carr, 2004). Dispositions turn abilities into action (Ritchhart, 2002): abilities become actions when the learner is generally inclined to apply them, and sees that this might be an appropriate occasion. They appear in the literature under various names: for instance, as habits of mind (Costa & Killick, 2000), mindsets (Dweck, 1999, 2006), key competencies (Rychen & Salganik, 2003), and learning power (Claxton, 2002). They have been seen as the building blocks of a learner identity:

> How shall we deal with Self? ….. I think of Self as a text about how one is situated with respect to others and towards the world – a canonical text about powers and skills and dispositions that change as one's situation changes from young to old, from one kind of setting to another (Bruner, 1996, p. 130)

Here we build on previous research that sets learning disposition into a sociocultural frame (Carr, 2001a, b; Carr, Smith, Duncan, Jones & Lee, 2009), connecting them to situation and setting: to disciplinary practices, and to resources or affordance networks.

*Disciplinary practices* are specialized "ways of representing knowledge, and ways of thinking and inquiring that come to count as knowledge" (Kelly, Luke & Green, 2008, p. viii). In science, for instance, a valued practice of the discipline is to conduct an experiment and to repeat and refine as a means of generating knowledge. Windschitl, Thompson & Braaten (2008) write about the scientific forms of inquiry associated with the 'epistemic nature of knowledge'. "Scientists create models in the form of analogies, conceptual drawings, diagrams, graphs, physical constructions, computer simulations" and they use these models for the following forms of inquiry:

> Meaningful learning in school science entails more than accumulating domain knowledge, it requires the appropriation of specialized epistemic discourses that allow students to organize, develop, and evaluate knowledge according to disciplinary standards. (Windschitl et al., 2008, p. 310)

Models are subsets of larger, more comprehensive systems of explanation (i.e. theories) that "provide crucial frames of reference" for *generating* hypotheses or working theories for *testing*, *revising*, *conjecturing* and *explaining* (p. 311-312)

Guiding our analyses is the view that a learning activity is distributed over people, places, and things: the learner as a "person-participating-in-a-practice" (Miller & Goodnow, 1995, p. 8). In order to represent the multidimensional nature of situated activity we draw on Barab and Roth's definition of an affordance network as the "collection of facts, concepts, tools, methods, practices, agendas, commitments, and even people ... that are distributed across time and space and are *viewed* as necessary for the satisfaction of particular goal sets" (2006, p. 6) (italics added). A closely related idea is the notion of a learner as an "agent-acting-with-mediational-means" (Wertsch, 1998, p. 24) where mediational means include language, signs and symbols, and other tools and artifacts. Learners act with mediating tools by "recognising and activating a tool's affordances that are suitable" for a particular purpose or context (McChesney & Cowie, 2008, p. 108). We describe and discuss an episode about Chase rolling marbles down wooden tracks as a means of exploring how learning dispositions and disciplinary practices might inform us around issues of authoritative competence (Greeno, 2006). For example, how might a perspective based on recognizing, activating, and adapting resources encapsulate mediated activity? Finally we highlight some issues around refining these concepts, discuss the notion of 'resourcefulness', and raise further questions that might be explored in different settings.

## Background

The episodes that form the data for this paper were included in the Final Report for a three-year research project on strengthening a culture of question-asking and question-posing in an action research project by the teachers and the children (Greerton Early Childhood Centre Team, Carr & Lee, 2008). This was part of a Centre of Innovation programme, funded by the New Zealand Ministry of Education. Children who attend this childcare centre are aged from infancy until the day they go to school (usually on their fifth birthday). Significant features of the centre's practice are: a culture of reflection and critique, a philosophy of shared leadership, and an environment that affords and promotes inquiry. An aspect of the latter is their use of Learning Stories as a formative assessment mediating tool or artifact. Learning Stories are characterized by digital photographs being taken, an episode of learning is described (in text, sometimes dictated by the learner), the learning is analyzed, and suggestions for further work are made. Each Learning Story is digitally stored, printed as artifacts for portfolios, re-visited with the children by the teachers, and sent home to parents and families (Carr, 2001a). Sometimes they are written to the learner, as they were in this case. The Stories here are about Chase, who, by the time he was four years old, owned a number of portfolios of learning episodes in which he was a participant, sometimes working on his own, sometimes working in a group.

The research study involved the sixteen teachers in this centre reflecting on their Learning Stories, writing alternative perspectives, and developing a framework of key features for the affordance network associated with their intention of question-asking and question-posing. The teachers dubbed this framework the 'Threads of Inquiry'. There were six: Continuity, Listening Dialogue, Growing Intelligence, Playfulness, Surprise and Uncertainty, and Real Work. The data for this paper came from three Learning Stories in the Thread of Inquiry entitled 'Continuity' and Robert's reflections on Surprise and Uncertainty. Comments from Robert and Lorraine also come from the concluding chapter of the Final Report.

## Robert's Stories

For several months Chase has been exploring the making of 'marble runs' with angled blocks (wedges), wooden tracks and marbles. Robert, one of the teachers, writes two stories about these marble runs. In the first (What it Takes to Get There) he (Robert) had introduced a 'provocation', asking Chase whether the marble would run into a wheeled cart if it was placed at the end of the run. He and Chase began to explore together, and the story continues:

> Chase, you thought this experiment would be OK so we put the cart at the end. We found it too high so first we had to build up the end of the run high enough so the marble could drop into the cart. You tried the marble down the track. Because we had built up the end it ran out of steam before it could get into the cart.

Chase then takes over, and Robert comments:

> And here is where your keenness to experiment and your extensive knowledge of marble runs showed through. As you positioned a block and tried the marble, it still did not make it. You placed a block under the lower end, raising it up, which stopped the marble even further from the cart, this did not faze you at all but with confident persistence you continued to add a block then test, then another and test again until you had success and the marble made it into the cart. I was really impressed with your willingness to meet the challenge getting the marble into the cart, presented even when it took many attempts. Your enthusiasm (for) the task showed through in the way you celebrated by excitedly jumping and laughing when the marble finally went into the cart.

In a second story (How Far Can We Go?), two months later, including photographs of a more complex marble run, Robert writes:

> When I watch you creating one of these marble machines, it is very obvious to me, by the way you test and adjust again and again that you are always asking questions of yourself and your creation and then through testing answering them. …
>
> Also it is not only myself that has noticed your talent at marble machines but also many of the other children as they are emulating your work. In particular I have noted that Dominic's marble creations have a definite Chase influence about them.

He adds a 'Teacher Reflection'; this time the comment is not directly addressed to Chase. Other teachers and Chase's family will read these stories, and re-visit them with Chase.

> It is really great to watch how Chase is building complexity into his marble runs, and his knowledge of what is needed to make the marble follow the track he has created is growing with it. The persistence that is needed to test and retest is a disposition that will always be of use (for) problem solving whatever the task. The social side of the marble tracks cannot be ignored either. The more interesting the track you build, the more others will want to try it out or make one as well, so with limited blocks and space this provides many opportunities for negotiation, compromise, and tolerance.

## Lorraine's Story

At about the same time as these stories about the marble runs, Lorraine Sands (the second teacher author of this paper) wrote a story about three children, including Chase, rolling reels (empty electrical cable reels) down a ramp handrail. She called this story 'The Experimenters Continue'. She writes:

> Walking down the ramp is often a place of congestion. Only because it's a good place to experiment with reels and rolling. I think that today as Chase and Tom rolled and chased, rolled and chased, the appeal may have been motivated by their lengthy experimentation with pipes, marble rolling tracks and now electrical reels. They (Chase and Tom) were building their knowledge base as they worked together and alongside each other, calculating speed, distance and trajectory.

Her commentary on the learning that was happening here began with the following comment:

> I think we have experts (like Chase and Tom) who have spent long hours working out their theories, and apprentices (like Dominic) who get captured by the excitement, watch intently and then start experimenting themselves. But practice is a key element to building a knowledge base that is shaped and re-shaped through experimentation, refinement and further risk-taking in related fields – hence the fluid movement between pipes, marble tracks and electrical reels.

Lorraine notes in the documentation that she asked Chase for his 'expert opinion' about why Dominic's wider reel had veered (wobbled) off course.

> He told me immediately, "Cos it's too fat out". And he was exactly right. His endless experimentation had given him the understanding that the inside width of the reel was a critical factor in the trajectory.

## Learning dispositions

The teachers here were particularly interested in learning dispositions, which had been a feature of their early childhood curriculum since 1996 (New Zealand Ministry of Education, 1996). The national early childhood curriculum includes a strands 'Exploration'. Learning outcomes (described as a combination of knowledge, skills and attitudes) in this strand include: the ability to make decisions, choose their own materials, and set their own problems; the attitude that not knowing and being uncertain are part of the process of being a good learner; an expectation that they take responsibility for their own learning; the knowledge that trying things out, exploration, and curiosity are important and valued ways of learning. At the same time this strand includes a goal that says: "Children experience an environment where they develop working theories for making sense of the natural, social, physical and material worlds" (p. 82), and the teachers were interested in this too.

In an earlier project Carr and colleagues had taken Perkins' three elements of a 'thinking' disposition (inclination, sensitivity to occasion and ability) into the 'middle' space between the individual and the context, calling on the work of Wertsch, who writes about 'living in the middle'. He has said that "a focus on the mediated action and the cultural tools employed in it makes it possible to live 'in the middle' and to address the sociocultural situatedness of action, power and authority" (Wertsch, 1998 p. 65). We described three processes of mediated action for the construction of learning dispositions, based on Perkins' triad: authoring, recognizing opportunity, and connecting the knowing (Carr et al., 2009). These ideas build on Bourdieu's notion of *habitus* (e.g. Bourdieu 1977, 1990) and owe a considerable debt to Greeno (2006; Greeno & The Middle Schools Mathematics Through Applications Project Group, 1998), Gee (2008) and Lemke (2000). In his 2006 commentary in a special issue of the Journal of the Learning Sciences on transfer of learning, Greeno concludes (p. 546) that "To act effectively in a way that counts as transfer, therefore, involves having or taking authority to go beyond what has been taught", and we have argued that these three processes can include the seeds of learning journeys over time.

*Authoring.* Greeno (2006, p. 538) describes the conditions for authoring, authoritative and accountable positioning, as aspects of interaction such as crediting individuals with ownership, initiating ideas and topics, and challenging and questioning. Robert emphasizes persistence as a learning disposition, and comments on Chase's persistence that is needed "to test and retest", and, in a comment in the first story, 'What it Takes to Get There', he says "To be able to enter into a task with such enthusiasm and willingness to experiment is a disposition that will make so many of life's challenges easier to meet". In a commentary for the research project on the first story he commented on his observation that for Chase "a setback was just motivation to research new ideas". He interprets Chase's work as "asking questions of yourself". In a commentary for the research project on the What it Takes to Get There episode, Robert comments on what kind of an affordance is a provoking question, and whether in this case it had re-positioned Chase's authority.

> When I first looked at this, I really had to question myself. Did my posing a question about the possibility of the marble making (it to) the cart, actually support Chase in 'question-asking' when it was myself not Chase who posed the question? …. I was just thinking about how glad I was that I held my tongue while I was working with Chase as he was trying to achieve the goal of getting the marble down the marble run and into (the trailer). I found this particularly hard when Chase started to build the run up in the wrong direction".

In a commentary for the research project on the second episode, How Far Can We Go, he said: "There is a definite culture of metered intervention within the (childcare) centre. By this I mean that the teaching team here are very conscious of when and by how much they project themselves into the children's learning. They may choose to set a provocation, or work as a role model, or mentor".

*Recognizing opportunity.* After Robert had increased the challenge in this activity he reminded Chase that "You thought this experiment would be OK", and he connected the growing complexity of the marble runs with Chase's growing 'knowledge of what is needed': "His knowledge of what is needed to make the marble follow the track he has created is growing with it". He points out that it is not only the teacher "that has noticed your talent at marble machines but also many of the other children as they are emulating your work". Lorraine's story revealed that it was probably the earlier experience by Chase and Tom with water flows (pipes) and marble runs that meant that they recognized the opportunity of combining some other resources - the electrical cable reels and the ramp hand rails - for more investigations of rolling and slopes. They were re-cognizing the resources. We have described this therefore as an example of 'resourcefulness'. This depended on a range of resources being available, and a 'permeable' curriculum that gave permission for unusual and innovative combinations and uses.

*Connected knowing.* Both teachers commented on the months of practising and experimenting, the frequent episodes of exploring trajectories of rolling and flowing. They connected up the children's funds of knowledge, developed over months of practice with running water down pipes in the sandpit, and rolling marbles down marble-runs. Lorraine specifically connects the learning over time, as does Chase's portfolio of Learning Stories.

## Disciplinary practices of science

The construction of models, like marble runs, can be starting points for scientific forms of inquiry and investigation. Windschtl, Thompson & Braaten (2008) comment that "Although different domains in science have their own fundamental questions, methods, and standards for 'what counts' as evidence, they are all engaged in the same core epistemological pursuit – the development of coherent and comprehensive explanations through the testing of models" (p. 313)

In the above episodes, Chase has been developing marble runs as an interesting project, with a purpose (sending the marble into a container along a more and more complex route). From a scientist's eye, these marble runs are also models that afford scientific forms of inquiry and investigation. Chase adjusts the position of the wooden tracks by placing wooden blocks under them. This adjustment process appears to be a repeated sequence of adding more blocks (thereby adjusting the tracks) and testing with a marble run. Robert, the teacher, identifies the activity as an experiment, and acknowledges Chase's fund of knowledge about marble runs (González, Moll & Amanti, 2005). Here is Chase as scientist, engaged in a disciplinary practice of experimenting. He constructs a ramp and tries it out with a marble run. If unsuccessful, he changes parameters such as the relative heights of the ends of the tracks, or the orientation where the tracks meet, and then tries another marble run. The iterative process of adjusting and testing is at the heart of a valued scientific practice of experimenting. This particular experiment also has a desired end goal. Success is when the marble rolls down the track and drops into the wheeled cart placed at the end of the run. It is a 'eureka' moment for Chase who jumps and laughs when his goal is reached, and we would claim this excitement is also part of the human activity of being a scientist, albeit not often acknowledged in popular images of scientists.

Nested within this practice of experimenting are other aspects of scientific activity. Adjusting one end of the track more than the other changes the angle of inclination so that the track becomes a sloping ramp. It is not always a simple process of just adding blocks to raise one end of the track; depending on the conditions of the context each end of the wooden tracks may need to be raised or lowered. Chase adjusts the ramp by adding and removing different numbers of blocks at either end of the tracks. The process of adding blocks in order to adjust the slope of the ramp also provides visual information for Chase. We claim that this process of adjustment or refinement is a disciplined practice of noticing, and noticing has focus and intention. Intentional noticing is described by Mason as making "a distinction to create foreground and background, to distinguish some 'thing' from its surroundings" (2002, p. 33). We infer that Chase notices aspects of the physical artifacts of the context; the wooden tracks, the marble, the blocks, and even the wheeled cart that was to receive the marble, all have observable material attributes. These attributes are the width and length of the wooden tracks, the design of the sides of the tracks, the roughness of the wooden track, and the size and smoothness of the marble.

Associated with the physical arrangement of the tracks as an inclined plane are the aspects of motion of the marble. Chase has already noticed that the speed of the marble is an affordance of the track-and-marble system because in one of his early attempts, the marble "ran out of steam before it could get into the cart". Robert also comments in the second story:

> This latest design changes direction not once but two or three times; it will often go through tunnels and has a collection point that catches the marble at the end. To do this you explore the concepts of force, acceleration, deflection, trajectory and motion. You have worked out that the marble does not have to go fast and in fact this latest version pictured works best if the marble is rolling down just fast enough so that it will drop from one ramp to the next without overshooting. What I also find interesting about your marble runs, Chase, is that they not only function very well, but are also pleasing to look at. You seem to have a real sense for what is aesthetically pleasing.

There is more than noticing within Chase's activity. He is *recognizing which attributes are important for his experiment, such as the properties of the artifacts*. Properties of tools are affordances and according to Pea (1993), an affordance refers to "the perceived and actual properties of a thing, primarily those functional properties that determine just how the thing could possibly be used" (p. 51). The height and width of the blocks afford different aspects of being a pillar or prop for the tracks, including any limits on the placement and number of blocks used before the pillar becomes unstable. The wooden tracks afford a sloping ramp where the tracks can direct the path of the marble, and the properties of the surfaces, wood and glass, affords motion. Where each wooden track meets both affords and constrains the ramp of aligned wooden tracks. These are affordances of the tools at hand for Chase and by activating the affordances he adjusts and re-adjusts the tools until the marble run is successful. This is a reflexive process where he attends to how the blocks can raise or lower the tracks, then shifts attention to the slope of the tracks, and then back to adjusting the heights of the tracks. When he has constructed a track with the desired slope, then he shifts attention to the trajectory of the marble.

Here Chase is engaged with affordances of the track-and-marble system that are related to phenomena that we identify as aspects of physics. He is noticing, recognizing and activating affordances of the tools or resources that are suitable for his intention, and for his pursuit of scientific forms of inquiry. Recognizing the affordances of a tool plays an important role for anyone adapting the design of a tool for a particular purpose or context, as required in scientific and technological practice. It is a key to innovation and improvisation. "'Being attuned to and activating affordances' can be rephrased as 'resourcefulness', that is, noticing, recognising, recruiting, and adapting the resources of a tool for particular contexts and purposes" (McChesney & Cowie, 2008, p. 109). Particular properties or affordances of tools provide resources, where a tool is activated or re-sourced for further activity.

## Concluding comment

Episodes like these may be part of a documented journey about becoming a competent learner, and recognizing what it is to be one. They are also part of a documented journey about becoming a scientist, and recognizing what it is to be one. The marble runs discussed in this paper might be described instances of 'everyday' science, set in a context of an early childhood centre. The documentation process of Learning Stories, however, is an opportunity for the 'scientist's' view to be recorded in text and photographs. The introduction this new artifact into the environment provides a resource that will be revisited by the learner and others, be read back to the learner, and be a topic of conversations more likely to include a scientific discourse. Commentary by Lee, Brown, Brickhouse, Lottero-Perdue, Roth & Tobin (2007) reminds us that

> The repertoires of school are often compartmentalized so that students' otherwise relevant knowledge is not invited and evoked, and the continuity over time is lost to the urgency of the banal moments of everyday life in school, (p. 335)

This did not appear to be so here. The repertoires of this early childhood centre provided opportunities for inviting, evoking, and provoking spaces for the learners' relevant knowledge and experience, foregrounding continuity over time in action, dialogue, and document. As we explored different lenses on these episodes, we came to see a common, if differently conceived, element of 'resourcefulness'. This provided the common ground between the learning dispositions in situation and participation in the forms of scientific inquiry such as model-making, testing and refining working theories (aspects of the disciplinary practices of science). The commonalities were in the recognition of affordances and the re-cognizing of opportunity as a consequence of the experience that developed strategies and knowledges in the domains of disposition and science. The 'play' with pipes, marble runs, and reels provided a dispositional and scientific milieu that had the capacity to shape a learning journey. In our view the episodes illustrated that *being resourceful* is the source of improvising and reinterpreting opportunity. It is an action that is sited 'in the middle' between the cognizing and re-cognizing mind and the affording environment. And it can take learning across the boundaries of place and time.

# Reading in the Context of Online Games

Constance Steinkuehler, Catherine Compton-Lilly, & Elizabeth King
University of Wisconsin-Madison, 225 North Mills Street, Madison WI 53706
constances@gmail.com, comptonlilly@wisc.edu, emking29@gmail.com

**Abstract:** Research suggests that text is an important component of videogame culture (Gee, 2003; Leander, & Lovvorn, 2006; Steinkuehler, 2007), but we have few empirical assessments of what kinds of texts are involved or youth's reading performance on them. This paper presents a series of four studies conducted to examine: What texts are a regular part of videogame play? What is their nature, function, and quality? And what is the nature of adolescent reading performance within such contexts? Our results show that *informational* texts, comprised of 20% academic language and with an 11.8 average reading level, are the most prevalent text type used for gameplay. Reading performance on such texts is no different than on school-related texts when topic and difficulty were controlled. However, when struggling readers when allowed to *choose the topic*, they performed at "independent" level (94-97% accuracy) even on texts that were 7-8 grade levels above their head.

In their recent *Reading at Risk* report (Bradshaw & Nichols, 2004), the National Endowment for the Arts documented a pronounced decline in reading in American youth and associated it with the equally pronounced increase in the use of "electronic media" such as television, videogames, and the Internet. Such technologies, the report authors claimed, "often require no more than passive participation" and "foster shorter attention spans and accelerated gratification" (p. vii); thus, the authors identified them as one (perhaps *the*) underlying cause of this new "risk" to reading among today's digital immersed youth. Emerging research on what youth actually do while engaged in such technologies, however, reveals a rich array of digital and print literacy practices (Black & Steinkuehler, 2007). They use text messages as a way to develop and sustain peer networks (Lewis & Fabos, 2005). They create elaborate textual representations of themselves on personal websites as an expression of identity (Guzzetti, 2006). They use the given narrative structures of anime, for example, as fodder for the articulation (and distribution) of their own stories (Black, 2008). And they engage in complex constellations of reading and writing around the videogame titles they play (Steinkuehler, 2007).

The goal of this investigation was to examine this latter phenomenon – reading related to naturally occurring online videogame play. Emerging research suggests that text is an often-hidden but nonetheless important component of participation in videogame culture (Commeyras, 2009; Gee, 2003; Leander, & Lovvorn, 2006; Steinkuehler, 2006, 2007, 2008), but we have few empirical assessments of what kinds of texts are involved in such activities, their quality and characteristics, or youth's reading performance on them compared to texts in other contexts. Precisely what kinds of texts are a regular part of videogame play? What is the nature, function, and quality of such texts? And how does the reading performance of adolescents on such game-related texts compare to their performance on school-related texts? Toward answering these questions, we conducted a series of investigations designed to explore the claims popular in "games and learning" literature that videogames do indeed entail rich forms of literacy. In this paper we detail a series of four studies we conducted in order to answer the three questions articulated above: (1) a survey of the textual resources gamer players used as a regular part of their gameplay; (2) a quantitative and qualitative evaluation of the nature, difficulty, and quality of the text resources identified in study one; (3) a study comparing adolescent reading performance on appropriately leveled reading materials in the context of games versus school; and (4) a preliminary (yet suggestive) pilot study of videogame reading when difficulty level is not controlled. All four studies were conducted using the massively multiplayer online game *World of Warcraft* (WoW) given its overwhelming success on the market (Woodcock, 2009), robust online textual community, and general popularity with adolescents and young adults. In what follows, we detail the method and findings of each study.

## Study One: What Texts are a Regular Part of Gameplay?

### Data Collection

Our first step in this investigation was to find out what texts were involved regularly in gameplay. Toward this end, we interviewed 25 expert and 21 novice WoW gamers (n=46) about the textual resources they used for gameplay. Each participant was asked to list to exhaustion any and all resources they used for the game and to judge the importance of each text listed by classifying it as either a "core resource" (a text they consult regularly and consider "core" to successful gaemplay), a "frequent resource" (a text they refer to frequently but do not consider crucial) or an "infrequent resource" (a text they refer to but not with any regularity).

### Findings

Using the resources generated by participants as our basis, we then inductively developed the following five categories of text based on function:

(1) *Information resources* are online reference materials providing detailed information about the game, strategies for playing it, and the history of the game's lore. The three most common resources referenced were wowhead.com, wowwiki.com, and thotbot.dom, which are database backed websites that organize information about in-game materials and quests that are written, harvested, and then discussed, revised, and scrutinized by the players themselves. Such sites are structured as encyclopedic, dynamically generated, online reference books and function as user manuals to the game that are created and maintained by those who play.

(2) *Discussion forums,* sponsored by the game company or various public or private sub-communities within the game, host text-based, asynchronous collective problem solving about complex systems in the game – activities which evidence informal science literacy characteristics such as evidence-based argumentation and model-based reasoning (Steinkuehler & Duncan, 2009).

(3) *Group organization resources* are online tools and texts that help groups within the game (such as guilds or raid groups) organize their collaborative gameplay, providing detailed instructions for specific activities, scheduling information and sign-up tools, for example.

(4) *UI mod sites* (short for "user interface modifications," also called "add on's") are online hubs for freely downloadable, player-generated bits of software that change the user interface of the game in some way (e.g., wowcurse.com) to enhance performance or player experience. Prior case study work suggests that, for some players, the use of such tools transitions into critique, debugging and "beta testing" practices that provide an important gateway into software development practices (Steinkuehler & Johnson, 2009).

(5) Finally, *fandom media* include creative fiction and non-fiction digital media literacy artifacts such as You Tube movies, fan fiction about the game, fan artwork, and other creative "literary" resources that the player community creates around the game.

Table 1 presents the each functional category of resource by number of unique members that were referenced during the interviews, their importance rating, the average number of references per member of the category, and an average weighted score of their importance calculated as [(number of core ratings)*10 + (number of frequent ratings)*3 + (number of infrequent ratings)*1] / (total number of references)].

Table 1: Game-related texts by functional category and rating of importance to gameplay.

| **Category** | **Unique Members** | **Importance Rating** | | | | ***Average Number of References per Member*** | ***Average Weighted Importance Rating*** |
|---|---|---|---|---|---|---|---|
| | | Core | Frequent | Infrequent | Total | | |
| **Information Resources** | **31** | 52 | 55 | 77 | **185** | ***5.97*** | *4.11* |
| **Discussion Forums** | **31** | 11 | 13 | 32 | **56** | *1.81* | *3.23* |
| **Group Organization Resources** | **34** | 31 | 15 | 21 | **48** | *1.41* | ***7.8*** |
| **UI Mod Sites** | **16** | 18 | 9 | 18 | **45** | *2.81* | *5.0* |
| **Fandom Media** | **9** | 9 | 4 | 7 | **20** | *2.22* | *5.45* |

*Information resources* were by far the most common, with participants referencing unique members within this category three times more frequently than any other type of resource (roughly six citations for each member on average compared to two). In contrast, *group organization resources* were rated as more important to regular gameplay with an average weighted importance rating (7.8) followed by player production and UI-Mod resources (5.45 and 5.0 respectively), and finally information resources and discussion forums (4.11 and 3.23 respectively). Figure 2 below shows the proportional make up of the "constellation of literacy" that comprises online gameplay (Steinkuehler, 2007). Thus, information resources comprise the majority of the texts related to games but group organization resources are viewed as more important to regular gameplay. The result is a complex picture where the *main body of game-related text* consists of standard expository and procedural text with the *most valued resources* being for in-group coordination.

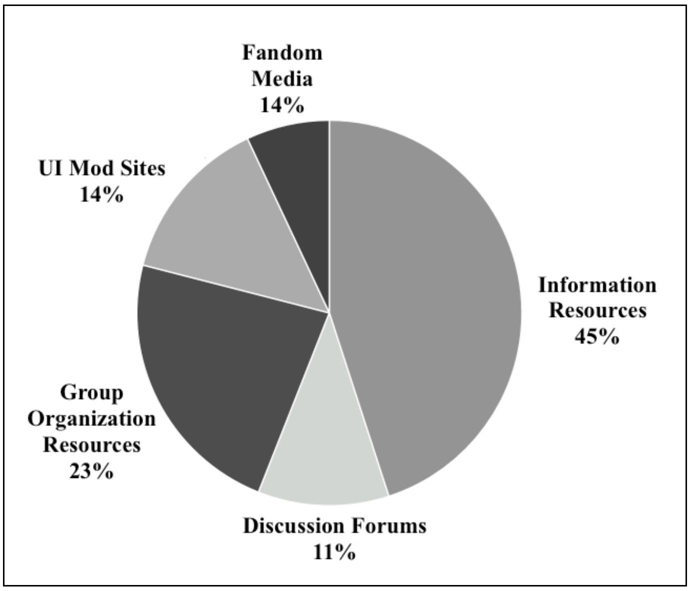

Figure 1. Proportional breakdown of the "constellation of game-related texts" by functional category.

## Study Two: What is the Nature and Quality of Game-Related Texts?

### Methods

Using the list of resources obtained in the first study, we identified the top three resources used by gamers as part of their play based on the total number of references: thotbot.com, wowwiki.com, and wowhead.com. All three similarly structured, database-backed websites function primarily as *information resources*. In order to assess the nature and quality of such texts, we randomly selected 50 pages total across the three identified resources for quantitative assessment (grade-referenced reading level, lexical analysis) and one representative page for detailed qualitative (multimodal, structural, and genre) analysis. Quantitative assessment of the 50-page random sample included statistical calculation of average reading level using three separate statistical approaches – Flesch-Kinkaid reading level (Flesch, 1948), Fry Readability (Fry, 1968), and SMOG reading level (McLaughlin, 1969) – and a lexical analysis (Laufer & Nation, 1995) to highlight the range of vocabulary used in such texts. Qualitative analysis of the single representative page included a survey of the modes of information used, the structure of the information presented, and the genres of text included.

### Findings

The average reading level of the 50-page random sample was $M$ = 10.86 ($SD$ = 2.30) on the Flesch-Kinkaid, $M$ = 12.98 ($SD$ = 2.08) on the Fry, and $M$ = 11.56 ($SD$ = 2.56) on the SMOG test. Thus, the most prevalent texts related to WoW are written at an average grade level of 11.8, placing is somewhere between *Sports Illustrated* (grade 11) and *Time Magazine* (grade 12). Although there is some variation in the reading level of game-related texts (roughly 2 grade levels), overwhelmingly such information resources require reading skills at the high school or high school graduate level.

Lexical analysis of the same 50-page sample reveals that 70% of the vocabulary used within the texts were words found within the most common 1000 words of the English language (K-1 words). A full 20% of the vocabulary used were "academic words" (Academic Word List words) – vocabulary common to school textbooks across a range of academic disciplines such as "compensation," "implication," and "obtainable". Only 4% consisted of game-related "specialized discourse" (Gee, 2003)– highly specialized terms relevant only to WoW gameplay itself such as "respec," "frost," "crit," (Off-List words). Thus, as predicted by Gee (2003) and others, game-related texts appear to be a useful bridge into academic forms of language.

Qualitative assessment of the one page representative sample nature reveals that such game-related texts are dense and complicated information sources in at least three ways. Figure 2 gives a simplified diagram articulating some of this complexity. First, symbolic information is thoroughly multimodal, including images, icons, symbols, color and font demarcations to specify information type, and hyperlinks to additional details (which display as call-out boxes on one's cursor) or link to related pages within or beyond the site itself. Second, only tacit page layout characteristics are used to cue the reader as to the source of information contained within a given page. The center of the main page features information "harvested" from the game engine automatically through site-related UI mods or "add-ons" that automatically users voluntarily use while playing. These "add-ons" collect information about the game and contribute those data back to the website database to be aggregated automatically as content within the main pages. The bottom of the page, however, features multiple tabbed sections including crucial threaded commentary and discussion of the information harvested and then re-presented in the main body of the page. In effect, the bottom half of the page provides human interpretation and analysis of the machine-generated data presented in the top half, creating a complex "split attention" effect (Mwangi & Sweller, 1998) requiring readers to synthesize information from two sources quite disparate in terms of multimodal tendencies, page layout formats, and underlying source or author.

Third and finally, such texts are particularly complicated due to their mix of genre. While the primary genres of game-related information resources are *expository* and *procedural,* each page within such sites actually features multiple forms – including transactional, narrative, and persuasive text as well as expository and procedural – with few clear demarcations among them. For example, a description of a single in-game quest very often begins with details about where the activity begins and ends (expository text), then shifts to quoted text delivered orally by the relevant "quest giver" character in the game world (narrative, first person text), followed by step-by-step instructions on how to complete the quest (procedural text), which are then quickly succeeded by player-written, collaborative arguments for why a given quest is important or not important to complete (persuasive texts), and finally, drifting conversation where players best one another in reports of how easy a given quest was overcome (transactional texts). Thus, if structural cues are one tool a reader uses to help predict and parse the content of a given text (Coiro & Dobler, 2007; Goldman & Rakestraw, 2000; Weaver & Kintsch, 1991), then multimodal, multi-authored, and multi-genre texts such as these present interesting challenges, even for strong readers.

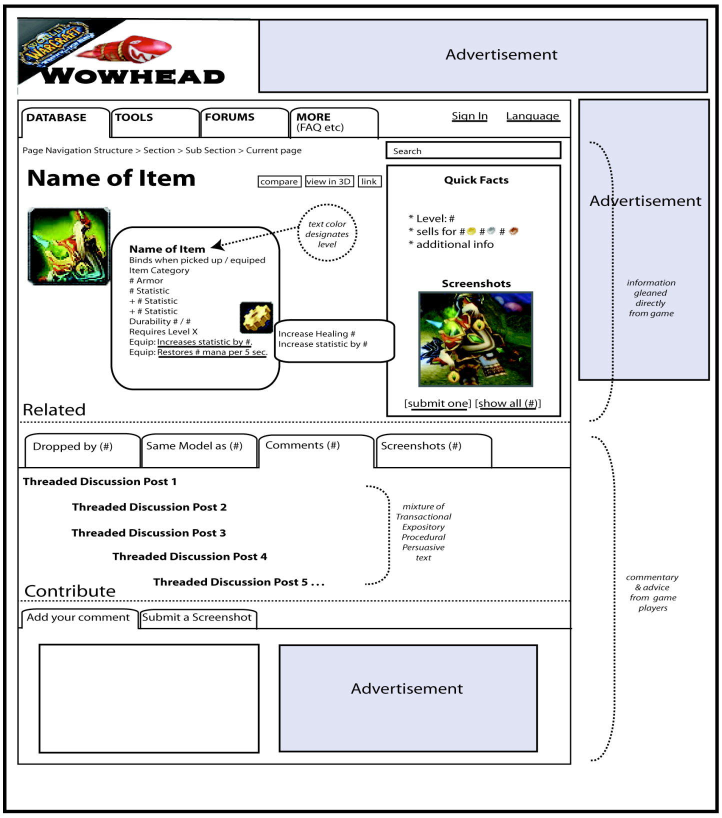

Figure 2. A schematic overview of the game-related sample page selected for qualitative analysis.

## Study Three: How Does Reading Performance Compare on Game-Related Texts versus School-Related Texts?

### Methods

Our third step in this investigation was to examine adolescent WoW players' reading performance (Clay, 1993/2002; Ekwall & Shanker, 1993; Goodman, Watson, & Burke, 2005) and comprehension strategies (Pearson & Johnson, 1978; Taylor, Graves, & van den Broek, 2000) on game-related text versus school-related text. Seventeen adolescent boys participated in the study, all of whom played WoW. Participants' reading levels were first assessed using the Qualitative Reading Inventory (QRI) (Leslie & Caldwell, 2006). They then read two texts aloud: (1) a passage from a social studies textbook, and (2) a game-related text that had been downloaded from one of the resources identified in study one. Each of the two texts were chosen by the resarchers to match the "instructional reading level" of the participant as determined by the QRI and the order of the two test texts were counterbalanced to mitigate ordering effects. The activity took about 90 minutes on average. Data included running records (Clay, 1993/2002) which noted the various reading behaviors of the students including substitutions they made in text, self-corrections, repetition of words and sentences, and attempts at word solving. Text retellings and responses to comprehension questions were used to assess reading comprehension. Finally, short interviews were conducted with each student to assess students' attitudes toward the texts and their perceived potential uses in the lives of students.

## Findings

Table 3 shows the quantitative findings from study three. All 17 adolescent boys who participated in this study read at or below grade level (n=10 and n=7, respectively). With reading selection calibrated to match each participants' reading level as determined by the QRI, there were no statistical differences between participants' accuracy or comprehension on the game related text ($M$ = 0.96, $SD$ = 0.03) versus the school related text ($M$ = 0.97, $SD$ = 0.02). Overall then, reading performance was remarkably consistent across the two texts.

Table 2. Participants' reading performance on the QRI, the game-related text, and the school related text.

| Student | Age | Grade | QRI Reading Assessment | QRI Text: Miscues | QRI Text: Compre-hension | Game Text: Level | Game Text: Miscues | School Text: Level | School Text: Miscues |
|---|---|---|---|---|---|---|---|---|---|
| Andy | 11 | 5 | 5 | 0.95 | 0.75 | 8 | 0.94 | 7 | 0.89 |
| Ben | 13 | 7 | 7–8 | 0.94 | 0.90 | 8 | 0.89 | 7 | 0.96 |
| Carl | 13 | 7 | 6 | 0.98 | 0.87 | 8 | 0.97 | 7 | 0.98 |
| Dexter | 12 | 7 | 7–8 | 0.98 | 0.80 | 8 | 0.95 | 7 | 0.98 |
| Ed | 14 | 8 | 5 | 0.95 | 1.00 | 8 | 0.92 | 7 | 0.94 |
| Fred | 14 | 8 | 6 | 0.95 | 0.87 | 8 | 0.94 | 7 | 0.97 |
| Gary | 14 | 9 | 6 | 0.99 | 0.87 | 8 | 0.99 | 7 | 0.98 |
| Harry | 14 | 9 | 7–8 | 0.97 | 1.00 | 8 | 0.95 | 7 | 0.93 |
| Isaac | 16 | 10 | 7–8 | 0.97 | 0.90 | 8 | 0.95 | 7 | 0.96 |
| Jack | 16 | 10 | HS | 0.97 | 0.90 | 10 | 0.99 | 7 | 0.99 |
| Kurt | 16 | 10 | HS | 0.98 | 0.80 | 11 | 0.99 | 12 | 0.98 |
| Lee | 16 | 10 | HS | 0.99 | 0.90 | 11 | 0.99 | 12 | 0.98 |
| Mark* | 16 | 11 | 6 | 0.98 | 0.75 | 8 | 0.97 | 7 | 0.96 |
| Ned | 16 | 11 | HS | 0.98 | 0.70 | 10 | 0.98 | 7 | 0.96 |
| Otto | 17 | 11 | HS | 0.98 | 0.80 | 11 | 0.99 | 12 | 0.98 |
| Pete* | 16 | 11 | HS | 0.98 | 0.90 | 11 | 0.99 | 12 | 0.98 |
| Quincy | 18 | 12 | HS | 0.95 | 0.80 | 11 | 0.96 | 12 | 0.98 |

We then identified two contrasting cases from within our data set (see asterisked rows in Table 3) for more detailed qualitative exploration in order to explore potential differences in participants' reading comprehension strategies and how they positioned themselves relative to the two text types. Pete (pseudonym) was in grade 11 and appropriately reading at the high school level; Mark (pseudonym) was also in grade 11 but reading at only the sixth grade level. While Pete scored 0.90 on the QRI measure of reading comprehension, Mark only scored 0.75. We transcribed and reiteratively coded each boy's retelling of the QRI text, the game text and the school text to identify similarities and differences between the two participants.

Both Pete (stronger reader) and Mark (struggling reader) used the structure of each reading to organize their retelling, but Pete adhered to school expectations when retelling school text, providing sundry details on each and given concise overviews at the beginning of each retelling episode. In contrast, Mark provided only inaccurate and sparse details on each reading and gave unclear and inconcise overviews for each text. Even when Mark (struggling reader) seems to understand the content of what was read, he had a hard time conveying it to tester. Both participants use I-statements in relation to the gaming text, but Pete (stronger reader) took on the role of “text analyst” of sorts, readily assuming an analytic position toward both texts and freely giving his opinion on the authors’ craft. In contrast, Mark (struggling reader) did not position himself as an evaluator or critic of text except in relation to his own purposes and needs for the content the text contained. For example, while discussing the school-related textbook excerpt, Pete (stronger reader) states, “I thought it was quite informative, used fairly simple and straight forward vocabulary and um, sentence structure and the like. So it was easy to understand, easy to tell it’s from a textbook.” (Pete, stronger reader) In contrast, Mark (struggling reader) discusses the purpose of the text only when directly queried, stating, “Our vocabulary…um, cause there were a lot of words in here that you had to try at” except when that assessment related to his own purposes and needs. When his own interests are evoked, his responses and evaluations become more elaborated. For example, when asked the purpose of the game-related text, he states “to explain the use of duel wielding - off-handed, one-handed, two-handed. To explain damage meters, whether DPS is better with two weapons or one two-handed weapon. To help you with the numbers I was gonna use it on my um, warrior and then my rouge to, like, go through different weapons I have in my bags and see which ones are better.” Thus, one notable difference between the two boys who contrasted in terms of reading comprehension performance was the extent to which each positioned himself as a critical consumer of the text: Mark (stronger reader) analyzed and critiqued the text’s composition and rhetoric without restriction while Pete (struggling reader) only engaged in such analysis when it was directly related to his own interests, preferences, and uses of the content of the text.

## (Pilot) Study Four: How Well Do Struggling Readers Perform on Difficult (Game-Related) Texts of Their Own Choice?

### Methods

Based on the qualitative differences found in study three – with contrasting readers (Mark and Pete) positioning themselves differently toward the text except when individual interests, preferences, and uses of the text content were evoked – we decided to conduct a follow-up study that might take individual choice (and therefore agency) better into account. In study three, we chose the text participants read and ensured that each text (school-related or games-related) was appropriately leveled to their reading ability as determined by the initial QRI. In study four, currently only in pilot phase [1], we allowed the participants to *choose the topic of the text* and *did not artificially lower its difficulty* (recall that the average reading level of game-related texts was found to be 11.8).

Three struggling readers from study three were recruited for participation. We asked each boy to specify three game-related topics he was interested in reading about. We then selected one reading for each boy that met the following criteria: (i) it was on a topic the given participant expressed interested in, (ii) it was from one of the three most frequently cited information resources identified in study one, (iii) was at least as difficult as game-related text generally (i.e., reading level of 11.8 or higher), and (iv) was at least two grade levels above the participants current reading level (as determined by the QRI in study three). Each participant answered preliminary questions assessing their attitudes toward reading generally and prior knowledge about the topic and then read the text aloud while the researcher took a running record (Clay, 1993/2002) using the same procedures as in study three. Participants were then asked to give a retelling of the text (used to assess reading comprehension) and to answer two follow-up questions assessing attitudes toward the text topic itself.

### Findings

Table 3 presents the pilot findings of this fourth and final study. All three participants were struggling readers with two participants reading three levels below their grade in school and one participant reading five levels below their grade in school. The game texts used ranged from grade level 12 in difficulty to grade level 14 (college), meaning that the boys were asked to read text that was seven to eight grade levels above their current reading level. Despite this large difference between text difficulty and current reading level, however, all three boys read at the “independent” level with an accuracy rate of 94-97%.

Table 3. Participants’ reading performance on difficult game-related text when individuals chose the topic.

| Student | Age | Grade | QRI Reading Assessment | Δ (Grade – Reading) | Game Text Level | Δ (Text Level – Reading Level) | Accuracy |
|---|---|---|---|---|---|---|---|
| Ed | 14 | 8 | 5 | -3 | 12 | + 7 | 94.0% |
| Fred | 14 | 9 | 6 | -3 | 13 | + 7 | 98.0% |
| Mark* | 16 | 11 | 6 | -5 | 14 | + 8 | 97.0% |

Of those errors that were made, the majority consisted of vocabulary words that were unfamiliar to the participants (e.g. "coup d'etat") or words they had read silently before but had never heard aloud (e.g. "subtle"). All three readers exhibited a high percentage of self-correction rates (37%, 31%, and 57% respectively), suggesting that one potential source of the performance difference between study three (assigned texts, reading difficulty controlled) and study four (texts on topics of their choice, reading level substantially higher than their current purported ability) is an increased willingness to correct errors during reading performance. In other words, in the face of challenge or difficulty, it may be that increased interest in the content of the text results in increased persistence in the face of frustration leading to higher overall achievement.

## Conclusions

While it may sometimes be tempting to see "electronic media" like videogames as something distinct from reading and in competition with it, a view expressed unequivocally within the *Reading at Risk* report (Bradshaw & Nichols, 2004), our findings suggest that games (and perhaps similar media) are not replacing text reading but rather sit in a complex and productive ecology with them. Perhaps like all new media before them, games simply highlight the enduring importance of text and text based literacy practices to everyday life. In study one, we found that, while group organization resources were considered the most important form of textual resource for regular WoW gameplay, *information resources were the most prevalent* type of text used. Closer analysis of such information resources in study two revealed that such materials read at the high school graduation level (11.8), which places them in terms of overall difficulty somewhere between *Sports Illustrated* and *Time Magazine*. This higher level of difficulty stems not from the use of highly specialized "gamer" discourse (which accounted for only 4% of the text overall) but rather from frequent use of academic vocabulary (20% of the text sample) and densely multimodal, multi-authored, and multi-genre nature. In study three, we examined adolescent reading performance on such texts versus adolescent reading performance on school textbook samples of comparable difficulty in order to ascertain whether or not there were any differences between these two contexts. Quantitatively, we found surprising consistency across both texts types in terms of accuracy and comprehension. Subsequent qualitative contrasting case analysis revealed no notable contrasts in the way one strong versus struggling reader positioned themselves toward the text and task *except* when the reader's own interests, needs, and uses for the text were evoked. Therefore, we conducted a fourth and final study (in pilot phase at the time of this writing) in which participants were able to choose the topic of the text and where we did not artificially ensure that its difficulty would be appropriate to their reading level. What we found was surprising in some ways yet predicted (Gee, 2003): All three "struggling" readers, when allowed to choose the topic, read text seven to eight grades above their reading level (as diagnosed by the QRI) with 94-97% accuracy rate – the highest level of mastery: independent.

Together, a picture emerges from these findings in which the reading activities that occur as a regular part of videogame play entail informational texts that include academic language and are structurally complex. Reading such game-related materials appears to entail the same reading performances and processes of reading activities required in classrooms. However, the fact that that activities related to them are *interest driven* appears to give them a serious edge over assigned and selected (school type tasks), potentially in particular for readers who are otherwise "struggling." This notion is not all that new, although this may be the first empirical evidence for it of this particular ilk. Scholars who study games and learning have noted that children and young adults, within their affinity spaces (Gee, 2004), often read text that is far more complicated and difficult than what they (are willing to) read in school. If such is the case, and our preliminary findings suggest it is, then we need to ask ourselves to what extent we are testing "interest" and calling it "ability." We may also need to consider whether the most powerful aspect of "games based learning" is not the complex system simulations they entail or the rules or roles or systems that constitute them but rather the fact that they are, in a way, Trojan horses for bringing interest-driven learning back into the frame of what we, as educators and learning science researchers, might think worth serious consideration.

## Endnotes

[1] At this time, we have completed only the pilot study with three participants; the full study (n=20) will be conducted in early November 2009, after submission of this paper but before the final conference event.

**Abstract:** This study investigated whether a peer feedback tool and a reflection tool would enhance group performance in a computer-supported collaborative learning environment. The underlying assumption was that group performance can be positively influenced by making group members aware of how their social and cognitive behavior is perceived by themselves, their peers, and the group as a whole. Participants were 120 fourth-year high school students working, with or without the tools, in dyads, triads and groups of 4 on a collaborative writing task. Results show that groups using tools perceived their team as being better developed, experienced higher levels of group satisfaction and lower levels of conflicts, than groups not using the tools. Results demonstrate that awareness, stimulated by peer assessment and reflection tools, enhances the social performance of a CSCL-group.

## Introduction

Collaborative learning, often supported by computer networks (computer supported collaborative learning, CSCL) is enjoying considerable interest at all levels of education. Collaborative learning, defined as the "mutual engagement of participants in a coordinated effort to solve the problem together" (Rochelle & Teasley, 1995, p. 70) has, among other things, been found to enhance the learners' cognitive performance (Johnson & Johnson, 1999) and to stimulate them to engage in knowledge construction (Stahl, 2004). The rapid development of information and communication technologies (ICT), has led to many computer applications (e.g., e-mail, chat, discussion forums, video conferencing, simulations, 3-D models, visualizations and external representations) which have proven to be useful tools or widgets to support collaborative learning (Janssen, Erkens, Kanselaar, & Jaspers, 2007).

Several researchers report cognitive and social benefits for groups in CSCL environments as compared to contiguous (i.e., face-to-face) groups. With respect to cognitive aspects of collaboration, researchers have found that students working in CSCL-environments report higher levels of learning (Hertz-Lazarowitz & Bar-Natan, 2002), make higher quality decisions, deliver more complete reports, participate more equally (Fjermestad, 2004; Janssen, Erkens, Kanselaar, & Jaspers, 2007), and engage in more complex, broader, and challenging discussions (Benbunan-Fich, Hiltz, & Turoff, 2003) than do students working face-to-face. With respect to social aspects, students working in CSCL-environments report higher levels of satisfaction compared to students in contiguous groups (Fjermestad, 2004).

There are, however, also contradictory results. Concerning the cognitive aspects of collaboration, students working in CSCL-environments sometimes perceive their discussions as more confusing (Thompson & Coovert, 2003), less productive (Straus, 1997; Straus & McGrath, 1994) and needing more time to reach consensus and make decisions (Fjermestad, 2004) than students working face-to-face. Also, students in CSCL-environments have been found to show lower levels of participation (Lipponen, Rahikainen, Lallimo, & Hakkarainen, 2003), and to experience higher levels of conflict (Hobman, Bordia, Irmer, & Chang, 2002), lower levels group cohesiveness (Straus, 1997; Straus & McGrath, 1994) and lower levels of satisfaction (Baltes, Dickson, Sherman, Bauer, & LaGanke, 2002). In other words, students working in CSCL-environments do not always reach their full potential. Two important reasons for the disparity between the potential of groups working in CSCL-environments and their performance lies in (1) the design of the CSCL-environment, and (2) the social and cognitive behavior of the group members.

With respect to design, CSCL environments often concentrate on functionality, focussing on the cognitive processes needed to accomplish a task and/or solve a problem (Kreijns & Kirschner, 2004). These functional CSCL environments coerce (Kirschner, Beers, Boshuizen, & Gijselaars, 2008) group members to limit their actions to cognitive processes to the detriment of socio-emotional processes. These socio-emotional processes, which are the basis for group forming and group dynamics, are essential for developing strong social relationships, strong group cohesiveness, feelings of trust, and a sense of community among group members (i.e., for creating a sound social space). Without such a sound social space, the group will not reach its full potential (Jehng, 1997). Groups in CSCL environments that lack social functionalities will ultimately perform poorly (e.g., Kreijns & Kirschner). For instance, despite technological advances, most CSCL still use text-based computer mediated communication (CMC) systems based on email, chat and/or discussion boards, which cannot easily convey visual nonverbal cues (Kreijns, Kirschner, & Jochems, 2003). The absence of these cues can cause specific problems for effective communication and interaction between group members since this removes possibilities for exchanging socio-emotional and affective information, and decreases information about group members' presence, self-image, attitudes, moods, actions and reactions (Short, Williams, & Christie, 1976). According to Short et al. the functions of these nonverbal cues are in some way related to forming, building or maintaining social relationships. Therefore, CMC can have negative effects on impression formation and group members' social behavior (e.g. Garton & Wellman, 1995; Walther, Anderson, & Park, 1994).

Second, group members form interpersonal perceptions during interaction (Kenny, 1994). Based on what they see and experience, they form impressions (e.g., norms, values, beliefs) about themselves, the group, other group members, and what the other group members think of them. These self-, other- and meta-perceptions are based on the cognitive behaviors (e.g., productivity) and social behaviors (e.g., dominance and friendliness) that they perceive during interaction. Based upon these perceptions, group members determine their own social and cognitive behavior, and develop social relationships with each other. However, research has shown that group members' perceptions of their own performance (i.e., self-perception) and of group performance are generally unrealistically positive, resulting in an illusion of group productivity (Stroebe, Diehl, & Abakoumkin, 1992). This tendency to believe that their group is performing effectively, while it often is not, can result in a reduction of effort by group members, a phenomenon also known as social loafing (Williams, Harkins, & Latané, 1981), which further undermines the groups' social and cognitive performance. However, group members are often not aware that they are loafing, or are unwilling to admit to it (Karau & Williams, 1993).

To overcome this obstacle to social and cognitive performance, CSCL environments can be augmented with computer tools or widgets that act as social contextual facilitators relevant for the learner's social interaction (Kirschner, Strijbos, Kreijns, & Beers, 2004). These tools, also known as 'social affordance devices', can positively affect social and cognitive performances in a CSCL environment (Kirschner, et al., 2004). Two operationalizations of such tools are used in this research, namely a peer feedback tool to make group members aware of the social and cognitive behavior of themselves, their peers, and how this is perceived by others, and a reflection tool to stimulate group members to reflect upon their individual behavior, why their peers see them the way they do, and to also reflect collaboratively (i.e., co-reflect) on the performance of the group as a whole. The aim of these tools is to make group members aware of their social and cognitive behavior and to enhance their social and cognitive performance and that of the group. The next sections deal with aspects central to these tools, namely peer feedback and reflection.

## Peer feedback

Feedback can be described as information provided to an individual to increase performance (Kluger & DeNisi, 1996). In a learning situation, this information can come from many sources such as teachers, computers, fellow students, and so forth. This study centers on peer feedback; information provided by fellow learners which is intended to increase performance. This information can be provided on the outcome performance (i.e., outcome feedback), or on how one is performing (i.e., process feedback). Feedback can be given by individuals or groups, and can also be received by individuals or groups. In this study, peers provide process feedback at individual and group level, in order to enhance interpersonal behavior. It is expected that enhancement of interpersonal behavior will have a positive effect on a group's social performance (Geister, Konradt, & Hertel, 2006; McLeod & Liker, 1992; Phielix, Prins & Kirschner, in press), as well as an indirect positive effect on a group's cognitive performance (Kreijns, Kirschner, & Jochems, 2003).

Process feedback can include cognitive or task-related information (e.g., task behaviors, actions and strategies), or social or non-task related information, such as information about interpersonal behavior (e.g., dominance and friendliness) or teamwork (Geister, Konradt, & Hertel, 2006). McLeod and Liker (1992) found that process feedback at the group level on the interpersonal behavior of student group members, such as dominance and group orientedness, changed the dominance behavior of individual group members. Two other studies investigating individualized peer feedback on interpersonal behavior of group members (e.g., communication and collaboration), found that such feedback led to increased cooperation, communication, satisfaction and motivation in group members (Dominick, Reilly, & McGourty, 1997; Druskat & Wolff, 1999).

Based upon these ideas, an individualized peer feedback tool (Radar) was developed and studied in which group members individually provide information about the social and cognitive behavior of themselves, their peers, and the group as a whole. The premise behind this tool is that it will positively alter the social and cognitive behavior of individuals and group. Because group members tend to overestimate their social and cognitive behavior (Kenny, 1994), this peer feedback tool also included the peer perspectives on the social and cognitive behavior of themselves, their peers and the group as a whole. This information should be gathered by use of a self and peer assessment, and based on specific traits because there is strong evidence that peer perceptions are formed by unconscious or tacit 'rating' of other group members on several traits, such as 'dominance', 'friendliness' and 'reliability' (Brok, Brekelmans, & Wubbels, 2006).

## Reflection

Simply providing group members' with information on their cognitive and social behavior is not enough to positively alter their behavior (Prins, Sluijsmans, & Kirschner, 2006). Group members also need to process this information and ask themselves whether they understand, accept, and agree with the feedback. In other words, they must reflect upon the feedback. Reflection is the intellectual and affective activities individuals engage in to explore their experiences (e.g., behaviors, ideas, feelings) in order to reach new understandings and appreciations (Boud, Keogh, & Walker, 1985). The feedback receiver needs to be challenged to reflect on his/her own performance, and determine whether the feedback provides clues for behavioral change (Prins, Sluijsmans, & Kirschner, 2006). Therefore, it is expected that peer feedback in combination with reflection will even be more effective than feedback alone (e.g., Schön, 1987).

According to Boud, Keogh, and Walker (1985), reflection can lead to new perspectives on experience, changes in behavior, readiness for application, and commitment to action. Therefore, reflection on peer feedback should make group members more aware of their own individual behavior, how their behavior affects others, and whether they should alter their behavior. Awareness can be defined as the "understanding of the activities of others, which provides a context for your own activity" (Dourish & Bellotti, 1992, p. 107). In order to make the group aware of its behavior, group members need to reflect collaboratively (co-reflect) on their cognitive and social performance. Co-reflection is defined as "a collaborative critical thinking process involving cognitive and affective interactions between two or more individuals who explore their experiences in order to reach new intersubjective understandings and appreciations" (Yukawa, 2006; p. 206).

Based upon these ideas, a shared reflection tool (Reflector) was developed and studied in which group members individually reflect and provide information on (1) their own individual perspective on their personal performance, (2) differences between their self perception and the perception of their peers concerning their personal performance, (3) whether they do or do not agree with the perceptions of their peers concerning their personal performance, and (4) their own individual perspective on group performance. Because group performance is determined by the individual effort of all group members, this tool also (5) stimulates group members to collaboratively reflect (co-reflect) on the group performance and reach a shared conclusion about this. Based on their shared conclusion, group members will (6) set goals in order to improve group performance.

## Research Questions

This study investigated whether a peer feedback tool and a reflection tool would enhance group performance in a CSCL-environment. To this end, an existing CSCL-environment was augmented with two independent, but complementary, tools. The first was an individualized peer feedback tool - Radar - which was meant to stimulate and provide group members with information about the social and cognitive behavior of themselves, their peers, and the group as a whole. This information was presented from both the perspectives of the group members themselves (i.e., self perceptions), their peers (i.e., peer perceptions) and the group as a whole. The second tool was a shared reflection tool - Reflector - which was meant to stimulate group members to reflect on and provide information about their own behavior and how this behavior was perceived by their peers, their personal perspectives on the group's performance, as well as to co-reflect on the group performance and reach shared understanding on this.

The following research questions will be addressed:

1) Do groups with Radar and Reflector perform better socially than groups without Radar and/or Reflector? In other words, do groups using Radar and Reflector develop better, have higher group satisfaction, experience lower levels of group conflict, and a have more positive attitude towards collaborative problem solving than groups without Radar and/or Reflector?
   Expected is that both Radar and Reflector will positively affect the social behavior in the group, leading increased social performance of the group. A combination of the both tools should be most effective.
2) Do groups with Radar and Reflector perform better cognitively than groups without Radar and/or Reflector? In other words, do groups with Radar and Reflector produce a group product of higher quality than groups without Radar and/or Reflector?
   Expected is that both Radar and Reflector will positively affect the social behavior in the group and that this should indirectly lead increased cognitive performance of the group, A combination of both tools should be most effective.

## Method

### Participants

Participants were 120 fourth-year students (66 male, 54 female) from an academic high school in The Netherlands. Students came from four classes and were enrolled in the second stage of the pre-university education track which encompasses the final three years of high school. Prior to the experiment, the participating students were randomly assigned by the teacher to dyads, triads and groups of four, and randomly assigned by the teacher to one of the three conditions (see Design). Therefore, group compositions were heterogeneous in ability and gender.

## Design

For this study two experimental conditions and one control condition were used. The first experimental condition ($n$ = 69) received the tools at the beginning (T1), halfway (T2) and at the end (T3) of the collaboration process. The second experimental condition ($n$ = 24) received the tools halfway (T2) and at the end (T3). The control condition ($n$ = 27) did not received tools during collaboration but only completed them at the end (T3).

## Measures

*Cognitive performance.* The grade given to the groups' collaborative writing task (i.e., the essay) was used as a measure of cognitive performance. The essays were graded by two researchers, both experienced in grading essays. The inter-rater reliability was high (Cronbach's $\alpha$ = .86).

*Social performance.* To measure social performance, previously validated instruments (Strijbos, Martens, Jochems, & Broers, 2007) were translated into Dutch and transformed into 5-point Likert scales (1 = totally disagree, 5 = totally agree). The Team Development scale ($k$ = 13, $\alpha$ = .88) provides information on the perceived level of group cohesion. The Group-process Satisfaction scale ($k$ = 9, $\alpha$ = .79) provides information on the perceived satisfaction with general group functioning. The Intra-group Conflicts scale ($k$ = 10, $\alpha$ = .88) provides information on the perceived level of conflict between group members. The Attitude towards Collaborative Problem Solving scale ($k$ = 9, $\alpha$ = .78) provides information on the perceived level of group effectiveness and how group members felt about working and solving problems in a group.

## Task and procedure

The students collaborated in dyads and groups of three or four on a collaborative writing task in sociology. Every student worked at a computer. Each group had to write an essay on a highly relevant current-events topic. Prior to this collaborative writing task, students collaborated for one month choosing the topic, searching for relevant sources, writing a short paper and giving a class presentation. Therefore, the sources required to write the essay were available for all groups. The collaborative writing task consisted of three 45-minute sessions over a period of one week. The groups collaborated in a CSCL environment called Virtual Collaborative Research Institute (VCRI; Jaspers, Broeken, & Erkens, 2002), which is a groupware program designed to support collaborative learning on research projects and inquiry tasks. VCRI will be further described in the Instruments section. Students were instructed to use VCRI to communicate with the other group members and to make complete use of the tools for peer feedback and reflection when the experimental condition allowed this. Students received content information and definitions regarding the six traits on which they had to assess themselves and their peers. Students were told that they had three lessons to complete the task, that it would be graded by their teacher, and that it would affect their grade for the course. The introduction to the task stressed the importance of working together as a group and pointed out that each individual group member was responsible for the successful completion of the group task. To successfully complete the task, all group members had to participate.

While groups used the tools, groups without tools continued working on their collaborative writing task. Time-on-task (writing the essay) was equal for all conditions. At the end of the final session (T3), the peer feedback tool and reflection tool became available for all conditions so that all participants could assess their peers and reflect on their behaviors. Finally, all participants completed a 30-item questionnaire measuring the social performance of the group.

## Instruments

### Virtual Collaborative Research Institute (VCRI)

The Virtual Collaborative Research Institute (VCRI) is a groupware program that supports collaborative working and learning on research projects and inquiry tasks (Jaspers, Broeken, & Erkens, 2004). VCRI contains more than 10 different tools, but only 5 were used for this experiment (see Figure 1). The Co-Writer (top left) is a shared word-processor for writing a group text. Using the Co-Writer, students can simultaneously work on different parts of their texts. The Chat tool (top center) is used for synchronous communication between group members. The chat history is automatically stored and can be re-read by participants at any time. Notes (bottom right) is a note pad which allows the user to make notes and to copy and paste selected information. Radar for peer feedback (bottom left) and Reflector for reflection (top right) will be described in the following sections. Windows of the available tools are automatically arranged on the screen, when students log on to the VCRI.

### Peer assessment tool (Radar)

VCRI was augmented with a peer feedback tool for stimulating and facilitating information of group members' social and cognitive behavior. This information is visualized in a radar diagram; therefore the peer feedback tool is named 'Radar' (see Figure 2). Radar provides users with anonymous information on how their cognitive and social behavior is perceived by themselves, their peers, and the group as a whole. The information gathered is based on specific traits that have been found to tacitly affect how one 'rates' other people (Brok, Brekelmans, & Wubbels, 2006). Radar provides information on six traits that are important for assessing behavior in groups. Four are related to social or interpersonal behavior, namely (1) influence; (2) friendliness; (3) cooperation; (4) reliability; and two are related to cognitive behavior, namely (5) productivity and (6) quality of contribution. These traits are derived from studies on interpersonal perceptions, interaction, group functioning, and group effectiveness (e.g., Bales, 1988; Brok, Brekelmans, & Wubbels; Kenny, 1994). These traits, as well as the reasons for their choice, are discussed in Phielix, Prins, and Kirschner (in press).

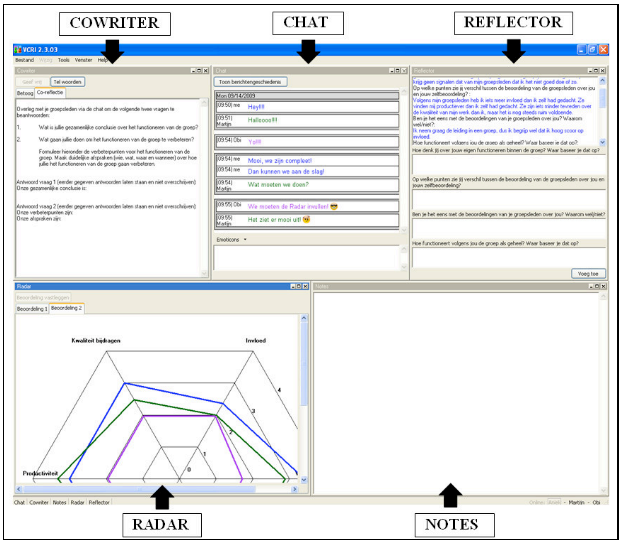

Figure 1. Screenshot of VCRI

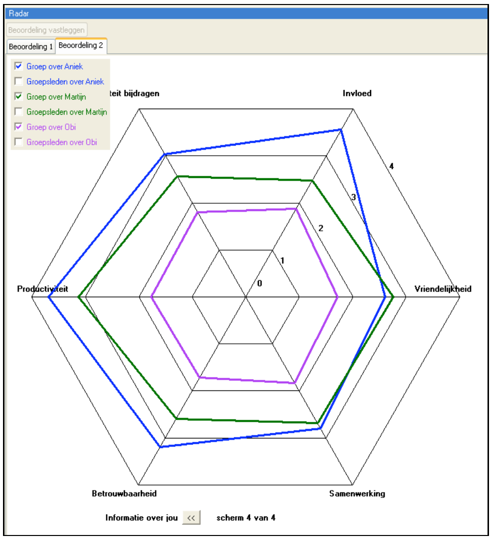

Figure 2. Output group assessment

In Radar, group members are both assessors and assessees. As assessor, to-be-assessed peers in the group can be selected and her/his profile will appear as dotted lines in the center circle of the radar diagram. Each group member is represented by a specific color. The assessor rates her/himself and all of the other group members on each of the six traits using a continuous scale ranging from 0 to 4 (0 = none - 4 = very high). Every range, (e.g., from 0 to 1) contains 10 points, so every scale contained 40 points of assessment. To make sure that all assessors interpret the six traits in the same way, assessors saw a text balloon with content information and definitions when they moved the cursor across one of the traits in the tool. For example, when the assessor moves the cursor across 'influence' a balloon pops up with the text 'A high score on influence means that this person has a big influence on what happens in the group, other group members behavior, and the form and content of the group product (the essay)'.

For groups of 3 and 4 members, the assessment is anonymous. Group members can see the assessments of the other group members, but not who entered the data. To stimulate students to complete Radar, they can only gain access to the individual and average assessments of their peers after they have completed the assessment themselves. When all group members have completed their self assessments and peer assessments, two modified radar diagrams become available. The first - Information about yourself - shows the output of the self assessment (e.g., Chris about Chris) along with the average scores of the peer assessments of her/him (e.g., Group about Chris). The self assessment is not taken into account for computing the average scores. To provide more information about the variance in the average score of their peer assessment, students can also choose to view the individual peer assessments about their own behavior (e.g., Group members about Chris). The second - Information about the group (see Figure 2) - represents the average scores of the group members, so that group members can get a general impression about the functioning of the group.

All group members are represented as a solid line in the diagram, each with a different color. The student can include or exclude group members from the diagram by clicking a name in the legend.

## Reflection tool (Reflector)

VCRI was also augmented with a reflection tool (Reflector) containing five reflective questions designed to stimulate reflection on different aspects of the group processes taking place. The questions were:

1. What is your opinion on how you functioned in the group? Give arguments to support this.
2. What differences do you see between the assessment received from your peers and your self assessment?

3. Why do you or do you not agree with your peers concerning your assessment?
4. What is your opinion on how the group is functioning? Give arguments to support this.
5. What does the group think about its functioning in general? Discuss and formulate a conclusion that is shared by all the group members.
6. Set specific goals (who, what, and when) in order to improve group performance.

The first four questions are completed in the Reflector, with completion indicated by clicking an 'Add'-button. This allows the student to share her/his answers with the rest of the group and allows her/him to see the answers of the others. Students can only gain access to the answers of their peers after they have added their own answers so as not to be influenced by one another. The fifth and sixth questions are completed in Co-Writer, in a specific section named Co-Reflection, which allows writing a 'shared' conclusion and formulating goals. The responses made by the students in the Reflector are not scored or evaluated.

## Data Analyses

To examine whether Radar and Reflector lead to higher social performance, a one way between-groups ANOVA (two-tailed) with planned comparisons is conducted with the dependent variables 'team development', 'group satisfaction', 'level of group conflicts', and 'attitude towards collaborative problem solving', as measured by the questionnaire at the end of the experiment.
To examine whether Radar and Reflector lead to higher cognitive performance, a one way between-groups ANOVA (two-tailed) with planned comparisons is conducted with the grade on the essay as dependent variable.

## Results

*Impact of tools on social performance.* A one way between-groups ANOVA (two-tailed) with planned comparisons was conducted to compare scores on 'team development', 'group satisfaction', 'level of group conflicts', and 'attitude towards collaborative problem solving', across each of the three conditions. Groups in Condition 1 used the tools from the beginning (T1) of collaboration process until the end (T3); Groups in Condition 2 received and used the tools halfway (T2) and at the end (T3); and Groups in Condition 3 did not use the tools during collaboration, but only completed them at the end (T3). Except where noted, tests were two-sided. The rule of thumb (Cohen, 1988) for effects sizes ($\eta^2$) was small $\geq .01$, medium $\geq .06$, and large $\geq .14$. Table 1 shows means and standard deviations for social performance scales per condition.

Table 1. Means and Standard Deviations for Social Performance Scales per Condition

| | Condition | *N* | *M* | *SD* |
|---|---|---|---|---|
| Team development | 1 – tools available at T1, T2 and T3 | 63 | 4.06 | .57 |
| | 2 – tools available at T2 and T3 | 24 | 3.47 | .61 |
| | 3 – tools available at T3 | 25 | 3.80 | .37 |
| Group satisfaction | 1 – tools available at T1, T2 and T3 | 62 | 3.98 | .56 |
| | 2 – tools available at T2 and T3 | 24 | 3.56 | .64 |
| | 3 – tools available at T3 | 25 | 3.71 | .59 |
| Intra-group conflict | 1 – tools available at T1, T2 and T3 | 62 | 1.95 | .59 |
| | 2 – tools available at T2 and T3 | 24 | 2.41 | .66 |
| | 3 – tools available at T3 | 25 | 2.23 | .50 |
| Attitude towards collaborative problem solving | 1 – tools available at T1, T2 and T3 | 62 | 3.79 | .59 |
| | 2 – tools available at T2 and T3 | 24 | 3.56 | .61 |
| | 3 – tools available at T3 | 25 | 3.65 | .55 |

As expected, groups that used the tools during the complete collaboration process (Condition 1), perceived their team as being better developed, $F(1, 68) = 6.10$, $p = .02$, partial $\eta^2 = .16$, experienced higher levels of group satisfaction, $F(1, 108) = 3.83$, $p = .05$, partial $\eta^2 = .09$, and experienced lower levels of conflicts, $F(1, 108) = 4.07$, $p = .05$, partial $\eta^2 = .10$, than students not using the tools (Condition 3).
Compared to groups that received the tools halfway (Condition 2), groups in Condition 1 perceived their team as being better developed, $F(1, 68) = 17.02$, $p = .00$, partial $\eta^2 = .16$, experienced higher levels of group satisfaction, $F(1, 108) = 9.02$, $p = .00$, partial $\eta^2 = .09$, experienced lower levels of conflicts, $F(1, 108) = 10.68$, $p = .00$, partial $\eta^2 = .10$, and had a more positive attitude towards collaborative problem solving, $F(1, 108) = 2.77$, $p = .05$, partial $\eta^2 = .03$ (one-tailed).
Compared to groups in Condition 3, groups in Condition 2 perceived their team as being less developed, $F(1, 38) = 5.40$, $p = .03$, partial $\eta^2 = .16$, compared to students not using the tools (condition 3).

Table 2. Means and Standard Deviations for Cognitive Performance per Condition

| | | Cognitive performance (grade essay) | | | |
|---|---|---|---|---|---|
| Condition | *N* | *M* | *SD* | *Min* | *Max* |
| 1 – tools available at T1, T2 and T3 | 69 | 6.81 | .71 | 4.0 | 8.5 |
| 2 – tools available at T2 and T3 | 21 | 6.54 | 1.04 | 4.5 | 8.5 |
| 3 – tools available at T3 | 27 | 6.36 | 1.61 | 4.0 | 8.5 |

*Impact of tools on cognitive performance.* Table 2 shows means and standard deviations for performance per condition as measured by the essay grades. No significant effects of Radar and Reflector were found.

## Discussion and Conclusion

The first aim of this study was to examine whether the use of a peer feedback tool (Radar) and reflection tool (Reflector) would lead to higher social performance, measured by: team development, group satisfaction, level of group conflict, attitude towards collaborative problem solving. As expected, groups using the tools perceived their team as being better developed, experienced higher levels of group satisfaction and lower levels of conflicts, than groups not using the tools or groups using the tools since halfway the collaboration process. Groups using the tools also experienced a more positive attitude towards collaborative problem solving, than groups receiving the tools halfway. Surprisingly, groups receiving the tools halfway perceived their team as being less developed compared to groups not using the tools. An explanation could be that Radar and Reflector made group members aware of their unrealistic positive perception on team development.

The second aim was to examine whether the use of Radar and Reflector would lead to higher cognitive performance, measured by the grade given to the essays. No significant effects of Radar and Reflector were found for grade given to the essays. The lack of a significant effect is probably due to the short period of time in which the groups had to collaborate in order to accomplish the task. Therefore, further studies will examine the effects of Radar and Reflector during a longer period of time (i.e., three months).

In conclusion, the effects of Radar and Reflector are very promising. They show that social group performance in CSCL environments, such as team development, group satisfaction, and level of group conflicts, can be enhanced by adding this easy to complete and easy to interpret peer feedback tool and reflection tool.

**Abstract:** While research suggests that educational television shows can contribute positively to a range of developmental outcomes for preschoolers, few preschool curricula make use of digital content to teach science. This study explored the impact of a curriculum that integrated hands-on activities with digital content from two public television shows aimed at introducing preschoolers to science, *Peep and the Big Wide World* and *Sid the Science Kid.* Impact was measured using parent reports of 398 low-income children's science talk using a random assignment design, where preschool teachers were assigned to implement either the media-rich science curriculum or a literacy curriculum. Results indicated that the science curriculum had a positive impact on caregivers' reports of children's talk about science. Though the study's outcome measure is an indirect measure of learning, the study suggests the potential for this and other media-rich curricula for introducing preschoolers to science.

## Context for the Study

Learning scientists are increasingly interested in preschool children's science learning. Learning scientists have examined young children's conceptual development (Gelman & Lucariello, 2002; Gelman & Brennamen, 2004), the roles that caregivers play in encouraging young children's talk about science at home that encourages curiosity and fosters the development of explanations (Crowley et al., 2001), and the effects of specific curricula that target preschoolers in developing children's inquiry skills and conceptual understanding (Clark-Chiarelli, Gropen, Chalufour, Hoisington, & Eggers, 2009). To date, however, there have been few studies exploring the role that digital media can play in supporting young children's science learning or that focus specifically on science learning of low-income children. This gap is noteworthy, since a significant focus of learning sciences research has been on the role technology can play in supporting science learning in K-12 settings (Pea & Collins, 2008) and on the requirements for enacting inquiry approaches to teaching science in low-income communities (Songer, Lee, & Kam, 2002).

There are several obstacles to designing and undertaking such studies in preschool settings. First, the use of technology in preschools has been controversial. Critics have argued that adults should not promote the use of video or computers by young children, arguing that these technologies make children passive and reduce their opportunities to learn from interacting with adults and peers (Healy, 2003). In preschools where staff members believe technology is likely to harm children, it may be difficult to recruit study participants. In addition, curricula that use technology can also be hard for teachers to implement, since many preschools have limited access to technology and teacher training opportunities (Davidson, Fields, & Yang, 2009). Thus, fielding a study of media-rich curriculum materials would require researchers to provide extensive technical and professional support. Third, there are few standards-based outcomes for researchers to use. Those few that have some evidence of validity and reliability are only available to those researchers involved in their development. As a result, researchers wishing to study outcomes will have to develop measures that are instructionally sensitive, yet not so closely aligned to curriculum content as to have limited value in persuading others of the objectivity of the measure.

This study investigates whether low-income preschool-aged children can learn from a media-rich curriculum that combines hands-on investigations with digital content from public television programs and games. Researchers at Education Development Center Inc. designed the curriculum used in the study, which was part of the *Ready to Learn Initiative*, a program to develop educational television programming and outreach activities that increase school readiness for 2- to 8-year-old children living in low-income households. In 2005, the U.S. Department of Education awarded one of two Ready to Learn programming grants to the Corporation for Public Broadcasting (CPB) and PBS. The award required an impact evaluation of the *Ready to Learn* Initiative's target audience of low-income children.

## Theoretical Background

The premise behind the curriculum in this study is that preschool teachers can implement a curriculum that integrates digital content from public television preschool science programs with hands-on activities in ways that promote early science learning. The curricular design is grounded in the literature on early science learning and on how and when young children can learn from digital media.

### Approaches to Promoting Early Science Learning

As is true for learning across a variety of domains and ages, young children's prior experiences are important for learning. Because children have every day experiences with life science and earth science phenomena, many preschool science curricula draw from these fields. For instance, Rule and Guggenheim's (2007) science curriculum centers on clay partly because young children often have prior experience working with clay. The curriculum progresses from using art clay to experimenting with mud, clay, and sands. Gelman and Brenneman's (2004) curriculum embeds the scientific method and vocabulary into lessons devised with familiar objects like the apples, seeds, baby pictures, and shoes of various sizes, all of which demonstrate the concepts of growth and change. The idea behind both curricula is young children can be introduced to science concepts by using familiar objects and phenomena.

Hands-on investigations of these phenomena enable students to develop critical skills for inquiry, including making observations and predictions. Because hands-on activities make observations concrete and more comprehensible to preschoolers, science curricula routinely call for children to experiment with objects by using the senses to explore and manipulate them. Many preschool science curricula teach students to record observations with drawings and then make predictions based on the observations (e.g., Chalufour & Worth, 2003). Long-term activities also promote deeper exploration of a topic by allowing preschoolers to observe, predict, verify predictions, and reflect on observed changes over time (Gelman & Brenneman, 2004). Such investigations also support the earliest stage of scientific thinking, false belief understanding, which occurs when a child realizes her observations or beliefs may be different from others' and that beliefs may even be false (Wellman, Cross, & Watson, 2001). False belief understanding is the first step towards the ability to falsify a theory (Kuhn & Pearsall, 2000).

In early childhood, encounters with science can help children cultivate students' interest in science and develop ways for talking about science and learn scientific vocabulary, two skills that correspond to important strands of proficiency in science (National Research Council, 2009). According to French (2004), children's interest in science activities can support the formation of mental representations of complex phenomena and promote communication about these phenomena. For example, preschoolers can verbally describe the inside and outside of an apple, describing the apple's color, texture, temperature, and lack of sound while the teacher records the information on a chart (Gelman & Brenneman, 2004).

To date, little research has focused on science learning for low-income preschoolers; an exception is a recent pair of studies focused on children's science learning in Head Start by Greenfield and colleagues (Greenfield et al., 2009). In one study, the researchers compared the developmental scores of Head Start children using the Galileo observational system (which rates children's skills in a range of domains). They found that in a cohort of more than 2,000 children, children's ratings and gains in science were significantly lower than in the other 7 domains measured (e.g., literacy). In another study, they found that many teachers reported low perceived self-efficacy with respect to teaching science and had trouble integrating science into their schedule. A third study was a quasi-experimental study of the ECHOS curriculum, which uses a combination of direct instruction and guided discovery to teach science skills. Relative to a control group, students in classrooms implementing the ECHOS curriculum were rated higher on four of the eight domains of the Galileo observational system.

### Young Children's Learning Using Digital Media

Research on young children's learning from digital media has been an area where there is a long history of research, including for low-income students (for a review, see Pasnik, Strother, Shindel, Penuel, & Llorente, 2007). For example, in the earliest days of public television programming for children, producers used research to study children's engagement and learning (Fisch, Truglio, & Cole, 1999; Morrow, 2005). A pair of experimental studies conducted by the Educational Testing Service in the first and second years of production for *Sesame Street* (Ball & Bogatz, 1970; Bogatz & Ball, 1971) found that children encouraged to watch the show grew in skills targeted by the show and were rated as more ready for school by their teachers than students assigned to a control group. A limitation of these and many of the other studies of the effects of educational television, including those that employed random assignment designs, is that they have been conducted in laboratory settings (Thakkar, Garrison, & Christakis, 2006). The lack of field-based studies is significant because achieving similar results in field settings (e.g., homes, day care facilities, or early childhood education centers) requires that a coherent sequence of curricular activities be enacted, something care givers in these settings may find challenging.

With the increasing availability of computers came developments in computer-assisted instruction that targeted young children's learning, primarily in the area of literacy. For this age group that is not yet reading, software programs facilitate the reading process by having the computer speak letter sounds, phonemes, and words to students as they read or interact with the computer. An intervention designed to increase phonological awareness (Olson, Wise, Ring, & Johnson, 1997) is fairly typical of such programs. In their software program, one set of tasks asks children to change the onset or rime of a word presented on a screen to match what the computer says (e.g., if the computer shows "buzz" and the computer says "fuzz," students must replace the "b" with an "f"). Another set of tasks requires children to try spelling words. The computer pronounces students' spellings back to them, providing them with feedback they can use to adjust their spelling. Studies of the effectiveness of these programs (e.g., Foster, et al. 1994; Baker & Torgesen, 1995) have found strong, positive effects on children's phonological awareness.

More recently, a number of interventions have been developed based on the idea that different media can be used *synergistically* (Neuman, 1995) to enhance children's learning. Interventions designed to promote learning from media synergy encourage co-viewing (watching and interacting with the television program with a peer, parent, or teacher) coordinate media viewing with non-media activities such as listening to a story, reading a book with a parent, teacher, or older sibling, or working on a practice activity related to skills targeted in the intervention. An intervention described by Prince and colleagues (Prince et al, 2002) provides a representative example of a media synergy intervention in practice. Teachers in that study were provided with a comprehensive *Between the Lions* curriculum that included whole episodes of the program, books related to themes covered during the program and enrichment activities. Teachers participated in intensive, daylong workshops to familiarize themselves with the resources and learn strategies for using them to supplement the literacy curricula already in place in their schools. During the school year, participating preschool, kindergarten, and first grade children viewed at least two *Between the Lions* episodes, read a book related in some way to the content of the episode viewed, and then participated in a hands-on activity that reinforced the skill or theme stressed in the episode. This and other studies (e.g., Chambers, et al., 2006) have found small, but positive, effects on children's reading skills. Similarly, recent evaluations of preschool math curricula that include computer-based math games revealed significant student math achievement gains (Clements & Sarama, 2008; Starkey, Klein, & Wakeley, 2004).

## The Public Media-Produced Science Curriculum

The 10-week media-rich early science curriculum studied integrated video from educational television programs and associated online games with classroom activities to foster skills for later success in science learning. Researchers randomly assigned teachers to the early science or an early literacy condition. Teachers played a leading role in every aspect of the curriculum, guiding students through whole-group hands-on investigations, small-group experiences, and individual exploration, as well as mediating children's experiences with digital content through active co-viewing. The curriculum combined full episodes of *Sid the Science Kid* (produced by KCET/Los Angeles with Jim Henson Productions) and self-contained "focused viewing" segments from *Peep and the Big Wide World* (produced by WGBH Educational Foundation). Over the 10 weeks, the children participated in 25 hours of the science curriculum, including time spent actively watching TV episodes and segments, playing online games, and participating in small and large group activities.

### Integration of Different Media and Formats for Learning

Video from *Sid the Science Kid* and *Peep and the Big Wide World* anchored the curriculum activities. Teachers showed entire episodes of *Sid the Science Kid* to introduce a weekly in-class investigation, periodically interrupting the video to highlight key science vocabulary and ideas. Students also viewed self-contained segments from *Peep and the Big Wide World* that engaged target content, vocabulary, and skills. Online games created by the producers provided additional support for the curriculum by targeting the same instructional strands. Both programs are intended to develop the early scientific knowledge of preschool children, the target age for the study. Researchers also adapted the hands-on activities suggested on the programs' websites for inclusion in the curriculum. Teachers led hands-on activities in whole group, small group, and individual settings.

### Focal Skills

The curriculum addressed the development of four instructional strands in early science: science content, vocabulary, skills, and scientific thinking. In conjunction with students' prior knowledge, hands-on exploration, and observations, each strand is essential for later scientific development. These strands align with three of the National Research Council's recommended strands for science learning in informal environments: 1) Experience excitement, interest, and motivation to learn about phenomena in the natural and physical world; 3) Manipulate, test, explore, predict, question, observe, and make sense of the natural and physical world; and 5) Participate in scientific activities and learning practices with others, using scientific language and tools (National Research Council, 2009). Teachers guided children in exploring *science content* that was conceptually linked to "Transformation and Change," the topic of the 5 *Sid* episodes selected for the study. Instructional content addressed freezing, melting, growth, decay, reversible change, and irreversible change. Activities were based on everyday experiences easily observable with the five senses. Teachers taught preschoolers *science vocabulary* words related to these science concepts. They also learned vocabulary for science skills, such as observing, collecting, sorting, and investigating. Teachers supported children in learning the *science skills* needed to make observations using their senses, and record them in drawings. Long-term investigations allowed children to make predictions and check them over time. Children practiced *scientific thinking* by comparing their observations with those of their classmates, as well as by participated in memory games.

### Teacher-Led Viewing

The curriculum called for early childhood educators to engage children in active viewing of segments and episodes. When showing video to the children, teachers introduced the key content and vocabulary, paused the video to encourage active processing of information, and reflected on areas of learning embedded in the video. After viewing each week's *Sid* episode, teachers supported children in repeating the hands-on investigations performed by the characters, such as planting a seed to watch it grow.

### Opportunities for Repeated Practice

The curriculum sequence gave children multiple opportunities to develop and practice focal skills. They watched whole episodes and focused viewing segments several times and participated in repetitive teacher-led, small-group, and individual activities. Review and repeated focused viewings occurred on consecutive days and over the course of the 10-week curriculum so that content, vocabulary, and skills introduced in earlier weeks were revisited in following weeks.

### Intensive Support for Implementing Early Childhood Educators

Preschools participating in the science curriculum received teachers' guides containing daily scripts and 10 weeks of activities, as well as materials such as potting soil, science journals, and a stipend for perishable items used during investigations. To increase the depth and quality of implementation, teachers received ongoing professional development from an instructional coach. This training began with two two-hour orientations to familiarize teachers with the curriculum and materials. Coaches subsequently provided on-site support that included modeling examples of good teaching practice, observation, and constructive feedback, as well as general assistance with implementation. Coaches made an average of eight visits to each class during implementation. The average visit was about two hours long. Between visits, coaches provided support by telephone and e-mail.

## The Current Study

The research question investigated was: *Can a media-rich science intervention implemented by teachers in early childhood centers positively impact low-income children's talk about science with their caregivers?*

The researchers conducted a randomized experiment to test the impact of the curriculum. They randomly assigned preschool teachers in each participating center to either a treatment or comparison group. The treatment group of educators implemented the science curriculum, while the comparison group implemented a literacy curriculum of the same duration and with rich media components. The use of the literacy curriculum was to facilitate clear interpretation of findings; evaluators wanted to avoid the possibility that results could be explained by children's excitement about media use.

## Sample

Eighty classes at 47 different early childhood education centers participated in the study. Some of these centers were some part of large-scale programs like Head Start, some were run by school districts, others were small, privately run facilities, some of which were home based. More than two-thirds of the early childhood educators (69%) had a postsecondary degree.

A total of 398 children (mean age at pretest, 4 years, 9 months) participated in the study. Fifty-three percent of the children were Hispanic, and 28 percent were African American. A majority (60%) of these children spoke English at home, and a third (31%) spoke Spanish at home. Some (8%) spoke both languages at home. Over all the children in the sample, 20 different languages were spoken at home. Seventy-nine percent were low-income, as indicated by the fact that their families were eligible for a subsidy to help them pay for tuition costs.

## Outcome Measure

A key challenge in measuring outcomes of preschool curricula in science is the paucity of measures of student learning (Greenfield et al., 2009). Given the resources of this study, it was not feasible to directly measure the impacts of the science curriculum by individually assessing children. Instead, the study team relied on a single measure of caregiver reports of children's talk about science. More intensive analyses of children's science talk in the home indicate the home is a site where children's interests are expressed and, in some cases, developed with the help of caregivers (e.g., Tenenbaum, Snow, Roach, & Kurland, 2005). Our measure aligned with Strand 1 of the NRC's (2009) informal science learning guidelines and sought to capture children's excitement, interest, and motivation to learn about science topics. Caregiver reports are a less precise way to learn about children's expressed interests, but they are more readily collected than discourse data for large-scale studies such as this one.

The measure used was a single index comprised of the sum of caregivers' response to 8 items. The study team asked caregivers to report on whether or not children reported in recent weeks that they had: pretended to be a scientist or science teacher, talked about doing investigations or experiments, expressed curiosity about the natural world, expressed an interest in why things change, expressed an interest in how things work, talked about freezing and melting, talked about decay, and talked about heat and change.

## Procedure

After random assignment had been completed, the study team provided training to coaches. The training for coaches included a review of the curriculum's goals and activities, as well as guidance regarding how to support teachers in learning how to implement the curriculum. The training also included a review of a weekly log form that coaches were to complete and that provided information on teachers' implementation of the curriculum. The team supported coaches' work by providing weekly opportunities to review progress and challenges with a coach coordinator, one in New York and one in California.

After coach training had been conducted, coaches established contact with classroom teachers to set up an orientation session to the curriculum. During the orientation session, coaches reviewed the curriculum goals, activities, and strategies, as well as expectations for implementation. In addition, the coaches reviewed materials that had been shipped to teachers and that included all the digital and print content needed to implement the curriculum. In the first 4 to 5 weeks, coaches led activities that had been scheduled that day, co-led them with teachers, or observed as teachers implemented the activities. In subsequent weeks, the study team gave coaches discretion as to how many times to visit sites, though they continued to make weekly contact with sites to complete implementation logs.

Within four weeks of completing the 10-week curriculum, the study team began contacting caregivers to conduct the survey. The team made up to 20 attempts to reach parents, caregivers, or guardians who had given consent for their children to participate in the study. Response rate for the parent survey was 56 percent, which was high for parent surveys in general and for this population in particular.

## Approach to Analysis

In the study, children were nested within classrooms; classrooms were the unit of treatment assignment for the study. Because of the multilevel nature of the data, and because a significant proportion of the variance for each of the four outcomes was associated with classrooms, the study team employed hierarchical linear modeling (Raudenbush & Bryk, 2002) to estimate treatment effects. After fitting a fully unconditional model to the data to estimate variance at each level (96% at Level 1, 4% at Level 2), two models were fit: one that included only the treatment indicator as a predictor and a second that examined the impact of the parent respondent on outcomes (whether the respondent was the father or another caregiver).

Prior to modeling, the study team conducted a factor analysis and analyzed the reliability of the outcome measure. These analyses suggested a single-factor structure, and together, the items had a modest internal reliability of $\alpha = 0.75$. Since scores were skewed, the team used a bootstrap resampling method to calculate the standard deviation of parameter estimates and transformed the outcome data (using the square of the measure). Squaring the outcome measure did not produce different model results, so outcome measure for all subsequent analyses was the mean score for the 8 items, to facilitate interpretation.

Because there were missing data, the study team used data for all children in the study, namely their gender, ethnicity, and family income level, to determine whether the students' caregivers with missing data differed in any way from those for whom their caregivers did complete surveys. The results of this analysis indicated that there were no differences between the group for whom complete data were available and the group for whom data were missing on any background characteristics. The science and comparison curriculum groups were also equivalent on these background measures and a measure of early literacy.

## Results

There was a statistically significant treatment effect of the science curriculum on science talk for both models fit to the data ($p < .05$). In Model 1 (Table 1), the mean outcome score of the science curriculum children was 0.712, compared with 0.634 for the comparison group children. The magnitude of the effect was 0.30 standard deviations. There was no statistically significant relationship between child gender and scores on the outcome measure.

Table 1: Impacts of the Curriculum on Science Talk: Model Results.

| | Model 1 | Model 2 |
|---|---|---|
| Intercept | 0.634 | 0.614 |
| Treatment is Science | 0.078* (0.0335) | 0.111** (0.0332) |
| Respondent is Father | | 0.161** (0.0545) |
| Respondent is Other | | 0.000 (0.171) |
| Treatment X Father | | -0.281* (0.1199) |
| Treatment X Other | | -0.101 (0.23484) |
| $r^2$ | 0.022 | 0.052 |
| *Adjusted* $r^2$ | 0.018 | 0.014 |

* $p < .05$, ** $p < .01$

Model 2 in Table 1 presents a slightly different picture of the results and shows that when the mother was the caregiver responding to the survey, the average score for children in the science condition was 0.725 and for comparison children it was 0.614. When the father was the caregiver responding to the survey, scores were higher for both treatment and comparison groups. Moreover, when fathers are respondents, scores of children in the literacy classrooms are significantly higher than scores of children participating in the science curriculum. The data do not permit the research team to analyze why the effect is different for fathers, but this could be a topic for future research.

## Discussion and Conclusion

This study provides preliminary evidence that preschool teachers can implement a media-rich science curriculum that can impact caregiver reports of children's talk about science. Caregiver reports of children's talk reveal something of what children find interesting and memorable enough to relay about their experiences in preschool. Preschoolers' reports of recent events are not easily recalled, so the finding that children in the study talked about topics in the curriculum is especially significant.

A key limitation of the study is the outcome measure, which is only an indirect measure of children's interest in science and not a good measure of what they may have learned from the curriculum. Future studies will require additional resources to implement testing of children individually, as well as better measures of learning aligned to the curriculum's goals. Although some measures are now under development, published results of validation studies are not yet available.

One conclusion that can be drawn is that the potential of this and other curricula merit further investigation. Such studies should focus not only on the outcomes or impacts of curricula but also on the processes by which students learn from them. Studies that can identify ways that hands-on activities and interactions with video and online games complement one another would be of particular interest. Differences among learners are likely to arise, and in the context of field-based studies, so, too, will differences in preschool teachers' ability to implement the curriculum under varying levels of coaching support. In addition to understanding impacts of curricula on student learning, developing an understanding about who learns what, and under what circumstances, are important goals for learning sciences research.

**Abstract:** This case study investigated scaffolding to support twelve 11th grade students' collaborative construction of evidence-based explanations and their evaluation of the credibility of evidence through the utilization of a web-based reflective inquiry environment on Biotechnology. Over eleven 90-minute lessons students investigated and evaluated scientific data relating to the cultivation of genetically modified plants. The analysis of pre- and post-tests on students' conceptual understanding of Biotechnology topics and their skills in evaluating the credibility of evidence revealed learning gains and suggested that the intervention was successful. Students' written explanations in task-related artifacts and the analysis of two groups' videotaped discussions showed that the students became sensitive to credibility criteria, questioned the sources of data and correctly identified sources of low and high credibility. Students' difficulty in applying methodological criteria suggests that this criterion should be addressed in future studies.

## Introduction

A central goal of science education is to support students' evidence-based reasoning by engaging them in seeking evidence and using it to critique scientific claims. According to the U.S. National Education Standards (NRC, 1996) students should be able to apply scientific reasoning to participate in informed decision-making at the local and national level about issues that impact on their everyday life, such as the global climate change and genetic engineering. Participating in such decision-making requires an understanding of the nature of science, as well as scientific knowledge and skills relating to the interpretation and weighing of evidence, issues which are underrepresented in the current practice of teaching and learning science (Chinn & Malhotra, 2002). Reaching decisions on many socio-scientific debates that scientists and the public need to take action on requires the existence of processes such as making sense of complex and diverse data sets that are difficult to analyze and comprehend, and weighing the relevance and examining the credibility of scientific evidence. "Practices such as weighing evidence…and evaluating the potential viability of scientific claims are seen as (some of the) essential components in constructing scientific arguments (Driver, Newton & Osborne, 2000, p.288). Driver et al. (2000) noted that insufficient time is typically given to evaluative tasks beyond the interpretation of data; for instance, questions such as "what trust can we place in data?" or "are there different possible interpretations of this data?" are not frequently addressed. Indeed, often existing inquiry curricula have explicit or implicit expectations that students treat data as non-biased and do not raise concerns over the credibility of the evidence.

As Yang (2004) pointed out, given the complex issues associated with the use of evidence in ill-defined problems there is a need for more intensive investigation of students' potential to use multiple sources of evidence and to critically judge claims based on evidence. Students' engagement in solving complex socio-scientific problems provides a good outlet for having them evaluate the credibility of multiple pieces of evidence. Socio-scientific issues are real-life problems that bombard the citizens of modern society and frequently represent dilemmas, stemming from ethical aspects that need to be taken under consideration (Sadler, 2004) and from biased interpretations or presentation of the data. As Gieryn (1999), a sociologist of science, argues "what happens in nature…depends upon the chef you ask: for some, nature is a seasoning thrown in to the flavor the social meat and cultural potatoes; for others, nature is what is finally brought to the table, what gets ladled into bowls, either thick stew with chunks of social left in or thin broth after the "meat" is methodically strained out and discarded; still others never bother to pick up any nature at the market –it is social down to the bottom of the pot." (Gieryn, 1999, p. ix.)

The work presented in this paper examines 11th grade students' assessment of the credibility of evidence and describes a research-validated pedagogical approach in supporting students' attending to such issues. This work contributes to the understanding of students' capacity to evaluate the credibility of evidence, given the need to prepare future citizens in critically evaluating the credibility of evidence and the limited discussions in the literature about students' evaluation of the credibility of evidence.

## Theoretical framework

### Defining the assessment of the credibility of evidence

We draw on Driver et al. (2000)'s work to provide an operational definition of evaluating the credibility of evidence. The credibility of different sources of information can be defined as the consideration of the grounds for confidence through the use of interrogatory tools, such as the critical asking of "reports about the origin of evidence, whether the evidence is simply correlational or whether there is a plausible theoretical mechanism, whether the results are reproducible, whether they are contested, or about the authority of the scientific source" (p. 301). Put simply, the researchers referred to two main parameters that are important for the assessment of the credibility of evidence: the source of the evidence and the methodology of the construction of the evidence (Driver et al., 2000). Learners need to examine the source of the evidence and think about questions such as: Is there evident bias or not? Was a piece of evidence peer-reviewed? Who is the author of the evidence? What is the author's agenda/background? What was the source of funding for producing each piece of evidence? As far as the methodology is concerned, learners need to think about the following: Does the evidence refer to a comparison of two different groups? Is there any control of variables? Were the results replicated?

### Students' difficulties in evaluating the credibility of evidence

There are several reports in the literature on studies of credibility and how to better support students in their credibility evaluation skills; however, only a small subset of those studies come from science education, with most of them focusing on topics such as internet searches and evaluating information online. Science education research has demonstrated students' difficulties in evaluating evidence to construct evidence-based explanations at the middle school level (Glassner, Weinstock & Neuman, 2005), high school level (Sandoval & Millwood, 2005; Dawson & Venville, 2009) and undergraduate level (Lippman, Amurao & Pellegrino, 2008). One of the most important and common difficulty students have in relation to evaluating evidence refers to an uncertainty as to what constitutes convincing evidence or valid evidence (Driver et al., 2000). Furthermore, previous research showed that one of the important reasons students faced difficulties in evaluating the credibility of evidence was the fact that they lacked the criteria they needed to be able to evaluate evidence (Wu & Hsieh, 2006).

At the middle school level, Pluta, Buckland, Chinn, Duncan and Duschl (2008) documented a widespread difficulty that the participants in their study, 724 US middle school students, faced with regard to the effective use of reasons and evidence. Students typically found it difficult to make judgments about the relative strength of evidence, and rather tended to treat all evidence as equally strong. They also had difficulty in understanding the need to provide justifications that were more elaborated than just mentioning the evidence that provided support. Seethaler and Linn (2004) examined 190 $8^{th}$ grade students' reasoning about tradeoffs in the context of a technology enhanced curriculum about genetically modified food and found that even though students were able to provide evidence both for and against their positions, they were less explicit about how they weighed those tradeoffs.

At the high school level, Kolsto (2001) interviewed 22 $10^{th}$ grade students on their views on the trustworthiness of knowledge claims, arguments and opinions on a socio-scientific issue. All students expressed problems and uncertainty when trying to sort out who to trust and what to believe. As a result, some claims were not questioned at all. Moreover, most students showed very little interest in empirical evidence underpinning knowledge claims and only a few expressed a positive interest in methodological aspects to assess the credibility of evidence presented to them.

Even at the college level, students sometimes had difficulty assessing the credibility of evidence in scientific arguments. Lippman et al. (2008) investigated 98 college students' understanding of evidence use in quality scientific arguments, by measuring students' ability to compare and analyze the quality of arguments and the use of evidence in essays. Their findings revealed that students inconsistently applied the epistemological criteria of empirical data serving as evidence in scientific arguments. Their insensitivity to blatantly inaccurate descriptions of evidence suggests students lack the deep understanding needed to assess the quality of evidence. They made reasonable, but not always ideal selections for the strong and weak evidence and focused on superficial aspects, such as ease of comprehension instead of the need for relevant empirical and disconfirming evidence.

It seems that training can support students in evaluating evidence. With respect to evaluating evidence, Sanchez, Wiley and Goldman (2006) reported that college students had a fragile understanding of the credibility of sources of evidence in internet sites and very few could verbalize it or use it to justify their evaluations of credibility. The researchers identified four key areas in which college students needed support: considering the source of the information, considering the evidence that was presented, thinking about how the evidence fit into an explanation of the phenomena and evaluating the information with respect to prior knowledge. In their study with 60 undergraduates who were randomly divided into two groups, one group of students received a short training course on criteria that could be used to evaluate internet sites such as: who the author of the information was, how reliable a site was, how well the site explained the information, identifying relevant information about the author, such as motivation, examining whether the information was consistent with other reliable sources and whether it was based on scientific evidence. Results indicated that college students were able to learn to use critical evaluation skills during short-term training and were better able to identify relevant from irrelevant sources.

The present study examined students' difficulties in evaluating the credibility of evidence during a decision-making process. The following research questions were addressed: How do 11th grade students evaluate the credibility of different sources of data when trying to reach a decision on a complex socio-scientific issue? What evidence do they use and how do they use it? How can this process be scaffolded?

## Methodology

### Participants

Two 11th grade intact classes in two public high schools in Cyprus participated in this study. The first class consisted of twelve students who took the course "Humans and Health" as an elective. The students of the class, in this case average students (mean GPA=14.7/20), were randomly assigned in four heterogeneous groups of three students each. The second class served as a control group and consisted of 13 students who took the course "Human and Health" as an elective in a different school.

The enacting teacher was a Biology teacher with a Bachelor's degree in Biology and 17 years of teaching experience. She is one of the authors and also a member of the group which designed the learning environment. The first author was present in the class during all lessons of the enactment to provide support with regard to the use of the web-based learning environment.

### The intervention: The Biotechnology and Genetically Modified plants learning environment

A problem-based learning environment on the topic of Genetically Modified Organisms (GMOs) was developed using the web-based platform of STOCHASMOS (Kyza & Constantinou, 2007). STOCHASMOS is a learning and teaching platform for supporting students' scientific reasoning through scientifically authentic investigations with an embedded authoring tool that can be used by teachers or instructional designers. The driving question that students were asked to answer was whether they would allow the cultivation of genetically modified (GM) plants in their country. Students were asked to make sense of real and diverse data sets mostly coming from scientific publications that were comparing GM and conventional plants from the perspective of the environment, economy and health. Data took multiple formats and included sources of low, average and high credibility. An example of high credibility data was the result of experimental research (e.g. research that entailed the comparison of an experimental and a control group and was published in a peer-reviewed scientific journal). An example of low credibility data was an opinion-based article, which reflected the views of the author, was not accompanied by data and did not substantiate claims.

The activity sequence consisted of eleven 90-minute lessons. The first three lessons consisted of hands-on experiments with DNA extraction, while for the next eight lessons students worked collaboratively through the STOCHASMOS learning environment of Biotechnology. A 40-min section in the fourth lesson was devoted to having students evaluate the credibility of two data sources in a context unrelated to Biotechnology. The aim of this activity was to reveal the criteria that students were intuitively using to evaluate credibility and to guide them into identifying the following criteria that were part of the scaffolding within STOCHASMOS: "author background", "type of publication", "funding" and "methodological criteria". In lessons 5 to 10, students evaluated data, captured evidence and went through the process of interpreting and explaining the data organized in the STOCHASMOS WorkSpace templates to develop evidence-based explanations about whether they would allow the cultivation of GM plants in their country. Students were prompted to evaluate the credibility of evidence throughout their investigation. The lessons concluded with the groups' in-class presentations of their work.

### Scaffolding through a reflective web-based inquiry environment

For the purposes of this research study, to "evaluate the credibility of evidence" means to assess the credibility and value of data that has been determined to be relevant for an inquiry-based investigation. Scaffolding was both human-provided and technology-supported. The scaffolding provided by the teacher included, among others, explicit instruction on how evidence and explanations are evaluated, based on given criteria. The scaffolding provided by peers included peer-evaluation of explanations, incorporated through the sharing work capability of the web-based platform used and the use of the chat-tool.

Technology-supported scaffolding was provided through the STOCHASMOS platform. The learning environment included the use of templates, which structured the students' task in creating evidence-based explanations for the impact of GM plants on economy, environment and health. The templates included passive prompts encouraging students to identify the source of the evidence and rate its credibility using a scale of 1 (low credibility) to 5 (high credibility). Drawing from the work of Driver et al. (2000), the main criteria for the evaluation of evidence in the context of this study were twofold and referred to: a) the source of the evidence and b) the methodology of the construction of the evidence. The source of the evidence referred to: author's background, type of publication and funding. Methodology was limited to having students examine whether the evidence referred to a comparison of two different groups, e.g. GM plants and conventional plants in this case.

### Data collection and Analysis

When designing this case study we sought to collect diverse data that would maximize triangulation and increase the validity of the conclusions. Thus we collected both outcome and process data, at the individual students' level as well as at the collaborative, group level. Data sources included pre- and post-tests on students' conceptual understanding of Biotechnology concepts and the credibility of evidence and all groups' videotaped discussions throughout the enactment. The tests that were administered to the enacting group were also administered to the control group twice over a period of three months, which was the approximate duration of the enactment, to control for the testing effect. The control group students did not take any Biotechnology related lessons.

The conceptual understanding individual test consisted of ten multiple choice questions and seven open-ended questions on topics related to Biotechnology. A scoring rubric was developed for scoring students' answers by the first two authors. Interrater reliability was computed (r=0.79). A test examining individual students' evaluation of the credibility of sources was administered prior and after the enactment. The test consisted of two open-ended tasks. The first task asked students to evaluate the credibility of a given source. The rationale behind this task was to assess the criteria that students were intuitively using to evaluate credibility. In the second task, students had to compare the credibility of two sources to decide which cell phone model to buy. The rationale behind this task was to assess students' skill in differentiating between a credible (results of a study that used random sampling, control of variables, comparison of two groups, and was published in an independent magazine) from a non-credible publication (advertisement publication indicating source bias as it came from a company that sold the product and had economic interest). In both tasks students had to justify their answer. A scoring rubric was developed for scoring students' answers by the first two authors. Interrater reliability was computed (r=0.83). Students' responses were also examined qualitatively, using phenomenographic analysis methods to extract categories from students' answers.

All lessons during the enactment were videotaped. Two of the four groups of students, Group 1 (mean GPA=14.9/20) and Group 3 (mean GPA=16.2/20), were selected for in-depth analysis. The first researcher viewed all videotaped lessons twice to isolate meaningful episodes that related to issues of assessing the credibility of evidence; a list of relevant keywords (e.g. evidence, credibility, believable, source, author, bias, results, comparison, type of publication, funding, graph, internet, scientist, journal, and the rating that students used to evaluate credibility) was identified a priori to help guide this process. A total of 18 episodes were identified for Group 1, ranging from 1 to 10 minutes each (total= 61 minutes) and 14 episodes for Group 3, ranging from 1 to 4 minutes each (total=29 minutes). Three additional episodes referred to the teacher talking about credibility in whole class discussion activities. The episodes were transcribed in the local language. They were then analyzed with respect to the four criteria that students were asked to evaluate: author background, funding, type of publication and comparison between two groups, to identify students' difficulties and describe the development of students' thinking with regard to the credibility of evidence over time. We also analyzed the data to examine whether discussions were scaffolded and by whom or what (e.g. took place while students were working within the STOCHASMOS environment or took place after prompting by the teacher).

## Results

### Effectiveness of intervention

To assess students' learning gains, we compared their pre- and post-tests using the Wilcoxon signed ranks non-parametric test because of the small sample size. The analysis indicated a statistically significant difference $z(12)=-2.91$, $p<.01$, and an effect size of 0.59. The enacting students' performance increased from a mean of 16.58 (SD=5.02) in the pre-test to a mean of 24.17 (SD=6.13) in the post-test. The maximum possible score of the test was 38. The control group students' performance increased from a mean of 13.5 (SD=6.13) in the pre-test to a mean of 14.5 (SD=5.23) in the post-test. However, the analysis using the Wilcoxon signed ranks non-parametric test did not indicate a statistically significant difference for the control group students $z(12)=-1.27$, $p>.05$.

## Students' evaluation of the credibility of sources pre- and post-enactment

### Results from the analysis of individual students

The students' performance increased from a mean of 4.5 (SD=2.24) in the pre-test to a mean of 8.42 (SD=3.40) in the post-test (maximum possible score=12). To assess students' gains with regard to their ability to evaluate the credibility of sources, we compared their pre- and post-tests using the Wilcoxon signed ranks non-parametric test. The analysis indicated a statistically significant difference, $z(12)=-3.09$, $p<.01$, and an effect size of 0.63. The control group students' performance increased from a mean of 4.75 (SD=2.01) in the pre-test to a mean of 5.20 (SD=3.36) in the post-test (maximum possible score=12). The Wilcoxon signed ranks non-parametric test analysis did not indicate a statistically significant difference for the control group students $z(12)=-1.14$, $p>.05$.

How did students' understanding of the credibility criteria change? In addition to the quantitative analysis of students' skills in evaluating the credibility of sources, a phenomenographic analysis of their answers was also conducted. As a result, students' answers were categorized in levels which are presented in Tables 1 and 2. The analysis of the first task, which asked students to evaluate whether a publication was credible or not, showed that students' answers shifted from opinion-based answers (based on merely copying information from the text), to more sophisticated answers (which identified one or more criteria for evaluating credibility). Table 1 shows the number and percentage of students' answers in each level for the pre-test and post-test (n=12), as well as illustrative examples of the scoring.

Table 1:Task 1 "How did students evaluate the credibility of a given source?"

| Category | Illustrative examples | Pre-test | Post-test |
|---|---|---|---|
| Level 1: Opinion-based/copying information from text | "I have the opinion that a person can only fight addiction with her own will (…) Therefore, I don't believe this publication". | 3 (25%) | 0 |
| Level 2: Source provided details or numbers or results or statistics | "It (the research study) is not convincing because it does not mention details (…) On the other hand it mentions statistical results". | 9 (75%) | 0 |
| Level 3: Based on one criterion (author, funding, source type, or methodology) | "The research study was conducted by the Acupuncture Center and it was published by the same center. Therefore they had interest in having positive results for advertisement purposes". | 0 | 8 (67%) |
| Level 4: Based on at least two of the criteria | "The duration of the research study was adequate, the participants were men and women of various ages, the publication was from a university, the author was a doctor, a general practitioner. I don't think Dr. X. had any financial interest, because it's his duty to help people so I believe in this research study". | 0 | 4 (33%) |

The analysis of the pre-test showed that most students (75%) initially thought that if a source provided details and numbers, or results and statistics it meant that it was credible (Table 1). The rest of the students (25%) provided an answer that relied on either their own opinion or verbatim information from the text. However, none of the answers on the post-test fell into the pre-test categories. Students based their answers on the application of one (67%), or two and more credibility criteria (33%). This suggests that by the end of the intervention students had appropriated these criteria.

The second task asked students to choose which one of two given publications was the most credible. Table 2 shows the number and percentage of students' answers in each level for the pre-test and post-test for task 2 (n=12), as well as illustrative examples of the scoring in each level.

Table 2: Task 2 "How did students compare the credibility of two given sources?"

| Category | Illustrative examples | Pre-test | Post-test |
|---|---|---|---|
| Level 1: No justification or opinion-based or copying information from text | "I think that the most convincing is the second publication because it seems more compelling". | 4 (33%) | 1 (8%) |
| Level 2: Source provided results | "It described the advantages of the cell phone in detail and provided specific results" | 1 (8%) | 0 |
| Level 3: Identified "source bias" only | It was "an independent research study (…) published by an independent company". | 1 (8%) | 4 (33%) |

| | | | |
|---|---|---|---|
| Level 4: Identified "comparison" only | "It presents a cell phone and compares it to another cell phone". | 5 (42%) | 0 |
| Level 5: Identified both "source bias" and "comparison" | "The publication was conducted by an independent company (…) and there was a comparison of two cell phones and the participants of the survey were chosen randomly". | 1 (8%) | 7 (58%) |

In the pre-test several students identified the fact that a comparison was conducted (42%), one student was able to indentify the bias of the source (8%), and another student identified both criteria (8%). In contrast, in the post-test, the vast majority of students (91%) correctly identified either "source bias" or both criteria.

## Students' collaborative shift from opinion-based explanations to criteria-based explanations

An analysis of the 40-min section in the fourth lesson, which was devoted to having students evaluate the credibility of two data sources in a context unrelated to Biotechnology, was conducted to examine the criteria that students were intuitively using to evaluate credibility prior to working in STOCHASMOS. This showed that students were capable of identifying the "author background" criterion unassisted, but needed the teachers' support to identify other criteria for credibility, such as "type of publication", "funding" and "methodological criteria".

An analysis of the total of 35 episodes revealed that the vast majority of students' discussions on credibility of evidence (24 episodes) were prompted and scaffolded as they took place while students were working with the STOCHASMOS templates. Only two episodes took place spontaneously. The teacher prompted students to consider the evaluation of the credibility of their sources in two of the episodes, while another two episodes referred to teacher-initiated whole-class discussions. In the remaining five episodes students attempted to verify their sources. The analysis of students' videotaped discussions revealed several themes and illustrated the shift of the students of the two selected groups (n=6) from level 2 in the pre-test to levels 3 and 4 in the post-test.

### Students became critical of and questioned the credibility of their sources

Baseline pre-test data showed that students sometimes even accepted advertisements as credible pieces of data and did not question the source of information. During the investigation, students became very critical of the sources they were basing their decision on. When Group1 students compared the expenses and income of GM to conventional maize they found the source non-credible. They expressed their concern that they were basing their conclusions about the effect of GM plants on economy on evidence that they did not find credible and they were puzzled by this fact. The group had some insecurity about their work and asked the teacher whether it was acceptable to make some observations and interpretations of data and reach some conclusions but then cite and evaluate their source only to find that they did not consider it a credible one. The same issue was troubling for students of Group 3.

Throughout the STOCHASMOS enactment and through their interaction with the learning materials and with their peers, students formed opinions about source credibility. These two groups' discussions about credibility focused on the need to evaluate all data sources and students gradually developed a critical stance toward the sources they were examining during their inquiry, which was evident in lessons 4 to 11.

### Students showed distrust to sources of average credibility and were sensitive to source bias of "funding" and "type of publication"

As expected, sources of average credibility stimulated the most discussion among students during their evaluation. Students correctly showed distrust to those sources and were troubled as to what they should believe and what not. During the fourth lesson, Group 1 focused on the impact of GM maize on economy and examined financial data. The discussion showed the distrust of this group to the source, mainly because the study had been conducted by a financial advisor in a company that provided advice to biotechnology companies and it was published on the website of the company, receiving funding by the same company. In general, students showed distrust in anything that was published on the internet. Student names are pseudonyms.

*Group 1: Lesson 4: min 2:24-11:00*

*Angelina:* *"…to evaluate the credibility of the source. "Author background", Brook is the financial advisor of PG economics, which provides advice to biotechnology companies. I don't believe him because everything is done by the company. And they make biotechnology products. And in the comparisons, it says here that the GM is less than the conventional (talking about the expenses of cultivation) and he has the company for biotechnology so (...)"*
*…I am not convinced. It's all for their benefit!"*

*Kate:* *Now let's look at funding. Since it was funded by the same company it's not credible. (Should we rate it with) One (1) or two (2)?*
*Angelina:* *One (1)!*
*Kate:* *It's not convincing at all (...) because they published it on the website of their own company.*

Similarly, in their attempt to evaluate the credibility of the same source, Group 3 students also identified funding as a potential problem and had the same strong idea that anything that was published on the internet was necessarily non-credible. However, it seemed that students gradually overcame that misconception. During lesson 8, Group 1 evaluated two sources on the impact of GM maize on people's health. Even though initially the group tended to believe that whatever was published on the internet was automatically non-credible, in this case they correctly identified that even though the publication was online, the source citation indicated that it was actually a journal publication.

*Group 1: Lesson 8*
*Rania:* *Wait. Yes, but (reading the title of the source), issue 29, p.26-28. Why would it then say publication on the internet? (laughing) Here I go again with my questions!*
*Kate:* *Wait. Here it's not convincing because it was on the internet.*
*Rania:* *Why does it say publication of the journal?*
*Aggela:* *Ok, they took a part and then put it on the internet.*
*Kate:* *Yes. So it* ***is*** *convincing (her emphasis).*

### Students easily identified journal publications as high credibility sources
Both Groups 1 and 3 had no difficulty evaluating a source that appeared in a peer-reviewed scientific journal, received funding from independent research organizations, was conducted by independent researchers or professors and included reported methodology that included a comparison of GM and conventional plants as a source of high credibility. Both groups rated all criteria with the highest possible score for credibility, which was 5 out of 5.

### Students had difficulty in applying methodological criteria
Students faced some difficulty in understanding what the methodological criterion of "the existence of a comparison between two groups" meant and needed support for its application. Students did not seem to understand that the criterion "existence of a comparison between two groups" referred to having an experimental and a control group, even after four lessons of applying the credibility criteria during the investigation.

## Discussion
The evidence suggests that the intervention was successful at increasing these students' conceptual understanding of Biotechnology-related concepts and at increasing their skills in evaluating the credibility of sources. Through their interaction with the learning environment, their teacher and their peers, students became critical of the sources of evidence. They paid attention to citing their sources and evaluating them when they were prompted to do so through the STOCHASMOS templates. They also paid attention to referring to their sources and commenting on their credibility during their in-class presentations of their work. Contrary to previous research, which documented middle school level U.S. students' difficulties in the effective use of reasons and evidence and stated their tendency to treat all evidence as equally strong (Pluta el al., 2008), the students in the present study had no difficulty in making judgments about the relative strength of evidence. This was evident by the finding that they correctly identified sources of low, average and high credibility. Students could also differentiate between weaker and stronger sources with regard to their credibility, as was evident by the analysis of their post-tests. This finding suggests that the intervention was successful with regard to supporting students' skills in evaluating the credibility of sources.

The fact that the majority of students' discussions regarding credibility criteria did not happen spontaneously but were, rather, a result of scaffolding showed students' need for support. The results of this study showed that a reflective web-based inquiry environment that prompted students to evaluate the credibility of their sources, combined with the use of given credibility criteria seemed to have provided an effective scaffolding mechanism toward the goal of making students develop a critical stance towards evidence. An epistemological shift was evident as students realized that there were two levels in evaluating the credibility of evidence: first an interpretation of data was necessary to make sense of the data that qualified as evidence and then as a second step, the credibility of the evidence could be assessed. They learned to question the evidence depending on the source it came from and at the same time they were puzzled and had reflective discussions about what to believe and what not, which would not have happened had they not been asked to engage in the task of evaluating the credibility of evidence they included in their investigation.

## Implications for practice

This study demonstrated the importance, necessity and effectiveness of a reflective, web-based inquiry environment as a scaffolding mechanism to support students' evaluation of the credibility of evidence. An inquiry environment that is designed to support students in their credibility evaluation skills should include sources of data of varying degrees of credibility (e.g. low, average and high credibility) to provide students with opportunities to use critical judgment to accept and reject evidence. It was also shown that the design of interventions to foster students' credibility evaluation skills can be based on the use of specific criteria. Criteria can be either provided a priori or can be derived by students. Depending on the age, grade, and achievement level of the students, credibility criteria can be either simple and focus on two major parameters, such as "source" and "methodology" or can be advanced and sophisticated and cover a greater number of aspects and parameters of credibility. The level of complexity has to be decided in advance as it directly affects the amount of information that students need to have access to in order to be able to make an informed decision regarding how believable each credibility parameter is for them. Students in this study had difficulty in focusing on methodological issues of the studies they evaluated. It is important to address methodological criteria, which are among the most important ones, in relation to the evaluation of the credibility of evidence in future studies.

# Arguing with Peers: Examining Two Kinds of Discourse and Their Cognitive Benefits

David Shaenfield, Teachers College – Columbia University
525 W. 120th St., New York, NY, 10027, United States
des2020@columbia.edu

**Abstract:** This study examines the extent to which meta-level regulation of argumentive discourse goals and strategies relates to improvement in argumentive discourse skill. A 7-month intervention was designed to provide dense experience in argumentive discourse and to promote meta-level regulation of discourse. Pairs of academically disadvantaged eighth graders conducted electronic dialogs with opposing pairs on a series of social topics. Analysis of intra-dyad discussion over the course of the intervention showed that participants producing a high proportion of meta-level utterances were more likely to show improvement in argumentive skill. This finding suggests that enhanced meta-level awareness of the strategies and goals of argument, along with rich engagement in argumentation, promote skill development.

## Introduction

The idea that students profit from collaborative learning continues to gain popularity, and some, although not extensive, empirical evidence exists to support it. The mechanisms involved, however, have not been well established. I seek to learn more about these mechanisms in the present work. The domain in which I conduct the work, argumentation, is one based in collaborative social interaction. Indeed, this social exchange, as suggested elsewhere (Kuhn, Goh, Iordanou & Shaenfield, 2008, Sampson & Clark, 2009), serves as a promising path to development of the individual expository argument skills that figure prominently in academic contexts.

The present work includes an additional layer in this collaboration by asking two peers who share the same position on a social issue to collaborate in argumentive discourse with a series of opposing pairs who hold an opposing position. I focus on the discourse between the agreeing pairs as they engage in the joint task of formulating their contributions to electronic discourse with a series of opposing pairs. In a preliminary study that provides a foundation for the present work and employed very similar methods, we compared a condition involving collaborating pairs with a condition in which individuals worked alone in formulating and implementing the same kind of electronic arguments with an opposing peer. When subsequently assessed individually at the end of a several-month period, those in the collaborating condition showed greater increase in argumentation skill (as indexed by frequency of use of direct counterargument, the same measure employed in the present work). I therefore seek in the present study to investigate what occurs in the collaborative discourse of same-side pairs that is beneficial to their individual skill development.

The hypothesis that guided the present study is that this benefit is metacognitive in nature. Meta-level regulation lies at the end of a meta-level developmental trajectory beginning with a young child's awareness of mental functions (Kuhn, 2000; Wellman, 1992). In the argumentive context, the focus is on metastrategic knowing – specifically knowing about how to effectively engage in an argument. This metastrategic competence includes knowledge of the goals of argumentation, including attention to the opponent's position and claims, and knowledge of different discourse strategies. Awareness is a first step toward meta-level competence. A high level of such competence is reflected in metastrategic evaluation, which enables the speaker to monitor the effectiveness of strategy use. Awareness and evaluation are both necessary along a path of meta-level development toward true meta-level regulation.

Meta-level regulation in the argumentive context involves the speaker's ability to control strategy use during argumentive discourse. Speakers at this level are able to choose and sequence different strategies effectively, based on their knowledge of the utility of the strategies, while understanding how the strategies lead to the dual goals of argumentation, identified by Walton (1989) as obtaining commitments from the opposing partner to support one's own arguments and critiquing the opposing partner's arguments to weaken their force. In addition, regulation allows for continuous adjustments in response to the other speaker's discourse strategies. This metastrategic effort reflects knowledge and control over a sequence of strategies involving counterargument and rebuttal (counterargument of a counterargument).

Three techniques were employed in the present work to support students' awareness of and reflection on their argumentive discourse. These were thought to be key in enhancing both their understanding of the goals of argumentation and their skill in implementing these goals. First, students worked in pairs. Previous research demonstrates the benefit of collaborative planning and implementation in the development of young adolescents' argument skills (Kuhn & Udell, 2003; Shaenfield & Moore, 2009; Sampson & Clark, 2009).

A primary benefit of collaborative planning is making knowledge explicit. Learning is shown to be enhanced when learners articulate the reasoning behind problem-solving behaviors (Chi & Van Lehn, 1991). In the context of planning argument discourse strategies, collaboration provides the opportunity for articulation of meta-level regulatory strategies. It was hypothesized that two students with the same goal and having to deliberate regarding each argumentive move would not only generate more effective contributions to the discourse but would also make the collaborative pair more aware and reflective regarding this discourse.

Second, following the work of Felton (2004), an explicit reflective activity was added. Some of the students' own dialog transcripts were made available as the basis for this activity. Third, students conducted their dialogs via instant-messaging (IM) software. In addition to capitalizing on teens' familiarity with the medium, this technique has the benefit of providing an immediately available and permanent record of the discourse, as a basis for reflection. In striking contrast, in real-time verbal discourse, the contents of each contribution to the dialog immediately disappear as soon as they are spoken.

A number of previous studies (Anderson, Nguyen-Jahiel, McNurlen, Archodidou, Kim, Reznitskaya, et al., 2001; Chinn, 2006; DeFuccio, Kuhn, Udell, & Callender, 2009; Felton, 2004; Felton & Kuhn, 2001; Kuhn et al., 2008; Kuhn, Shaw, & Felton, 1997; Kuhn & Udell, 2003; Nussbaum, 2003, Nussbaum & Kardash, 2005; Nussbaum & Sinatra, 2003; Reznitskaya, Anderson, McNurlen, Nguyen-Jahiel, Archodidou, & Kim, 2001; Schwarz, Newman, & Biezuner, 2000; Udell, 2007) have reported gains in argumentation skill as a result of engagement and practice.

Previous research (DeFuccio et al., 2009; Felton, 2004; Felton & Kuhn, 2001; Kuhn et al., 2008; Kuhn & Udell, 2003) has shown that young adolescent arguers tend to limit themselves largely to discourse strategies addressed to articulation of their own positions. Over time, a shift is seen toward greater attention to the opponent's claims and, eventually, efforts to address and weaken them. As this occurs, a shift in the awareness of the goals of argumentation may also be developing. Growth of the meta-strategic aspect of argumentation, alongside skill development, may be critical for progress. Previous studies of argument skill development have not explicitly addressed the relationship between this meta-level development and skill development itself. To further understand the relationship between developing meta-level regulation and developing dialogic argumentation skills, the intra-dyad discussion between same-side partners was recorded on audiotape for subsequent analysis.

## Method

The research employs a two-group repeated measures design using an untreated control group to compare the effects of the intervention on argument discourse skill. The entire study took place in repeating phases over seven months.

### Participants

Participants were the entire eighth-grade student body of 49 students not assigned to individualized education programs (IEP), drawn from three classrooms, in an urban public middle school. The school primarily serves African American and Latino families from a lower-income community; 80% of students are eligible for free lunch and 14% are eligible for reduced-price lunch. The city school system classifies the student body of the school as academically disadvantaged, with student achievement is several years below grade level. The city education website lists the student body ethnicity ratios as 54% Black or African-American, 40% Hispanic or Latino, 4% White, 1% Asian or Pacific-Islander and 1% Native American. One class of 26 students (17 females and nine males), participated in the intervention, while the remaining 23 (10 females and 13 males), drawn from two classrooms, served as a control group.

### Procedure

#### Pretest Assessment

The purpose of this phase was to assess all 48 students' individual initial skill levels in dialogic argument, for comparison at final assessment. Students' opinions regarding capital punishment (CP) were assessed individually by questionnaire. This assessment allowed students to be classified as holding a pro or con position on CP. Each student was then paired with a classmate holding an opposing (pro or con) view on CP. Each pair conducted a dialog on the CP topic mediated by iChat (instant messenger chat software) installed on laptop computers. The specific instruction was to attempt to convince the other opponent that his or her opinion was the better one. Pairs of pro and con students were positioned to face opposite sides of the classroom to reduce the possibility of verbal or eye contact. The software saved a transcript of the dialog for analysis. Sessions were approximately 25 minutes in length.

## Initial Intervention

The initial phase of the intervention took place over the course of 11 successive 45-minute class periods, twice per week. On the days when the experimental group was participating in the intervention, the control group attended their regular social studies class. The experimental group's first topic was whether children should be required to attend a town school or whether it's permissible for parents to teach them at home if they wish.

*1. Individual position and assessment (session 1).* Students' positions regarding the first topic were assessed individually by questionnaire, allowing students to be classified by position on the topic.

*2. Dyadic electronic arguments with opposing-view pairs (sessions 2-7).* Students were paired with a classmate holding the same view (home okay or school mandatory). An attempt to form the greatest number of same-gender dyads was made but not possible to implement completely due to the uneven gender make-up of the intervention group. However, the majority of pairs were same-gender. The two members of a pair remained paired throughout the topic. The paired students collaborated in engaging in a series of e-dialogs with other dyads holding the opposing view. In one case, to accommodate an uneven number of students, a trio was formed. Dyads were instructed and reminded to collaborate with one another in constructing their input and, once in agreement, to take turns typing it on the laptop. An audio tape recorder continuously recorded the intra-dyad discussion. Sessions averaged 25 minutes in length.

Dyads engaged a different opposing dyad at each session. During the dialog period, several adults circulated to address any technical difficulties and to remind partners to collaborate. Dyads were also provided with a series of "reflection sheets" to promote their representing and reflecting on their own and the opposing pair's arguments. The "Other Argument" sheet asked the students to determine what the other side's main argument was, their dyad's "comeback" (counterargument) to that argument, and how the dyad could improve this comeback. The "Own Argument" sheet asked the students to identify one of their main arguments, the other side's counterargument to that argument, the dyad's comeback (rebuttal) to the counterargument, and to suggest how that comeback could be improved.

*3. Preparation for final, class-level e-argument (sessions 8 & 9).* Session 8 marked the beginning of a culminating activity with respect to the topic. Students worked within their same-side teams, preparing for what was to be a final "showdown" debate at session 11. Within each of the same-side teams, each of the dyads that had worked collaboratively to this point were divided, one assigned to an "Other Argument" (OTH) team and the other to an "Own Argument" (OWN) team. Each preparation team had an adult coach who facilitated the group process. The materials available to each team were as follows: The "Own Argument" teams had copies of the "own argument" reflection sheets that had been produced by each team. The "Other Argument" teams had copies of the "other argument" reflection sheets that had been produced by each team. Coaches had transcripts of all dialogs on hand for reference if requested by the students.

The OWN team was told that their goal in preparing for the showdown was to be familiar with the possible counterarguments the opposition could assert and prepare rebuttals to use in the showdown. The team created a set of "own argument – counter – rebuttal" sequences that were recorded onto the OWN argument sheet. To do this, first they selected the three most convincing arguments for their position. The reflection sheets were provided as references to complete the OWN argument sheet counter and rebuttal sections. The OTH team was told that their task was to be familiar with effective counterarguments to use when faced with other arguments advanced by the opponents in favor of their position. The team created a set of "other argument – counter" sequences that were recorded onto the OTH argument sheet. During this preparation session, these team members identified the three most damaging arguments raised by the opposition and, using the provided or newly generated materials, decided on their counterarguments.

*4. The Showdown (session 10).* Students on each side were divided into two teams of 6-7 members – Team A and B based on the recommendations of the coaches during the preparation phase, so as to create two teams of overall comparable skill. The division was done such that each team contained members who in the preparation phase specialized in generating the best "own arguments" for their position, as well as members who had specialized in countering the "other arguments" of the opponents.

During the first half of the showdown, Pro Team A debated with Con Team A. At half time, a team change took place and B Teams from each side continued the showdown. The showdown consisted of a single electronic dialog between the two sides lasting approximately 30 minutes. All members of the team collaborated and came to an agreement on the text to be sent to the opposition.

*5. Judging and feedback (session 11).* The electronic dialog produced in the showdown was represented in an argument map prepared by the researchers. All the arguments, as well as the corresponding counterarguments and rebuttals, were represented and connected by lines to show their interrelation. Different colors were used to label contributions as effective, ineffective, or neutral argumentive moves. A point system was also applied, which made it possible to declare a winning side. The argument map as well as the graph representing the outcome was presented to the students for their examination the week following the showdown.

### Subsequent Intervention Phases

The intervention was repeated during the second and again during the third trimester of the school year, with new topics. The second topic addressed whether disruptive students should be expelled from school or allowed to remain. The third topic, linked to the social studies curriculum, addressed whether the United States should offer military intervention to a small country requesting it. Due to time limitations created by school scheduling conflicts, the second and third interventions included only five dialogic sessions instead of six.

### Posttest Assessment

The pretest assessment involving individual dialogs on CP was repeated for all students. In the intervention group, one student participating in the initial assessment left the class after the first topic and was not included in the posttest assessment. Another student who joined the intervention classroom during the second topic was also not included in the posttest assessment.

## Results

### Overall effect of the intervention

Dialogs were coded based on the argument discourse coding scheme developed and used in previous research (Felton, 2004). The main indication of improvement was the increase in counter-critique strategy moves – a counterargument that directly weakens the force of the opponent's preceding argument. The proportion of Counter-C usage for the intervention group increased from 20.67% (SD = 29.67%) at initial assessment to 40.91% (SD = 19.28%) at final assessment, while the control group increased nominally from 18.84% (SD = 28.45%) at pretest to 19.93% (SD = 32.44%) at posttest. A significant group X time interaction was found, $F(1, 46) = 4.89$, $p=.032$, partial $\eta 2 = 0.096$.

### Intra-dyad Discourse Analysis

Analysis of the intra-dyad discussions is based on the 163 intra-dyad discussion transcripts of the discussion between members of a dyad as they participated in the sessions of the intervention. A coding scheme was developed to distinguish meta-level discursive moves about strategies (planning, evaluating, or predicting) from simply discussing the content of the arguments (see Table 1).

Table 1: Intra-dyad discourse coding scheme

| Code | Examples |
|---|---|
| **METACOGNITIVE STRATEGIES** | |
| PLANNING [PL] | -We could mention how effective the expulsion will be towards the kids in the school. Maybe we explain that better?<br>-I meant we can use the friends reason.<br>-What should we say to that? |
| PREDICTING [PR]: Predicting effect or consequence of strategy that hasn't happened | -They are still writing. What do you think they are going to talk about?<br>-They will say that he could learn English in school or they could get him a Spanish teacher.<br>-Don't know how they will come back from that |
| EVALUATING [EV]: Analysis of performance and strategy effectiveness | -We stuck a hole in their argument<br>-We gave them a good comeback<br>-They proving our point! Look what they keep writing!<br>-What's our main argument? |
| **METACOGNITIVE KNOWLEDGE** [MC] | -I don't even know why I'm arguing with this side. I got so many ideas in my head |

| | |
|---|---|
| | -Can we just talk to everybody instead of typing?<br>- You know what, we can use this! We can use this! This is our comeback! Our Counter-Counter argument. |
| **NON-METACOGNITIVE** | |
| NULL [N] | -Oh man |
| OFF TASK [OT] | -I'm MAD hungry. How much time til lunch? |
| TECH [TC] | -They just responded<br>-I don't think our network is connected |
| READING FROM SCREEN [RS] | -They said, "Aris needs to make friends" |
| TYPE-ALOUD [TA] | -We… think… the… boy… should… be… home… schooled |
| DICTATION [DT] | -…receiving a fatal warning, F-A-T-A-L. |
| DIVISION OF LABOR [DL] | -Let me type now |
| ARGUMENT DISCUSSON [AD]<br>Discussion of content (not discourse) | -He could hire a tutor |

### Relation between Meta-Level Intra-Dyad Discourse and Strategic Gain

To examine the relationship between meta-level discourse and strategic performance from initial to final individual assessment, students were categorized into two additional groups for each topic. The strategic improvement categorization is based on whether they increased or didn't increase with respect to a key indicator of strategic improvement, the proportion of Counter-C utterances from initial to final assessments.

For Topic 1, six students (three dyads) were dropped from the analysis of the first topic due to not participating in the intervention. Simply put, the partners didn't interact with one another during the entire first topic of the intervention. In consultation with the classroom teacher, these six participants were arranged in better pairs for the second and third topics. Of the 19 participants, 14 were classified as showing improvement from initial to final assessments. Of the 14 that improved, eight were also classified in the high-meta intra-dyad category, i.e., they were equal to or above the median for total number of meta-level utterances, and six were classified in the low-meta category. Of the five that didn't improve, two were above or equal to the median and three were below. While suggestive, these proportions were not significantly different ($a$ = .628, Fisher's Exact Test).

For Topic 2, of the 25 participants, 19 improved from initial to final assessments and six didn't. Of the 19 that improved, 13 were above or equal to the median for proportion of meta-level utterances and six were below. Of the six that didn't improve, all were below. These proportions were significantly different ($a$ = .005, Fisher's Exact Test).

For topic 3, of the 25 participants, 19 improved from initial to final assessments and six didn't. Of the 19 that improved, 13 were above or equal to the median for proportion of meta-level utterances and six were below. Of the six that didn't improve, all were below. These proportions were significantly different ($a$ = .005, Fisher's Exact Test).

### Relation between Total Utterances and Strategic Improvement

A similar analysis was conducted to determine if total intra-dyad talk related to strategic improvement. Two groups were formed per topic – the *high-talk* group, at or above the median, and the *low-talk* group below the median. The relationship between total talk frequency and strategic improvement, even while suggestive for topics 2 and 3, was not significant for any of the topics. Thus, it appears to be meta-level talk specifically, rather than talk in general, that is predictive of strategic gain.

## Discussion

The present results confirm that argumentation skill can be developed among young adolescents over the course of a goal-based, collaborative activity offering dense opportunities for engagement in discourse. Consistent with earlier findings (Kuhn et al., 1997, 2008; Kuhn & Udell, 2003), the intervention was effective in enhancing students' dialogic argument skills in addressing a new topic that had not been included in the intervention. Students in the intervention group exhibited an increased proportion of usage of skilled argument strategies (Counter-C) and a decreased frequency of usage of less advanced (Exposition) strategies, compared to the control group.

These findings are inconsistent with claims that argument skills are entirely domain specific (Stein & Miller, 1993). Participants in the present study only engaged each other on the capital punishment (CP) topic twice – once before the intervention as a pretest and once at the end as a posttest. The pretest did provide students with some experience with the topic, but no more than it did students in the control group. Improvements within a domain could be due to acquisition of specific content-bound arguments within the domain, but transfer to a different domain requires a more complex account.

It warrants emphasis that this progress was observed in a group of significantly academically disadvantaged students. Prior to the intervention, these young adolescents had little occasion to practice sustained argumentive discourse in their daily lives. Observation of their classroom experience showed that they experienced only infrequent opportunities to express their views and then only in response to a teacher's question, rather than in debate with one another. Yet these students readily engaged the activity and the majority showed clear advance in skill.

The contribution of the present study lies in the insight it offers regarding the mechanisms that make the method effective. The intervention created conditions in which focused peer discourse was required and supported. The results indicate that its value lay not in talk per se, the quantity of which did not predict improvement. Instead, it has been proposed here, a major value of such discourse is its support of meta-level representation and regulation of discourse processes. The findings support this hypothesis. Students producing a high proportion of meta-level utterances during peer discourse tended to make the greatest progress in individual argument skill. This relationship was statistically significant for the latter two of the three phases of the intervention period. During the first topic, we can speculate, students were settling into an activity that was very new to them and gains were less consistent overall.

The present results, it should be emphasized, don't simply show that students displaying a high proportion of meta-level utterances did better on the argument skill posttest. Rather, frequent expression of meta-level utterances with a collaborating partner is associated with advance in individual argument skill. This advance, note further, could be observed across the range of initial skill levels. Initially less competent and initially more competent individuals both improved when they engaged in frequent meta-level talk.

Why might engaging in meta-level regulatory discourse lead to skill advance? Meta-level understanding of the goals of argumentation and of strategies to achieve these goals develops over time with engagement and practice. Such meta-level discussions aren't simply reflecting the individual's current understanding of task and strategies. The discussion is part of the process, along with engaging the opposition, of constructing the understanding.

The most useful and likely accurate way to conceptualize the relationship between meta-level understanding and strategic engagement with a cognitive task is most likely as one of mutual bootstrapping (Kuhn & Pearsall, 1998). Implementation and practice of strategies leads to greater understanding and valuing of them, in bottom-up fashion, while top-down monitoring and management of strategies plays an increasing role. This is not a new idea, but the present study contributes to our understanding of how this process may work by examining and identifying differences between cases in which it works well and less well over an extended period of time. The Counter-C strategy was used in combination with less advanced strategies over the course of the intervention. Both the effective use of advanced strategies and ineffective use of less-advanced strategies may "feed-up" to the meta-level and strengthen awareness of the utility of each strategy. Meta-level understanding also "feeds down" to the strategic level. Increasing awareness of the coordination of task objectives and effective strategies to reach task objectives guides strategy implementation.

As microgenetic research has repeatedly shown, enhanced meta-level awareness of strategies, and particularly more advanced strategies, doesn't mean that less-advanced strategies cease to be used (Siegler, 2006). More likely, however, meta-level understanding was under construction throughout the intervention through repeated engagement rather than emerging in a single observable moment of change.

In summary, the present results support the conclusion that the opportunity for explicit meta-level discourse contributes to meta-level understanding, which has been shown here to relate to the development of strategic skills. We are far from a complete understanding of the mechanisms involved and more observation of them in action is needed. In particular, the need to understand how top-down and bottom-up processes reciprocally support one another will arguably require more attention to individuals' understanding of their practices, rather than simply performance of them.

**Abstract:** An important instructional practice for teachers in learner-centered science classrooms is to be able to work productively with students' ideas and questions. Eliciting and thoughtfully attending to students' thinking in order to help them advance in their learning is no easy matter, however. This study examined how teachers enacted instruction to elicit, connect, and build upon their elementary students' ideas and questions during an innovative twelve-week learner-centered environmental biology unit. The purpose of the study was to identify and describe successes, issues, and challenges related to incorporating students' ideas and questions into science instruction. Primary data sources included field notes taken during classroom observations and teacher interviews. We present three contrasting cases of teachers to highlight evidence that shows teachers' differing strategies for eliciting students' ideas and questions, and for developing students' ideas, questions and questioning skills. We discuss practical implications for designers of inquiry-based science curricula and professional development.

## Introduction

Learning sciences research has identified as a key design principle that learning environments must be "learner-centered," that is, they must attend to and make use of what students bring to the classroom learning situation (National Research Council [NRC], 2000a). By eliciting and attending to what students bring, teachers can actively engage students' ideas about and orientations to what and how they are learning (Schwartz & Bransford, 1998). Moreover, making use of students' contributions in teaching can help transform students' discipline-oriented thinking and ways of participating in disciplinary practices (Baranes, Perry, & Stigler, 1989).

To support student sense-making effectively in learner-centered science environments, teachers need to shift from the typical pattern of talk in classrooms (e.g., Cazden, 1988; Mehan, 1979) to new forms of discourse that promote productive thinking and participation. In addition, teachers need to be able to make creative use of the diversity of student ideas during instruction. This entails making productive adaptations to students and their contributions as instruction unfolds. A challenge for designers is to develop flexibly adaptive curriculum materials (Schwartz, Lin, Brophy, & Bransford, 1999) that provide the structure for teachers to enact ambitious science instruction while at the same time provide support and room for teachers to make use of what students bring to the learning context. Even with such materials, teachers are likely to diverge in their approaches to and success in creating richer forms of discourse in classrooms.

In this study, we examined teachers' instructional moves to elicit and develop students' ideas and questions as they enacted a twelve-week learner-centered environmental biology unit with their fifth grade students. The unit was designed specifically to help teachers reconfigure their classrooms for science learning in ways that were more learner-centered, with a particular focus on creating opportunities for teachers to elicit and work with students' ideas and questions as a source for student-led investigations of habitats. A central aim of our study was to gain insight into the ways in which teachers' enactments enabled them to work with students' ideas and questions to help advance learning. To this end, we present three contrasting cases of teachers to highlight evidence that shows teachers' differing strategies for eliciting students' ideas and questions, and for developing ideas, questions and questioning skills.

## Theoretical Framework

Formulating and refining questions that can be answered through scientific investigations is a fundamental ability required for science inquiry (NRC, 1996, 2000b, 2007). Developing scientific questions is a creative act at the heart of scientific activity (Shodell, 1995). In practice, however, student questions are rare in classrooms, compared with teacher questions (Carlsen, 1993; Dillon, 1988). Moreover, students find it challenging to take an ill-formulated question posed at the outset of an inquiry and clarify or refine it in ways that can productively guide inquiry (Krajcik, Blumenfled, Marx, & Soloway, 2000; Lehrer, Giles, & Schauble, 2002; van Zee, Iwasyk, Kurose, Simpson, & Wild, 2001). Thus, a critical challenge is to help teachers use curriculum to enable students to both to generate and develop questions that can guide inquiry.

Research on student question generation suggests that teachers' actions are critical. When teachers establish discourse patterns (e.g., brainstorming, "K-W-L" sequences) that elicit student questions and engage students in discussion about their observations of familiar contexts, more questions are likely to emerge in the science classroom (Penuel, Yarnall, Koch, & Roschelle, 2004; van Zee, et al., 2001). In these discussions, teachers' use of "wait time" and reticence from immediately judging student contributions give space for more student questions to emerge (Gallas, 1995; Rowe, 1986). Besides observation, other sources of student questions that teachers can tap are prior knowledge, cultural beliefs, information from media, and family experiences (Chin & Chia, 2006; King, 1994; Reeve & Bell, 2009).

Not all student-generated questions can be investigated in classrooms and those that can be pursued often require the assistance of the teacher and peers to develop. Some questions students pose can be researched using books or digital resources and are answered readily with reference to facts; others are "wonderment" questions that invite hypothesis generation and prediction (Scardamalia & Bereiter, 1992). Teachers can encourage the latter type of questions by engaging students in extended problem solving activities (Chin, Brown, & Bruce, 2002) and in student-led investigations (Hofstein, Navon, Kipnis, & Mamlok-Naaman, 2005). In addition, putting students into collaborative learning situations where they must clarify questions and design investigations together can help develop students' questions (Marbach-Ad & Sokolove, 2000). Finally, teacher discourse moves such as "revoicing" that explicitly align different student contributions and ideas to content and to set up contrasts among students helps develop questions provides a motivating context for the development of questions (O'Connor & Michaels, 1993).

## Curricular Context

The research described here is part of a larger design-based research project that included the creation of an elementary school science inquiry unit as a means to support science instruction that is challenge-based (Schwartz, Lin, Brophy, & Bransford, 1999), leaner-centered (NRC, 2000a), and authentic in the sense that students engage in tasks that are relevant to the science topic under study and to their own lives and interests. This curricular unit was created via a school-university partnership, subsequently piloted by teachers in the district, and then revised collaboratively with teachers and researchers. Cornerstones of the unit were student-choice and student-driven inquiry related to an over-arching challenge, all couched in socially interactive group work. The newly revised unit was then systematically studied as it was being implemented by a cadre of teachers in their elementary classrooms, which exemplifies the tenets of a research into practice, practice into research approach (Design-Based Research Collective, 2003). In this curriculum unit, titled *The Isopod Habitat Challenge* (IHC), students move through phases of inquiry as a means to solve their ultimate challenge—to create an optimum habitat for isopods. Students first share their ideas and questions about isopods, take part in a teacher-guided investigation, and then participate in student-generated investigations to answer their questions. As students move through each phase, they revisit and revise their initial ideas and questions, conduct new research, revise their ideas and reformulate their questions again, and then present their final habitat plan in a public forum.

The unit materials included features that are *educative* (Davis & Krajcik, 2005), meaning features meant to help teachers learn, to better support student learning. Educative features in the materials included overviews of the instructional stance, organization, and phases of the unit, flexible pacing guides that supported teacher planning, and embedded notes that signified decision points (i.e., critical junctures) during instruction where it was especially important to attend to student thinking. The lesson materials also included prompts such as idea generating (e.g., brainstorming) and questioning prompts that were meant to help teachers elicit student ideas and questions. Materials for students included an *idea journal* for developing and recording ideas and questions and for iteratively investigating key questions as they progressed through phases of inquiry, as well as a *team planner* for collaboratively designing the habitat for their isopods. Teachers had access to the unit materials online through the school district website.

University researchers and two teachers who initially piloted the unit led three formal professional development sessions to support teachers' learning of how to use the curriculum materials with students. All of these sessions took place after school hours in participating teachers classrooms. The focus of the professional development sessions included instruction on science content, descriptions of lessons and activities, modeling of lessons and activities through video clips, pacing of the unit, classroom management, and discussion on effective instructional strategies for teaching science as inquiry. Time was also spent troubleshooting challenges that teachers encountered during unit enactment as well as celebrating and sharing successes. In addition to the formal professional development sessions, the teachers were in close contact via email and in-person meetings at school sites with university researchers who were involved in the unit development. This frequent electronic and in-person communication, or "just in time" professional development provided individualized support to the teachers while they were enacting the unit in their classrooms.

## Methods

The overarching research question guiding this study was, *For a curriculum unit that aims to develop students' skill in posing scientific questions, how do teachers vary in the ways they elicit, re-voice, connect, and/or build upon students' science ideas and questions?* We approached the question by focusing, as past research has, on teachers' instructional moves to elicit and help students to go further with their ideas and questions. By analyzing differences among teachers using the same curriculum materials, our comparative case approach enabled us to examine how teachers' enactments shaped their students' learning opportunities.

### Setting and Participants

A total of eight teachers across five elementary schools in one mid-size suburban school district in the Pacific Northwest enacted IHC over 12 weeks in their fifth grade classrooms. We present case studies of three of the teachers from three different schools in the district. The three teachers, Ms. Atwell, Mr. Jimenez, and Ms. Lesh (pseudonyms), were purposefully selected as contrasting cases for the present study. Mr. Jimenez was a M.A.-level teacher in his $15^{th}$ year and taught at an elementary school whose student population was diverse (24% Asian American, 40% Caucasian, 22% Hispanic, 6% African American, and 8% multi-ethnic), with a high percentage of students receiving free or reduced price lunch (47%). Ms. Atwell was a M.A.-level fourth-year teacher who taught at an elementary school that was predominately Caucasion (60%) and Asian American (19%), with a small percentage of students receiving free or reduced price lunch (13%). Ms. Lesh was a B.A.-level fourth-year teacher at an elementary school that was comprised primarily of Asian American (52%), Hispanic (19%) and Caucasian (17%) students, with 29% of students receiving free or reduced price lunch.

Within the sample, the three teachers' students represented three different levels of accomplishment with respect to the unit's goals. Students in Ms. Lesh's class had the highest average score on the post-assessment and Mr. Jimenez' students scored lowest. Ms. Atwell's students scored in the middle. Preliminary analyses of observation data suggested these three teachers also differed with respect to their approaches to implementing the unit, such that the differences in student results might be analyzed in terms of these differences.

### Procedures

Data sources included narrative documents of lessons produced by integrating field notes and observation protocols completed by classroom observers, as well as semi-structured teacher interviews conducted by researchers during and after teachers' enactment of the unit. The classroom observations were spread across the 12-week unit, enabling observers to visit classrooms and record lessons at the beginning, middle, and end of the unit. We used as the basis for analysis a set of narrative documents from 18 classroom observations across the three teachers. The narratives were comprehensive descriptions of classroom events, targeting teacher and student actions, interactions, and conversations.

In analyzing narratives, we developed and employed a coding scheme based on discourse interactions, focused particularly on patterns of teacher "uptake" (Nystrand & Gamoran, 1991) of student ideas and questions during instruction. The coding scheme was developed through an iterative process of creating codes based on hypotheses, coding evidence of elicitation and uptake, modifying and refining codes, and recoding consistent with recommendations for qualitative data analysis by Miles and Huberman (1994). Independent coding of narratives was conducted with two coders who met regularly to compare evidence for codes and calibrate their approaches for identifying evidence. Differences were resolved through discussion and consensus. In instances where both coders were uncertain about a piece of evidence, a third researcher provided judgment to help clarify and reach agreement. A short statement of justification was written for each piece of evidence that linked the evidence to a code.

Interviews were conducted with each teacher at two time points: once midway through the unit and a second time at the conclusion of the unit. Specific to the present study, the semi-structured interviews addressed teachers' perspectives on students' experiences, ideas, and questions during instruction, and included questions on what teachers did in response to student contributions. For example, teachers were asked whether and how students' ideas influenced their teaching, the kind of guidance they provided to students during student-led research activities, and how they tried to respond to students' problematic ideas. Interviews were audio recorded, transcribed, and then used to further explore developing patterns and themes that emerged from the analyses of narrative data.

### Constructing the Cases

We sought to select cases that, through analysis, could provide guidance to teachers about how to work productively with students' ideas in ways that went beyond simple elicitation. To this end, we took an explanatory, multiple-case study approach (Yin, 2003) that focused on explaining variation in individual teacher enactment from curriculum use. In this approach, researchers take as their aim not simply to describe the phenomena under study, but to seek out explanations for why cases unfold the way they do. Yin's (2003) recommendation is that researchers develop a set of initial possible "rival explanations" for patterns in the data that they expect to find, both as a guide to instrument design and as a method for guarding against confirmation bias.

## Results

In this section we highlight evidence from our analyses focused on teachers' strategies for eliciting students' ideas and questions, as well as strategies for developing ideas, questions and questioning skills. We frame these strategies as *instructional moves* – actions meant to facilitate learning typically through a combination of speech and gesture. *Strategies for eliciting* refer to instructional moves made by teachers in an effort to draw out and make student ideas and questions visible. *Strategies for developing* pertain to the "next step" instructional moves made by teachers to respond to student thinking. Though we identify and describe instructional moves separately, we recognize that they are oftentimes intertwined during instruction and that teachers typically enact sequences of moves to support learning.

Overall, our findings show that all three of the teachers were effective in employing instructional moves to elicit student ideas and questions. Moreover, their strategies for eliciting were similar. However, teachers differed widely in their next step instructional moves and how they worked with student ideas and questions to help students go deeper in their thinking; the teacher whose students scored the lowest on the student assessments made the fewest of these kinds of moves. To illustrate these similarities and differences, we present below summaries of teachers' moves with examples that characterize their instruction.

### Strategies for Eliciting Ideas and Questions

All three teachers used the elicitation prompts in the unit materials as well as their own strategies. Among the three teachers, we identified two common strategies for elicitation – posing questions to elicit students' ideas and questions, and inviting students' ideas and questions. The teachers used these strategies to elicit both procedural and wonderment thinking. That is, teachers asked and invited procedural questions that addressed basic information about how to accomplish teacher-structured tasks as well as how to carry out student-generated ones. They also asked and invited wonderment questions that dealt with hypothesizing and predicting, explaining and clarifying, and making sense of investigative experiences and results.

#### Mr. Jimenez

Mr. Jimenez tended to pose questions to elicit student thinking about procedural knowledge for engaging in tasks, such as what materials to use for investigations, the steps to follow, and how to record work. During activities and investigations, Mr. Jimenez asked basic information questions to check in on students' progress (e.g., what are you doing?) and help students in carrying out their tasks (e.g., what will you do next?) When students experienced difficulties in carrying out their procedures, he tended to pose elicitation questions to help students move forward in their investigative process (e.g, how does that help answer your question?).

Mr. Jimenez also engaged in a regular elicitation pattern of inviting students to share their group work experiences and outcomes. He tended to structure these opportunities as whole-class reporting sessions in which students from different investigative groups take turns stating their group ideas, questions, and findings. Elicitation invitations included such prompts as "what did you research?", what did you find out?" and "let's have each group tell us what they did". In the following excerpt, Mr. Jimenez invited students to report their findings as he recorded them on a smart board:

S1: They live under rocks and in soil.
S2: When you touch them they roll up...
T: Okay… what was the other comment you said?
S: They roll up.
T: Oh, okay, they roll up.
S3: They are in different segments.
S4: They have eyes.
S5: They don't have eyes!!
T: There is some disagreement, let's write them both down for now. If you have any other ideas, please share.

## Ms. Lesh

Ms. Lesh posed procedural and planning questions to her students to ensure that they clearly understood how to do tasks and to help them in the planning process of their investigations. During whole class discussions about planning procedures for investigations, Ms. Lesh tended to invite students to help determine steps and reason through the benefits or drawbacks of following particular steps. For example, while collectively planning an experiment in which they were going to examine isopods' food preferences, Ms. Lesh elicited students' ideas regarding the number of isopods needed for the experiment by asking, *how many isopods do we need to be able to answer our question?* Students then offered their ideas and reasons for various numbers. One student's response to the elicitation was to select either 3 or 5 isopods, *"because if isopods moved in even numbers to both sides, it wouldn't be possible to decide."*

When students encountered difficulties during small-group activities and investigations, Ms. Lesh typically elicited their ideas about how the problem/issue might be resolved, rather than offering an immediate solution. She also monitored groups closely, encouraging anticipatory thinking by eliciting students' predictions about what might happen next as they were proceeding through investigations. She tended to ask students while they were working in groups to explain what they were doing.

After group investigations, Ms. Lesh tended to have students report out their results as well as their successes and challenges in carrying out their investigations. Of note is that Ms. Lesh elicited wonderment questions primarily when prompted to do so in the materials (e.g., prompts in the materials to generate student-driven questions about isopods).

## Ms. Atwell

Ms. Atwell posed questions to elicit students' procedural knowledge for carrying out tasks as well as their ideas for planning and conducting investigations. Similar to Ms. Lesh, she tended to ask students to report out on their designs for student-led investigations and then elicit from students their reasoning for their design decisions (e.g., why did you decide to do it like that?). She also tended to pose questions to elicit students' ideas about conceptual topics. These elicitation questions were typically framed as wonderment questions (e.g., what do you think?) that probed students' grasp of science ideas (e.g., what is a habitat – what are your ideas?), their ideas about what makes for a good researchable question (e.g., what does a scientific question involve?), and the kinds of questions that students were working with (e.g., what is your question?).

She also elicited conceptual questions from students and structured discussions in a manner that encouraged students to clarify (e.g., what do you think she means?), build upon (who can add to what was said?), or counter one another's ideas (e.g., who has a different idea about how we can set this up?). After investigations, her whole class elicitations tended to focus on what students learned (e.g., what did you find out?) as well as what new questions they had (e.g., what questions do you have now?).

## Strategies for Developing Ideas, Questions and Questioning Skills

All three teachers worked with their students to generate, refine and pursue questions that served to frame students' investigations and guide their inquiries. In addition, students in all three classes appeared to benefit when teachers made suggestions and pressed students to clarify and refine their questions and investigations. However, the three teachers differed in their level of attention to students' ideas, questions, and questioning skills. Here we highlight the diverse ways in which teachers attended to student thinking.

## Mr. Jimenez

Mr. Jimenez tended to incorporate student thinking into whole-class activities and discussions, but often did not go beyond simple acknowledgement of students' contributions. There were very few instances where he tried to really work with students on developing their ideas. When he did try to do so, it tended to be in the context of supporting students in designing investigations. In the following excerpt, Mr. Jimenez tried through his elaborations and questions to support students in thinking about controlling variables in their procedures:

> T: So, what materials do you think are necessary to do this investigation or experiment?
> S: Soil.
> T: Soil, okay (writes on "soil" on board). About how much soil do you think is necessary for this?
> S: A handful.
> T: Okay, a handful, uh, so, if we just say a handful and we just put it in the runway, how are we going to know if the other side is going to have the same amount, okay? So, what can we do with the soil?
> S2: Use cups.
> T: Use cups, okay? Okay, so that's important, so we need to keep the amount of soil the same, that's another variable that we need to keep the same.

Another way that Mr. Jimenez incorporated student thinking into whole-class activities was by having groups report out on their group activities and learning, and asking individual students to share ideas and questions. But when students shared results, posed a question, or raised an issue, he tended to simply acknowledge the contribution and would then move on to another topic. For example, when Mr. Jimenez encouraged groups to bring out their ideas, he often responded to contributions by saying “next group”, “okay”, and “so, now we are going to…”. In this way, Mr. Jimenez structured discourse so that ideas and questions were elicited but fell short on leveraging those contributions to help deepen students’ thinking.

## Ms. Lesh

Ms. Lesh actively worked with students to ensure that their questions and procedures were feasible. She regularly pressed students to refine their questions, often engaging individual students in elaborating on their questions so she could then help tighten them. When pressing students to be detailed in their procedures, she explained that as scientists “you have to be exact” and regularly reminded them to “put in more detail” and “be more specific”. When supporting students in refining their research questions, she tended to revoice their questions and press them to elaborate. Through her questions of their research questions, students were prompted to clarify and make their questions more feasible for classroom investigation.

During end-of-investigation discussions, Ms. Lesh connected student findings and insights to the work of other groups when the opportunity arose. For example, when a student reported observations that were similar to the work of another group, Ms. Lesh made explicit the similarities in findings. When Ms. Lesh took up students’ conceptual ideas, she tended to value and validate their ideas with supportive comments like “you’ve got it” and “excellent” and expressing excitement through gestures such as high fives. When students were off the mark in their ideas, she tended to try and redirect student thinking through clarification questions (e.g., are you really asking about day or are you interested in light vs. dark?) and explaining her interpretation of students’ ideas.

## Ms. Atwell

Ms. Atwell worked continuously with students to help them learn how to ask researchable questions. In the following excerpt, she asked questions to help a student refine a question, and also used the conversation to model for the class how she was thinking when listening to what students were saying:

> S: what does the climate need to be for them?
> T: what do you mean by climate?
> …
> T: (to whole class) What I’m trying to do is paraphrase in my mind what I think she’s saying. It’s a good thing for you to do when you’re listening, too.
> T: (to student who asked question) We have temperature questions, but it seems like you’re going a little further.
> S: Does the isopod’s habitat need to be hot and dry or cold and moist?

Ms. Atwell held inquiry discussions and structured them to involve students in clarifying their own ideas and questions and exploring others’ perspectives. She also invited students to help each other think through their ideas and questions. For example, when a student shared her prediction about isopods preferences for location, Ms. Atwell asked the class, “does anyone want to respond?” She then allowed students to ask clarification questions regarding the initial prediction and encouraged students to provide reasons why they did or did not think the prediction would hold true. In this way, she established a discourse environment in which students saw their task as sense making and knowledge building.

Similar to Mr. Jimenez and Ms. Lesh, Ms. Atwell asked groups to report out their designs for their student-led investigations and, once investigations were conducted, encouraged groups to report their findings. Differently, however, Ms. Atwell tended to pose questions, encourage students to pose questions, and gave clear feedback when recognizing student thinking. For example, when a student group was describing the reasoning for their second research design, both Ms. Atwell and a student engaged the group:

> S1 (G1): Since in the first investigation they liked the moist side…
> T: Good thinking – I like how you built on knowledge you already had.
> S2: I have a question, why did you decide to do it like that?
> S1 (G1): We wanted to have it super light and super dark on each side.
> T: So, were you thinking if you had more contrast you might get better data?
> G1: Yes *(multiple students respond).*
> T: Thanks team.

## Discussion and Conclusions

Our comparative case studies revealed that the three teachers differed in the ways they developed or took up student questions posed in investigations in ways that potentially help explain observed differences in student learning across classrooms. In Mr. Jimenez' class, where students scored lowest on a test of their skill in posing investigable questions, the teacher made few moves to help develop student thinking. By contrast, in the two other classrooms where students did better on the assessment, the teachers used multiple strategies for developing student questions. Even when implementing the same curriculum unit, which provided explicit guidance about how to elicit questions and called for multiple iterations in students' design of investigations, there was significant variation in how teachers took up the materials.

Implementation variation of this kind is hardly surprising (see, for example, Schneider, Krajcik & Blumenfeld, 2005), but the particular ways teachers varied and were similar in this study points to specific aspects of developing students' questioning skills that future curriculum materials may need to consider. Strikingly, all three teachers (as well as others we observed in this study) were able to use the curricular guidance in the materials to elicit student questions. The teachers in interview data, not reported here, all found this aspect easy and interesting to enact. By contrast, teachers had a harder time consistently helping students develop their ideas. Sometimes, as we report elsewhere (Phillips, Harris, Penuel, & Cheng, 2010), it was because teachers had to balance considerations of time with the need to give students multiple opportunities to develop their thinking. But in the successful teachers' classrooms, we also found evidence of classroom norms developed through sequences of moves described above. The individual moves employed were in some cases simple and straightforward, but orchestrating them in class was a skill that varied from teacher to teacher in the study. A single move can be described and pointed out easily, but learning how to orchestrate them into coherent, effective sequences of "next step" moves takes time and is likely to develop primarily through reflective practice.

One conclusion from our findings is that the IHC curriculum materials must provide greater educative support for teacher learning to develop students' questions. The team that designed the unit shared our conclusion and developed additional resources to support future teachers' enactment that illustrate ways to develop teacher questions. Some of these resources included video exemplars from the two teachers in the study who were more successful in developing student questions. For its part, the district in the study plans to take the results of our implementation analysis and share our list of discursive moves with science instructional coaches. Their plan is to use the moves as a lens for observing and mentoring teachers to make the most of the curriculum materials.

Future research is needed on strategies to develop students' questioning skills that compare the efficacy of different sequences of moves for developing questions. Our analysis did not permit a fine-grained analysis to distinguish how successful the two teachers who had a broader repertoire of moves for developing questions were. It may be that some strategies are more effective with some students, depending, for example, on their prior experience with planning investigations. Given that questioning is such a fundamental aspect of science and most students remain novices at posing and investigating their own questions, research in this area is an important focus for learning scientists to pursue.

# Mentor Modeling: The internalization of modeled professional thinking in an epistemic game

**Abstract:** Players of *epistemic games*--computer games that simulate professional practica—have been shown to develop epistemic frames: a profession's particular way of seeing and solving problems. This study examines the interactions between players and mentors in one epistemic game, Urban Science. Using a new method called *epistemic network analysis*, we explore how players develop epistemic frames through playing the game. Our results show that players imitate and internalize the professional way of thinking that the mentors model, suggesting that mentors can effectively model epistemic frames, and that epistemic network analysis is a useful way to chart the development of learning through mentoring relationships.

## Introduction

There is a broad consensus that mentoring is an important part of young people's intellectual, social, and emotional development (Freedman, 1999). In this paper, we look at one powerful form of mentoring—the mentoring that takes place in professional training—and examine how one feature of professional mentoring—modeling— can be used to help players in a computer game learn real-world skills, knowledge, values, and ways of thinking. The context for this study is the epistemic game Urban Science, a game modeled on a practicum course for graduate urban planning students (Shaffer, 2006b). Epistemic games are computer-based role-playing games that simulate professional training.

A critical element of professional practica is the interaction between young professionals and their mentors (Schön, 1983, 1987). In the urban planning practicum, students meet regularly with planning consultants: experienced professionals with whom the students talk about their work. These reflective conversations play a critical role in developing a professional way of thinking. In Urban Science, mentors--who are also called planning consultants--do the same for the players. As in the planning practicum, planning consultants in Urban Science help novices with the intricacies of the work, provide feedback, and inspire them when they are stuck.

A central role of professional mentors, however, is to model the way of thinking that is unique to their profession: what Shaffer (2006a) calls the epistemic frame. This paper looks at whether this same form of mentoring takes place in one epistemic game, and if so, whether it has the same effect as mentoring in the professional context. We ask to what extent players in an epistemic game imitate the epistemic frame that in-game mentors model, and whether this imitation leads to the internalization of a professional way of thinking. While the results are specific to this study, the type of mentoring and learning that happens in epistemic games could be useful models for designing new types of educational settings, in schools or elsewhere.

## Theory

There is a wide body of research on mentoring and its effects on youth development that focuses on the role that mentors can play in promoting positive behavior and habits in youth (DuBois & Silverthorn, 2005). In terms of cognitive development, Vygotsky (1978) is important for his work on how the development of the child's higher cognitive processes depends on the presence of mediating agents in the child's social learning environment. While Vygotsky himself "emphasized symbolic tools-mediators appropriated by children in the context of particular sociocultural activities, the most important of which he considered formal schooling" (Kozulin, 2003), scholars have extended the discussion of those mediating agents to emphasize mediation through another human being. Much of the literature on social mediation is concerned with how adults can facilitate the child's problem solving process by arranging and structuring the problem for them, and by participating in the problem-solving itself. Joint problem solving (Wertsch, 1978) and other situations where a child's current capabilities are extended through the support of an adult, are often framed as "scaffolded" learning (Wood, 1999) or as cognitive apprenticeship (Rogoff, 1990). Mediating strategies like scaffolding, while perhaps too context-dependent and numerous to be simply classified (Kozulin, 2003), have been well described (Schaffer, 1996), but how particular aspects of social mediation contribute to a child's cognitive development is unclear. How social learning processes are converted into internal developmental processes Vygotsky leaves murky, suggesting that showing "how external knowledge and abilities in children become internalized" is an important agenda.

In particular, he describes how children imitate problem-solving techniques. As Vygotsky (1978) puts it, "using imitation, children are capable of doing much more in collective activity or under the guidance of adults." Children can imitate adults or more advanced peers to handle problems that would otherwise be beyond them. As Valsiner and Van der Veer (1999) point out, Vygotsky's use of the concept of imitation is more sophisticated than simple copying; it is part of a learning and developmental process. When Vygotsky argues that children "can imitate only that which is within… [their] developmental level" (1978), he is describing what he calls the zone of proximal development. Problems that are in the learners' zone of proximal development are not just those problems that they cannot yet do alone; they are problems that they have the potential to one day solve by themselves. Thus, imitation leads to internalization.

While Vygotsky used this social learning process to describe young children who were learning to do simple math problems, the scope of the process is larger. The movement from imitation to internalization is the process by which, as Vygotsky puts it, learners "grow into the intellectual life of those around them" (1978). Researchers have described how knowledge is situated in the activity, context, and culture in which it is used (Collins, Brown, & Holum, 1991; Lave & Wenger, 1991). Hutchins (1995), for example, examined the role that more experienced naval navigators play in novice crewmembers' development of essential navigational skills and knowledge. The quartermaster monitors the actions of the novice watch standers as they attempt their duties, and is ready to help or take over if they are unable to complete the task to the ship's requirements. More generally, participating in the practices of a professional community, under the supervision and guidance of mentors, gives individuals access to that profession's repertoire of ways of seeing and solving problems (Lave & Wenger, 1991). Mentoring practices in professional communities are situated in the activities that the learner is attempting to master.

Many professions have institutionalized this mentor-mentee relationship in the form of a professional practicum. Schön (1983, 1987) describes how novices participate in practices they wish to learn in "simulated, partial, or protected form" under the guidance of a senior practitioner. This way of learning is suitable for learning the mores of a professional community because professionals, more than knowing basic facts and using basic skills, have a particular way of thinking (Goodwin, 1994). They make decisions based on a set of professional values, and defend those choices with profession-specific modes of argumentation and standards of evidence--that is, with a particular professional epistemology (Schön, 1983). To learn to participate in the community of practice that Lave and Wenger describe, professionals-in-training need to learn to assume an identity and values consonant with the fundamental purposes of their profession (Sullivan, 1995).

Shaffer (2006b), building on professional repertoire, communities of practice, the role of practica in professional preparation, and Vygotsky's explanation of development, introduces epistemic frame theory. "The work of creative professionals is organized around epistemic frames," Shaffer (2006b) argues: the "skills, knowledge, identities, values and epistemology that professionals use to think in innovative ways." Yet epistemic frames are not merely collections of these unrelated elements. As Shaffer (2006b) argues, "the epistemic frame of a profession is the combination—linked and interrelated—of values, knowledge, skills, epistemology, and identity" that professionals use to see and solve problems. Professionals use their epistemic frame in the context of professional action. By simulating the world of professional practice, practica provide learners with the occasion to practice professional action, and thus develop a particular epistemic frame.

In professional practica, where learners are faced with problems that are often beyond their capabilities, mentors are there to guide them. Throughout the practicum, mentors monitor learners' performance, intervening at critical moments of confusion and struggle (Schön, 1983, 1987). While in these cases the mentors may sometimes instruct in the conventional sense (Schön, 1983, 1987), they mainly function as coaches whose conversations with the learners' highlight how to navigate the obstacles of the profession. As the novices engage in the activities of the profession, the mentors reflect, and invite the learners to reflect, on the work. In this facilitation, mentors reveal to apprentices ways to go about solving problems: they model (Collins, et al., 1991). Through these reflective conversations, mentors model a way of working that requires the complex of skills, knowledge, values, identity and ways of thinking associated with the community of practice. In short, they model the epistemic frame. In modeling the epistemic frame, mentors offer learners a professional vision that they can imitate and eventually internalize.

Shaffer (2006a) describes epistemic games as simulations of professional training, and he and others have shown that those who play them develop epistemic frames (2006a, 2006b; Svarovsky & Shaffer, 2006) which can persist months after the game is over (Bagley & Shaffer, 2009). As in practica, epistemic games feature mentors who lead learners to the right way of working. In Urban Science, for example, planning consultants guide the players through a series of activities drawn directly from ethnographic study of an undergraduate planning practicum. Urban Science provides us a case study of mentor-learner interactions that can show the formation of an epistemic frame. Conversations between players and mentors in Urban Science can show the extent to which a player not only uses elements of the epistemic frame of a practice, but the extent to which the player uses elements of the frame the way a more experienced practitioner does.

In order to accurately capture players' demonstration of epistemic frames while playing epistemic games, we have developed a method to measure how game participants link the elements of the epistemic frame during game play. Epistemic Network Analysis (ENA) is a method designed to assess learner performance based on the theory of epistemic frames. This method measures whether players develop a particular epistemic frame over the course of epistemic game play (Shaffer, et al., 2009). Epistemic games are based on a theory of learning that looks not at isolated skills and knowledge, but at the way skills and knowledge are systematically linked to each other, and linked to a set of values, epistemology and identity markers. To assess a way of thinking about a professional domain means to measure a learner's formation of connections between frame elements, because this construction of a network of skills, knowledge, values, identity, and epistemology allows the learner to see and solve problems as a professional does (Shaffer, et al., 2009). ENA measures how epistemic frame elements become linked through the co-occurrence of those elements in discourse. Mapping the connections between frame elements the way that social network analysis maps connections between people, ENA assumes that the more times frame elements occur together in discourse, the more closely they are related.

This study examines how players of Urban Science develop the epistemic frame of urban planning through one particular feature of the game, namely the mentors' modeling of the epistemic frame. Specifically, we look at players' pre and post interviews and the reflective conversations between mentors and players to see whether the players imitate and internalize the epistemic frame that the mentors model. We ask three questions. First, did the players of Urban Science develop planning epistemic frames? Second, during the game, did the players imitate the epistemic frame that the in-game mentors modeled? Finally, did the players' epistemic frames during the game persist when the mentors were not present after the game?

## Methods

### Study Design

In the epistemic game Urban Science, students play the role of urban planners charged with redesigning neighborhoods in their own city. Game activities were modeled on an ethnographic study of a graduate-level planning practicum, Urban and Regional Planning 912, at the University of Wisconsin-Madison. Offered as part of a summer program called College for Kids at the University of Wisconsin-Madison, fourteen middle-school age students played Urban Science four hours a day during weekdays for four weeks during the summer of 2007. Players had no prior experience with urban planning.

The four planning consultants in the game were graduate students who underwent a one-day training in the urban planning profession, the game's activities, and mentoring strategies. The mentors met before each session to plan for the day's activities, and after each session to reflect on how the session went.

### Data Collection

Data were collected through individual interviews with each player before and after the game. The interviews were composed of questions about science, technology, and urban planning practices. Pre and postgame interviews from the game were recorded and transcribed. The questions asked were:

- What do think urban planning is?
- Do you think urban planning is important?
- What do you think it means to be a planner?
- How would you say urban planners get information for the plans they propose?
- Do planners ever work with other people?
- Do you think environmental issues are important to cities?

Data were also collected through recorded and transcribed interactions between the players and mentors during the game. Interactions consisted of one-on-one conversations where the mentor approached a player at work and asked a prepared set of questions, including:

- What are you working on?
- How is it going?
- If not going well: What have you tried? Why?
- If going well: Why is it going well?

Other interactions consisted of team meetings where the players stopped working, and met as a group to reflect on the work that they had been doing that day or during the previous activity. The mentor facilitated the meeting, asking questions that included:

- What were you working on today/before?
- How did it go?
- What did you try/How did you do it? Why?
- How would you do it differently next time? Why?

Some interactions were spontaneous conversations during game play. These interactions were initiated by players in need of some help, or by a mentor who observed that guidance was needed. The mentor usually asked the questions detailed above, but depending on the nature of the situation, the conversations varied.

## Data analysis

### Coding

Transcriptions from individual interviews were segmented into units representing one complete answer to a question, and included any follow-up questions or clarifications between the player and the interviewer. Transcriptions from in-game interactions between mentors and players were segmented into units representing one complete interaction between a player, or group of players, and mentor. A single rater coded all excerpts for elements of an urban planning epistemic frame: the interrelated set of skills, knowledge, values, identity and epistemology of the profession. The in-game interactions were coded both for the players' epistemic frames and the mentors' frames. Table 1 describes the analytic codes used in our qualitative data analysis of the in-game discourse. The analysis of the pre and post interviews used the same analytic codes.

Table 1: Analytic codes used in qualitative data analysis of in-game discourse

| Code | Description | Player Example | Mentor Example |
|---|---|---|---|
| Skills | Abilities needed to become an urban planner | Crime I managed to keep low by just not adding too much high density housing. | Are there other things you can change into housing? |
| Knowledge | Aspects of urban planning domain knowledge | One of the stakeholders wants a lot of housing…. and I'm making sure that the business, trash, and crime don't go up too high. | Anything else in terms of zoning that you think you might have to balance? |
| Identity | Feelings of belonging to a urban planning community or of being a professional | Mentor: What did they say?<br>Player 1: that our plan was sophisticated….<br>Mentor: did you feel sophisticated, presenting?<br>Player 1: more… than school | But is there a way we can look at it as planners? |
| Values | Things that are important to urban planning practice | It was pretty easy to please my stakeholders, but this plan probably wouldn't work very well for anyone else. | They [stakeholders] are all concerned about the same thing or different things? |
| Epistemology | Ways of thinking about or justifying activity within the urban planning community | That's a justification we can have for crime, that when we added the needed housing for people who work in the Schenk-Atwood neighborhood and need to live there, in order to do that, crime went up by one incident per year. | Alright, so then what would be a justification for the stakeholder who wants it way lower, what would you say to that stakeholder? |

For example, if during a conversation with a planning consultant a player mentions the value of serving stakeholders and the skill of zoning particular parcels to create a site plan that will satisfy those stakeholders, that player's excerpt is coded for values and skills, and those elements are considered linked at that moment. Similarly, if during a conversation a mentor asks a player to justify a particular zoning choice in light of a particular stakeholder's needs, that mentor's excerpt is coded for values and epistemology, and those elements are considered linked in that moment.

## Dynamic epistemic network graphs

### Epistemic adjacency matrices

For this study, the epistemic frame of urban planning is assumed to have 5 elements: skills, knowledge, identity, values, and epistemology. For any participant in Urban Science, we look at each data segment for evidence that the participant is using one or more of the elements of the urban planning epistemic frame. To construct an epistemic network from data such as this, we create an adjacency matrix for that player at that data point, recording the links between the elements of the frame for which there is evidence. For example, if in a particular segment, a player uses skills and knowledge, a link would be considered to exist between them.

By representing the epistemic frame in use during a segment as an adjacency matrix, we use the tools of network analysis to examine the cumulative impact of strips of activity on a developing epistemic frame. To construct a player's cumulative adjacency matrix, we sum the adjacency matrices of the segments of interest. We computed a series of epistemic adjacency matrices:

- one for each player's pre interview
- one for each player's post interview
- one for each player's in-game interactions, weeks 1-3
- one for each player's in-game interactions in week 3 only
- one for the players' collective in-game interactions, weeks 1-3
- one for the mentors' collective in-game interactions, weeks 1-3

### Derived Network Characteristics
Weighted density provides a measure of a frame's complexity: the overall strength of association of the frame (Shaffer, et al., 2009). We compute the weighted density of an epistemic network by calculating the square root of the sum of the squares of the associations between individual elements in the network. In order to compare weighted densities when there were a variable number of strips of activity, we normalized the data by calculating an adjusted weighted density. We calculated the adjusted weighted density by dividing the weighted density by the number of its constituent strips of activity.

Relative centrality is a measure of the relative weight of an epistemic network's constituent frame elements. By extension from the weighted density of the network as a whole, we compute the weight of a frame element from the square root of the sum of squares of its associations with its neighbors. Measuring the strength of association for a given frame element emphasizes those elements with tighter linkages to individual neighbors. We compute the relative centrality of an individual frame element by dividing its weight by the frame element with the greatest weight in the network (Shaffer, et al., 2009).

### Statistical tests
To compare the complexity of the players' epistemic frames between pre and post interviews, we calculated the weighted density of their frames based on their answers to pre and post interview questions. We then used a paired t-test to determine whether or not the weighted density of the players' frames significantly increased between the pre and postgame interviews.

To determine whether the players' in-game frames persisted after the game, we tested whether the adjusted weighted density of the players' 3rd week frames was correlated with the weighted density of their post interview frames. One player's third week consisted of only one interaction, so that player's data was removed.

## Results
Data in this section support three claims about the experience of players in the epistemic game Urban Science. First, players developed epistemic frames by playing Urban Science. Second, the players imitated the epistemic frame modeled by the in-game mentors. Third, the players' frames, as developed in the game, persisted even when the mentors are not present, after the game.

### Developing an epistemic frame
The matched pair questions players answered in post interviews contained more co-occurring frame elements than those answered in pre interviews. As a result, the weighted density of the players' post interview frames was significantly greater than that of their pre interviews (mean pre=0.1, mean post=4.4; $p<0.01$).

These changes in weighted density corresponded to a qualitative difference between players' pre and post frames. For example, one player, when asked, "What do you think it means to be a planner" in the pre interview, replied, "You sort of sketch out and you sort of visualize what will go where and how that will work out." In the post interview, the player answers the same question with considerably more detail:

> "I think it means collecting as much information as you can and it means listening to peoples' opinion and taking them into consideration. It also takes humor because you're not going to plan a place by yourself, you're going to have to collaborate with a lot of people and it takes a lot of compromising and coming up with justifications. The main goal is trying to plan and design a city and trying to improve it and making it the best you possibly can to fit the people's needs and what they want and trying to come up with a solution for all the different opinions and point of views."

Before the game, the player's answer was very vague and said generally that planners think ahead by sketching and visualizing, without any mention of the process of learning about stakeholders' needs, or working with colleagues to meet the needs of the stakeholders and the community as a whole. After the game, the player's more elaborate response refers to important elements of the epistemic frame of urban planning, like research, collaboration, compromise, and justification in the service of improving a community for its constituents.

### Imitating the modeled epistemic frame

In their conversations with players, mentors modeled the planning epistemic frame. For example, in week 1, a mentor reinforced a planning value by prompting a team of players arguing about zoning decisions to remember that their job is to represent the needs of stakeholders:

> Mentor: Are you arguing your opinion or your stakeholder's opinion?
> Player 1: My stakeholders.
> Player 2: My stakeholders' opinion. I don't agree with it, but I'm arguing for them.

The mentor's question makes clear what the correct answer is. The players' responses adopt the mentor's use of the professional term "stakeholder" and the planning value of advocating for the stakeholders' opinions as opposed to one's own whims.

The mentor then follows up with another question designed to remind the planners that they are collaborators, not adversaries:

> Mentor: My other question is: whose team are you on?
> Players 1 & 2: My stakeholders…
> Player 1: Oh, our team. Our team!

By bringing to the players' attention that they are on a team together, the mentor gets Player 1 to shift her perspective from that of a simple advocate for one stakeholder group to that of a colleague whose job it is to work with a team to serve the greater public good by satisfying all of the stakeholder groups.

In week 2, player 1, now on a different team with a different mentor, and working with a different stakeholder group, now thinks of her teammates' stakeholder groups when considering zoning changes:

> Mentor 2: ….do you feel like there are some decisions you would adjust based on what you heard here and going forward to a final plan?
> Player 1: yeah cause we gotta compromise, I can't only want these people's views to push through all the problems.
> Mentor 2: So what are some of the ones you feel you might have to adjust? Taxes was one…
> Player 1: I don't know we have a lot of things in common… Robert's group doesn't really care about greenspace, but… Cheryl's group does want more greenspace and so does mine so that's one thing we have in common and also everyone here increased housing in their plan… and I think everyone wants low crime… I don't think anyone wants high crime…

The player is now prepared to compromise because she knows that planners do not only serve one group of stakeholders. She is ready to figure out how to serve the stakeholders by finding what they want "in common."

In other words, players emphasized the same frame elements that the mentors emphasized. In terms of relative centrality, the players' frame elements followed the same sequence as those of the mentors (Figure 1):

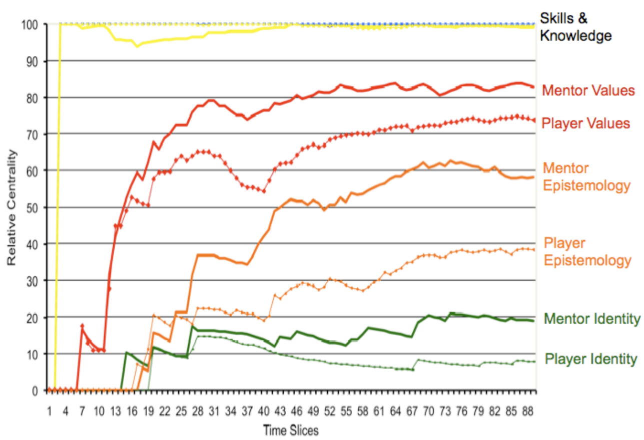

Figure 1: Collective relative centrality of players' and mentors' epistemic frames

Together, knowledge and skills were the most central for both players and mentors; as the most central frame elements, their relative centrality was always at or near 100. For both the mentors and players, the values frame element was the third most central element, the epistemology frame element was the fourth most central element, and the identity frame element was the least central element. In the conversations between mentors and players, mentors modeled a particular planning epistemic frame, and the players emulated that frame.

### Internalizing the modeled epistemic frame

Comparing players' frames as adopted in the game with their frames as demonstrated in post-interviews shows a significant relationship between them. The adjusted weighted density of the players' frames in the third week of the game correlates to the weighted density of the players' post interview frames ($R = 0.6535737$, $p = .021$).

In summary, these results suggest that a) players began to develop an urban planning epistemic frame by playing Urban Science; b) during the game, players adopted the version of the urban planning frame that was modeled by in-game mentors; and, c) the planning frame that the mentors modeled and players imitated persisted after the game when the mentors were not present.

## Discussion

This study examined whether a feature of one particular form of mentoring—the modeling of professional thinking that takes place in a professional practicum—was reproduced in the epistemic game Urban Science. Specifically, we looked at whether mentors' modeling of professional thinking contributed to players' development of the epistemic frame of urban planning. We addressed this issue in three parts.

First, we used ENA to examine the weighted density of players' epistemic frames in pre and post interviews. The players' post-interview frames were significantly denser. This change suggests that in answering the post-interview questions, players saw more connections between the urban planning epistemic frame elements than in the pre-interview. That is, the players of Urban Science began to develop a more complex urban planning epistemic frame. If, as Shaffer (2006b) suggests, professional thinking is characterized by "the combination—linked and interrelated—of values, knowledge, skills, epistemology, and identity," players of Urban Science appear to have developed a professional way of thinking by playing Urban Science.

Next, we used ENA to examine the relative centrality of individual frame elements of both the players' and mentors' frames, as enacted in their conversations together. In game conversations, the players emphasized the same frame elements as the mentors. As might be expected of more experienced practitioners, the mentors connected more frame elements more often, suggesting a more mature epistemic frame. But the ordinal position of the players' epistemic frame elements, and thus the shape of their epistemic frame, was the same as that of their mentors'. In other words, the players of Urban Science were able to imitate the mentors' professional way of talking about urban planning work. If, as Vygotsky (1978) argues, children "can imitate only that which is within…[their] developmental level," the players' successful emulation of the mentors' modeling suggests that the game's activities were within the players' zone of proximal development.

The zone of proximal development only describes the potential for internalization. In order to determine whether the mentors' modeled frame was adopted, not parroted, by the players, we compared the weighted density of the players' frames in the third week of the game with their post-interview frames. The weighted densities of these frames were correlated, suggesting that the imitated frame persisted after the game. This persistence is evidence that the players internalized professional thinking such that they no longer needed the mentors' scaffold. The urban planning professional thinking was in the players' zone of proximal development during the game, but in their actual development level when the game was finished. While it is unclear exactly when the transformation took place, the players of Urban Science began to achieve some autonomy in their ability to think as professionals, and that this autonomy was derived from their interactions with mentors. Vygotsky's hypothesis presupposes that learning processes, such as the imitation of modeled behavior, are converted into internal developmental processes. While this study does not claim to completely demonstrate the process by which children internalize external knowledge and abilities, the results presented here suggest that the imitation of modeled behavior is one step in the process of internalization. A second significant finding is that epistemic network analysis was shown to be a useful way to measure the development of epistemic frames, as well as the relationship between the players' and mentors' frames.

This study has limitations, which include a small sample with insufficient grounds for making causal claims, coarse-grained treatment of the epistemic frame, no treatment of mentoring strategies, and the use of a new and in-development method for understanding epistemic frame development. Still, the results here suggest several implications for people interested in mentoring, and in particular the ways players of games receive guidance from mentors. This study shows that mentors can model the sophisticated way that urban planners think, and that players of the game not only imitate the mentors, but develop the ability to think as urban planners themselves. In subsequent studies we are further examining the role of professional mentoring in epistemic games, and in particular, using epistemic network analysis to investigate the process by which players of epistemic games internalize epistemic frames.

# Where to find the mind: Identifying the scale of cognitive dynamics

Luke Conlin, Department of Curriculum & Instruction, Benjamin Building, College Park, MD 20742 USA, luke.conlin@gmail.com
Ayush Gupta, Department of Physics, Toll Building, College Park, MD 20742 USA, ayush@umd.edu
David Hammer, Departments of Physics and Curriculum & Instruction, , Toll Building, College Park, MD 20742 USA, davidham@umd.edu

**Abstract:** There are ongoing divisions in the learning sciences between perspectives that treat cognition as occurring within individual minds and those that treat it as irreducibly distributed or situated in material and social contexts. We contend that accounts of individual minds as complex systems are theoretically continuous with distributed and situated cognition. On this view, the difference is a matter of the scale of the dynamics of interest, and the choice of scale can be informed by data. In this paper, we propose heuristics for empirically determining the scale of the relevant cognitive dynamics. We illustrate these heuristics in two contrasting cases, one in which the evidence supports attributing cognition to a group of students and one in which the evidence supports attributing cognition to an individual.

## Introduction

Researchers have been divided on how to answer the question "Where is the mind?" (Cobb, 1994) The "cognitivist" perspective takes the individual as the unit of theoretical and empirical focus, under the assumption that cognition is something that only brains do. While cognitivists do not ignore the social and material contexts in which cognition takes place, they analyze cognition by decomposing it into the information processing of individuals (Anderson, Reder, & Simon, 1997). That stance contrasts with situated and distributed views, which contend that cognitive processes cannot be neatly attributed to contributions of individuals when they interact with each other and their environment. Arguments for situated cognition often cite the example of a dieter solving the problem of taking three quarters of half a cup of cottage cheese by pouring out half a cup of cottage cheese, cutting it into fours, and removing one quarter (Lave, Murtaugh, & De La Rocha, 1984). A paradigmatic example of distributed cognition describes the information processing within an airplane cockpit to show that it is the cockpit as a whole—the people and instruments together as a unit—that "remembers" the safe landing speed of the airplane (Hutchins, 1995). Each challenges the attribution of cognition to an individual mind by arguing that cognition is irreducibly situated in a material and social context. The dieter's knowledge of finding ¾ of ½ a cup is inseparable from the physical materials they use to solve the problem. Likewise, no one part of the cockpit "knows" the ever-changing safe landing speed of the airplane.

There have been a number of arguments regarding the relationship between these perspectives. Cobb (1994) took them to be complementary, with one in the background of the other; Sfard (1998) also considered them complementary but "incommensurable"; Greeno (1997) took them as competing alternatives. In this article, we review an argument for theoretical continuity among these perspectives, by which they represent different scales of a complex system, rather than as fundamentally different approaches. Rather than consider the choice of perspective a matter of *a priori* theoretical commitments, we propose treating that choice as empirical. We offer heuristics for matching the choice of unit of analysis to the dynamics evident in the data, arguing that the cognitive unit can be modeled at the grain size(s) at which there are observable stabilities and coherent dynamics in cognitive activity. We then illustrate the use of these heuristics with two example analyses demonstrating empirical evidence for group and individual cognitive units, respectively.

## Manifold resources

Minsky's (1988) is probably the most widely known account of mind as comprised of manifold cognitive and metacognitive parts. He described a "society of mind" made up of a very large number of "agents." One agent he proposed was *More*. When *More* was active it was comparing two amounts and deciding which was greater. *More* was a society itself, made up of agents that corresponded to different ways of comparing different sorts of amounts, and the agents that made up more were made up of other agents. The model presented a complex system of interactions and structures at a wide range of scales. That work influenced many others' accounts, including diSessa's "knowledge in pieces" (1988) and Dennett's (1991) multiple drafts model of consciousness; it resembles and may have been influenced by "schemas" (Rumelhart, 1980).

We refer to “resources” as a generic term for the parts in such models of mind (Hammer, Elby, Scherr, & Redish, 2005). On this view, what we experience as “states of mind” correspond to stable patterns of resource activations, stability that might be only local and contextual or over extended timescales; a stable pattern of resource activations may become a resource in itself, much like Minsky’s *More*. But a stable pattern of activated fine-grained cognitive elements is not necessarily constrained to an individual mind: the pattern and its stability might extend over multiple individuals and artifacts. In this sense, the unit of “cognition” – the pattern of resources and its stability – might at times be individual or be distributed. Our claim is that empirical determination of the extent and locus of stability of such cognitive coherence should guide our sense of the unit of cognition, not *a priori* theoretical commitments.

Consistent with the views of cognition as situated and distributed, there are behaviors and cognitive dynamics that can emerge out of the interaction of multiple individuals and artifacts. Great strides have been made in the last quarter century in modeling how complex behaviors can emerge from interacting agents following surprisingly simple sets of rules. Paradigmatic examples include flocking birds (Kennedy & Eberhart, 1995), synchronized flashes of fireflies (Mirollo & Strogatz, 1990), and foraging of ant colonies (Dorigo & Stützle, 2004). Thelen and Smith (1994; Smith, 2005) have argued for complex systems-based models of cognitive development in individuals, again taking a mind to be made up of many interacting parts in dynamic interaction with each other.

Meanwhile, social science has advanced a variety of accounts of interactive dynamics, such as in conversations tending to abide by simple rules (Grice, 1989) and in shared interpretive frameworks (Goffman, 1974) that are maintained explicitly and implicitly by attending to and responding to verbal, facial and behavioral metamessages (Bateson, 1985; Tannen, 1993). These too may be understood as complex systems, at this larger scale. We suggest that these can be seen as similar dynamics at different scales, that a “society of mind” model of individual cognition is theoretical continuous with a “mind of society” model of social cognition. Thus one can model the dynamics of cognition via the synchronized activity of many cognitive resources, whether those resources are within an individual mind or distributed across minds and materials.

## What to look for: Heuristics for Data-Based Choice of Unit of Cognition

On this view, rather than as *a priori* commitment, the scale of the relevant dynamics may be determined by the evidence at hand. Our core purpose here is to propose four heuristics for making that determination: *clustering*, *persistence*, *resistance*, and *transition*. We extracted these from a range of recent work dealing with a variety of dynamics relevant to cognition including conceptions, behaviors, framing, and epistemologies (Conlin, Gupta, Scherr, & Hammer; Frank, Kanim, & Gomez, 2008; Scherr & Hammer, 2009). The heuristics are not a coding scheme, but rather a guide for empirically grounding the choice of the unit of analysis. In what follows we describe the heuristics and then apply them to two specific examples to show how they can do work in finding an appropriate unit of analysis for modeling cognition.

### Clustering

The basic idea of clustering is that a coherent cognitive state can be characterized by the ‘hanging together’ or simultaneous activation of multiple elements in the same domain or across domains. For example, how we recognize someone as greeting us is by the clustering of behavioral and speech patterns such as a hand extended for hand-shake, a smile on the face, an elevated vocal pitch, and the utterance of socially-accepted greeting words such as “Hello.” Together, these behaviors help us interpret the activity as a “greeting.” Scherr & Hammer (2009) found clusters of various kinds of behaviors (e.g., facial expressions, gestures, pitch, posture) that tended to occur synchronously within and across students working on physics worksheets in groups of four.

### Persistence

If clusters are to be suggestive of cognitive stabilities then they need to be more than just fleeting happenstance; they should persist over time. In the case of a hand-shake the behaviors might persist for a few seconds, while in other cases clusters could remain stable over much larger time scale. For example, while watching a thriller movie, behaviors such as stiff posture, intense gaze on the screen, and low perceptivity of the environment could form a cluster that persists over several minutes. In (Scherr & Hammer, 2009) stable clusters of behaviors were found to last from as little as a few seconds up to several uninterrupted minutes.

### Resistance to Change

In general, the stability of the state of a system is inferred in its ability to sustain itself in the face of perturbations. In certain moments, minor changes in the makeup of the cluster (whether the unit is the individual or the group) could challenge the coherence of physical and cognitive activity. Still, the clusters characterizing the cognitive coherence may be so stable that they can persist despite the perturbation/disturbance. Think of a greeting that lacks an important element, say, when one person extends a hand but the other person does not shake it. This can be a palpable challenge to the "greeting" frame, but it does not always result in a breakdown of the rest of the greeting activities. Fine-grained analysis of the phenomenon can illuminate how particular clusters react to naturally occurring perturbations, providing evidence on the stability and transition dynamics of clusters. More importantly, such analysis can provide empirical insight into whether the cluster (of resources, behaviors, etc.) in that moment is stabilized by an individual or a group.

### Transitions

Sudden transitions in behavior help mark the spatial and temporal boundaries of the stabilities. If there are multiple stable states in the cognitive dynamics of an individual or a group, then we should be able to see distinct transitions amongst the stable states. For this reason it is often easier to notice changes in clusters than to notice the stable clusters themselves—when something suddenly changes it highlights what was just a local stability. When a greeting is over, all of the behaviors that are characteristic of greetings end at about the same time, possibly turning into another cluster corresponding to, say, a conversation.

For an empirical example, the behavioral clusters of Scherr and Hammer (2009) were found only after noticing distinct transitions in behavior. That there were noticeable transitions led the researchers to find and clarify what the transitions were *from* and *to*, which upon further analysis were found to be coherent clusters of behaviors. The behavioral transitions are easily and reliably identified: before discussion three independent coders agreed on the timing of 90% behavioral transitions (to within five seconds). Transitions are often the result of "bids", i.e. minor changes in the clusters of behaviors. Bids that do not precipitate a transition to a new behavior cluster are evidence of the stability of the cluster. Bids that lead to a marked transition between stable clusters are also evidence of the coherence of those clusters.

In the examples that follow we will report on the clustering, resistance, and transitions of phenomena at the individual level and at the group level. We attend to the students' physical behavior (gesture, gaze, posture, etc.) as well as the substance of their discourse in applying these heuristics.

## Data Analysis

Our data is from an introductory algebra-based introductory physics course at a large public university. The students are mostly third-year life sciences majors. We draw our observations from video taken during tutorial sessions – 50-minute sessions, facilitated by teaching assistants, in which the students work in groups of four on ungraded guided-inquiry worksheets focusing on conceptual and epistemological development in physics.

First, we present an example of group-level dynamics in behavior and *epistemological framing*, that is a sense of "what is it that is going on here" with respect to knowledge (Hammer, *et al*, 2005). In the process we will show how the evidence of clustering, persistence over time, resistance to change, and spontaneous transitions all support this account in terms of group-level stabilities and dynamics. We then present a second example that supports an individual unit of analysis but not group-level cognition, in order to show a contrasting case of the scale of the unit of analysis.

More typically, we expect, the relevant scale may shift over the course of an episode, and we expect that analyzing those dynamics will be a fruitful direction for further analyses. For the present, we focus on articulating heuristics for identifying the scale of the dynamics, and for that purpose we have chosen "cleaner" examples.

## The Group as a Unit of Analysis

The first example[i] comes from a Newton's Third Law tutorial, where four students (Amanda, Bridget, Camille, and Dianna) are working together on a series of worksheet questions about a collision between a truck and a car. The particular question they are considering during this clip asks: "Suppose the truck's mass is 2000 kg while the car's mass is 1000 kg. And suppose the truck slows down by 5 m/s during the collision. Intuitively, how much speed does the car gain during the collision?" Camille is the first to offer a response, asking whether the car gains 5 m/s since the truck slows down by 5 m/s. This is an excerpt from the ensuing discussion:

| | | |
|---|---|---|
| 1 | Amanda: | The car is half as heavy, so it'll gain twice as much |
| 2 | Camille: | Ah, shoot (laughs) |
| 3 | Dianna: | Or something, Idunno. |
| 4 | Amanda: | That's what they want us to think, but this is not the real answer |

| | | |
|---|---|---|
| 5 | Bridget: | This is not the right /one/. Apparently, I think that's what they want us to say.<br><br>*…about ten seconds of silence…* |
| 6 | Dianna: | This is going...five...five meters per second, that's it's what? Acceleration or velocity? |
| 7 | Camille: | Speed. Velocity |
| 8 | Amanda: | (together with Camille) velocity. |
| 9 | Bridget: | Slows down by...?? |
| 10 | Dianna: | Velocity? |
| 11 | Camille: | Mm hmm. (pause) So the car gains ten meters per second? |
| 12 | Bridget: | I guess. |
| 13 | Dianna: | Didn't he say something about how like...something in class, like...if something's touched, the velocity, or something was changed...what was he talking about in class? Something?<br><br>*…about ten seconds of silence…* |

Camille's first intuition differed from Amanda's and Bridget's. Camille says, "the truck slows down by 5 m/s, the car speeds up by 5 m/s" but Amanda says that it would be 10 m/s because "the car is half as heavy." The discussion, however, quickly dies out and the students continue to engage in the school routine of completing the worksheet (writing best-guess answers, and occasionally seeking confirmation of vocabulary terms), until Dianna overhears the word "intuitively" from a different group's conversation, and expresses her own frustration:

| | | |
|---|---|---|
| 14 | Dianna: | I hate that word, "intuitively." |
| 15 | Camille: | See intuitively, I would think that it'd slow down, I mean speed up five meters per second. |
| 16 | Bridget: | Isn't the car...do they mean /once they hit/? |
| 17 | Amanda: | Because it is slowing down. |
| 18 | Camille: | If the if the truck if the truck if the truck, suppose the truck slows down by five meters in the collision, so if the truck is slowing down, then /I guess/ the car has to be speeding up. |
| 19 | Dianna: | The car's not moving |
| 20 | Amanda: | Yeah, it's not moving |
| 21 | Bridget: | But I think...does that mean- |
| 22 | Camille: | No, but I'm saying it says how much does does the car gain, cause it, yeah... |
| 23 | Bridget: | cause like it goes psh (gestures collision with hands) |

A vigorous discussion follows Dianne's statement as the students now focus on their own reasoning, not the worksheet; their voices and behaviors are animated as they try to communicate their ideas with gestures and explanations; and they pose original questions, such as what if the car and truck were equally heavy (not shown in transcript). During this strip of discourse, they clarify the details of the collision and the resulting speeds.

In what follows, we apply our heuristics to empirical observation of the students' behaviors and reasoning in these two segments to argue for the *group, rather than individual students* as the unit that determines the stability and dynamics of the behavioral and reasoning patterns.

## Clustering of Behavior and Reasoning: Group as Unit

As students go through the tutorial, multiple elements of their behaviors – gaze, body posture, extent of gestures, and tone of voice – are coordinated or clustered in particular patterns. Scherr and Hammer (2009) identified four stable clusters of behaviors exhibited by groups in tutorial, and these clusters account for most of the groups' time spent in tutorial (Conlin, Gupta, R. E Scherr, & D. Hammer, 2007) We will only mention the two clusters that are relevant here, *blue* and *green*.

(a) (b)

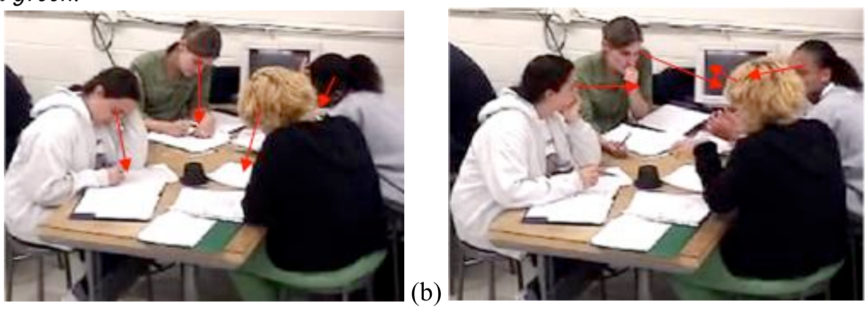

Figure 1. (a) The students exhibiting the "blue" cluster of behaviors, and (b) the students exhibiting the "green" cluster.

In the first segment of the episode, the group is exhibiting the *blue* behavioral cluster (see Figure 1a) -characterized by downward gaze, hands writing or resting on the table, scant and mostly deictic gesturing, low or flat voices, and intermittent speech with no overlap. In the second segment, the students transition *as a group* to the *green* behavioral cluster (Figure1b), in which they tend to make eye contact, sit up, gesture, and speak in animated voices with overlapping speech. The arrows in Figure 1 show how the gaze of the students is coordinated – and the locus of their gaze shifts in synchronous patterns making it meaningful to talk about the *group* as gazing towards the worksheet during the earlier segment and towards one another during the second segment.

These behavioral clusters also often indicate locally stable ways in which the students were framing the activity, either as *completing the worksheet* or as *having a discussion* (Scherr & Hammer, 2009). At first, their speech is in the service of finding the answer to the worksheet question. Amanda, Dianne, and Bridget all but say this explicitly by suggesting that Camille write down an answer that "they want us to think" rather than one that makes sense to her. Furthermore, their answers are brief and only weakly supported with justification. Dianna tries to settle the vocabulary ("five meters per second, that's its what, acceleration or velocity?") and tries to remember the information the professor gave in class about collisions. The content of their speech taken in conjunction with their behaviors suggests that the group is initially framing the activity as *completing the worksheet*. After Dianna expresses her frustration with the word "intuitively," the group starts to clarify and piece together the mechanism of what happens during a collision, rather than simply comparing the speed before and after. Their speech and behaviors are clustered around *having a discussion* about a physical phenomenon: Bridget, Amanda, and Dianne try to clarify the conditions of the collision; Camille reasons about the reactions of the truck and car as related, "if the truck *is slowing down*, then /I guess/ the car *has to be speeding up*" (emphasis added); Bridget's gestures try to simulate the motion of the car.

## Transition in Behavior and Reasoning: Group as Unit

There is a sharp transition in behavior at both the individual and the group levels that starts with Dianna's commentary that she "hates that word, 'intuitively.'" Her affective stance shook the group away from the worksheet, opening up the space for a more personal discussion. Everyone looks up to pay attention to Dianna – a sharing among friends. To Camille, this provided the space to clarify her original intuition, an action she did not take in the first part of the episode when the focus was on figuring out what "they want us to think." Camille's emphasis on the word 'intuitively' and tone support this interpretation. Next, Camille emphasizes the compensation of speeds between the truck and the car; Amanda gestures the speeding up of the car after the collision. The emotional outburst of Dianna cued them to think about and communicate their personal opinions, leading to a cascade of utterances towards mechanistic pursuit of the phenomenon. The coordinated nature of the transition in behavior (from *blue* cluster to the *green* cluster) and framing (from *doing the worksheet* to *having a discussion*) makes it appropriate to think about the *group* as transitioning rather than four individuals separately making these transitions. This supports the theoretical coupling of framing and behavior, since behaviors act as the metamessages that comprise and maintain the group's framing (Bateson, 1985).

### Resistance of Behavior and Reasoning: Group as Unit

*Bids to switch frames* – instances in which one students' behaviors and/or reasoning stand in contrast to that of the established coherent frame (Scherr & Hammer, 2009) – can provide valuable insight into the dynamics and appropriate scale for a cognitive unit. In this episode, while the group is exhibiting the blue behavioral cluster engaged in *completing the worksheet*, Dianna makes a bid to have a discussion (turn 13). This is evident through her behavior, since she sits up, speaks more loudly, and has much more pronounced prosody when asking, "Didn't they say something about how like...what was he talking about in class?" One by one, the other students briefly look up as she is talking. As she trails off, however, the other students return to their blue cluster behaviors one by one. There is no talking for 10 seconds as the group goes back to completing the worksheet. Dianna's bid to change behaviors was not taken up.

Epistemologically, Dianna's question is a bid to try to remember what the professor said in class, a departure from the group's engagement in finding the worksheet-directed intuitive answer to the gain in the car's speed. That the rest of the group simply turns back down to their worksheets without responding to her question sends the message that they did not see this as a productive line of pursuit. Dianne's deviation from the shared cluster of behaviors and framing could not disrupt it, rather it was Dianne who returned to that shared activity. This illustrates the stability of the cluster and its extension beyond single individuals.

### Persistence of Behavior and Reasoning: Group as Unit

Additional evidence for the *group* being the appropriate unit of analysis here comes from examining what keeps the behavior or framing stable during these segments. We find that the behaviors serving as meta-messages communicating the fine-grained stances students are taking in their utterances. When a student makes animated gestures or talks loudly, it sends the message of a discussion or argument in contrast to hunching over your personal worksheet. Seeing one member clarifying an idea might prompt a second student to add to it, which supports and encourages the effort of the first creating feedback loops that help in the persistence of the activity. The moment-to-moment behaviors and utterances establish a shared understanding of the nature of the activity – that is self-sustaining. Before the transition, individual behaviors such as hunching over the worksheet, exchanging short vocabulary or quick questions in low voices, reinforces the *group's* shared sense of the activity of filling the worksheet; and later, after the transition, their pursuit of a mechanistic explanation of what happens in the collision is built out of bits of contribution from the different members. In either segment, the persistence of behaviors and reasoning is a group endeavor, even though individuals are enacting these behaviors and utterances.

## The Individual as a Unit of Analysis

The second example[ii] comes from a tutorial on shadows and light. In this tutorial, students try to build a model of light by exploring the patterns and motions of light created by a light bulb and an aperture. The question being considered by the group during the clip is, "Why does the light on the screen moves to the left when the bulb is moved to the right?" Veronica and Jan have a disagreement over the mechanism of light shining through the aperture. Here is a piece of the conversation:

| | |
|---|---|
| Jan: | All the rays are going like this. So, it's kind of like polarizing it. |
| Veronica: | Mmm, not really. |
| Jan: | You sure? |
| Veronica: | It's just, well, it's just, guys, you're making it- you're trying to make it too difficult. It's just, the light goes out. It only goes through that one circle. So, obviously, if it is down here, and I'm looking through that circle. Look, you're sitting down here. You're looking at this big cardboard. You're looking up through that little circle. All you're going to see is what's up there. It's a direct line. |
| Jan: | Look, I see what you are saying, alright? But, I'm just trying to make it like physics-, physics-oriented. |
| Veronica: | It *is* physics-oriented, that's just the way it is. |
| Jan: | Okay. |

### Clustering of Behavior and Reasoning: Individuals as Unit

Throughout the conversation presented as well as before and after it, Veronica is sitting up, looking at the other group members, speaking in a loud, animated tone, and gesturing (Fig 2). Jan, who is sitting across the table from Veronica, for large parts of the tutorial, is hunched over, and drawing on the tutorial worksheet. During the moments of the conversation above, she does look up at Veronica and speak in a clear and loud voice, but these were fleeting moments. The larger pattern was of students conducting themselves differently. This lack of synchronicity and coordination among the behaviors suggests a clustering at the individual level in this case, not at the group level.

Figure 2. Veronica is gesturing as Jan is writing on her worksheet.

Again, the contrasting behaviors indicate that Jan and Veronica are framing the activity differently, also evidenced by their very different epistemological stances. Veronica is appealing to her intuitive sense of mechanism of how light travels, while Jan tries to make what Veronica is saying more "physics-oriented," by using technical terminology. Veronica objects with a different take on what it means to be physics-oriented, namely that it is "just the way it is." For Veronica, the activity is about making sense, while Jan is trying to get the formal answer.

### Persistence and Resistance of Behaviors and Reasoning: Individuals as Unit

Both Veronica and Jan activate a stable set of epistemological resources throughout this clip. In fact, this stability persists on much larger timescales than one tutorial period. Lising & Elby (2005) analyze Jan's work throughout the course and argue that her epistemological stance, in which there is a barrier between formal and everyday reasoning, is relatively stable and robust throughout the semester.

The persistence of each student in their epistemological framing is stable in spite of direct challenges from each other. Veronica expresses impatience with Jan by bluntly correcting her with, "Mmmm, not really." She criticizes Jan for "trying to make it to difficult," and proceeds to explain the phenomenon with common-sense reasoning. Jan contents that she is just trying to make it "physics-oriented," with the implication that Veronica's common-sense explanation is not physics-oriented. Veronica defends herself from this challenge: "It *is* physics-oriented. It's just the way it is." When Jan responds with, "Okay," the group goes silent. It appears that they just agree to disagree, persisting in their epistemological framing despite the explicit bids made to change them.

### Transition in Behaviors and Reasoning: Individuals as Unit

Just as there is no coherent clustering at the group level, there are no clear transitions at the group level between clusters. This seems to be the exception rather than the norm, since most of the time groups spend in tutorial is in one of four behavioral clusters separated by sharp transitions (Scherr & Hammer, 2009). This counts as evidence *against* the group being the unit of cognitive analysis during this clip. This lack of group transitions, taken in conjunction with the other heuristics above, constitutes a strong empirical case for taking the individual as the unit of analysis here.

## Conclusions

Our argument is two-tiered. On one tier, we analyze the behavior and discourse within two episodes of student group work in introductory physics tutorials. We found evidence for stabilities and dynamics of cognition at the group level and the individual level, using four empirical heuristics for identifying the scale of the cognitive unit. In the first example we demonstrated that the clustering, persistence, resistance, and transition reflect dynamics at the level of the group as a whole. It is the collective group frame that enables them to reason about the mechanisms involved in a collision in a more sophisticated way. In the second example we demonstrated how clustering, persistence, and resistance resided not with the group but rather on the level of individual students' epistemological stances and their conceptual understanding of how light travels. Veronica and Jan held different views not only of light but also of physics, and these views remained stable in the face of their mutual bids to change the other's mind.

One tier up, we are arguing that these analyses demonstrate how the choice of cognitive unit can be made empirically by attending to the dynamics and stabilities evident in the data. This is in contrast to the positions on both sides of the ongoing debate about the unit of analysis, with cognitivist and situativists basing their decision largely on theoretical considerations. We introduced four empirical heuristics for identifying the scale of cognitive dynamics. Our analyses of the two episodes highlight the utility and generativity of our empirical heuristics, although we do no claim that these span the set of evidentiary supports for determining the cognitive unit. All of this is underwritten by the resources and framing model of mind, since resources can be distributed within an individual mind or across several individuals and artifacts. Hopefully our approach will enable greater communication and collaboration between cognitivists and those who model cognition as situated and/or distributed.

## Acknowledgments

We would like to express our thanks to the National Science Foundation for financial support, and to the Physics Education Research Group at the University of Maryland, College Park, for helpful discussions.

# Representational Technology For Learning Mathematics: An Investigation of Teaching Practices in Latino/a Classrooms

Phil Vahey, Teresa Lara-Meloy, SRI International, 333 Ravenswood Dr. Menlo Park CA

**Abstract:** This paper explores representation- and language-rich mathematics instruction in two classrooms with low-income Latino/a students. The two classroom teachers were part of a larger study investigating the use of SimCalc in middle school, and their classrooms had learning gains greater than the mean gains for the study overall. Prior analyses documented that these two teachers implemented exemplary classroom discourse practices: they engaged students in discussions with high intellectual work and showed high levels of responsiveness to student statements (Pierson, 2008). Such practices are consistent with both the research on representationally-rich mathematics environments, and instructional practices for students from non-dominant communities. We use transcript excerpts to illustrate these teachers' practices in detail. We found that these two teachers enacted some similar practices, but they also had different teaching styles, different approaches to connecting representations, and different ways of supporting mathematical discussions.

## Introduction and Significance

As the population of Latino/a students increases in U.S. schools, so do concerns with their needs in mathematics classrooms. One concern is performance on assessments. Only 13% of Latino/a students scored at or above proficient on the 2005 8th grade NAEP exam, compared to 39% of white students and 47% of Asian students (Gándara & Contreras, 2009). Many schools attempt to address these concerns by placing large numbers of Latino/a students in remedial courses designed to address the needs of students who are "at risk," a decision which may exacerbate the situation. Research shows that the problem lies not in the students but in their access to quality teaching. In general, low-income Latino/a students attend racially segregated poor schools and have little access to the kind of teaching that supports the development of conceptual understanding or academic discourse (Gándara & Contreras, 2009). However, there are examples of classrooms where this is not the case. Quantitative data from the SimCalc study (Vahey, Lara-Meloy, Knudsen, 2009) and qualitative research with this student population has shown that Latino/a students can learn complex mathematics and participate in mathematical discussions (i.e. Moschkovich, 2002) when they have access to quality teaching.

In this paper we examine the teaching practices of two teachers, providing a sharp contrast to the perspective that Latino/a students need 'remedial" teaching. We analyze two instances of mathematics instruction that support conceptual understanding and mathematical discussion as students participate in representation-rich mathematics environments. There is reason to believe that there is consonance between the literature on improving instruction for low-income students from non-dominant linguistic backgrounds and the literature on the use of representationally rich technologies in mathematics (Vahey, Lara-Meloy, & Knudsen, 2009). Both highlight the use of multiple ways to represent ideas, point to supporting students as they make connections among these multiple representations, and point to the importance of language rich practices. However, there has not yet been a systematic attempt to integrate the representational affordances of technology with research on improving mathematics instruction for students from non-dominant linguistic backgrounds. This leaves educators with little guidance on how to use technology for this underserved student population.

This paper begins to address this gap by using two lenses to describe the instructional practices of two teachers who were successful in using technology to support students in their primarily high-poverty Latino/a classrooms in learning important conceptual mathematics. We explore the ways in which these successful teachers engaged in practices that were consistent with (or at odds with) research-based recommendations for mathematics instruction that is (a) representation-rich, and (b) supports mathematical discussions.

## Background

We ground our exploration in the Scaling Up SimCalc study (Roschelle et al., in press) for three key reasons. First, SimCalc is based on a rich theoretical and empirical base, and so provides an excellent proxy for representationally rich technology use more generally. Second, the Scaling Up SimCalc study was a large scale randomized controlled experiment that not only found significant results across a wide range of student demographics, but also collected a rich array of data including many videotaped lessons. Finally, the study included large numbers of Latino/a(1) students (about half of the 1621 total students) from poor schools, many in the Rio Grande Valley, which borders Mexico and is one of the poorest regions in the United States (the study denotes this area as Region 1, as it is served by the Region One Education Service Center). The SimCalc study is an ideal place to begin our exploration into the connections between research on representationally rich technologies and instructional recommendations for teaching students from non-dominant language groups.

## The Scaling Up SimCalc Study

For over fifteen years the SimCalc project has had the goal of ensuring that all learners have access to complex and important mathematics (Kaput, 1994). To achieve this goal SimCalc places motion phenomena at the center of learning (see Figure 1), enabling students to build on existing cognitive and social competencies. Students in our studies, including traditionally low-achieving students, construct rich stories about motion over time, and use narratives as a resource for interpreting graphical and tabular representations of motion. SimCalc also allows students to play and replay a motion simulation as many times as they wish, providing more students access to these fundamental resources than is possible using traditional static media.

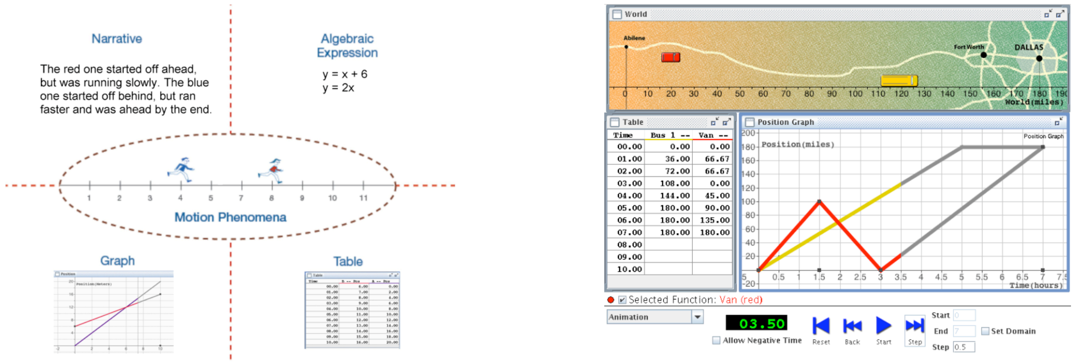

Figure 1. SimCalc linked representations (left); SimCalc MathWorlds® activity screenshot (right)

This engagement with motion leads to the study of functions through linked simulations, graphs, tables, and symbols. Students engaged with SimCalc can directly manipulate a mathematical representation such as a graph, and immediately see the effects on other linked representations (Roschelle et al., 2000). Formal mathematical vocabulary and symbolic forms can then be introduced *after* students have experiences with motion, narratives, tables, and graphs. In this way the vocabulary and symbols are *about* something, and can be understood as a compact and precise way of describing phenomena. The features of direct manipulation, multiple representations, and experience-before-formality may be particularly beneficial to students from non-dominant linguistic backgrounds, as these features alleviate some of the language demands found in mathematics classes, allowing students to work directly with mathematical objects (Vahey, et al., 2009).

These same features can allow students to more fully participate in classroom discussions. The linked representations provide a shared set of referents for students and teachers to explore: they can replay a motion or make changes in one representation to see the changes in the others. Students have opportunities to use a wider range of verbal and nonverbal communication acts, such as pointing: "See, right *here* the boy starts running faster." Students also have opportunities to use academic mathematical language for a communicative goal (e.g., Does *going longer* refer to *time* or *distance*?). This multi-faceted approach is consistent with recommendations for supporting mathematical discourse and developing vocabulary (Moschkovich, 2007a, 2007b) and it contrasts with traditional approaches to teaching academic language that rely on drill and practice or memorization.

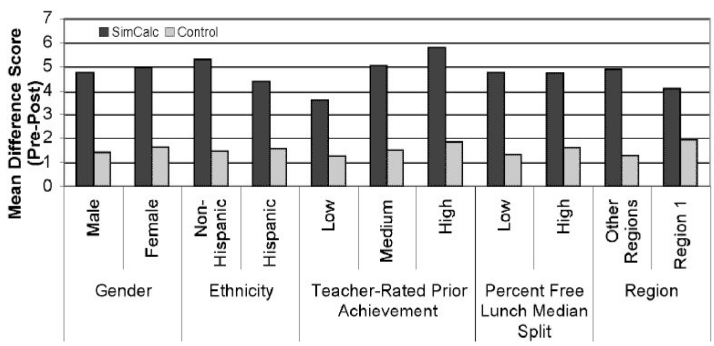

Figure 2. Mean student-learning gains by subpopulation group.

The Scaling Up SimCalc study found the SimCalc approach to be successful in meeting the needs of a variety of teachers and their students. Ninety-five seventh grade teachers across varying regions in Texas participated in a randomized controlled experiment in which they implemented a SimCalc-based three-week replacement unit. An analysis of the results showed a large and significant main effect, with an effect size of 0.8

(Roschelle et al., in press). This effect was robust across a diverse set of student demographics including gender, ethnicity, teacher-rated prior achievement, and poverty level (measured by the percentage of the campus eligible for free or reduced price lunch) (Figure 2). Consistent with our other data, we see that the students in Region 1 (the Rio Grande Valley) who used SimCalc had greater learning gains than students in the control condition, and these learning gains included improvement on items that target conceptual understanding.

## Theoretical Framing

We take a socio-constructivist theoretical approach. We assume that students learn through interacting with materials and technological artifacts while participating in discourse, that mathematical dscourse is multi-modal and multi-semiotic (O'Hallaran, 2000), and that it includes not only talk, but also other tools such as inscriptions or animations and several modes such as oral, written, and gestural.

### Recommended instructional practices for all students

Research in mathematics education describes teaching that promotes conceptual development as having two central features: one is that teachers and students attend explicitly to concepts, and the other is that students wrestle with important mathematics (Hiebert & Grouws, 2007). Teachers face a considerable challenge in balancing both of these features in their teaching. In particular, teachers working with Latinos/as often focus on procedural rather than conceptual aspects of mathematics (Gándara & Contreras, 2009). In contrast, effective environments for students from non-dominant linguistic backgrounds should provide "abundant and diverse opportunities for speaking, listening, reading, and writing" and "encourage students to take risks, construct meaning, and seek reinterpretations of knowledge" (Garcia and Gonzalez, 1995, p. 424). These practices require that teachers view language as a resource, not a deficiency (Gándara & Contreras, 2009), and reject models of their students as intellectually disadvantaged (Garcia and Gonzalez, 1995).

Framing research on students from non-dominant linguistic backgrounds is complex. This student population is heterogeneous (e.g. in some geographical areas this population includes students from many countries who speak many languages). Within our relatively constrained population (students from two classes in the Rio Grand Valley) almost all students are labeled as Hispanic. Although we do not have an exact account of how many students in these classrooms were learning English, it is likely that students in these two SimCalc classrooms, like students in this geographic area in general, vary along a spectrum of monolingual to bilingual. We assume that some students in these classrooms may be learning English; some students may be first generation immigrants, and some families may have lived in Texas for several generations. With that complexity in mind, we examine teaching practices for these two teachers because we believe they are illustrative of teaching strategies that support gains in conceptual mathematics for Latino/a learners, some of whom are likely to be learning English.

#### <u>Use of representations</u>

A key feature of mathematics is the use of representations, not only to overcome the limitations of human memory (as in the use of simple lists), but also to embed computational rules into symbol systems (e.g. algebraic notation), and to re-represent complex relationships in ways that can be more easily perceived by those who have facility with the representational system (e.g. the graph of a function) (Ainsworth, 2006). The use of representations is both a requirement for full participation in everyday quantitative reasoning (e.g. it is necessary to interpret graphs commonly shown in daily newspapers), and an important tool that can allow students to engage with mathematical objects as they also grow in their mathematical skills and understanding (Kaput, 1994). Representations, and dynamic representations in particular, can be particularly powerful learning tools when they are part of mathematical discourse: they can support shared focus of attention, allow gestural and physical communication to supplement verbal communication, and provide meaningful feedback that is consistent with the mathematical phenomena under investigation (Moschkovich, 2008; Roschelle et al., 2000).

Recommendations for instruction for students from non-dominant linguistic backgrounds (e.g. August and Shanahan, 2006; Echevarria et al., 2004) also include the use of representations. These recommendations focus on the use of visual artifacts to (a) offload demands on language, and (b) represent abstract ideas using illustrations or objects (e.g. holding up an illustration of a triangle when referring to a triangle in a geometry lesson), rather than as a way to provide insight into complex mathematical concepts.

#### <u>Use of mathematical discussions</u>

One way to engage students in both attending to and wrestling with important mathematics is through mathematical discussions. It is generally accepted that "mathematical discourse" and "academic language" are important for all students to develop, and are especially important for students from non-dominant communities. As students participate in these activities they are learning to communicate mathematically by making conjectures, presenting explanations, constructing arguments, and so on. When describing mathematical discourse we should not confuse "mathematical" with "formal" or "textbook." Textbook definitions and formal ways of talking are only one aspect of school mathematical discourse. It is also important to avoid construing everyday and academic mathematical discourse as opposites (Moschkovich, 2007a), as some everyday experiences may provide resources for communicating mathematically.

Some recommendations for teaching reduce mathematical discourse to addressing vocabulary through direct instruction, drill and practice, or memorization. In contrast, other recommendations are based on research that shows that academic discourse is more than vocabulary, and that vocabulary is most successfully learned through instructional environments that are language rich, actively involve students in using language, require both receptive and expressive understanding, and require students to use words in multiple ways over extended periods of time (Blachowicz & Fisher, 2000). Additionally, for mathematics instruction, learning to communicate mathematically is not primarily a matter of learning vocabulary, as students also need to develop conceptual understanding and learn to describe patterns, make generalizations, and use representations to support their claims (Moschkovich, 2002 and 2007b).

## Analysis

In our exploration we examine and summarize the teaching strategies in one lesson selected from the classes of each of two teachers from Region 1, Teacher E and Teacher M. We chose these classes because these students are commonly labeled "at-risk" for poor mathematical performance: one class is 96% Latino/a (Teacher E) and the other is 100% Latino/a (Teacher M); and both classes are in schools where over 84% of the students are eligible for free or reduced price lunch. However, a previous quantitative study (Pierson, 2008) found that students in these two classrooms had gains greater than the mean gains for all classes using SimCalc. Pierson's analysis indicates that one possible reason for these gains may have been that these two teachers engaged their classes in discussions with high intellectual work, and showed high levels of responsiveness to student statements (Pierson, 2008). Intellectual work reflects the cognitive work requested from students with a given turn of talk. Responsiveness is an attempt to understand what another is thinking, displayed in how the teacher builds, questions, clarifies, takes up or probes that which another says.

Pierson (2008) shows that, for the 13 classes that had video data available, these two types of teacher moves were correlated with student gains. The two selected teachers stand in contrast with another teacher from a nearby school with a similar student population (95% Latino/a students and 93% students on campus on free and reduced lunch) who had lower than average intellectual work, responsiveness, and student gains. Our question moving forward is: in what ways did these two teachers, selected for exemplary mathematical discourse practices, engage in practices that were consistent (or at odds) with recommended instructional practices for the use of representationally rich mathematics environments and supporting mathematical discourse? Given the correlational findings in Pierson, our goal here is to provide a more detailed qualitative description of interactions in these two classrooms. These two descriptive cases ground both research and practice: while the correlational study showed *that* the quality of these two teachers' discourse was related to student gains, our goal here is to describe *how* these two teachers enacted these practices during a lesson.

The data for this study are records of teacher activity at the front of the classroom over a single lesson. Thus, our analyses will focus on teacher's uses of talk and inscriptions. Our data will not let us investigate non-observable features such as teacher beliefs, or those features that take an extended time to develop, such as the initial setting of classroom discourse norms. The classroom videos and transcripts we analyzed for teachers E and M show the same lesson from the SimCalc 7th grade curriculum, entitled "On the Road." During this lesson, students are expected to write stories explaining the motion of a bus and a van over several trips from Abilene to Dallas. Students must make sense of piecewise linear functions (see Figures 3 and 4) of increasing complexity. Students are asked to interpret functions that consist of multiple slope lines, including some with zero and negative slopes. In the first situation, students observe a position graph and corresponding computerized simulation of the motion of a bus and a van, and then write an explanatory story. In the second situation, students are asked to predict the motion of the bus and the van based on the graph before viewing the simulation to verify their predictions.

In our analysis we first partitioned the classroom videos into a set of curricular segments. These segments are based on curricular topics, as dictated by the teacher (and, of course, heavily influenced by the SimCalc materials). Within each segment we investigated episodes in which the participants focused on a particular mathematical topic. While the materials influence these topics, episodes were typically driven by the particular classroom interactions, and we expect episodes to vary significantly by classroom. In this paper we focus on representative classroom episodes that illustrate how these teachers (a) made significant use of representations or (b) engaged students in significant mathematical classroom discourse.

Our analysis shows that Ms. M and Ms. E used various strategies during these lessons. Since some of the teaching strategies were similar across the teachers and others differed, we emphasize that no single aspect of the teaching accounts for student gains, that there is no single way to enact best practices, and that there is no simple formula for teaching this student population. In fact, a strength of this analysis is to show that teachers with different teaching styles can instantiate best practices in such a way that students commonly labeled "at risk" can and do learn complex and conceptual mathematics. Additionally, although we present examples of how the teacher used representations and supported discussion separately, these two are dialectically related, and this separation is only for the purpose of our illustration.

### Teaching Practices that Connect Representations

As the teachers led class discussions based on position graphs, we note that both teachers consistently pushed the students to make connections between the two functions represented on each graph, and across multiple representations (simulation, narrative, and graph). In addition, after several attempts to have the students describe these connections, the teacher would then explicitly state the connection she considered most salient to the activity. Both teachers did this on occasions where the students had already described the desired connection, as well as cases in which the students had not, presumably so that all students had some exposure to the desired connection.

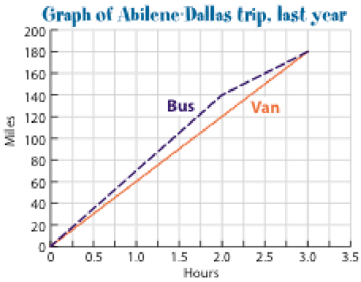

Figure 3. Last year's graph of the Abilene-Dallas trip.

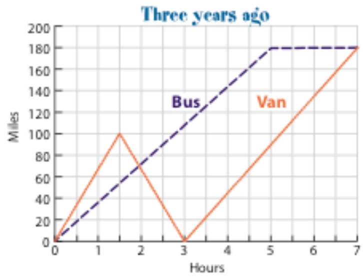

Figure 4. The trip from three years ago.

### Example 1: Ms. E (see Figure 3)

Ms. E conducted this class is in a computer lab, with a 1:1 student to computer ratio. Students were seated facing the computers, lined up along the wall. The teacher had a document camera projecting her workbook in the center of the room. During whole group discussions, she often pointed or traced her pencil over the graphs or text in her workbook projected via the document camera. This type of gesturing is a common strategy for helping students connect what is being said with the activity tasks. The following episode took place early in the lesson. The students worked in pairs at computers as they viewed the simulation that is represented by the graph in Figure 3. As this episode begins, the teacher was orienting the students to a whole-class discussion.

T: Ok. Did everybody get a chance to go through the simulation?
Ss: Yes.
T: It says: (Reading from the workbook) "What information can you get about last year's trip from looking at and analyzing the graph? Write down everything you can think of and be sure to include the speeds of the vehicles." Ok. So the first thing that we noticed is that we have two graphs. One represents who and who?
Ss: The bus and the van.
T: Ok. Very good. The bus and the van. Ok. What can you tell me by looking at the graph?
Yuri: The bus was going faster --
Amy: -- The bus was going faster but then it slowed down and the van caught up.
T: Ok. Yuri and Amy said that the bus was going faster but then what happened Amy?
Amy: The bus slowed down and the van caught up.
T: Ok. [Writing in her workbook] "The bus was going faster." So let's write that down.

In this excerpt we see the teacher explicitly asking the students to connect the graph to the simulation they had just viewed ("One represents who and who?", "What can you tell me by looking at the graph?"). However, it is not obvious (to the teacher or to the observer) whether the students were relying on their recollection of the simulation, the markings on the graph, or both. For example, the teacher asked for information that could be derived from the graph, but the source of Yuri and Amy's response is unclear, as they could have been referring to the simulation. Although the teacher accepted these responses in this interaction, she followed this conversation with a detailed analysis of the speeds of the bus and the van, using statements that connected the information they had gathered from the simulation with the details in the graph. This is shown in Example 3, in which we analyze how the teacher leveraged student language as a resource for not only connecting representations, but also for supporting conceptual understanding and language development.

### Example 2: Ms. M (See Figure 3)

Ms. M's class was also held in a computer lab, with one student at each computer facing the front of the class. The relevant SimCalc software file was displayed for the class with a projector. Ms. M seemed to have a good rapport with her class, often teasing them and being willing to entertain their outlandish stories. In this example we see Ms. M asking students to read their stories to the class (as in Example 1, the class had already viewed the corresponding motion simulation). Ms. M challenged Dan's story not by questioning the (possibly inappropriate) content, but by questioning the relationship between the story and the graph.

| | |
|---|---|
| T: | Everybody listen to Dan's story. Go ahead Dan. |
| Dan: | Alright. The bus driver is going 70 miles per hour. But then a monster got in the way and the bus driver had to slow down to 40 miles per hour. And, then he shot him with an emergency shotgun, (student laughter) but not before the monster ate him. But at the end they played in memory of him. But I had to take over and drive the bus-- |
| T: | -- But the bus -- was already there, if I'm interpreting correctly, you already said that they got there and that's when the monster attacked him? |
| Dan: | No! [unintelligible] |
| T: | Read it again. Go ahead. |
| Dan: | "The bus was going 70 miles per hour. But then all of a sudden, a monster gets in the way (he makes a monster growl)." |
| T: | And it slowed down? |
| Dan: | Yeah. And the bus, it slowed down, he got scared, and took the emergency shotgun and shot him but not- not- |
| T: | While he was driving? |
| Dan: | Yeah, while he was- like this (pretends to shoot a gun, students laugh). |
| T: | Okay. That's kind of scary. |
| Dan: | But not before the monster ate him. So I had to take over and drive the bus. And the game is played in memory of him (reads imagined name and date of birth and death). |
| T: | But okay, in the real world, okay, if they eat something, how is it staying constant? (gestures to the graph projected on the board) How does it stay constant (gestures to the graph of the bus)? 40 miles per hour. Unless you were there while he was being eaten, and you put your foot, and you stayed steady. Understand? |
| Dan: | Yeah |
| T: | So maybe if you would have arrived in Dallas (points to Dan) and then the monster could have eaten the bus driver. |

In this excerpt we see the teacher challenging Dan to describe exactly how his story related to the graph. She points out that in Dan's story the driver is eaten en route, without the bus stopping She pushes Dan to make the connection between his story and the fact that the graph shows the bus slowing from a constant speed of 70 mph to another constant speed of 40 mph. While she was apparently willing to accept that the monster scaring the driver would result in the bus slowing down in a manner consistent with the graph ("And it slowed down?...Okay"), she was not willing to accept that the monster could then eat the driver with the bus staying at the constant speed of 40 mph. Instead she provided an alternative narrative ("So maybe if you would have arrived in Dallas and then the monster could have eaten the bus driver").

In sum, we see that both teachers leverage the simulation capabilities of SimCalc to provide a shared context of motion that can be referred to by all students. They also used SimCalc's position graphs to provide a shared mathematical representation that grounded the discussion, and a set of stories that were used to explain the graphs and simulations. The teachers then spent considerable effort pushing students to make connections between these representations. In terms of their teaching practices for connecting representations, Ms E does this during the whole group discussion before writing stories, and Ms. M does this principally in response to students' stories. Noticeably absent is the use of representations as a purely visual aid designed to make abstract ideas concrete to language learners. In the next section we analyze how these teachers scaffolded the use of language in ways suitable for students from non-dominant linguistic backgrounds, and how this language use helped students interpret the representations as well as the target mathematical concepts.

## Teaching Practices that Support Mathematical Discussion

In the lessons observed, neither teacher used explicit vocabulary instruction, vocabulary drill and practice, or memorization for vocabulary. Instead, both teachers addressed vocabulary in the context of language-rich instruction focused on making sense of the mathematics. Thus, they used many of the research based recommendations for vocabulary development: environments that are language rich, actively involve students in using language, require both receptive and expressive understanding, and require students to use words in multiple ways over extended periods of time (Blachowicz & Fisher, 2000). We also found that both teachers wove together everyday and academic meanings, vocabulary, and ways of talking. Both teachers accepted, built on, and used student contributions to introduce academic language. They often used and built on students' informal contributions and their own informal descriptions to include technical language in their discussions, and used colloquial language to further illustrate their own formal descriptions.

Despite these similarities, the two teachers addressed vocabulary using different approaches. Ms. M began her lesson by clarifying colloquial language used in the problem, for example "traffic tie-ups," and by asking students to describe what they saw on the map (roads, cities, towns, etc). In contrast, Ms. E asked her students to go straight into the simulation without previous discussion of the map or of the meaning of terms used in the problem. Ms. E also made heavy use of gesturing and pointing to the workbook (which was projected on a screen). She used her finger to point to the problem text as she read out loud, and frequently pointed to segments of the graph as the class discussed the problem. Below we provide two examples of the ways that each teacher's practices reflected recommendations for supporting mathematical discussions and the development of academic discourse.

### Example 3: Ms. E (see Figure 3)

This excerpt follows immediately where Example 1 ends. After asking the students to determine "how fast" the bus was going, the teacher used student responses to introduce the word "speed," using the phrase "constant speed" as represented in the graph:

T: How fast was the bus going? Ok we're going hours and miles. Miles and hours.
S: 60 miles per hour.
T: Ok. How did you determine that?
S: Divided the 180 miles by 3 hours.
T: Ok. If I divide the final distance divided by the final time. Ok. That's gonna give me a speed. You're right. But you told me first he was going fast and then he slowed down. So was this a constant speed?
Ss: No.
T: No. Ok. So I need to determine the speed to see how fast he was going before he started slowing down. Ok?

In this example, the teacher moved from a general description of "the bus was going faster then slowed down" (shown in Excerpt 1) to asking students to find the specific speeds at which the bus was traveling. She used the students' responses to her questions to introduce into the discussion mathematical concepts and phrases such as speed, constant speed, and changing speed, all grounded in a discussion of how these three were represented in the graph.

### Example 4: Ms. M (see Figure 4)

The following segment takes place towards the end of the lesson, after students have written stories about two motion situations. This example illustrates how Ms. M moved back and forth between formal and informal descriptions of a horizontal segment and clarified the mathematical significance of that segment on the graph:

T: Now look at the bus. The bus looks pretty normal this time, right? Because we know that right here is a straight, horizontal line right. And what does the flat line tell us?
S: It's going nowhere.
T: It's going nowhere. And what kind of slope is it?
S: Zero.

In this example, Ms. M combined formal academic language to describe the line as "horizontal" with a more informal description of the line as a "flat line." She repeated the student's contribution and followed it with a question about the slope, introducing the formal mathematical concept of a zero slope. Ms. M used colloquial language to lead the class to academic language, interweaving both types of language while grounding the discussion in the graph. In sum, neither teacher used explicit instruction of technical terms, but rather wove together both everyday and academic language to support a discussion about mathematical concepts. Our continuing analysis shows that both teachers' discourse was oriented to mathematical concepts rather than to vocabulary definitions.

## Conclusions

This exploration into the practices of two teachers shows some connections between instruction that is both representation and language rich, and thus supports both conceptual mathematics learning and discussions that are oriented to mathematical concepts. The analysis shows that these two teachers shared some practices but also had different styles, approaches to connecting representations, and ways of addressing vocabulary. We find it promising that this data shows that teachers can have an impact on the mathematics learning of students mistakenly labeled "at-risk." This beginning analysis is also promising in that these teachers are enacting many of the research-based teaching practices for providing representation- and language-rich learning environments.

## Endnotes

(1) We use the term "Latino/a" to be consistent with current usage, although "Hispanic" is the term commonly used in Texas to designate people of Latin American—specifically Mexican—descent.

In this study we build on the closely related constructs of teacher attention and responsiveness to explore how one fifth-grade teacher facilitates scientific inquiry. We illustrate the dual use of responsiveness and framing through the case study of Mrs. Charles, who skillfully elicits and builds on students' ideas in her science classroom. In our analysis, we found that ranking the extent of this teacher's responsiveness was inadequate for describing the nature of her teaching and for uncovering ways in which this teacher might progress. Analyzing Mrs. Charles's practice in terms of her framing of the situation, however, began to reveal patterns and nuances in the nature of her responsiveness. We argue that it is through the overlay of her epistemological framing onto an analysis of her responsiveness that we get a fuller picture of Mrs. Charles's practice: inviting and valuing students' contributions while encouraging exploration of certain ideas over others.

## Introduction

Reform in science education calls for active student engagement in scientific inquiry (NRC, 1996), where children propose, evaluate, investigate, and synthesize ideas to develop causal explanations of phenomena (Duschl Schweingruber & Shouse, 2007). While research has documented that children have abundant nascent resources for reasoning about and making sense of the world around them (diSessa, 1993; Metz, 1995; Tytler & Peterson, 2004), transforming these abilities into expertise in scientific inquiry still requires substantial work, both for the learner and for the teacher. Students must engage extensively and productively in practices like reasoning mechanistically (Russ, Scherr, Hammer & Mikeska, 2008), modeling (Schwarz, Reiser, Davis, Kenyon, Acher, Fortus, Shwartz, Hug & Krajcik, 2009), and seeking coherence among ideas (Sikorski, Winters & Hammer, 2009). If students' own ideas and reasoning are to serve as the building blocks for both the process of scientific inquiry and the scientific understandings that constitute the products of inquiry, instruction cannot be scripted or prepackaged (Duschl et al., 2007). Instead, the teacher has the responsibility to elicit, interpret, and follow up on students' reasoning in the moment, in a fashion that values students' ideas as objects of inquiry (Cohen, 2004).

The teacher's role in facilitating scientific inquiry is quite different from what her role would be in a traditional science classroom. Listening and attending to the sense students are making, rather than focusing primarily on how their responses align with scientific canon, requires not only a shift in how the teacher conceptualizes her role in the classroom (Empson and Jacobs, 2008), but contrasts with the social and institutional objectives to which teachers are held accountable (Levin, 2008). Additionally, children frequently have difficulty articulating their thinking, and therefore it requires a teacher's focused attention and effort to interpret student meaning (Sherin & van Es, 2009). The closely related constructs of noticing and responsiveness have emerged in the mathematics education literature as a means of describing what it is teachers attend to in students' thinking and what it is they pursue in their follow-up moves (Empson & Jacobs, 2008; Franke, Carpenter, Levi, & Fennema, 2001; Pierson, 2008; Sherin & van Es, 2009). This literature analyzes teachers' actions as they progress to higher levels of noticing and attending to children's mathematical ideas, emphasizing *what* the teacher responds to without an intentional focus on *why* a teacher might be attending to certain ideas over others. Understanding why a teacher notices or responds to specific ideas or in specific ways can inform efforts to promote teacher change.

In this preliminary study, we explore how to account for the 'what' of a teacher's responsiveness in terms of a possible 'why'—the teacher's framing of the situation. We exemplify how a teacher's facilitation of scientific inquiry can be described in terms of the relationship between her responsiveness and framing, and illustrate this with a case study of one fifth-grade teacher embarking on pedagogical change.

## Framing of the Classroom Activity

Teachers have a tacit understanding of what it means for their students to "do science" that shapes what it is they attempt to enact in their classrooms. A person's answer to the question, "What is it that's going on here?" is what we refer to as his or her *framing* of the situation (Goffman, 1986; Hammer, Elby, Scherr & Redish, 2005; Tannen, 1993). With respect to elementary science, there are many possibilities for how a teacher might answer this question. For example, "doing science" in the classroom may involve reading the textbook, following prescribed experiments, or engaging in debates about natural phenomena. Consistent with Hammer, Russ, Mikeska, and Scherr's (2008) definition of scientific inquiry, we hope teachers will come to see classroom science as the *pursuit of plausible, mechanistic accounts of natural phenomena*.

The theoretical construct of framing, as we use it here, is distinct from but related to a more colloquial use of "framing" as one's intentional portrayal of a situation to others. When we describe how a teacher frames the classroom activity, we are referring to her own perception of the situation rather than to how she deliberately represents a task for her students. For us, the power of framing lies in its ability to describe a person's implicit understanding of the nature of the broader situation she finds herself in. In this sense, we consider framing at a comparatively large grain size. There are multiple aspects to any given framing: social interactions, tool use, and body language, as well as what it means to "know" something in science, that is, the *epistemological* nature of the scientific endeavor. This component of framing differs from epistemological beliefs in that framing accounts for what the teacher does in the classroom, that is, her actions and the roles she takes on while teaching science. This does not always coincide with her explicitly stated, decontextualized views about teaching and the nature of science (Abd-El-Khalick, Bell & Lederman, 1998; Lederman, 1999).

In cases where framing has been used to describe how students reason about science, there is evidence to suggest that their framing constrains both the types of knowledge they employ and how they use that knowledge (Hammer, et al., 2005; Louca, Elby, Hammer & Kagey, 2004). We take this as an indication that a teacher's framing could describe the lens through which she attends to student thinking. This may elucidate how and why she is responsive to certain ideas over others, and how she uses these ideas in her response.

## Responsiveness to Student Thinking

Previous work in mathematics education suggests that how a teacher listens can transform how children talk and, ultimately, influence what they learn (Jacobs, Lamb, Philipp, & Schappelle, 2009; Sherin & van Es, 2009). When studying teachers participating in video-based professional development, researchers found that what teachers attend to—what they notice about the mathematical details of the child's idea—is intertwined with how they respond to students (Empson & Jacobs, 2008; Jacobs, et al., 2009). Classroom studies of teacher noticing use moment-by-moment statements of students and teachers as the units of analysis (Pierson, 2008; Sherin & van Es, 2009). For example, Sherin and van Es (2009) focused on instances when student ideas were presented in class and then determined whether or not teachers noticed these ideas. Pierson (2008) quantified patterns in teachers' follow-up utterances in whole class discussions to characterize a teacher's responsiveness, which she defines as "the extent to which teachers 'take up' students' thinking and focus on student ideas in their moment-to-moment interactions" in the classroom (p.25). Pierson found a significant correlation between student learning and the highest level of teacher responsiveness that she articulates (High II). In defining High II responsiveness, Pierson identifies four types of teacher follow-up moves: an invitation to further explain the idea, offering a contradiction or counterclaim related to the idea, an invitation for other students to make sense of the idea (agree/disagree, etc.), or uptake of the student's idea through revoicing or expanding the reasoning. In our work, we acknowledge the dynamic relationship between attention to students' ideas and responsiveness, and we examine how a teacher responds in order to infer what she is noticing about a student's ideas.

When accounting for the actions of an experienced teacher implementing a module in scientific inquiry, we found that utterances and follow-up questions provided too small of an analytic grain size to adequately make sense of *why* the teacher was choosing to respond in a particular way to students' ideas. Our purpose in this paper, therefore, is to argue that it is more useful to characterize a teacher's progress in promoting scientific inquiry in terms of *both* responsiveness and framing. In our analysis, we aim to show how a teacher's own framing of scientific inquiry influences how she hears and responds to students' ideas.

## Methodology

This study is part of a larger NSF-funded project to, in part, identify what constitutes teachers' progression in their abilities to facilitate scientific inquiry (1). During the first year of professional development, practicing third-through sixth-grade teachers from a large school district in southern California attended a one-week summer workshop in August 2008, and biweekly teacher meetings during the 2008-2009 school year. During these sessions, teachers participated in (a) "science-talks" designed to model what scientific inquiry is, and (b) discussions of classroom video, often taken from their own classrooms, where children's scientific reasoning is on display. We expected that many of the teachers would not initially focus closely on the substance of student reasoning for the reasons described in the introduction. We found, however, that a few teachers did in fact attend to students' ideas in ways that existing measures of responsiveness would categorize as high. For this paper, we focus on one of the latter teachers, Mrs. Charles (pseudonym), and describe how we identified what might constitute progress for her in promoting scientific inquiry in her classroom.

The data sources for this study include video recordings of Mrs. Charles's implementation of a 15-hour module. On the first day of the module, the supporting curricular materials suggest that teachers pose the following question to their students:

> Suppose that one night it rains. When you arrive at school you notice that there are puddles of rainwater in the parking lot. But when you go home you notice that the puddles are gone. What happened to the rainwater?

Rather than follow a scripted curriculum, teachers were encouraged to pursue ideas and questions which students brought up during the discussion of this first question. Additional data included classroom field notes taken by the second author, and video and/or field notes from debriefing sessions with the second author after each day's instruction.

Analysis proceeded in phases. Initially both authors independently viewed all of the classroom video, identifying instances when Mrs. Charles was responsive to students' ideas that were raised in class. We use responsiveness in a broad sense to mean noticing and responding to a student's idea either by rephrasing the idea, probing for further clarification, or shifting the direction of the discussion in a way that addresses the idea (Levin, Hammer, & Coffey, 2009). Finding that Mrs. Charles was generally responsive to students' ideas, each author then identified and transcribed several episodes representing the various types of activities in the classroom (small group discussion, small group experimentation, whole class discussion). Analytic memos summarizing the student ideas and interpreting Mrs. Charles's responses within these episodes were compared by the two authors to try to understand the nature of Mrs. Charles's responsiveness. By means of the cyclical, interpretive analysis cycle (Clement, 2000) (2), we continued to analyze video episodes and modify our account of Mrs. Charles's responsiveness until we found a pattern that fit the data and presented a reasonable, coherent account of her actions. We argue below that it was only by applying the construct of framing to our analysis of Mrs. Charles's actions that we were able to understand why she consistently responded in particular ways to students' ideas. The coupled use of these constructs—responsiveness and framing—is the main focus of this preliminary work, and we save for future analysis the endeavor of quantifying the frequency with which Mrs. Charles frames science in any given way.

## Findings

Mrs. Charles took very quickly to the practice of giving students space to express their ideas. From the initial opening question about a puddle, Mrs. Charles facilitated discussions and encouraged experimentation based on the questions students posed about various topics related to evaporation. For example, after listing on the board several student-generated questions, Mrs. Charles asked: "What do you think that we should explore up there [on the board], that we've been talking about today? And how do you think we should explore it? What do you think we should do?" Students' ideas were welcomed, made public, discussed, and clarified so that they could become objects of inquiry for experimentation. The following segment of transcript, taken from a student-initiated class debate, exemplifies how Mrs. Charles provides space for students to describe their own reasoning and critique others' ideas.

| | |
|---|---|
| Mrs. Charles: | What do you think?! Susan. |
| Susan: | Um, when you were reading it (…) um, the size of the parking lot. I don't think that would affect it, because you're talking about a puddle, which is not, like you're not measuring [pause] |
| Mrs. Charles: | Talk to this table. They were the ones who put it on. I have nothing to do with it. I just read it. [To Cody:] Go. |
| Cody: | Well, um. Well, the heat comes down on the parking lot, 'cause the parking lot is really big, then the heat won't go to that one little water spot. It will go to everywhere, and it won't be hot in that water spot. If it's smaller, it will focus in on that, on a littler spot, and it'll be hotter. |
| ... | [1 min and 40 sec of debate between Cody and Susan] |
| Mrs. Charles: | Andrea, did you want to add something to it? |
| Andrea: | It actually does matter, because, um, if the parking lot's bigger, the sun would go everywhere in the parking lot, and it wouldn't be as hot in that one area where the |

| | |
|---|---|
| | puddle is. And if it's smaller, it would be hotter because it's a smaller area and more heat would be able to go in there, in that one area. |
| Mrs. Charles: | Brian, you're shaking your head. What's going on? |
| Brian: | Wouldn't the sun go to every single place? |
| Susan: | Yeah, but that's what I was doing. |
| Cody: | Yeah, but it wouldn't be as hot, 'cause it has to cover all those places. |

This episode is representative of Mrs. Charles's interactions throughout the module in that she facilitates discussions between students, allowing their reasoning to develop in response to critiques from classmates rather than looking to an authority figure for approval or disapproval. Mrs. Charles promoted experimentation—not the assertion of a teacher or text—as the ultimate authority on "what worked", and often led student discussions toward empirical investigation. During the module, Mrs. Charles guided her class in four cycles of exploration, each consisting of students (a) generating a variety of questions while discussing some aspect of the puddle, (b) selecting which questions to pursue, (c) designing and implementing experiments to test those ideas, (d) reporting outcomes, and (e) finding new questions and topics of investigation. Each cycle lasted approximately 2-4 hours spread over one to two class periods, and students spent a considerable portion of this time engaged in experimenting. This overall organization of the module emerged from Mrs. Charles rather than from professional development or project directives and was driven more by students' ideas than most other teachers' module implementations were during this first year of the project.

Analyzing Mrs. Charles's classes, we find evidence of her responsiveness to student thinking. She consistently responds to students by restating the idea or asking others what they think of the idea without "taking over" the students' thinking. This, according to the literature, is evidence of attention to students' ideas (Empson & Jacobs, 2009; Pierson, 2008; Sherin & van Es, 2009). A closer analysis of extended episodes, however, revealed a consistency underlying Mrs. Charles's responsiveness, a consistency arising from what we suspect to be a relatively stable framing of what science class is all about.

## Framing Influencing Responsiveness

Mrs. Charles's frequent attention to one specific aspect of students' ideas, the potential testability of an idea, is what caused us to question the sufficiency of analyzing Mrs. Charles through the lens of her responsiveness alone. This section provides two extended examples of Mrs. Charles being responsive to her students in a way that promotes science as a fundamentally empirical endeavor. These episodes, although representative of the typical teacher-student interactions in her classroom, were chosen because they effectively portray the nuances of what aspects of student thinking Mrs. Charles notices and responds to, and to what ends she uses these ideas.

### Example 1

While interacting with small groups, Mrs. Charles frequently steers students to consider further experimentation. Just prior to the following episode, Mrs. Charles had asked the whole class to draw what they saw happening to the puddle during their experiments on the previous day. While visiting a small group, she elicits one student's thinking, challenges the epistemological basis of his claim, and then poses a question that both answers that epistemological challenge and suggests a course of action for the students:

| | |
|---|---|
| Mrs. Charles: | Okay, so what is it you have there [on your drawing]? |
| Matt: | Okay. So the heat goes, like, down into the water. And then the water turns into its gashus or gas-e-ous [laughs]--its-its-its gas form--which is called water vapor. And so, like, this is what's happening. |
| Mrs. Charles: | How do you know that it's the heat from the sun that's causing it, and not the heat from the ground? |
| Matt: | Well, it could be the heat from the ground, but the ground got heated up from the sun. So it's originally from-from heat, right? |
| Mrs. Charles: | [to boy sitting next to Matt] So wha'd'ya think? Do you agree with him? |
| Matt: | 'Cause the ground got heat from the sun, and the sun. So it's like both. |
| Mrs. Charles: | How would you test that to prove it? |

Mrs. Charles displays responsiveness throughout this interaction by eliciting ideas, engaging with the specifics of a student's idea, challenging the student's thinking without promoting her own reasoning as a substitute, and inviting others to make sense of that student's idea. Upon closer inspection, we find that Mrs. Charles's responsiveness is focused primarily on the aspects of Matt's idea that lend themselves to empirical investigation.

Matt's response to Mrs. Charles's initial elicitation describes a causal chain of events that begins to account for what happens to the puddle: heat from the sun goes down to the water, which then causes the water to change into its gas form. Mrs. Charles follows up with a responsive, substantive probe ("How do you know … ?") about one specific aspect of Matt's reasoning—that the heat affecting the water comes "down" from the sun. Mrs. Charles's question could be a way of asking Matt to expound on his mechanistic understanding, and perhaps she has reason to believe that the nature of the heat source is vital to his budding model. Her subsequent follow-ups, however, do not continue to press for explanation. Rather, her final comment ("How would you test that to prove it?") is a clear invitation to design an experiment.

The aspect of Matt's reasoning that Mrs. Charles chooses to focus on—where the source of the heat comes from—is perhaps the most practical component of Matt's explanation to investigate empirically. Identifying the source of the heat translates nicely, although not simply, into experimental treatments, where the "ground" surface temperature is controlled, and where a fixed amount of light can reach the puddle. However, a direct empirical investigation of the process Matt alludes to, of how "the water turns into its ... gas form", is not nearly as straightforward. In this sense, Mrs. Charles's highlighting of "heat goes, like, down into the water" rather than "the water turns into its ... gas form" is consistent with a framing of scientific inquiry as fundamentally about developing questions and conducting experiments to answer those questions.

## Example 2

This second example is taken from a group of students in the midst of a controversy: one student is adamant the "stuff" they observed rising off their puddle was heat, and the others insist that it was water vapor. As before, Mrs. Charles elicits students' ideas and follows up on the content of those ideas, and she probes with an epistemological question as opposed to responding to the main point of contention.

| | |
|---|---|
| Mrs. Charles: | K, wha'd'you guys think? |
| Susan: | *She* [Ella] thinks it's water. |
| Ella: | *She* [Susan] thinks it's not water vapor. And then, we think that it *is* water vapor, but then she's gonna raise her hand, say her opinion and stuff- |
| Mrs. Charles: | [to Susan] Why do you think it's not water vapor? |
| Susan: | Because- |
| Mrs. Charles: | What do you think it is? |
| Susan: | Um, I think it's heat because the blacktop is, like, really, like, hot? |
| Mrs. Charles: | Mmm hmm |
| Susan: | And if you put a puddle on it, it's, like, gonna, like, react? to it? |
| Mrs. Charles: | Okay. |
| Susan: | And so, I think what's coming up is, like, heat. |
| Mrs. Charles: | How do you know that if you put a puddle on something hot it's gonna react to it? |

Again, Mrs. Charles displays responsiveness to student thinking in that she elicits student ideas, acknowledges ideas, highlights specific elements of an idea, and challenges the student to support her claim. Even when Ella is reflecting on the nature and ramifications of the group's disagreement, Mrs. Charles chooses to be responsive to the scientific substance of the student's thinking, asking Susan what she thinks the "stuff" is. What is interesting is that Mrs. Charles follows up by probing how Susan would know something would react, as opposed to choosing to pursue the idea under debate, that is, whether the "stuff" is heat or water vapor.

As Mrs. Charles leaves this group, she reinforces that she wants the students to devise an experiment. While the group continues to debate, one member directly asks Mrs. Charles what that "stuff" rising off the puddle is. She responds by saying, "I don't know. What d'you think, and how can we prove what we're thinking?" Here the topic of the implied experiment is central to the controversy: what that "stuff" is. Mrs. Charles asks the student what he thinks the "stuff" is, but instead of asking *why* he thinks that, she focuses on how he could prove what the "stuff" is. Nominating this idea for experimentation provides further evidence of this nuanced aspect of her responsiveness.

## Framing as a way to understand a pattern in Mrs. Charles's Responsiveness

How do we account for the nature of Mrs. Charles' responsiveness and consider what progress for her might look like? In the analyses above, we exemplify how Mrs. Charles seems to attend to one specific aspect of students' ideas—their potential for empirical exploration. We suggest that, in general, interpreting a teacher's actions in terms of her framing of science can elucidate *what* she is responsive to and *how* she is responsive. In the case of Mrs. Charles, this analysis finds her responsiveness taking the form of guiding students towards experimentation as a way to "prove" their thinking. The component of Mrs. Charles's framing that is most relevant here has to do with her stance on how students go about constructing scientific knowledge, which we will refer to as her *epistemological* framing (Hammer, et al., 2005). Along with the consistent nature of her responsiveness to ideas that are testable, additional sources of data (comments about her class during debriefing sessions and the iterative exploration cycles during the module) provide further evidence to suggest that Mrs. Charles frames the inquiry module as an opportunity to pose critical questions about phenomena and investigate them empirically.

The epistemological component of Mrs. Charles's framing treats knowledge as inherently empirical: we have ideas in science, but we have to test them to know if they are correct. This captures an important component of the nature of science: that science is accountable to empirical findings (Abd-El-Khalick & Lederman, 2000; McComas, 1998). Experimentation, however, is only one part of inquiry. Many teachers' conceptualizations of inquiry involve setting up experiments and identifying the observable outcomes, but do not involve the development of theories or models of natural phenomena (Chinn & Malhotra, 2002; Windschitl, 2004). Therefore, teachers' ideas of what science *is* may require subtle, but important changes.

Although the students' ideas and questions provide the terrain for exploration in Mrs. Charles's class, a desirable and sophisticated inquiry practice, we found that her consistent epistemological framing of science inquiry as primarily empirical investigation also resulted in less desirable aspects of classroom science. For example, Mrs. Charles's endorsement of pseudo experiments, such as one group designing a diorama inside a condensation chamber, or another group following online directions to create a cloud in a bottle. Additionally, because the students were encouraged to explore any questions they were interested in pursuing, this resulted in the divergence of different groups of students into different lines of research. Divergent explorations did not ultimately feed into the larger purpose of constructing an explanatory account of evaporation and related phenomena. Therefore, our findings reveal that Mrs. Charles's epistemological framing led her to focus on particular aspects of students' ideas—the testability or potential fruitfulness of the ideas—which resulted in iterative cycles of questions, experimentation, observation, new questions over the course of the 15-hour module. The construct of framing allows us to make sense of *why* Mrs. Charles attended to particular aspects of students' ideas, as well as illuminates a direction for progress for a highly responsive teacher that already views students "as 'havers' of ideas and classroom communities as groups that productively entertain these ideas" (Cohen, 2004, p.21).

## Discussion

The teacher education literature suggests that really listening to and engaging in students' ideas is a characteristic or skill that takes time for teachers to cultivate (Empson & Jacobs, 2008; Franke, Carpenter, Levi, & Fennema, 2001; Pierson, 2008). In an informal interview with Mrs. Charles, she readily admitted that prior to participation in this professional development project she did not enjoy teaching science, and she described her previous science class as "more traditional" because she followed scripted lessons. During her first year of participation in professional development designed to cultivate more sophisticated practices for facilitating scientific inquiry, Mrs. Charles created a science classroom where the students' ideas took center stage. The students' own reasoning provided a basis for developing and pursuing questions surrounding the 'disappearing' puddle.

When analyzing Mrs. Charles's practice in the classroom, we find that she was highly responsive to students' ideas (Pierson, 2008). Mrs. Charles's classroom interactions and follow-ups demonstrated a variety of clearly responsive moves: she provided space for students to articulate their ideas; she took up student thinking by rephrasing, challenging and building on it; she probed for further clarification; and she shifted the direction of the discussion in ways that addressed student ideas. Simply describing the extent to which Mrs. Charles was responsive, however, does not offer a thorough account of Mrs. Charles's facilitation of scientific inquiry. A closer analysis of her responsiveness revealed a pattern: she tended to respond to ideas that lent themselves to empirical testing and often guided students toward experimentation by challenging how they might "know", "prove", or "test" their ideas. Framing helps make sense of the nuances in Mrs. Charles's responsiveness because it can account for *why* Mrs. Charles chose to take up particular ideas and respond in particular ways. In the case of Mrs. Charles, one component of her epistemological framing—her implicit understanding of how students should address the question, "How do we *know* this proposed idea is valid?" while engaging in scientific inquiry—may have contributed to a very specific kind of responsiveness.

This analysis of Mrs. Charles's practice helps us think about what progress for her might entail. Although Mrs. Charles frequently offered glowing testimonials about what her students were doing as a result of her pedagogical changes, Mrs. Charles expressed a concern during a debriefing session near the end of the module implementation. Prior to class she had created posters summarizing the students' questions and explorations throughout the module; however, she had trouble recording what they had *accomplished* or where they had "*arrived*". Considering this dissatisfaction in terms of Mrs. Charles's framing of scientific inquiry provides insight into how to address her concern and also illuminates a potential path for teacher change. While Mrs. Charles skillfully helped students develop and investigate questions, her framing of science as empirical investigation may have limited her ability to recognize opportunities for other components of scientific inquiry. An alternate framing of scientific inquiry as theory construction *and* experimentation may result in Mrs. Charles modifying the ways in which she is responsive. For example, with this expanded framing of inquiry we may see Mrs. Charles lead students in synthesizing their observations in pursuit of a theoretical model of evaporation. While Mrs. Charles encouraged each group to share out the results of their experiments, these findings were not woven back into a collective explanation for evaporation and the water cycle. Instead, the students' empirical findings were sufficient to suggest whether or not a given variable affects the process of evaporation and became the endpoint of that exploration. Mrs. Charles's comments suggest that *she* sees this endpoint as partially inadequate and unsatisfying. Indeed, there is great potential in what Mrs. Charles has already been able to establish in her classroom. Empirical investigation *is* an appropriate way for students to address questions and resolve competing ideas in science. Even the organization of Mrs. Charles's class, where various groups of students pursued different but related topics of investigation, can be a productive model of scientific collaboration and an appropriate means of arriving at scientific knowledge (Brown, Ash, Rutherford, Nakagawa, Gordon & Campione, 1993). By building on Mrs. Charles's existing framing of science, we can help her expand her notion of inquiry to include the coordination of evidence with theory construction, and potentially satisfy her desire to help the students "arrive" at shared explanations for phenomena.

This study is taken from a larger project aimed at, in part, characterizing teacher progress in facilitating scientific inquiry. The construct of *teacher learning progressions* (Schwarz et al., 2009; Thompson, Braaten & Windschitl, 2009), can document how teachers fundamentally alter their view of what can and should take place in the science classroom, and how to hear and develop the beginnings of science in children's thinking. Instead of postulating a progression informed only by data on novice "starting" points and expert "end" points, our larger project attempts to follow the journey of multiple teachers participating in intensive, long-term professional development. Our case study of Mrs. Charles provides a small vignette in that larger story of change. This account of Mrs. Charles's first year can inform how we conceptualize progress and influence what we do during future professional development. For a teacher that easily adopts a student-centered stance in the classroom and is often responsive to student ideas—at least for use in experimentation—defining a learning progression involves more than an analysis of moment-by-moment responsiveness. Understanding Mrs. Charles's epistemological framing of scientific inquiry in the classroom helps illuminate a direction for progress for her, where we can honor and build on what she has already successfully been doing with students.

# Representational Practices in the Activity of Student-Generated Representations (SGR) for Promoting Conceptual Understanding

Orit Parnafes, School of Education, Tel-Aviv University, Israel, oritpa@post.tau.ac.il

**Abstract:** This research aims to investigate student-generation and elaboration of visual representations as a tool for promoting understanding of difficult conceptual domains. The paper focuses on students' naturally occurring representational practices as identified in an activity of student-generated representations (SGR). The research is based on observations of pairs of students, ages 10-14, generating representations while trying to understand the phenomenon of the moon phases. The activity involves a few stages. First, each student generates a representation to promote his or her own understanding of the phenomenon. Then, the students negotiate and co-construct representations with their peers. Finally, they design representations for explaining the phenomenon to an external audience. The analysis identifies various representational practices utilized by students for making sense of the phenomenon, developing explanations, and communicating their ideas to their peers. The analysis examines how these practices support students in achieving some cognitive and communicative goals.

## Introduction

This research aims to investigate student-generation and elaboration of visual representations, as a tool for promoting understanding of difficult conceptual domains. In particular, it examines students' practices of using drawings and visual representations to advance their own understanding.

Generally speaking, the idea of SGR can be motivated by combining two important components that have been shown valuable for learning: First, a wide range of research has shown that *learning with visual representations* enhance learning and understanding (e.g., Larkin & Simon, 1987; Scaife & Rogers, 1996; Ainsworth, 1999; Parnafes, 2007). Second, research has shown that *self-generated explanations* (Chi, Bassok, Lewis, Reimann, & Glaser, 1989; Chi, de Leeuw, Chiu, and La Vancher, 1994) promote deeper understanding. This research proposes to combine the two components and investigate the potential of *student-generated visual representations* as a means for explaining difficult phenomena to promote learning and genuine understanding.

Student-generated explanations can take different forms (or representations). In most studies the self-generated explanations are either verbal or textual. Chi et al. (1994) mention that other forms of nonverbal constructive activity, such as diagram drawing, may also be effective at enhancing learning. This is particularly important given that our world is rich in visual images, and this era is characterized in an ever increasing amount of innovative and sophisticated diagrams and visualizations that enhance various types of information in many fields (e.g., Tufte, 2001). It is only sensible to enrich students' repertoire of self-explaining tools to include visual means to enhance their own understanding and learning of researched phenomena. Furthermore, humans think occasionally with images and visual models and those could be expressed in order to be operated on and communicated with. Yet, if we look at school practices, students' opportunities for expression involve, for the most part, verbal and textual forms. Visual forms are mainly offered to students as resources, and rarely as forms for expression and self-generation.

This rational is stimulated also by examining representational practices in scientific areas. Scientists use representations in their practice to promote their own understanding, to think with in order to make scientific progress, and to communicate with other scientists (Latour, 1986; Lynch and Woolgar, 1990; Ochs, Jacoby, & Gonzales, 1994; Nersessian, 2002). DiSessa et al. (1991) studied students' competencies in various representational practices. They show that students, as young as elementary school students, have sophisticated competencies for creating, critiquing and inventing new representations (meta-representational competencies). Developing these competencies, they conjecture, is important in enhancing students' representational innovation, as well as deepening their understanding of any kind of representation (diSessa, 2004). From a meta-representational point of view, the competency of grappling with a tough conceptual field through the *generation and elaboration* of representations was not explored. This may well be an important competency to develop, given that it is a common practice in scientific work, involving a fair amount of inventiveness and creativity.

Research programs that have already been conducted on SGR (e.g., Ainsworth & Loizou, 2003; Roy & Chi, 2005; Cox & Brna, 1995; Cox, 1999; Gobert & Clement, 1999; Hall, Bailey, & Tillman, 1997) demonstrate the increasing interest of the research community in self-generated representations. While much of this research comes from cognitive science, comparing various cognitive differences between experimental settings, there is a growing research that uses qualitative methods for examining activities of students' SGR in an open ended setting (Bamberger, 2007; diSessa, 2004; Danish & Enyedy, 2007; Enyedy, 2005; and Nemirovsky & Tierney, 2001).

The current research explores the proposal that SGR can be a powerful tool for thinking and for developing understanding of difficult topics. One path of exploration of the current research, and the focus of this paper, is examining students' naturally occurring practices of SGR, and analyzing the means by which these practices shape and facilitate their developing explanations and conceptual understanding. The analysis attempts to address the question: In what ways could naturally occurring SGR practices support the achievement of conceptual and communicative goals in the process of developing and elaborating explanations of difficult phenomena?

## Methods

### Data collection

The research is based on observations of 7 pairs of students (see table 1), generating representations while trying to understand the phenomenon of the phases of the moon. The students were 10-14 years old (4-8th grade). Each pair attended a session of one to two hours.

Table 1: the research subjects.

| | Gender | Grade level |
|---|---|---|
| Rose and Natalie | Two girls | 5th grade |
| Merav and Maya | Two girls | 5th grade |
| Tal and Rotem | Two boys | 5th grade |
| Ran and Gil | Two boys | 4th grade |
| Liron and Itai | Two boys | 5th grade |
| Roni and Tom | Two boys | 6th grade |
| Or and Meital | Two girls | 8th grade |

The scientific domain selected for this study is the *Phases of the moon.* The instructional design of the sessions involves four parts, following a beginning, in which the students receive a brief explanation about the research and the session.

1. *An introductory activity:* a brief interview about what the phases of the moon are, the cycle of the moon phases over a month, and the system of moon, Earth and the sun including relations between rotations and revolutions. The interview usually ends with soliciting students' initial explanations about the causes of the phases of the moon.
2. *Personal representations:* the students are asked to draw some representations (diagrams or sketches) to explain the cause of the phases of the moon.
3. *Collaborative representations:* the students are asked to share their representations with one another and to explain the cause of the phases of the moon to their peer based on the representations. Then, they should negotiate and co-construct a shared representation that they both agree on. This part is usually the longest of all parts and the students go through several drafts as they refine their shared understanding.
4. *Presentable representations:* the students are asked to produce a diagram for people that are not present in the activity. Student design a PowerPoint presentation in this phase. In some cases, this stage is conducted in a separate session, a few weeks or even months after the first session.

During the session, the researcher's role is mostly a participatory observer. In principle, interventions are kept to the minimum, and if made, it is for the purpose of clarifying meanings, or asking challenging questions when the students seem to be satisfied with their state of explanation. The sessions are videotaped and then digitized for further analysis. The representations produced are collected and scanned.

### Data analysis

The methodological orientation of this research encompasses a fine-grain detail qualitative analysis of case studies. The theoretical framework is developed in an approach similar to the grounded theory methodology (Glaser & Strauss, 1967; Strauss & Corbin, 1990). The construction of a theory is done by generating categories from evidence taken from a few focus cases. These categories are then explored in other cases, which may support the categorical concept or suggest modifications to make it more generalized.

To conduct the analysis, the various sources of data are examined: 1. The representational forms that the students produced during the session; 2. The video recordings of the interaction between the students as they work together, including their actions such as pointing to aspects of the representations, gesturing, highlighting, arguing, refining, agreeing, disagreeing and so forth. From this close examination some categories emerge concerning *actions and practices of SGR*. These categories were applied on two of the sessions and refined through several iterations of applications. When the framework stabilized and the categories demonstrated usefulness and insight with regards to the issue at hand, the categories were applied on other case studies. The analysis is carried out using the Transana[i] video analysis software.

## Preliminary findings

The preliminary findings are presented in this paper in the form of a set of categories of actions and practices of SGR produced by the analysis. In addition, a sample analysis of one episode is provided to demonstrate how some of the actions and practices support the achievement of conceptual and communicative goals in the process of developing and elaborating explanations using the generation and elaboration of representations.

### The System of Categories

The system of categories includes two sets of categories. The first set includes categories of observed actions operated on the representations, and the second set includes categories of practices for achieving cognitive and communicative goals. Below is a description of each category with some accompanying examples.

#### Observed Actions Operated on the Representations:

A. *Generating representations* - Students draw representations, either from scratch, or, they continue elaborating a representation that already appears on the paper. Students generate representations with various degrees of innovation and inventiveness. Some of their drawings are customary representations of objects and relations between them (see Figure 1 on the left). Generating representations can also be done by borrowing a representation invention or convention from other resources. Resources can include representational aspects drawn by the peer, or a conventional representation seen in a textbook or elsewhere (See Figure 1 in the middle). Ultimately, a representation could be generated by making a representational innovation, in which students use various common signs (circles, lines, words, numbers, and colors) inventively. In Figure 1 on the right, students use big circles to indicate the field of view from different positions on Earth.

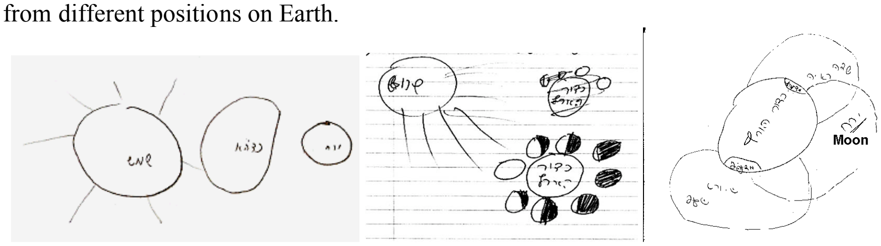

**Figure 1 - various degrees of inventiveness in generating representations**

B. *Gesturing over a representation* - Students make gestures to express various ideas. There are various types of gestures that are found to be used by students through their discussion, including pointing, animating and covering a representation. For example:

a. Animating: Figure 2 shows a selection of animating gestures on the static drawing for representing motion. The two pictures on the left demonstrate gestures that represent the motion of the sun rays from the sun to the moon. The two pictures on the right show gestures that represent the rotation of the Earth around its axis, and the revolution of the moon around the Earth, accordingly.

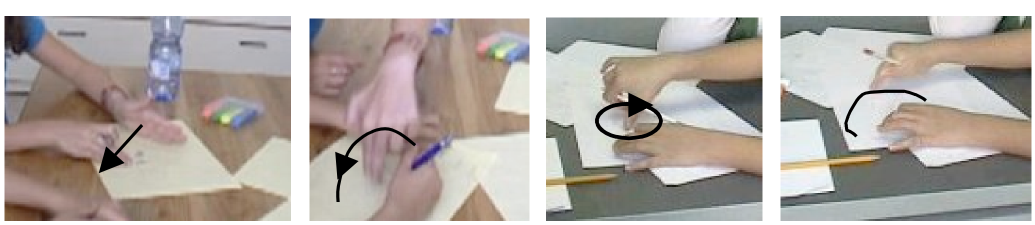

**Figure 2 - animating gestures for representing motion**

b. Covering: Students cover parts of the representations with their hands. In Figure 3 on the left, the student covers parts of the representations to highlight only one moon on which she wants to focus. This is an example of covering and hiding details to reduce destruction from unnecessary details (in this case, drawn by her peer). In the picture on the right, the student covers with her hand half of the moon – the part that is not seen by people looking from the Earth. In this, she tries to reason about the part that is seen from Earth.

**Figure 3 - covering gestures**

C. *Highlighting selected details* - The students select certain details in the representation and highlight them either by circling, shadowing, or making any other form of highlighting. For example, when Natalie talks about the day and night on Earth, she highlights the line splitting the Earth into two halves – the one that's facing the sun, and the one that is not. Another example is highlighting and shadowing a part of the moon that is not facing the sun to show that half of it is shadowed. The students keep highlighting and shadowing the part even though it is already shadowed.

D. *Transforming a representation* - Students transform a piece of an existing drawing by adding details, changing, and deleting. They add details that were not on the original drawing, change some aspects, or delete aspects of the representation. For example, Natalie explains that the moon in the picture cannot be seen from Israel but can be seen from the US. Rose argues with her, saying that even US cannot see it because this moon is dark – the Earth casts shadow on it. She darkens the moon (it was only a blank circle before) and in that transforms the representation to represent a dark moon.

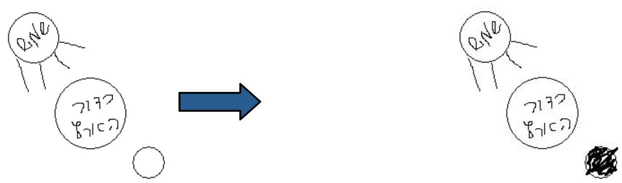

**Figure 4 - Transforming a representation**

As with the "generating representations" category, students transform representations with various degrees of innovation and inventiveness.

## 3.2 Practices Used for Achieving Cognitive and Communicative Goals

Students generate representations, gesture over, highlight and transform representations as a means for achieving some task-related goals. Following are five functions identified in the data for achieving cognitive and communicative goals in this sense making activity.

E. *Organize information* – Students organize on the paper all the relevant information – usually the objects and their spatial relations. This is usually happens at the beginning of producing a drawing.

F. *Construct and communicate an explanation* – Students use representations to generate an explanation either for enhancing their own understanding, or to communicate their explanation to their peer or to the researcher.

G. *Manage complexity* – Students use the representations to reduce or organize epistemological complexity. This can be done by freezing a state in a dynamic process, or by selecting a focus on only one state, by ignoring some details, etc.

H. *"See" better – perceptual aid* - Students use various common signs (circles, lines, words, numbers, and colors) inventively to achieve some communicative goals and to "see" new ideas better.

I. *Claim accountability* - A student uses the representation as evidence for her previous arguments or her peer's previous argument. The representations enable students to make their arguments with reference to the external representations they have produced. They can point to objects in the representations that they wanted to argue about, or to elaborate their ideas on, agree or disagree to statements with reference to them. The instructor can use this practice as well to set the students' attention to a particular issue and to talk about it.

Following is a sample analysis of one short episode. The episode was identified as one in which representations are used for the function of "seeing better" (category H). It is analyzed to reveal how the various actions operated on the representations support the specific cognitive and communicative goal.

## Practices of Using Representations to "see better" – Sample Analysis

Rose and Natalie are 5th grade students. They are towards the end of the third part of the activity, where they made an impressive development in their explanations and understanding. This is their last attempt of explaining the phases of the moon before they move on to the fourth part, where they'd try to generate representations for an external audience. They already explained nicely what happens in the mid month phase (according to the lunar calendar) – when the moon is full. Now, they try to see how other phases are formed. They are now focusing at the location of the moon described in Figure 5:

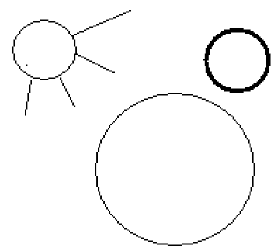

**Figure 5 - The moon in a new location**

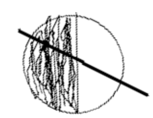
Natalie colors the moon in the new location – the part facing the sun is now lit (the colored part is the lighted part). Rose adds a line splitting the moon to two other halves, an important move for highlighting the observer's point of view and how the moon is seen from Earth:

> Rose: So we… what we actually, see, is this part *(drawing a line almost vertical to the colored part)*, more or less…



Her explanation combines both the illumination of the moon (represented by the colored and non-colored parts of the moon), and the part that is seen from a particular position on Earth. She makes a representational innovation, using a line to see the illuminated part seen from Earth. This representational innovation enables the students to "see better" what is actually seen from Earth.

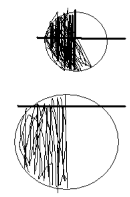
Indeed, following Rose's elaboration of which particular part of the illuminated moon is seen, Natalie gains a meaningful insight:

> Natalie: Ah! One moment, *(takes Rose's hand away from the representation)* the moon doesn't really get larger and smaller, it's simply what we see. We see only the illuminated part [Rose: right!] *(Natalie colors the illuminated part again)*, and now it's like, only half of it, and it's possible that if we'll look before… so maybe it'll be only this part. This line here [Rose: right]. It depends *(looks at me)* on when we look and… when the moon...

This is a moment of "aha" for Natalie. She realizes that the moon does not really get larger and smaller (an idea she kept voicing throughout the session, meaning that only parts of the moon are seen due to occultation), but it is the observed illuminated part seen from Earth that changes. She summarizes by saying that this is a combination of "when we look" (the point of view) and "when the moon" (how it is illuminated). This is a clear case where seeing better leads to a clear development of conceptual understanding.

Rose reiterates the same ideas and combines, more explicitly, the moon illumination and the way an observer sees the moon from Earth:

Rose: So in fact, when the moon is here, so this part is lit *(colors again the half moon that faces the sun)*, and Earth, say, this part *(draws a line on the Earth to show the field of view)* sees relatively this part *(draws a line on the moon to split it – the line is parallel to the line she drew on the Earth)* here, something like that, from the moon, that's lit



Natalie: That's why we see it… These are the phases of the moon!

Rose makes a creative use of signs to emphasize this integration. She colors the half of moon facing the sun, and the other half remains blank to indicate illumination. Next, to represent the observer's point of view, she draws a line splitting the moon into halves, which is parallel to a line representing the field of view of the observer. The half moon facing the Earth is what the observer can see of the moon.

This is an example of how transforming a representation (category D) in an innovative way can facilitate seeing better (category H) of a specific aspect of the phenomenon that is crucial in making sense and understanding it. Rose and Natalie transform the drawing of the moon in a way that highlights and makes visible two important aspects:

1. The illumination of the moon by the sun, represented by the colored part.
2. The part of the moon visible from Earth, represented by the line that splits the moon to the part that faces the Earth, and the part that is hidden from the Earth.

The combination of these two aspects constitutes the core of the explanation of the phases of the moon. The inventive way by which they transformed the representation signifies precisely this important combination.

## Conclusions and further analysis

The analysis classified students' various SGR practices that were used authentically by students when they were asked to generate representations to understand the phases of the moon, and then to communicate their ideas to their peers. These practices support their efforts in thinking, reasoning and making sense of a difficult phenomenon, and maintained their attempt to explain the cause of the phenomenon to their friend, and exchange ideas.

The sample analysis demonstrates the practice of performing certain actions to help one seeing better a particular aspect of the phenomenon. In this case, this was a central aspect at the core of the scientific explanation – the phases of the moon are caused by the combination of the illumination of the moon by the sun and the visibility of the part of the moon from Earth. The students transformed the illustration of the moon in a creative way that expressed this combination, and in fact, helped seeing the shape of the moon seen in the specific phase. The action of "transforming a representation" supports the students' efforts in "seeing better", to facilitate their thinking, reasoning and making sense of a difficult phenomenon, and sustained their attempts to explain the cause of the phenomenon to their friend, and exchange ideas.

In a later analysis, students' trajectories of developing understanding will be described in detail. The SGR practices will then be examined in conjunction to the paths of development, to suggest ways in which such practices could support the process of learning and understanding. Such interrelations will serve to answer questions such as what practices should be fostered, which ones should be discouraged, how specific practices contribute to the development of conceptual understanding? Could some of these practices be taught? How such practices could be supported and enhanced by adequate technological innovations? These can serve as the basis for instructional recommendation of using SGR for science learning.

## Acknowledgments

I wish to thank Andy diSessa, Mariana Levin, David Hammer, Billie Eilam, and Yael Kali for helpful comments related to this work. I thank the participants of the Student-Generated Representation research group at Tel-Aviv University, Orly Shapira, Hadas Shachar, and Meytal Saat, for help in conducting this research. This work was partly supported by a grant to O. Parnafes by the Tel-Aviv university foundation for research promotion.

[i] The data was analyzed with the support of video analysis software – Transana (Wisconsin center for education research, http://www.transana.org). The software was developed specifically for educational research, and it enables uploading video movies, transcribing them, writing notes and interpretations, and creating small clips for easier access and examination.

# Tracing knowledge re-organization - a fine grain analytical framework for looking at students' developing explanations

Orit Parnafes, School of Education, Tel-Aviv University, Israel, oritpa@post.tau.ac.il

**Abstract:** This paper presents an analytical framework for tracing knowledge re-organization through self-generating explanations and representations. The analytical framework, inspired by the knowledge in pieces perspective (diSessa, 1993), is applied on one case study, to illustrate the type of insight the framework could provide. The scientific domain explained by the students in the case study is the phases of the moon. Pairs of students ($5^{th}$ grade/11 year old) met for an hour and a half to generate and elaborate paper and pencil representations in order to explain and develop their understanding of the cause for the phases of the moon. The analysis traces the development of their explanations as an indication of their developing understanding, by tracing the re-organization of knowledge pieces throughout the process.

## Theoretical and methodological approach

This paper presents an analytical framework for tracing knowledge re-organization through the process of self-generating explanations and representations. The analytical framework is based on the knowledge in pieces perspective (diSessa, 1993). The analytical framework is presented using a case study in which two students develop their explanations and representations regarding the phases of the moon. The focus on one motivating case study is used as an opportunity to look into some contentious issues of conceptual change.

Conceptual change is an established research field in which numerous theories exist (e.g., Carey, 1999; Nersessian, 1989; Strike & Posner, 1990; Vosniadou & Brewer, 1992; Wiser, 1988; diSessa, 1993), concerning what students know (specifically about "deep and difficult" topics), how that changes over time, and how to mediate that change. Within the field, there are critical disagreements (diSessa, 2006). One of the critical centers of dispute is the question of the fundamental attributes of the nature of students' intuitive knowledge and how it changes and develops into scientific knowledge.

Some researchers (e.g., Strike & Posner, 1990; Nersessian, 1989; Wiser, 1988) draw parallels between individual's conceptual change and scientific revolutions (Kuhn, 1962). For example, Strike & Posner (1990) argue that students' concepts change from one set of concepts to another, incompatible with the first. Similar to scientific revolutions, what needs to be changed during the process of conceptual change, are some central commitments. Vosniadou & Brewer (1992) maintain that students' knowledge is organized in the form of coherent models and that conceptual change involves a shift from one model to another due to the reinterpretations of the presuppositions that gave rise to the initial models. A considerable part of science and mathematics education research refers to student knowledge in terms of "conceptions" (e.g., misconceptions, preconceptions, or alternative conceptions) that students have about particular concepts. Preconceptions are known to be robust, intact elements of cognitive structure, and demonstrate resistance to instruction. The misconception movement pays little attention to students' productive ideas and the continuities between what students already know and what they need to understand.

The "knowledge in Pieces" theory (diSessa, 1993) suggests a somewhat distinct view on intuitive knowledge and conceptual change. The name "knowledge in pieces" (KiP) suggests an underlying epistemological commitment that knowledge is constituted by a multiplicity of diverse pieces, rather than being a coherent system (e.g., theory-like). Smith, diSessa & Roschelle (1993) provide a constructivist view of learning in which students' ideas play productive rather than destructive roles in the acquisition of expertise, and that the process of conceptual change is a process of reorganization (rather than replacement) in which existing pieces of knowledge are modified in terms of the contexts in which they are activated and used.

The analytical framework presented in this paper, espousing the KiP perspective, provides means for tracing the reorganization of intuitive knowledge elements using a moment-by-moment approach, and demonstrates their productiveness in a more advanced state of understanding. A sample analysis of parts of the case study is presented in order to provide the gist of the way the framework is applied. A detailed analysis is presented in Parnafes (in review).

## The scientific domain – the phases of the moon

Research on students' understanding of the phases of the moon agree that students have difficulties understanding the cause of this phenomenon, and that they usually give a range of alternative explanations (e.g., Sadler, 1987; Baxter, 1989; Barnett & Morran, 2002; Hansen & Barnett, 2004; Kavanagh, Agan & Sneider, 2005; Trundle, Atwood & Christopher, 2007). The literature documents a range of students' alternative conceptions that include the following: The phases of the moon occur due to clouds covering parts of the moon; due to a shadow cast on the moon by the earth; due to a shadow cast on the moon by other planets (Baxter, 1989); or due to a viewer's geographic position on earth, and the supposition that people in different geographic locations see different moon phases (Schoon, 1992; Trundle, Atwood & Christopher, 2007). These alternative conceptions are considered to be fairly robust, hard to change by instruction, and persistent, many times until adulthood (Barnett & Morran, 2002; Baxter, 1989; Trundle, Atwood & Christopher, 2007).

The scientific explanation for the phases of the moon is that half of the moon is illuminated by the sun, and the portion of the illuminated half seen from earth varies as the moon revolves around the earth (Figure 1).

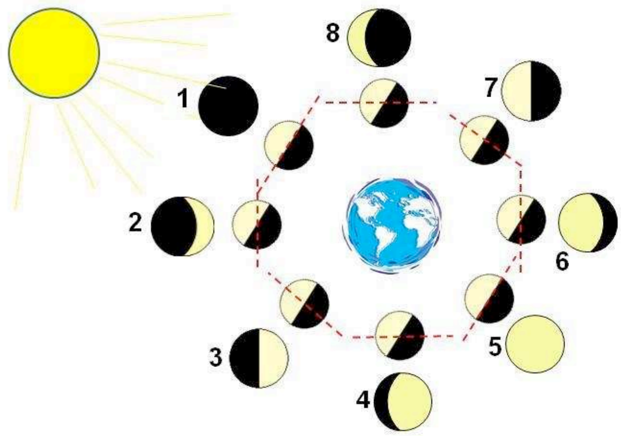

**Figure 1 - The phases of the moon (The internal circle of moons represents the different locations of the moon, illuminated by the sun in the same way throughout the month. The dashed lines show which part of the moon is seen from earth at each location. The external circle of moons represents the way in which the moon is seen from earth in different locations)**

A fair amount of the existing research concerns the classification of students' conceptions about the phases of the moon, and looks at trends of development following specific kinds of instructional interventions, or examines differences among different age groups. A common practice for studying trends of development is developing codes for students' conceptual understanding, and then classifying students' responses based on the type of understanding the codes collectively reflected (e.g., Callison & Wright, 1993; Barnett & Morran, 2002; Trundle, Atwood & Christopher 2007). This paper suggests going beyond this grain level and describing the structure of knowledge and the way it changes in a finer grain level. Taking a finer grain approach means keeping track of more diverse and low level elements rather than a rough unit such as a misconception, and examining how they change on small time-scales. At the fine grain size the "transformation" of a misconception into a scientific conception can be modeled and traced in detail, and in that provide useful instructional implications.

## Methods

### Data Collection

The study presented in this paper is based on observations of pairs of 11 year old (5th grade) students, as they generate representations and explanations and elaborate them while trying to understand the cause for the phases of the moon. During the session, the researcher's role was mostly that of a participatory observer. In principle, interventions were kept to a minimum, and if made, they were made for the purpose of clarifying meanings, or asking challenging questions when the students seemed to be satisfied with their state of explanation. The session was videotaped and then digitized for further analysis, and students' representations were collected and scanned. The sessions lasted an hour and a half and included the following four parts:

1. *An introductory activity:* a brief conversation about what the phases of the moon are, and the model of rotations and revolutions of the earth, moon and sun.
2. *Personal representations:* the students are asked to draw some representations (diagrams or sketches) to explain the cause of the phases of the moon.
3. *Collaborative representations:* the students are asked to share their representations and to explain the cause of the phases of the moon to one another. Then, they co-construct a shared representation.
4. *Presentable representations:* the students are asked to produce a diagram that explains the cause for the phases of the moon to people that are not present in the activity. At this point, the students design a PowerPoint presentation.

### Data analysis and analytical framework

The analytical framework relates students' explanations to their conceptual understanding by considering their explanations as the external performance made on the basis of their conceptual understanding. Their conceptual structure is therefore inferred from the examination of their explanations. The analytical framework describes students' conceptual structure, in the context of developing explanations, as containing (see Figure 2):

1. *An explanatory frame*: a hierarchical structure that provides the rationale for the explanations, consisting of finer grained knowledge pieces such as general schemes and models;
2. *Attended information:* pieces of information that students attend to when attempting to construct explanations. These pieces of information could have a high epistemological status. For example, students rarely argue with direct observations ("I saw the moon several times during the day, so I know it can be seen in daylight",) personal experience ("I know it is night in the US when it is day here, because we make phone calls to my uncle in NY"), an authoritative piece of evidence (facts! "I read it in a science book" or "the teacher told us that…"). Because these pieces of information frequently have a high epistemological status, they support the explanation and contribute to its persistence.

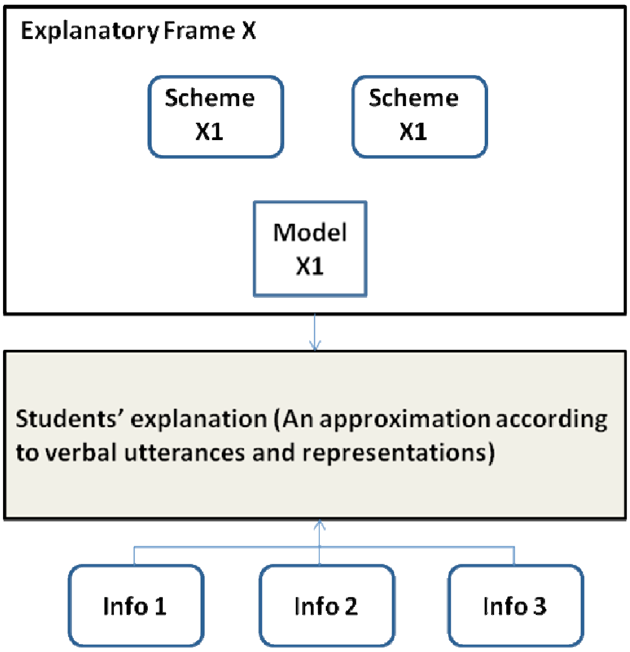

**Figure 2 - A schematic diagram of knowledge pieces used in an explanation**

An explanation is "satisfactory" when the explanatory frame, providing the rationale for the explanation, fits the attended information, or in other words, if these two components feel coherent (Thagard, 1997, Hammer, 2000) for the students at the moment.

A key element in the analysis is the movement from a "satisfactory" explanation to a "better" explanation. A "better" explanation is determined by the quality of coherence, which is characterized by its *resolution* and by its *range* (diSessa, personal communication). Resolution means the amount of available detail used in an explanation. Range means the part of the phenomenology covered by the explanation. In a sense, resolution provides the depth of the explanation and the range provides the breadth. The use of the framework in one case study is demonstrated in the following analysis.

## Analysis and findings

### Rose and Natalie explain the phases of the moon

The students in this study began the session having two different explanatory frames, which they tried to integrate with no success. When the researcher asked a specific question, she apparently provoked a higher resolution, which later on led to a co-construction of a new explanatory frame. A further elaboration of this frame led to a sophisticated explanation that is in line with the normative explanation.

#### Two different explanations for the phases of the moon

At the beginning of the session, after an introductory conversation, each student drew a representation in order to try and personally understand the cause for the phases of the moon (see Figure 3, Figure 4).

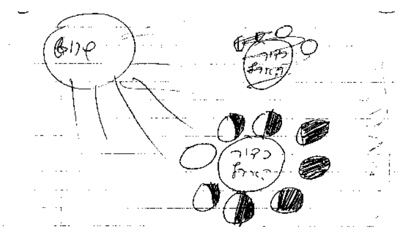

**Figure 3 - Rose's representation**

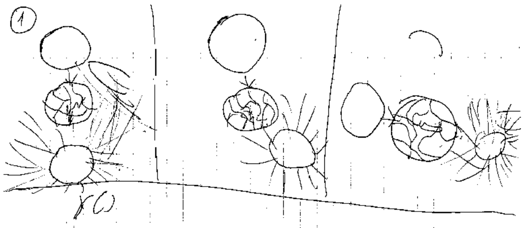

**Figure 4 - Natalie's representation**

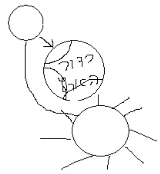
When the students were asked to communicate their representations, Natalie focused on an observer's view who sees different parts of the moon when standing in different places on earth:

> …and in the first time, say, the moon is here *(Natalie draws the moon in front of the earth)*, and **only this part of the earth sees the moon** *(Natalie draws an arrow, and an arc on the earth, facing the moon)*, **and this part sees less** *(draws an arc on the side of the earth)*

> This part *(draws another arc on the other side of the earth)*, **this part doesn't see it at all, so in this part it's like there is day** *(Natalie draws the sun)*, **there s sun,**



Natalie explained that in different positions on earth, different parts of the moon can be seen, and integrated into this explanation, the consideration of day and night as experienced on earth.

Rose began generating her representation again, laying out her own explanation as she drew: in the dark phase, the earth blocks the sun rays, hence the moon does not get any light and it is dark:

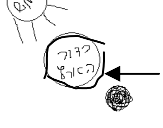
> *(Rose draws the sun and the earth) When the moon is here (draw one moon on the other side of the earth)* **The earth entirely blocks the sun** *(darkens the moon)*, **and then the moon, like, doesn t get any light**

Rose's original representation looks quite like any standard textbook illustration of the phases of the moon: a sun shining on the moon and earth, with multiple moons drawn around the earth. It is likely that Rose was using a convention she'd seen before in a textbook. However, unlike in the textbook illustration, Rose drew the moon closest to the sun (location 1) as a full moon, and the one farthest from the sun (location 5) as a dark moon.

Rose was going to draw other moons around the earth to explain other phases, when Natalie stopped her, saying that Rose's drawing and explanation (so far) were exactly in the same as her explanation. Natalie indicated that, as in her explanation, the moon that Rose had just drawn is the "dark phase." However, while Rose referred to the dark phase as the occasion in which the earth casts a shadow on the moon, Natalie referred to this phase as the occasion in which the moon is not within the observer's field of view.

Natalie So this is like…This is what I said, it's like the day, **we have sun on the entire earth almost,** *(illustrates with her pen the half circle of the earth facing the sun)*, almost, **and the moon, you can't see the moon**

**Except for this part** *(illustrates the half circle facing the moon)*, and there…



Rose: No, it's like, **you cannot see the moon at all, it's dark** *(swiping her hand from the sun to the moon, showing that the earth blocks the sun light)*

**Interpretation:**
The last exchange marks a breakdown in the students' communication based on their two different explanatory frames. The discussion went on for a while, but they each remained within their framework. The following is an analysis of the organization of knowledge pieces that played out in each explanation.

Rose explains the phases within the "casting shadow" explanatory frame that provides the rationale for the explanation. A few schemes are included in this explanatory frame along with a model they operate with:

| **Explanatory Frame A** | **"casting shadow"** |
|---|---|
| Scheme A1 | Objects cast shadows in their shape on other objects |
| Scheme A2 | The shadow cast on the obscure object is determined by the alignment of the source of light, the obscure object and the blocking object |
| Model A1 | A moon revolving around the earth, illuminated by the sun  |

The explanatory frame fits with two pieces of attended information, forming a "satisfactory" explanation:

| | |
|---|---|
| Info 1 | The moon looks different every day, varying gradually from an empty to a full moon |
| Info 2 | A textbook illustration (similar to Figure 1) |

The explanation is satisfactory in the sense that it forms low resolution coherence. The explanatory frame fits, to some extent, with the two pieces of information: the earth casts shadow on the moon differently when the moon is in different locations. Yet, Rose does not look at details such as the proportions of phases mapped to percent of shadowing. If she looked into the details of her explanation she would notice that the shadow which is presumably cast on the moon does not correspond to the phases she had drawn, to name one example.

Natalie bases her explanation on two explanatory frames. The first explanatory frame is the "occultation" frame, and the second is the "illumination" frame. A few general schemes construct each explanatory frame along with a model they operate with:

| **Explanatory Frame B** | **"occultation"** |
|---|---|
| Scheme B1 | Partial views of an object are occluded from the observer by obstructing objects. |
| Scheme B2 | What is seen from a particular position is what is within the field of view |
| Scheme B3 | Change in position entails change in the field of view |
| Model B1 | The visibility of the moon from different locations on the earth  |
| **Explanatory Frame C** | **"illumination"** |
| Scheme C1 | A source of light illuminates the part of an object facing it |
| Model C1 | The sun as a source of light illuminating the earth   |

The explanatory frame fits with four attended pieces of information:

| | |
|---|---|
| Info 1 | The moon looks different every day, varying gradually from an empty to a full moon |
| Info 3 | Every day, is constructed of day time and night time |
| Info 4 | When it is day time here, it is night time in countries on the other side of the earth |
| Info 5 | The moon is usually seen at night |

The two explanatory frames fit, to some extent, with the four pieces of information, and in that sense the explanation is satisfactory: different placement positions provide different occultation, and in Natalie's drawing, the moon is apparently seen at night and is obscured during the day. This shows low resolution coherence because Natalie attended to a very general aspect of the phenomenon and tried to account for it, but without getting down to the fine details of the phenomenon. For example, the occultation frame cannot account for the precise shapes of the moon seen throughout the month. In addition, it also shows narrow range coherence - the only one location selected for drawing the moon (location 5) happens to be the location where the moon is seen at night, which fits the pieces of information labeled no. 4 and no. 5. Other locations may challenge the coherence.

At this stage, neither of the students challenged their explanation by getting to a higher level of resolution or extending the range. Each student, presumably, judged her explanation as "satisfactory" in general. When interacting, each student reasoned about her peer's ideas using her own frame.

## What happens when the moon is between the sun and the earth?

After a relatively long discussion in which each student explained her representation, the students were asked to produce a shared representation and collaboratively explain the phases of the moon. They made an honest attempt to integrate their explanations; however, they each still reasoned within their explanatory frame and the changes in their explanations were minor. The following instructional move set the stage to a major reorganization. The researcher added another moon to their drawing, between the sun and the earth (location 1), and asked them what is seen at this phase. This particular question was intended to promote further thought that may result in increasing the resolution of their explanations.

OP: **What is seen here?**

Rose immediately said: "When the moon is there, so, like, we see all of it. Right? Because the sun lights it." Her idea that a source of light could actually illuminate an object all around led to a deeper examination of how objects are illuminated exactly, and in particular, how the moon is illuminated in location 1. This discussion resulted in a reorganization of their explanatory frames. The students gradually developed the "combined illumination with point of view" frame, as they discussed the particular details of a specific location of the moon (increasing resolution) and later reasoned about various locations of the moon (increasing range). They kept refining the explanation to the point where a high resolution and a wide range of coherence were achieved, in which point their explanation resembled the scientific explanation. For a detailed analysis see Parnafes (in review).

Rose and Natalie ended the session with an approximately normative explanation of the phases of the moon, saying that half the moon is illuminated by the sun, and the portion of the illuminated half seen from earth varies as the moon revolves around the earth. Although there were still particular ideas that each of them emphasized, they shared this collaborative explanation for the most part. The "combined illumination with point of view" frame is constructed of a few general schemes along with a few models they operate with:

| **Explanatory Frame E** | **"combined illumination with point of view"** |
|---|---|
| Scheme B2 | What is seen from a particular position is what is within the field of view |
| Scheme B3 | Change in position entails change in the field of view |
| Scheme C1 | A source of light illuminates the part of an object facing it |
| Scheme E1 | If the source of light is very big, relatively smaller objects will not cast shadows on other objects |
| Model A1 | A moon revolving around the earth, illuminated by the sun  |
| Model B1 | The visibility of the moon from different locations on the earth.  |
| Model E1 | The sun as a source of light illuminating the moon  |
| Model E2 | A big sun illuminates the earth and the moon  |

Schemes B2, B3 and C1 were used in previous explanations, sometimes in different contexts, with different models. Scheme E1 is used to explain why there is no shadow on the moon in location 5.

The pieces of information attended by both Rose and Natalie, play an important role in the explanation, and they fit with the explanatory frame for the most part. Only one of these pieces of information begins to lose its status. The piece of information labeled no. 5, specifying that the moon is experienced only at night, is acknowledged as inaccurate and as presenting partial information. Natalie emphasized this when she reasoned about the moon in location 5. But as she moved on to think about other locations, she began to comment that the moon is sometimes seen also during the day.

## Discussion

The analysis above was meant to demonstrate the kind of insight the presented analytical framework could bring to issues of conceptual change, and to potential instructional implications. Let us look at some of the issues.

It is still common within the science education community to believe that students' understanding involves alternative conceptions that are robust and are an obstacle for learning the scientific model. The two students in this study might be said to have "misconceptions." In fact, their initial explanations are documented in the literature as common misconceptions: 1. "the phases of the moon occur due to the shadow cast on the moon by the Earth" (e.g., Baxter, 1989); 2. "The different phases of the moon are seen from different parts of the Earth" (e.g., Schoon, 1992).

The above analysis demonstrates a more complicated model of students' understanding, built from finer-grained pieces of knowledge, whereas a configuration of these might appear, roughly, as a misconception. Breaking "misconceptions" into smaller elements, the way that is done in this analysis, suggests productive paths of development.

An important element of the analysis is tracing the knowledge pieces that play out in the explanation. What happens to them when the explanation develops? Are they being transformed? Eliminated? Replaced? It is striking that throughout the session there were not many new schemes used. Most of the schemes in the new explanatory frame E, have already been used in previous explanatory frames B, C and D, and are now re-used in new contexts and with new models. For example, the scheme of illumination (scheme C1), applied previously only on the sun-earth model to reason about the day and night, is now applied on the moon-earth model as well to infer how the moon is illuminated.

The significance of this observation lies in supporting the view that student's intuitive knowledge has continuity and productiveness through the process of conceptual change. It demonstrates that students' explanations are compiled from conceptual resources that are neither right nor wrong, although they may be applied appropriately, inappropriately, in composition with other such schemes or in isolation. The same schemes used in one explanatory frame can be re-configured to form a more adequate explanatory frame. In this sense, knowledge is reorganized (rather than replaced) in such a way that existing pieces are modified in terms of the contexts in which they are activated and used. This also means that students' intuitive pieces are also productive in some contexts and should serve as a basis for constructing scientific knowledge (Smith, diSessa & Roschelle, 1993). In addition to the productiveness of previously used schemes and models, previous explanatory frames may also be productive and useful for explaining other contexts. For example, the casting-shadow frame that is not useful for explaining the phases of the moon, can still be productive for explaining other contexts, e.g., eclipse phenomena. This is a process of shifting contexts, rather than knowledge replacement.

The analysis suggests some instructional implications. If students construct understandings that are composed of a cluster of schemes and models to form an explanatory frame that fits with other elements in their knowledge, they are most likely to respond to a provided "right explanation" by developing two explanations: "an explanation that makes sense" (may look like a "misconception") and "a school explanation" (written in exams with no understanding). The KiP approach suggests students' intuitive ideas should be engaged in order to facilitate continuity of understanding. Increasing resolution and increasing range is one example of a way to support this continuity. Such an approach engages both students' previously constructed knowledge structure, and their intuitive knowledge pieces.

## Acknowledgments

I wish to thank Andy diSessa, Mariana Levin, David Hammer, Billie Eilam, and Yael Kali for helpful comments related to this work. I am grateful for a productive discussion with the Patterns group in UC Berkeley. I thank Orly Shapira for help in conducting this research and for editorial work. This work was partly supported by a grant to O. Parnafes by the Tel-Aviv university foundation for research promotion.

# Perceptions of the relationship between evolutionary theory and biblical explanations of the origins of life and their effects on the learning of evolution among high school students

Pratchayapong Yasri, Rebecca Mancy, University of Glasgow, Glasgow, UK
p.yasri.1@research.gla.ac.uk, r.mancy@educ.gla.ac.uk

**Abstract:** This study explores the perceived relationship between evolution and the biblical account of creation amongst Thai high school students in Christian schools and the impact of these perceptions on learning. Evidence was found for the following perspectives: *creation only* and *compartmental (incompatible models); NOMA*, *fusion*, and *complementary (compatible models)*. Each perspective is related to an approach to learning: *rejection* of one explanation, *switching* between explanations instrumentally according to the context, *differentiating* between areas of reality explained by each, *integration* of the explanations and *refinement* of one explanation through the other. Furthermore, students who held *compatible* perspectives had the potential to engage positively with learning about evolution, those adopting a *rejection* approach tended to engage with evolution in order to falsify it and the student who took a *switching* approach demonstrated detached learning. The study therefore provides an example situation in which learning within one discipline affects learning in another.

## Introduction

Evolution is considered to be a unifying theme in biology; however, its development has relied on the combined effort of professionals in disciplines ranging from biology and medicine to physics and geology, engaged in observing, collection and experimentation to enrich and validate the theory. The area is also becoming ever more interdisciplinary as evolutionary models and frameworks are adopted by those working in domains as diverse as the social sciences and informatics. Research in the area therefore not only produces a body of knowledge that is central to the discipline of biology, it also stimulates scientific collaboration between professionals in different fields; teaching of evolution usually takes place in the context of biology, yet it is central to work in a broad range of discipline areas. Nonetheless, despite its inherent interdisciplinary importance as both a subject of study in its own right and a methodological tool, it has always been the subject of considerable debate, partially fuelled by its relationship with another disciplinary area, that of religion.

Specifically, evolutionary theory is perceived by some to directly contradict religious explanations of the origins of life. There has been a recent renewal of debates pertaining to the teaching of the origins of life and evolutionary theory in formal education (Berkman et al, 2008) with a majority of clashes occurring in relation to Christian groups (Padian 2009). We take the perspective that it is important to understand the ways learners perceive the relationship between religious and evolutionary accounts of the origins of life, as well as their impact on learning, in order to develop teaching approaches which simultaneously respect learners' beliefs and allow them to engage positively with evolution. A range of studies have gathered data on learner beliefs but have largely relied on quantitative approaches using pre-defined categories; we explore the relationships from the perspective of learners, allowing categories to arise from the data.

This paper uses a phenomenographic approach to analyze data collected via individual and in-depth interviews, providing evidence of different understandings of the relationship between evolution and creation as perceived by high school students attending Christian schools in Thailand. The findings reveal five different perspectives of the relationship among the students: *creation only, compartmental, NOMA, fusion* and *complementary* perspectives. Each perspective is related to an approach to learning: *rejection* of one explanation, *switching* between explanations instrumentally according to the context, *differentiating* between areas of reality explained by each, *integration* of the explanations and *refinement* of one explanation through the other. Furthermore, each approach reported here gives rise to different ways of engaging with evolution. Those who adopted *differentiating, integration* and *refining* approaches had the potential to engage positively with the lesson whereas those who adopted *rejection* approach tended to engage the lesson in order to falsify it. Finally, the student who took a *switching* approach demonstrated *detached learning* that appeared to take the form of cognitive understanding with little emotional engagement. A model is proposed that links these findings to perspectives from the literature. More generally, the study suggests that, at least in some contexts, learning of disciplinary material is strongly influenced by learning that takes place within other disciplines, with disciplinary epistemology playing a role in this.

This paper begins by presenting models of the relationship between science and religion, as applied to evolution and creation, drawn from the literature. It then explains the methodological approach implemented in this study, followed by findings, discussion and educational implications.

## Background

The word *evolution* is generally associated with Charles Darwin who described the theory of evolution in *On the Origin of Species* (Scott 2005), and more recent developments of this theory. Evolutionary theory explains changes in species of living organisms over time as due to variation amongst individuals and the processes of natural selection (Darwin 1859). In more recent versions of evolutionary theory, variation is claimed to arise randomly with respect to function, with natural selection acting as a directional force that increases the relative frequency of adaptive traits among the population (e.g. Dawkins 1986).

Another explanation of the origin of life is provided in the Bible and other religious texts. Specifically in the context of Christianity, the Bible explains that God created the Universe, the Earth and all living things (Alexander 2008). The explanation has been interpreted in a variety of ways, ranging from the literal to interpretations of the biblical creation story as a metaphor (Scott 2005). These interpretations have different implications for the relationship with the scientific theory of evolution. Although many Christians see no incompatibility between the biblical account and evolutionary theory (for example, those who see the biblical creation story as metaphorical), some interpretations lead to apparent incompatibilities between the scientific and religious claims regarding origins, with those subscribing solely to the religious viewpoint in its strong form often referred to as "creationists".

Various understandings of the relationship between evolution and biblical accounts of the origins of life have been identified with Alexander (2007) describing four models relating science and religion (*conflict, complementary, fusion* and *NOMA* models). We now provide an overview of these models as a backdrop to our own study. Alexander's work appears to be based on broader philosophical perspectives on the relationship between science and religion (e.g. Barbour 2002), but we concentrate on his work as the most recent source identified.

### 1. The conflict model

The first model identified by Alexander (2007) is the *conflict model*, according to which science and religion are considered to be in fundamental opposition. In this view, the two explanations provide incompatible answers to the same fundamental question. We note that this view can be divided into two: *evolution only* and *creation only* models.

The first subcategory maintains that evolution provides a sufficient and convincing explanation of the origins of life and that there is no place for God or supernatural powers in the scientific arena. This view has been shown to be widespread amongst science teachers and students in a number of settings. For instance, Ingram and Nelson (2006) found that over 60 percent of science students at the Midwestern University accepted the explanation of evolutionary biology, but did not accept biblical interpretations. In contrast, proponents of the *creation only* model reject the theory of evolution and accept that in the Bible (Scott 2005). This model is also found to be accepted by professionals in various domains. For example, Berkman *et al.* (2008) reported that 38 percent of American people stated that they would prefer that creation was taught in schools, not just in addition to, but in place of evolution.

### 2. The "*NOMA*" model

The second model is called *NOMA* after the *Non-Overlapping Magisteria* model proposed by Stephen Jay Gould in 2002 (Alexander 2007). In this view, science and religion deal with different domains of reality. Specifically, Gould (2002) suggests that science and religion focus on different fundamental questions: the magisterium of science relates to the facts of empirical data while the magisterium of religion covers questions concerning ultimate meaning and moral value. The two domains do not overlap by definition thus there is no conflict between the two.

This model corresponds to the viewpoint taken by a range of scientists and has been used by science teachers to support the teaching of evolution. For example, Ladine (2009) notes that separating biblical explanations from the theory of evolution enables him to teach evolution in Christian institutions comfortably and allows Christian students to be open to learning about evolution.

### 3. The complementary model

The *complementary model* provides another way in which evolution and creation can be considered as compatible. Alexander (2007, p.4) explains that "this model maintains that science and religion are addressing the same reality from different perspective, providing explanations that are not in any kind of rivalry to each other, but rather are complementary". For example, one instantiation of this model would be that the belief that God directs the processes of evolution. Proponents of this perspective often argue that putting faith and scientific reason together enables us to better understand the whole range of reality (Berry 2007).

### 4. The fusion model

The final model identified by Alexander (2007) is called the *fusion model*. In this approach, there is no clear distinction between the kind of knowledge provided by evolutionary theory and religious explanations: both focus on the same reality and provide the same knowledge. Alexander (2007, p.3) explains that those who take this perspective "tend to blur the distinction between scientific and religious types of knowledge altogether, or attempt to utilize science in order to construct religious systems of thought, or vice versa".

## Aims of this study

The models identified by Alexander (2007) appear to have been identified from theoretical perspectives from the philosophy of science. Although a number of studies provide evidence for the existence of some of these perspectives, these mainly take the form of evaluations of particular curricula or courses. These studies generally rely on quantitative approaches that offer participants pre-defined categories based on the tutors' own experience or theoretical perspectives drawn from the literature. As a result, it may be that additional perspectives, or variants of these, exist amongst the student population. Furthermore, most empirical studies have been carried out in Western countries (USA, UK, EU countries), thus alternative perspectives may arise in other cultural contexts. Of particular importance to education, the ways in which these perceptions influence learning have not been investigated in detail.

The specific research questions addressed in the study were thus as follows: (1) How do Thai students at Christian schools perceive the relationship between evolution and creation? (2) How does their perception of the relationship relate to their account of the learning process in which they engaged while studying evolution?

The study reported here contributes to the broader literature on the educational implications of perceptions of the relationship between evolution and creation by investigating these viewpoints through discussions with students, without providing pre-defined categories. It focuses on developing a deeper understanding of students' perceptions of the relationship between the accounts of the origins of life, as well as on identifying the impacts of these perceptions on their learning of evolution. Because we expected to encounter less polarized responses in a context where the relationship between creation and evolution has been less politicized than in the Western world, we focus our study on students in Christian schools in Thailand where the Christian population generally adheres to Baptism, Presbyterianism and Pentecostalism. This new cultural context also extends our knowledge to beyond the Western world, potentially allowing additional perspectives to be identified.

## Methodology and method

Since this study aims to identify the different ways that students perceive a specific phenomenon – that of the learning of evolution in their Christian school – phenomenography is chosen as a methodological framework for the study and associated data analysis (Marton 1981). A phenomenographic approach is appropriate for an empirical study such as this that aims to understand the ways in which people experience a particular phenomenon (Marton 1981), with particular emphasis on describing, analyzing and understanding the different ways in which people experience a situation from their personal viewpoint (Micari et al 2007). Researchers using phenomenography normally collect data from individual interviews which are transcribed and analyzed to identify common and contrasting perspectives relating to the phenomena of interest (Marton 1981).

Nine high school students, aged 17-18, currently enrolled in Christian schools in Bangkok took part in this study, alongside 2 teachers. In principle, all students should have encountered evolutionary and biblical explanations of the origins of life in the school context as evolution is a compulsory part of the science curriculum and Christian schools provide Bible Study classes that cover origins. To allow participants the freedom to describe freely the relationship between biblical and evolutionary perspectives on the origins of life, the 30-minute semi-structured interviews employed open-ended questions carried out in their schools. The interview consisted of two parts: firstly, the participants were asked to express their belief concerning the relationship between evolution and creation in a general sense; secondly, they were encouraged to talk about their experiences of learning about these in the classroom.

For data analysis, all interview records were transcribed in Thai. Based on the two sections of the interview, participant narratives were analyzed along three dimensions: their general perceptions of the relationship between the two explanations; the ways in which they approached the task of learning about the two explanations; and the types of their engagement with evolution. Similar and contrasting perspectives relating to each dimension were drawn from the narratives by grouping similar statements into categories to allow common themes to arise, whilst differences were also actively sought between descriptions in order to differentiate between participant perspectives.

Findings were also validated by using *data triangulation* and *investigator triangulation* (Marthison 1988). For data triangulation, we considered both the relationship between our findings and those from the philosophical literature and also interviewed teachers. Teachers and students were interviewed using a similar interview schedule; however, students reported on their own perceptions whilst teachers referred to their own position and to the learning of their students via questions relating to the issues they had encountered when teaching about evolution. For investigator triangulation, two researchers were involved in the data analysis that took place in two phases. The first author identified categories of relationship according to processes of phenomenography. Relevant sections were translated into English and the categories identified were compared to those considered in the literature. In the second phase, the categories were further refined in conjunction with the second author using a process of consensus, until both were comfortable. During the second stage, the categories were compared with Alexander's (2007) distinctions.

## Findings

### 1. The relationship between evolution and creation

Analysis of the student narratives provided five perspectives on the relationship between evolutionary and biblical accounts of the origins of life among participants in this group, summarized in Table 1. Four of the perspectives correspond roughly to categories identified by Alexander (2007), while the other has not been described in this context. The first two categories, *creation only* and *compartmental,* are both *incompatible* perspectives, while the remaining three, *NOMA, fusion* and *complementary* are *compatible* perspectives.

Expressing views in relation to the first of the *incompatible* perspectives, four students (Pavee, Prakhun, Nicha, and Thida) explained that they accepted the biblical explanation of God's creation and rejected evolutionary accounts, considering that it is impossible to reconcile the explanations. Three of these students (Pavee, Prakhun, and Nicha) gave their religious beliefs as the reason for their position, whereas Thida instead emphasized purpose, explaining that belief in God's creation gave her life purpose, whereas evolution did not and she was therefore more comfortable with the former. Their view is named *creation only* and corresponds to the subcategory of Alexander's (2007) *conflict model* where evolution is rejected.

Providing evidence for the second of the *incompatible* perspectives, Praporn explained that she viewed evolutionary and creation perspectives as different, but made no attempt to resolve this apparent contradiction, preferring to use the knowledge relating to each instrumentally in the relevant classes, using the different explanations as appropriate according to the context. This perspective, which we call *compartmental*, is not discussed by Alexander (2007) and we can find no evidence for it in the philosophy of science literature. This is perhaps unsurprising since the philosophy literature focuses explicitly on the relationship between science and religion, whereas the student holding this position actively avoids considering the connection.

In the first of the three *compatible* perspectives, Daungjai and Mothana expressed the view that evolution and creation address different kinds of fundamental question and realities: while evolution deals with the facts of scientific evidence, creation deals with religious concerns, such as belief, values and purpose of life. This perspective is named *NOMA* after Gould's (2002) model. Other *compatible* perspectives were held by Sadudee and Apai who believed that scientific and religious explanations pertain to the same reality, but are nonetheless compatible. Specifically, Sadudee appeared to hold a view most closely aligned with a *fusion* model whereby no clear distinction is made between scientific and religious knowledge, suggesting that evolution can be viewed as scientific creation and creation as scientific belief. Finally, Apai explained that he believed that in time, scientific and religious understandings of the world would become aligned, and that science would confirm his religious beliefs, in a way that is reminiscent of Alexander's (2007) *complementary* perspective.

Table 1: Perceptions of the relationship between evolution and creation

| *Category name* | *Representative statements* |
|---|---|
| Conflict (Creation only) | Since evolution is different from the biblical explanation, I do not believe it. […] Science is too small when compared to God. It cannot prove or disprove the existence of God. (Nicha) |
| | Creation is a purposeful plan of God. I am not purposeless any more in this sense. I know where I am from and where I will go after this. So, I am really happy that I am a beloved daughter of God. Although this idea is like children's thought, it can create my happiness. It is impossible that science can explain everything. (Thida) |
| Compartmental | These two theories seem different in various aspects, like time and process. However, I tried to ignore these differences when I studied. (Praporn) |
| NOMA | To me, evolution is a kind of scientific knowledge, but creation is a kind of religious belief. They are fundamentally different. [Science] deals with the matters and evidence. [Religion] deals with people's ethos and values. It explains what the purpose of life is. It teaches us how to be a good person. (Mothana) |
| Fusion | It is possible that God created small living things and let them evolve until they became billions of species as we can see at this moment. However, God is the origin of life, in my opinion. I do not reject evolution. […] We should open our mind to receive a full range of knowledge. [A Christian biology teacher] can make evolution to be scientific creation and make creation to be scientific belief. (Sadudee) |
| Complementary | I believe in creation because I am a Christian. And also, I believe in evolution because it is reasonable. To me, science is about God and God is about science. […] I treat science as a powerful tool to confirm that there is a God. (Apai) |

## 2. Learning approaches

Five approaches were found to be used to negotiate the relationship when learning about the scientific and religious accounts (see Table 2). Firstly, when Pavee, Prakhun and Nicha (*creation only*), learned about evolution in school, they took the Bible as their starting point, comparing new material to their knowledge of the biblical creation story and rejecting other explanations, in approach we name *rejection*. In addition to declining evolutionary theory, they actively engaged with learning about evolutionary theory with the explicit aim to critique the theory in order to reinforce their own religious perspective. Like these students, although Thida (*creation only*) did not learn about evolution in her formal schooling, she consulted books, websites, and people in the church in order to reinforce her belief and argue against evolutionary theory.

Secondly, Praporn (*compartmental*) referred to having two modes of functioning, turning on “the switch of scientific mode” when learning about evolution, and turning it off again when in religious education classes. In relation to her approach when undergoing assessment, she answered questions about evolution as accurately as possible to gain good marks, despite not believing the explanations provided, or wishing to engage with them in a deep way. We name this approach *switching*.

Thirdly, Daungjai and Mothana (*NOMA*) used what we call a *differentiating* approach, attempting first to differentiate between the realms of applicability of the two accounts, and using the distinction to avoid internal conflict and confusion. Daungjai referred to metaphorical interpretations of the Bible in generating the distinction, whereas Mothana referred to the role of religion being to inform moral decisions and values.

Fourthly, Sadudee (*fusion*) was interested in finding the *integration* of evolution and creation and ways in which to coherently combine evolution and creation, suggesting that perhaps God had created life and that evolution explains the development of life forms into the broad range of species existing today.

Finally, Apai (*complementary*) was interested in learning about evolution and the complexities of life almost as *refinement* of the existence of God, claiming that when aspects of the two perspectives appeared not to correspond, that this was because of the current limitations of our scientific knowledge. For him, science is a powerful tool to allow human beings to see God more clearly.

Table 2: Approaches for negotiating the relationship in learning contexts

| *Approach* | *Representative statements* |
|---|---|
| Rejection | I think it is better to know both explanations. It is because I can know how others think about evolution. I want to know more as I can find reasons to reject it. (Prakhun) |
| | God is the truth. What he says is an ultimate truth. Other explanations that oppose to the biblical account must be wrong. I have to deny them. (Thida) |
| Switching | In a science class, I tried to be a science person by answering all questions about evolution scientifically. When I studied about creation in a religion class, I turned the switch of scientific mode off and turned the religion one on. I tried to be a religious person. I answered everything according to religious beliefs. (Praporn) |
| Differentiating | They have different purposes. So, what I really did was I tried to differentiate both of them first. And then, I tried to understand which aspects that evolution wants to deal with and which aspects that creation tries to imply. (Mothana) |
| Integration | What I am looking for is the intersection between evolution and creation (Sadudee) |
| Refining | My stance is I will not immediately reject what I do not understand. I will think that it might be possible in some way. Although I cannot entirely understand how evolution and creation can be perfectly matched, I think it might be possible in the future. I treat science as a powerful tool to confirm that there is a God. I just think that there is a God and He is the truth. And then, other findings will verify His existence. (Apai) |

## 3. Types of engagement with evolution

Data analysis demonstrated that the perspectives and approaches above can be linked to at least three different types of engagement with evolutionary theory and the understandings that arise from them: *engagement*, *learning to falsify* and *detached learning* (see Table 3).

Firstly, all students who held *compatible* perspectives (*NOMA, fusion and complementary*) appeared to be positively engaged with learning about evolution, claiming that their perspective helped them to avoid confusion and demonstrating enthusiasm and interest in the area. Whilst those with a *NOMA* perspective were interested in evolution principally for the scientific knowledge itself, those taking a *fusion* or *complementary* perspective also saw learning about evolution as a way of clarifying their understandings of religion. Secondly, those who hold a *conflict* view explained that they were actively engaged in their studies or studied outside of the classroom with the explicit aim of learning more about evolution in order to critique evolutionary explanations and thus strengthen arguments for their religious viewpoint, engaging with the primary purpose of *learning to falsify*. Finally, the student who took a *compartmental* view demonstrated *detached learning*, only acquiring knowledge about evolution because it was part of the school curriculum.

Table 3: Types of engagement with evolutionary theory

| *Type* | *Representative statements* |
|---|---|
| Engagement | I did not feel uncomfortable or want to reject it. In contrast, it was exciting to know how evolutionary processes work. The more I can see how science is complicated, the more I am sure that there is a |

| | |
|---|---|
| | God. As the Bible says, God is the source of wisdom. He gave the wisdom to us in order to let us see His works. (Apai) |
| Learning to falsify | There was no negative impact on my study at all. I even could get a good grade in that term. Basically, I am confident with God's creation. But I also wanted to know about evolution so that I can argue against it. (Pavee) |
| | At that time, I did nothing, as I did not want to create any controversial issue in the class. However, in my mind, I already rejected it. Then, I tried to ask my friend's father and other people in the church about this. They gave me a lot of information. […] In addition, I read many books that support what I believe. I tried very hard to protect my belief. I stopped doing that when I felt that I did not wonder about the existence of God anymore. (Nicha) |
| Detached learning | In a science class, I tried to be a science person by answering all questions about evolution scientifically. When I studied about creation in a religion class, I turned the switch of scientific mode off and turned the religion one on. I tried to be a religious person. (Praporn) |

## Discussion and implications

In relation to earlier work, the study described here allows for the identification of additional perspectives not demonstrated in other empirical research. Based on the findings and in relation to the four models proposed by Alexander (2007), we claim that there are two primary ways of viewing the relationship between evolution and creation: *incompatible* and *compatible*. Figure 1 provides an overview of the findings, linking together perspectives on the relationship between evolution and creation, approaches to learning and engagement with evolution, as well as situating these within other perspectives in the literature.

In the *creation only* perspective, creation is accepted and evolution is not considered to provide an acceptable explanation; in the *evolution only* perspective, evolution is judged to be plausible and religious accounts are rejected; in the *compartmental* perspective, both explanations are considered to be internally consistent but are in conflict with one another, with no decision made as to the veracity of each. Although the first two models are discussed by Alexander (2007) and others, the *compartmental* model appears not to have arisen in earlier work and we suggest that it should be added as a subcategory of the *incompatible* perspectives. Furthermore, the data collected in this study therefore demonstrate the existence of incompatible amongst Christian students in Thailand, despite the background of Buddhist communities and the less politicized context.

The findings also reveal at least three categories of *compatible* perspectives, corresponding to those identified by Alexander (2007): *NOMA*, *fusion* and *complementary*. Students taking the *NOMA* perspective consider that evolution and creation are addressing different kinds of question and through seeking the different aspects of reality to which each explanation applies, avoid conflict. Students who hold a *fusion* view, do not seek distinctions, but rather attempt to integrate the two explanations through blending, perceiving no clear distinction between them. Finally, students taking a *complementary* viewpoint look for complementarities between the explanations and consider them to be mutually supportive. The data provide empirical evidence for the existence of all three compatible perspectives amongst Thai high school biology students.

The categories indentified above were triangulated by interview data given by two biology teachers working at the Protestant school who had both been teaching biology for at least 5 years, and at least one of whom had taught evolution to the four students from the sample who were studying at this school. The teachers themselves appeared to hold a *NOMA* perspective. Moreover, they provided a third-person perspective on student learning describing examples of situations that correspond to *conflict*, *fusion* and *complementary* perspectives amongst their students. For example, one teacher stated that 'some of my students declined answering exam questions scientifically but they wrote their point of view instead, for example, God created all things (*conflict* perspective) and that 'some of them answered the questions according to scientific explanations discussed in the class but they concluded that all of those are controlled by God (*fusion or complementary*).

The different perspectives and associated learning approaches identified appear to give rise to a range of ways of engaging with evolutionary theory, which in turn support different educational outcomes for the students (see Figure 1). According to our proposed model, those students taking one of the *compatible* perspectives (*NOMA, fusion* and *complementary*) are able to learn about evolution without any conflict with their religious beliefs. These perspectives support either neutral or positive relationships between the learning that goes on in these two disciplines. However, students holding the *incompatible* viewpoints demonstrate different kinds of influences on their understanding and engagement. Not surprisingly, it was among students who interpreted the Bible literally that serious misconceptions (Scott 2005) were identified:

> Evolution is about monkeys and humans. It claims that we are from monkeys. Natural selection is the reason why those monkeys could be humans. Those monkeys tried to adapt themselves to environments in which they lived. (Thida)

More subtly, despite rejecting evolution, some students who *learn to falsify* (and potentially also those using *switching*) may demonstrate convincing understanding of evolution:

> There was no negative impact on my study at all. I even could get a good grade in that term. Basically, I am confident with God's creation. But I also wanted to know about evolution so that I can argue against it and answer questions related to the topic. […] I actually should feel bored while I was studying. But it is not true. On the contrary, I was really keen to learn it. […] It is weird, I know, that I wanted to know in order to reject it. (Pavee)

Although Pavee appears to have understood evolutionary theory sufficiently to do well on the course, his learning is qualitatively different from that of students who accept evolution as accurate.

In his introduction to the *Cambridge Handbook of the Learning Sciences*, Sawyer (2005, p.2) emphasizes the educational importance of "deeper conceptual understanding", contrasting this with factual and procedural knowledge. However, the comments from students and teachers indicate that conceptual understanding does not necessarily lead to acceptance of evolutionary theory. As educators, we need to ask the question of the kind of learning – conceptual understanding or acceptance – we aspire to engender, as well as the moral implications of these intentions in a context where disciplinary knowledge may potentially threaten belief systems that are important to learners. There is evidence to suggest that some pedagogical approaches can support the acceptance of evolutionary theory without threatening religious beliefs. However, it is interesting to recognize that although accepting evolution as plausible may be a prerequisite to studying evolutionary biology, it may be possible to use evolutionary approaches as a methodology in other areas (such as the social sciences) whilst rejecting biological evolution. Indeed, approaching evolution from this perspective may even provide new pedagogical approaches.

At present, one of the most promising pedagogical approaches, as described in Ladine (2009), is the explicit exploration of the NOMA model with students. Ladine (2009) explains to students that he values religious studies as moral development and science as the discipline for naturalistic explanation, and provides evidence that this approach gives rise to positive engagement with evolution amongst his students. In an open-ended question that formed part of a course evaluation questionnaire, students of a private Christian college in the US explained that they had learnt that "evolution doesn't take God out of the picture," "learning that evolution and religion can coexist," and "that evolution may not really be as much of an evil lie as I have always been taught" (Ladine 2009, p.391).

Alternative pedagogies based on the other approaches associated with *compatible* perspectives – *integration* and *refining* – may also be developed. However, it is necessary tread carefully in this area. It was slightly surprising to us to realize that although three students (Pavee, Nicha and Sadudee) noted that evolutionary theory explains changes in species over time and is therefore not strictly concerned with origins of life (biogenesis), two of these students (Nicha and Sadudee) nonetheless rejected evolution. In other words, being explicit about this particular aspect of integration is not sufficient to allow students to accept evolutionary theory as they can nonetheless see conflicts in relation to other aspects, including timescale and purpose.

Even if we do not see the need for students to appropriate evolutionary theory, using an approach such as that described by Ladine (2009) may nonetheless be easier to justify on ethical grounds than leaving students to generate their own understandings of the relationship, as this can lead to a state of uncomfortable confusion:

> To be honest, I am confused, as I don't know what is true. However, I try to ignore that. I try not to think about it too much. As I know, if I ask biology teachers, of course, they will use scientific evidence to explain it to me. If I ask religious teachers, they are going to let me read what the Bible says. There is no way to find their compatibility. So, it is better to keep quiet and forget it. (Praporn)

Finally, however, it is our hope that explicitly addressing the relationship between the two disciplines in order to encourage more sophisticated understandings of this may be to engender greater respect amongst learners in the classroom.

It is important to note some limitations of this study. The dataset was limited primarily due to political unrest in Thailand in 2009 at the time of data collection, making data collection from a larger sample, or indeed follow-up interviews, impossible. A single interview with each participant, is, however, reasonable in the context of this study since we intended to capture student positions at a single time point, rather than to establish how these changed over time. Since we were interested in their perceptions (a first-person account), the primary data source was student interviews, although two teachers were also interviewed. The nature of phenomenography, which aims primarily to develop well-defined categories of experience of a particular phenomenon, means that at least at early stages, these may constitute only a subset of categories that exist, and that furthermore, individuals included in the sample may be, in fact, unique. This does not detract from the validity of the study itself, but makes it difficult to generalize the results until further investigation has been carried out. Our claim is that the perspectives described have been uncovered; however, we make no claim as to their relative prevalence in the population either amongst the larger population from which they were drawn (high schools students at Christian schools in Thailand) or more generally.

More generally, the findings reported here reveal that at least in some areas, learning within one discipline can be strongly influenced by knowledge and learning within another: specifically, theology is shown to impact on scientific understandings. In line with Gould's (2002) claims about the different types of knowledge associated with religion and science, this impact may have its roots in the epistemology of science and religion more generally.

Indeed, Ladine (2009), while discussing perspectives of evolution and creation asserted that including God in the explanation of science indicates misunderstanding of the nature of science. It is therefore interesting to note a tendency amongst those students holding *compatible* perspectives to refer to science and religion more generally in their comments, despite being asked about evolution and creation.

For researchers, this study demonstrates the importance of an interdisciplinary approach to the study of learning in real world contexts. Specifically, it highlights the significance of disciplinary understandings of the nature of knowledge and reality, and informs theory in the learning sciences by exploring their effects on conceptual understanding of disciplinary material. In order to support student understanding and acceptance of disciplinary knowledge, we need to view our practice not as isolated within a discipline, but take account of its position in relation to knowledge and epistemologies appropriate to other disciplines. As educators, we need to be aware of the possible interactions between the epistemological paradigms underlying the disciplines in which we teach in order to address any conflicts sensitively and intelligently.

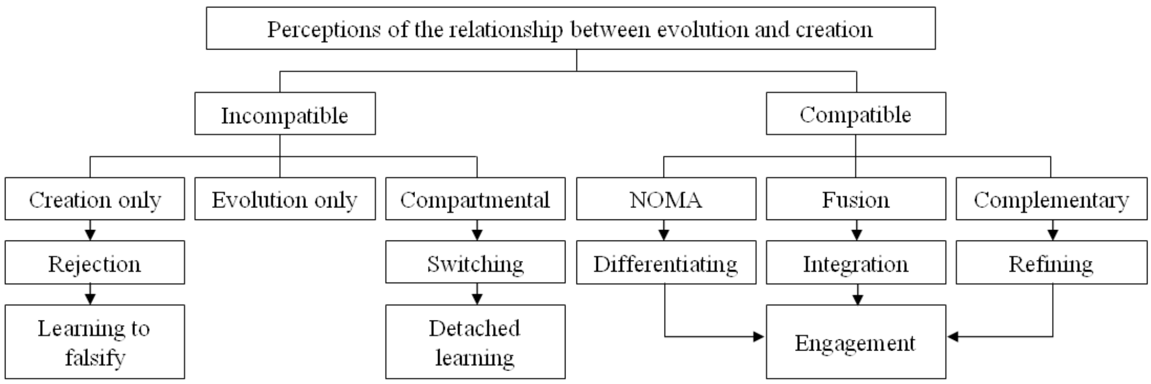

Figure 1: Proposed model relating the relationship between evolution and creation

## Acknowledgment

We would like to thank to the Royal Thai Government for the financial support provided to the first author throughout this study.

# Interactional Achievement of Shared Mathematical Understanding in a Virtual Math Team

Murat Perit Cakir, Gerry Stahl, Alan Zemel
Drexel University, 3141 Chestnut St, Philadelphia PA
mpc48@drexel.edu, gerry.stahl@drexel.edu, arz56@drexel.edu

**Abstract:** Learning mathematics involves specific forms of social practice. In this paper, we describe socially situated, interactional processes involved with collaborative learning of mathematics in a special online collaborative learning environment. Our analysis highlights the methodic ways group members enact the affordances of their situation (a) to visually explore a mathematical pattern, (b) to co-construct shared mathematical artifacts, (c) to make visible the meaning of the construction, (d) to translate between graphical, narrative and symbolic representations and (e) to coordinate their actions across multiple interaction spaces, while they are working on open-ended math problems. In particular, we identify key roles of referential and representational practices in the co-construction of deep mathematical group understanding. The case study illustrates how mathematical understanding is built and shared through the online interaction.

## Introduction

Developing pedagogies and instructional tools to support learning math with understanding is a major goal in mathematics education (NCTM, 2000). A common theme among various characterizations of mathematical understanding in the math education literature involves *constructing relationships* among mathematical facts and procedures (Hiebert & Wearne, 1996). In particular, math education practitioners treat recognition of connections among *multiple realizations* of a math concept encapsulated in various inscriptional forms as evidence of deep understanding of that subject matter (Kaput, 1998; Sfard, 2008; Healy & Hoyles, 1999). For instance, the concept of function in the modern math curriculum is introduced through its graphical, narrative, tabular, and symbolic realizations. Hence, a deep understanding of the function concept is ascribed to a learner to the extent he/she can demonstrate how seemingly different graphical, narrative, and symbolic forms are interrelated as realizations of each other in specific problem-solving circumstances that require the use of functions. On the other hand, students who demonstrate difficulties in realizing such connections are considered to perceive actions associated with distinct forms as isolated sets of skills, and hence are said to have a shallow understanding of the subject matter (Carpenter & Lehrer, 1999).

*Multimodal interaction spaces*—which typically bring together two or more synchronous online communication technologies such as text-chat and a shared graphical workspace—have been widely employed in CSCL research and in commercial collaboration suites such as Elluminate and Wimba to support collaborative learning activities of small groups online (Dillenbourg & Traum, 2006; Soller, 2004; Suthers et al., 2001). The way such systems are designed as a juxtaposition of several technologically independent online communication tools not only brings various *affordances* (i.e. possibilities-for and/or constraints-on actions), but also carries important interactional consequences for the users (Cakir, Zemel & Stahl, 2009; Suthers, 2006; Dohn 2009). Providing access to a rich set of modalities for action allows users to demonstrate their reasoning in multiple semiotic forms. Nevertheless, the achievement of connections that foster the kind of mathematical understanding desired by math educators is conditioned upon team members' success in devising shared methods for coordinated use of these rich resources.

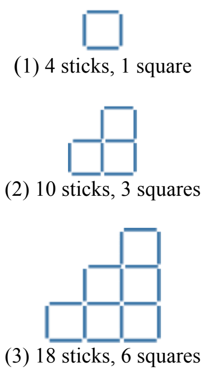
Although CSCL environments with multimodal interaction spaces offer rich possibilities for the creation, manipulation, and sharing of mathematical artifacts online, the interactional organization of mathematical meaning-making activities in such online environments is a relatively unexplored area in CSCL and in math education. In an effort to address this gap, we have designed an online environment with multiple interaction spaces called Virtual Math Teams (VMT), which allows users to exchange textual as well as graphical contributions online (Stahl, 2009). The VMT environment also provides additional resources, such as explicit referencing and special awareness markers, to help users coordinate their actions across multiple spaces. Of special interest to researchers, this environment includes a Replayer tool to replay a chat session as it unfolded in real time and inspect how students organize their joint activity to achieve the kinds of connections indicative of deep understanding of math.

In this paper we focus on the practical methods through which VMT participants achieve the kinds of connections across multiple semiotic modalities that are often taken as indicative of deep mathematical understanding. We take the math education practitioners' account of what constitutes deep learning of math as a starting point, but instead of treating understanding as a mental state of the individual learner that is typically inferred by outcome measures, we argue that deep mathematical understanding can be located in the practices of collective multimodal reasoning displayed by teams of students through the sequential and spatial organization of their actions. In an effort to study the practices of multimodal reasoning online, we employ an ethnomethodological case-study approach and investigate the methods through which small groups of students coordinate their actions across multiple interaction spaces of the VMT environment as they collectively construct, relate and reason with multiple forms of mathematical artifacts to solve an open-ended math problem. Our analysis has identified key roles of referential and representational practices in the co-construction of deep mathematical understanding.

## Data & Methodology

The excerpts we analyze in this paper are obtained from a problem-solving session of a team of three upper-middle-school students who participated in the VMT Spring Fest 2006. This event brought together several teams from the US, Singapore, and Scotland to collaborate on an open-ended math task on combinatorial patterns. Students were recruited anonymously through their teachers. Members of the teams generally did not know each other before the first session. Neither they nor we knew anything about each other (e.g., age or gender) except chat handle and information that may have been communicated during the sessions. Each group participated in four sessions during a two-week period, and each session lasted over an hour. Each session was moderated by a Math Forum staff member; the facilitators' task was to help the teams when they experienced technical difficulties, not to instruct or participate in the problem-solving work. Figure 6 below shows a screenshot of the VMT Chat environment that hosted these online sessions.

During their first session, all the teams were asked to work on a particular pattern of squares made up of sticks (see Figure 1 below). For the remaining three sessions the teams were asked to come up with their own shapes, describe the patterns they observed as mathematical formulae, and share their observations with other teams through a wiki page. This task was chosen because of the possibilities it afforded for many different solution approaches ranging from simple counting procedures to more advanced methods, such as the use of recursive functions and exploring the arithmetic properties of various number sequences. Moreover, the task had both algebraic and geometric aspects, which would potentially allow us to observe how participants put many features of the VMT software system into use. The open-ended nature of the activity stemmed from the need to agree upon a new shape made by sticks. This required groups to engage in a different kind of problem-solving activity as compared to traditional situations where questions are given in advance and there is a single "correct" answer—presumably already known by a teacher. We used a traditional problem to seed the activity and then left it up to each group to decide the kinds of shapes they found interesting and worth exploring further (Moss & Beatty, 2006; Watson & Mason, 2005).



| N | Sticks | Squares |
|---|---|---|
| 1 | 4 | 1 |
| 2 | 10 | 3 |
| 3 | 18 | 6 |
| 4 | ? | ? |
| 5 | ? | ? |
| 6 | ? | ? |
| ... | ... | ... |
| N | ? | ? |

**Session I**

1. Draw the pattern for N=4, N=5, and N=6 in the whiteboard. Discuss as a group: How does the graphic pattern grow?
2. Fill in the cells of the table for sticks and squares in rows N=4, N=5, and N=6. Once you agree on these results, post them on the VMT Wiki
3. Can your group see a pattern of growth for the number of sticks and squares? When you are ready, post your ideas about the pattern of growth on the VMT Wiki.

**Sessions II and III**

1. Discuss the feedback that you received about your previous session.
2. **WHAT IF?** Mathematicians do not just solve other people's problems - they also explore little worlds of patterns that they define and find interesting. Think about other mathematical problems related to the problem with the sticks. For instance, consider other arrangements of squares in addition to the triangle arrangement (diamond, cross, etc.). **What if** instead of squares you use other polygons like triangles, hexagons, etc.? Which polygons work well for building patterns like this? How about 3-D figures, like cubes with edges, sides and cubes? What are the different methods (induction, series, recursion, graphing, tables, etc.) you can use to analyze these different patterns?
3. Go to the VMT Wiki and share the most interesting math problems that your group chose to work on.

**Figure 1:** Task description for Spring Fest 2006

Studying the collective meaning-making practices enacted by the users of CSCL systems requires a close analysis of the process of collaboration itself (Stahl, Koschmann & Suthers, 2006; Koschmann, Stahl & Zemel, 2007). In an effort to investigate the organization of interactions across the dual-interaction spaces of the VMT environment, we consider the small group as the unit of analysis (Stahl, 2006), and we apply the methods of Ethnomethodology (EM) (Garfinkel, 1967; Livingston, 1986) and Conversation Analysis (CA) (Sacks, 1962/1995; ten Have, 1999) to conduct case studies of online group interaction. Our work is informed by studies of interaction mediated by online text-chat with similar methods (Garcia & Jacobs, 1998; O'Neill & Martin, 2003), although the availability of a shared drawing area and explicit support for deictic references in our online environment as well as our focus on mathematical practice significantly differentiate our study from theirs.

The goal of Conversation Analysis is to make explicit and describe the normally tacit commonsense understandings and procedures group members use to organize their conduct in particular interactional settings. Commonsense understandings and procedures are subjected to analytical scrutiny because they "enable actors to recognize and act on their real world circumstances, grasp the intentions and motivations of others, and achieve mutual understandings" (Goodwin & Heritage, 1990, p. 285). Group members' shared competencies in organizing their conduct not only allow them to produce their own actions, but also to interpret the actions of others (Garfinkel & Sacks, 1970). Since members enact these understandings and/or procedures in their situated actions, researchers can discover them through detailed analysis of members' sequentially organized conduct (Schegloff & Sacks, 1973).

We subjected our analysis of VMT data to intersubjective agreement by conducting numerous CA data sessions (ten Have, 1999). During the data sessions we used the VMT Replayer tool, which allows us to replay a VMT chat session as it unfolded in real time based on the timestamps of actions recorded in the log file. The order of actions—chat postings, whiteboard actions, awareness messages—we observe with the Replayer as researchers exactly matches the order of actions originally observed by the users. This property of the Replayer allows us to study the sequential unfolding of events during the entire chat session. In short, the VMT environment provides us a perspicuous setting in which the mathematical meaning-making process is *made visible* as a joint practical achievement of participants that is "observably and accountably embedded in collaborative activity" (Koschmann, 2001, p. 19).

## Analysis

The following sequence of drawing actions (Figures 2 to 6 below) is observed at the beginning of the very first session of a team in the VMT environment. Shortly after a greeting episode, one student, Davidcyl, begins to draw a set of squares on the shared whiteboard. He begins by drawing three squares that are aligned horizontally with respect to each other, which is made evident through his careful placement of the squares side by side (see Figure 2 below). Then he adds two more squares on top of the initial block of three, which introduces a second layer to the drawing. Finally, he adds a single square on top of the second level, which produces the stair-step shape displayed in the last frame of Figure 2. Note that he builds the pattern row-by-row here.

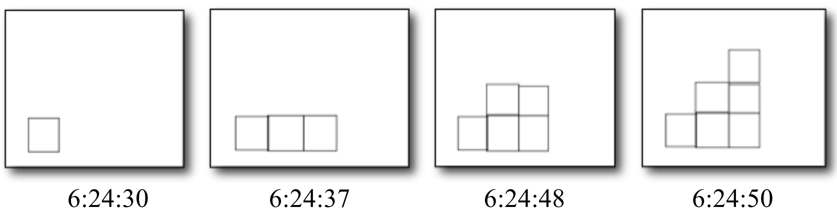


**Figure 2:** First stages of Davidcyl's drawing activity.

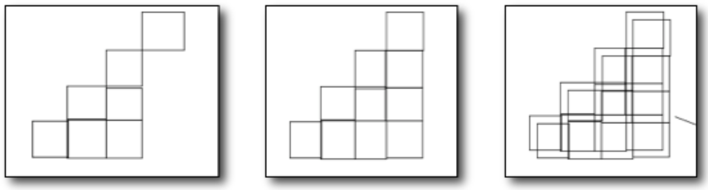
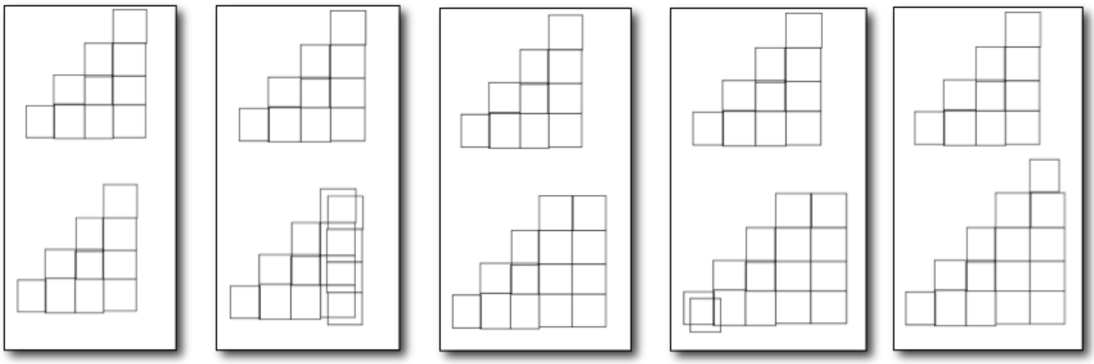
Next, Davidcyl starts adding a new column to the right of the drawing (see Figure 3). He introduces a new top level by adding a new square first, and then he adds 3 more squares that are aligned vertically with respect to each other and horizontally with respect to existing squares (see second frame in Figure 3). Then he produces a duplicate of this diagram by using the copy/paste feature of the whiteboard (see the last frame in Figure 3). Here, he builds the next iteration by adding a new column to the previous stage, starting the new column by making visible that it will be one square higher than the highest previous column.

Afterwards, Davidcyl moves the pasted drawing to an empty space below the copied diagram. As he did earlier, he adds a new column to the right of the prior stage to produce the next stage. This time he copies the entire 4$^{th}$ column, pastes a copy next to it, and then adds a single square on its top to complete the new stage (Figure 4). Next, Davidcyl produces another shape in a similar way by performing a copy/paste of his last drawing, moving the copy to the empty space below, and adding a new column to its right (see Figure 5). Yet, this time the squares of the new column are added one by one, which may be considered as an act of counting. In Figure 4, the new column is explicitly shown to be a copy of the highest column plus one square. In Figure 5, the number of squares in the new column are counted individually, possibly noting that there are N of them. The likelihood that the counting of the squares in the new column is related to the stage, N, of the pattern is grounded by Davidcyl's immediately subsequent reference to the diagrams as related to "*n=4,5,6*".



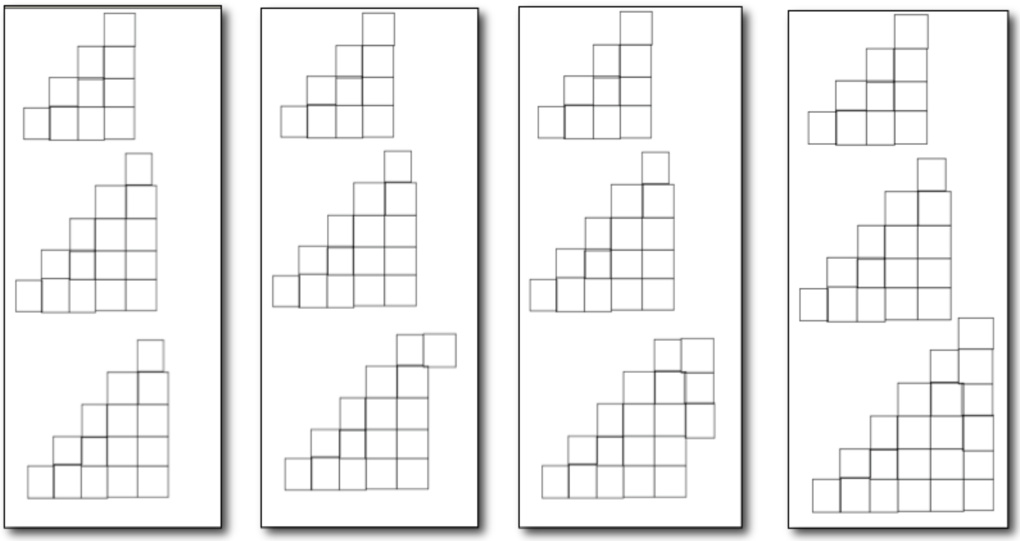
6:24:51 6:25:00 6:25:07

**Figure 3:** Davidcyl introduces the 4th column and pastes a copy of the whole shape.



6:25:13 6:25:42 6:25:45 6:25:47 6:25:52

**Figure 4:** Davidcyl uses copy/paste to produce the next stage of the pattern



6:26:04 6:26:10 6:26:14 6:26:20

**Figure 5:** Davidcyl's drawing of the 6th stage

Shortly after his last drawing action at 6:26:20, Davidcyl posts a chat message stating, "*ok I've drawn n=4,5,6*" at 6:26:25. Figure 6 shows the state of the interface at this moment. The "*ok*" at the beginning of the message could be read as some kind of a transition move (Beach, 1995). The next part "I've drawn" makes an explicit verbal reference to his recent (indicated by the use of past perfect tense) drawing actions. Finally, the expression "*n=4,5,6*" provides an *algebraic gloss* for the drawings, which specifies how those drawings should be seen or treated. Once read in relation to the task description, Davidcyl's recent actions across both spaces can be treated as a response to the first bullet under session 1, which states "Draw the pattern for N=4, N=5, and N=6 in the whiteboard" (see Figure 1 above for the task description). The discussion that immediately followed Davidcyl's drawings and his last chat statement is displayed in Table 1 below.

Davidcyl's posting at line 26 is stated as a declarative, so it can be read as a claim or assertion. The references to "*n*" (i.e., not to a particular stage like 2nd or 5th) invoke a variable as a gloss for referring to the features of the general pattern. Moreover, the use of the clause “more…than” suggests a comparison between two things, in particular the two cases indexed by the phrases “*nth pattern*” and *“(n-1)th pattern*” respectively. Hence, Davidcyl’s posting can be read as a claim about how the number of squares changes between the $(n-1)^{th}$ and $n^{th}$ stages of the pattern at hand. The two cases compared in the posting correspond to two consecutive stages of the staircase pattern. Davidcyl’s prior drawing work included similar transitions among pairs of particular stages. For instance, while he was drawing the $4^{th}$ stage, he added a column of 4 new squares to the right of the $3^{rd}$ stage. Hence, Davidcyl’s narrative uses the drawings for particular cases as a resource to index the properties of the general pattern, which is implicated in the regularity/organization projected by his prior drawing actions.

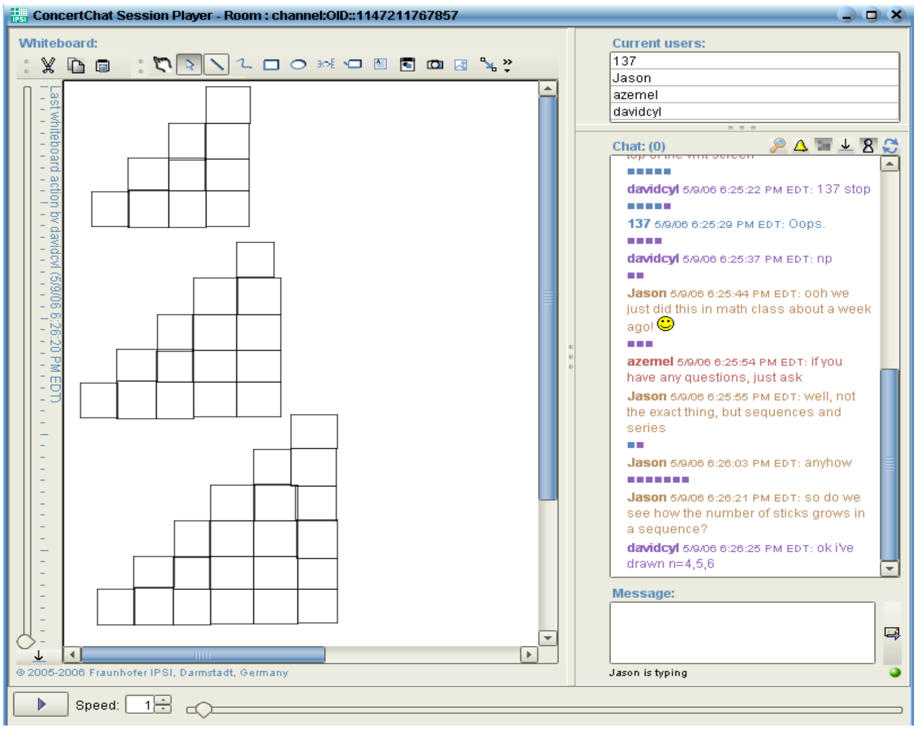


**Figure 6:** The state of the VMT environment when Davidcyl posted “ok I’ve drawn n=4,5,6” at 6:26:25.

**Table 1:** Chat discussion following the drawing activity

| Chat Index | Time Start Typing | Time of Posting | Author | Content |
|---|---|---|---|---|
| 26 | 18:27:13 | 18:27:32 | davidcyl | the nth pattern has n more squares than the (n-1)th pattern |
| | 18:27:30 | 18:27:47 | 137 | *[137 has fully erased the chat message]* |
| | 18:27:47 | 18:27:52 | 137 | *[137 has fully erased the chat message]* |
| 27 | 18:27:37 | 18:27:55 | davidcyl | basically it's 1+2+..+(n-1)+n for the number of squares in the nth pattern |
| | 18:27:57 | 18:27:57 | 137 | *[137 has fully erased the chat message]* |
| 28 | 18:28:02 | 18:28:16 | 137 | so n(n+1)/2 |
| 29 | 18:27:56 | 18:28:24 | davidcyl | and we can use the gaussian sum to determine the sum: n(1+n)/2 |
| 30 | 18:28:27 | 18:28:36 | davidcyl | 137 got it |

In the next line, Davidcyl elaborates on his description by providing a summation of integers that accounts for the number of squares required to form the $n^{th}$ stage. In particular, the expression “*1+2+..+(n-1)+n*” describes a method to count the squares that form the $n^{th}$ stage. Since Davidcyl made his orientation to columns explicit through his prior drawing work while he methodically added a new column to produce a next stage, this expression can be read as a *formulation* of his column-by-column counting work in algebraic form. In other words, Davidcyl achieves a (*narrative*) transition from the *visual* to the *algebraic*, which is informed by his methodic construction of specific stages of the staircase pattern that allowed him to isolate relevant components of the general pattern and derive a systematic counting method.

As Davidcyl composes a next posting, 137 posts a so-prefaced math expression at line 28, "*So n(n+1)/2*" that (a) shows 137 has been attending to the organization of Davidcyl’s ongoing exposition, (b) displays 137's recognition of the next problem-solving step projected by prior remarks, (c) offers an algebraic realization of the procedure described by Davidcyl, and (d) call on others to assess the relevance and validity of his claim. Davidcyl's message at line 29 (which is produced in parallel with line 28 as indicated by the typing times) is a more elaborate statement that identifies how his prior statements, if treated as a Gaussian sum, yield the same expression that 137 put forward at line 28 (viz. "n(n+1)/2"). Given that 137 anticipated Davidcyl's Gaussian sum, Davidcyl announces in the very next posting that "*137 got it,*" which recognizes the relevance of 137's posting at that particular moment in interaction, and treats 137's coordinated contribution as an act of understanding.

## Discussion

Given the characterization of deep mathematical understanding in the math education literature, methodic ways through which participants coordinate their actions across the whiteboard and chat spaces are of particular interest to our investigation of mathematical understanding or meaning making at the small-group level. The episode we analyzed above includes a situation where a user, who has been active in the whiteboard, moves on to the other interaction space and posts a message referring to his prior drawing work. The chat message sequentially followed the drawings, and hence presumed their availability as a shared referential resource, so that the interlocutors can make sense of what is possibly referred to by the indexical expression "*n=4,5,6*" included in the posting. Davidcyl's explicit orientation to timing or sequencing is further evidenced by his use of the past perfect tense and his temporal positioning of the message immediately after the final step of the drawing. Moreover, the chat posting reflexively gave further specificity to the prior drawing work by informing everyone that the diagrams should be seen as specific cases of the staircase pattern described in the task description. This suggests that temporal proximity among actions can serve as an interactional resource/cue for the participants to treat those actions in reference to each other, especially when the actions are performed across different interaction spaces. In short, Davidcyl has demonstrated a *method* that one can call *verbal referencing*, which is employed by VMT users when they need to communicate to each other that a narrative/symbolic account needs to be read in relation to a whiteboard object.

Davidcyl's use of the algebraic reference "*n=4,5,6*" at this moment in interaction is also informative in terms of respective limitations of each medium and their mutually constitutive function for communication. Davidcyl's chat message not only provided further specificity to the recently produced diagrams, but also marked or announced the completion of his drawing work. This is revealing in terms of the kinds of *illocutionary acts* (Austin, 1962) that can be achieved by users in this dual-media online environment. In particular, although a drawing and its production process may be available for all members to observe in the shared whiteboard, diagrams by themselves cannot fulfill the same kind of interactional functions achieved by text postings such as "asking a question" or "expressing agreement." In other words, whiteboard objects are made interactionally relevant through chat messages that either (a) project their production as a next action or (b) refer to already produced objects. This can also be seen as members' orientation to a limitation of this online environment as a communication platform; one can act only in one space at a given time, so it is not possible to perform a simultaneous narration of a drawing as one can do in a face-to-face setting. Therefore, each interaction space as a communicative medium seems to enable and/or hinder certain kinds of actions, i.e., they carry specific *communicative affordances* (Hutchby, 2001) for collaborative problem solving online.

The way Davidcyl has put some of the features of the whiteboard —like dragging and copy/paste—into use in the episode described above demonstrates some of its key affordances as a medium for producing shared drawings. In particular, we have observed how copying and pasting is used to avoid additional drawing effort, and how collections of objects are selected, dragged, and positioned to produce specific stages of a geometric pattern. Such possibilities for action are supported by the object-oriented design of the whiteboard. Davidcyl's drawing actions show that, as compared to other physical drawing media such as paper or blackboard, the electronic whiteboard affords unique possibilities for constructing and modifying shared mathematical diagrams in ways that have mathematical, collaborative, semantic and communicative power.

It is analytically significant that Davidcyl changed from building the pattern row-wise in Figure 2 to building it column-wise subsequently and that he "computed" the height of the new column in several different ways in Figures 3, 4 and 5. This indicates that he did not have an explicit solution "in his head"—a mental model that he just had to illustrate in the world with the whiteboard. Rather, he worked out the solution gradually through emergent whiteboard activities and his recognition of what appeared in the whiteboard. Significantly, the other group members could observe the same thing.

An important concern for our group-cognitive approach is to investigate how students make use of the technological features available to them to explore mathematical ideas in an online environment like VMT. Drawing features such as copy/paste, dragging, coloring, etc. are important affordances of the shared whiteboard not simply because of their respective advantages as compared to other drawing media. The mathematical significance of these features relies on the way single actions like copy/paste or dragging are sequentially organized as part of a broader drawing activity that aims towards constructing a shared mathematical artifact. For instance, through such a sequence of drawing actions Davidcyl demonstrated to us (as analysts) and to his peers (a) how to construct a stair-step pattern as a spatially organized assemblage of squares, and (b) how to derive a new stage of the stair-step pattern from a copy of the prior stage by adding a new column of squares to its right. Moreover, Davidcyl's engagement with the squares (rather than with the sticks that make up the squares) displays his explicit orientation to this particular aspect of the shared task (i.e., finding the number of squares at a given stage). Hence, the availability of these drawing actions as a sequence of changes unfolding in the shared visual space allows group members to witness the *reasoning* process embodied in the sequential and spatial organization of those actions. In other words, the sequentially unfolding details of the construction process provide specificity (and hence meaning) to the mathematical artifact that is being constructed.

Besides figuring out ways to connect their own actions across dual-interaction spaces, VMT users also coordinate their actions with the actions of their peers to be able to meaningfully participate in the ongoing discussion. The ways participants produce and deploy mathematical artifacts in the shared space implicate or inform what procedures and methods may be invoked next to produce other mathematical artifacts, or to modify existing ones as the discussion progresses towards a solution to the task at hand. For instance, 137's competent contribution to Davidcyl's sequentially unfolding line of reasoning in Table 1 shows that shared mathematical understanding at the group level is an interactional achievement that requires coordinated *co-construction* of mathematical artifacts. The *co* prefix for the term "co-construction" highlights the *intersubjective* nature of the mathematical artifacts produced during collaborative work; they are not mere mental constructs easily ascribed to certain individuals. As we have just observed in the excerpt above, *intersubjectivity* is evidenced in the ways participants organize their actions to display their relevance to prior actions. 137's anticipation and production of the next relevant step in the joint problem-solving effort serves as strong evidence of mutual understanding between him and Davidcyl. Moreover, the term *construction* signals that mathematical artifacts are not simply passed down by the mathematical culture as ready-made Platonic entities external to the group. Once enacted in group discourse, culturally transmitted artifacts such as "Gaussian Sum" need to be made sense of and appropriated in relation to the task at hand. Hence, our use of the combined term *co-construction* implies an interactional process of sense making by a group of students—even in an excerpt like the present one in which one individual takes an extended turn in the group discourse to develop a complex presentation. The fact that it is a visible construction worked out in collaborative media and designed for reception by others makes it a co-construction from which the speaker is as likely to learn as are the other group members.

When co-construction takes place in an online environment like a chat tool, the construction process must take place through observable interactions within technical media. This requires student groups to invent, adapt or appropriate methods to co-construct mathematical artifacts. It also makes it possible for them to explicitly reflect on the *persistent traces* of their co-constructions by investigating the persistent content provided by the technology. Therefore, the persistent nature of actions provides the necessary infrastructure for joint action, and hence is a key affordance of CSCL environments like VMT, where actors work at a distance in a disembodied environment. In addition, the persistent records of interactions also allow researchers to analyze the co-construction process as it unfolded in real-time, as this paper demonstrates.

Through similar case studies of other VMT sessions, we observed that students make use of additional resources (such as the explicit referencing tool, locational pronouns, color names in chat) to methodically achieve referential relationships between shared diagrams and chat messages (Cakir, Zemel & Stahl, 2009). Chat postings use a broad and sophisticated array of such methods to refer to matters constructed graphically. Due to their recurrent appearance as a practical concern for the participants in this dual-media online environment, we refer to the collection of these methods as *referential practices*. Referential practices are of particular importance to the study of mathematical understanding as a group-cognitive phenomenon, because they are enacted in circumstances where participants explicitly orient to the task of achieving relationships between the textual and graphical contributions that they have been exchanging online—a phenomenon that is given significance in the math education literature as characterizing deep mathematical understanding. Likewise, one can use the term *representational practices* to refer to the spatial and temporal organization of whiteboard actions that produce shared diagrams, which simultaneously give further specificity to the mathematical artifacts that the team has been working on—e.g., Davidcyl's methodical sequencing of copy/paste operations to indicate growth patterns. Through referential and representational practices, participants co-construct mathematical artifacts that reify mathematical understandings. The understanding or meaning is not simply located inside students' individual brains or in the chat/drawing artifacts themselves. The meaning is embodied in the sequentially organized and coordinated actions through which those artifacts were co-constructed. To sum up, group referential and representational practices play a key role in the ways mathematical artifacts are (a) appropriated by active teams from historically developed cultural tools, and (b) emergent from ways of communicating and symbolizing within local collectivities as shared, meaningful resources for mathematical discourse, collaborative learning and group understanding.

**Abstract:** The Scaling Up SimCalc project implemented three large-scale studies designed to evaluate the impact of a Learning Sciences-based replacement unit targeting student learning of advanced middle school mathematics. Strong main effects in each study consistently showed the approach to be effective in enabling a wide variety of teachers in a diversity of settings to extend student learning to more advanced mathematics. In this paper, we take a closer look at *equity* of learning, the extent to which students within and across subgroups and classrooms had comparable learning gains. We describe four different patterns of equity and inequity that have emerged in our hierarchical linear modelling and in-depth case studies. We then present a number of conjectures about possible mechanisms by which opportunity to learn may be unevenly distributed between and within classrooms engaged in the same replacement unit. We discuss implications for instructional design, research methodology, and Learning Sciences theory.

## Introduction

In an on-going research program, we have been studying large-scale implementations of the Learning Sciences-based SimCalc approach to integrating representational technology, curriculum workbooks, and teacher professional development (see Roschelle et al., in press). The SimCalc program's slogan, "Democratizing Access to the Mathematics of Change and Variation," suggests a significant concern with equity (Kaput, 1994). Indeed, the design experiment research preceding our current large-scale work focused deliberately on giving diverse students in traditionally underperforming settings an opportunity to learn more advanced mathematics concepts. Hence, design experiments were conducted in diverse and economically challenged places such as Fall River, Massachusetts; Syracuse, New York; Newark, New Jersey; and San Diego, California (Roschelle, Tatar, & Kaput, 2008). This concern with equity was also reflected in the subsequent large-scale experiments, which occurred in Texas. We deliberately recruited schools in multiple regions of Texas to reflect that state's considerable economic, linguistic, and ethnic diversity (Roschelle et al., in press).

Equity has been an elusive goal in the reform of mathematics education. For example, prior research found that middle- to higher-achieving students benefitted from instruction that focused on integrating concepts and procedures, but lower-achieving students did not (Baxter, Woodward, & Olson, 2001); and achievement gaps in mathematics between white students and non-white students persist (Neal, 2005). Furthermore, there are competing definitions of equity (Lynch, 2000). Does it involve providing high-quality resources for all classrooms, ensuring that learning activities have ways for all students to participate meaningfully, closing achievement gaps, or perhaps some combination of these things? In this paper, we explore equity in the context of a large-scale implementation of a Learning Sciences–style approach, one integrating dynamic representations and visualizations to address learning of more advanced mathematical constructs.

After providing a brief overview of the program of research, we examine equity in the Scaling Up SimCalc Project. First, we describe four patterns of equity and inequity we have observed related to student achievement. We use a variety of indicators across multiple units of analysis. Second, we consider a variety of conjectured explanations for inequitable classrooms that are emerging in ongoing data analyses. Two highlighted conjectures are blocked access to learning resources and teacher talk that is not responsive to students and does not place a high level of intellectual demand on students. Other possible explanations for inequity are also considered.

## Overview of the Scaling Up SimCalc Project

The Scaling Up SimCalc Project (Roschelle et al., in press) implemented two randomized controlled experiments (with one embedded quasi-experiment) designed to address the broad research question, "Can a wide variety of teachers use an integration of technology, curriculum, and professional development to increase student learning of complex and conceptually difficult mathematics?" There were two interventions, one for seventh grade and one for eighth grade. Each intervention integrated the representational technology SimCalc

MathWorlds, curriculum workbooks, and teacher professional development organized around a 2-3 week replacement unit on rate, proportionality, and linear function. The replacement units incorporated the following hallmarks of the SimCalc approach to the mathematics of change and variation:

1. Anchoring students' efforts to make sense of conceptually rich mathematics in their experience of familiar motions, which are portrayed as computer animations.
2. Engaging students in activities to make and analyze graphs that control animations.
3. Introducing piecewise linear functions as models of everyday situations with changing rates.
4. Connecting students' mathematical understanding of rate and proportionality across key mathematical representations (algebraic expressions, tables, graphs) and familiar representations (narrative stories and animations of motion).
5. Structuring pedagogy around a cycle that asks students to make and compare their predictions.

The SimCalc MathWorlds software provides a "representational infrastructure" (Kaput, Hegedus, & Lesh, 2007) that is central to enabling this approach. Most distinctively, the software presents animations of motion. Students can control the motions of animated characters by building and editing mathematical functions in either graphical or algebraic forms. The program developers view student use of the software and teacher explanations and teacher-led discussions as complementary activities.

In the scaling research, across over 100 seventh- and eighth-grade classrooms throughout the state of Texas, the main effects of the treatment in the three main studies were positive, with student-level effect sizes of .63, .50 and .56; classrooms that used a SimCalc replacement unit had students who learned more advanced mathematics.

## Four Patterns of Equity and Inequity

Programs can be more or less equitable at a variety of levels. While overall there were robust learning gains, here we drill down more deeply at demographic and regional levels, as well as the classroom level, to examine three patterns of equity and inequity.

### 1. Equity at the Demographic and Regional Levels

As Figure 1 shows, at the highest level of aggregation, we found learning gains to be equitable across major demographic and regional groups. In the treatment group, we found no statistically significant differences in gains between gender or ethnic groups, or among students in schools serving different levels of socioeconomic populations. We also found no differences among geographic regions. This is particularly notable for "Region 1" of Texas, which covers the Rio Grande Valley along the Mexican border and has a high-poverty population mainly of Mexican descent. The effects of SimCalc were similar in this region to those in other regions sampled in the study (e.g., the more cosmopolitan regions near the state capital, Austin). These findings of equity were replicated in the Eighth-Grade study (see Roschelle et al., in press).

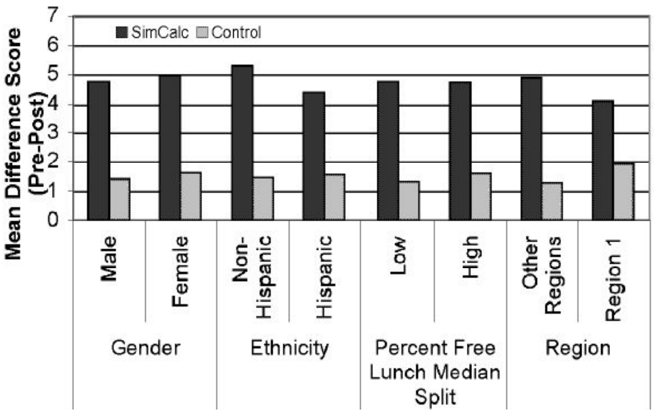

Figure 1. Mean student-learning gains by subpopulation group (Seventh-Grade Study).

### 2. Within-Classroom Spread of Learning Gains

While equity of learning occurred at this highly aggregated level, at the classroom level, do students learn equitably? To begin to examine this issue, we discuss the work of Empson, Greenstein, Maldonado, and Roschelle (2009) who report comparative case studies of three teachers who participated in the Seventh-Grade Study and taught with the SimCalc replacement unit. Two of the teachers, "Ms. Garfield" and "Ms. Driver" (pseudonyms), had mean classroom gains at or above the average mean gain found in the treatment group. The third teacher, "Mr. Simmons," had a mean classroom gain that was lower than the average by a third of a standard deviation. Note that mathematical knowledge for teaching (MKT) was not a predictor of student learning in these three cases. Mr. Simmons scored the highest of the three on our MKT assessment. Indeed, he was a former computer specialist. In a more detailed analysis of MKT we argue that MKT is just one of a variety of resources in the classroom instructional system (Shechtman, Roschelle, Haertel, & Knudsen, in press).

To investigate equity, we examine two aspects of learning in the classroom: overall gains and variation between students in gains. As Figure 2 shows, while the median gain in Mr. Simmons' class was relatively low, there was also a notable spread in achievement among his students. A few students performed very well in this classroom, but many students did much more poorly. In the two other cases, gains were both higher and less variable (as evidenced by less spread) among students. If one defines equity as equal learning gains for *all* students, then Mr. Simmons' classroom illustrates inequity.

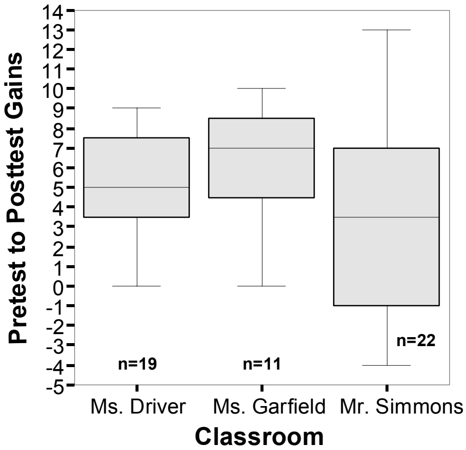

Figure 2. Boxplots of distributions of student gains on the 30-item assessment across the case study classrooms.

## 3. Within-Classroom Pretest-Posttest Slopes Tend to Be Steeper in Lower-Achieving Classrooms

Another approach to investigating equity is by examining the relationship within a classroom between students' prior knowledge (i.e., their pretest scores) and their learning gains. Pierson's (2008) dissertation investigated some of these patterns across classrooms. To illustrate, Figure 3 shows student achievement data in which each student is represented by an ordered pair where the x-coordinate represents his or her pretest score, and the y-coordinate represents the corresponding posttest score. The figure displays such data and best-fit regression lines for two classrooms. The variable of interest with respect to equity is the pretest-posttest achievement slope. Some classrooms have steeper slopes and some have flatter slopes. In other words, pretest scores are stronger determinants of achievement in some classrooms. Some claim that more equitable classrooms are those in which the pretest-posttest slope is closer to 0. In other words, *all* students achieve equally regardless of their prior knowledge.

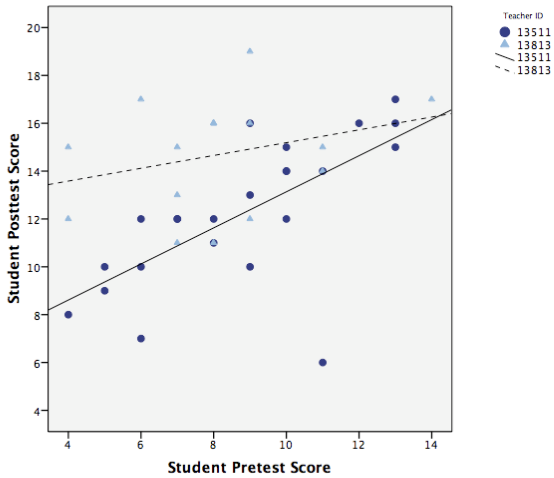

Figure 3. Scatter plot and regression lines for student pretest and student posttest scores in two SimCalc classrooms.

Pierson found in her HLM model a negative relationship between the mean achievement and pretest-posttest slopes at the class level ( $\tau_{01} = -.4309$). In other words, the higher the class posttest average, the smaller the pre-post achievement slope.[1] Classrooms that learned more overall (i.e., had higher average posttest scores) also learned more equitably.

### 4. The "Low-Low" Effect

We also investigated equity of learning across students' prior achievement levels (both as rated by their teachers and indicated by their pretest scores). We asked teachers to rate their students as low, medium, or high achieving prior to using the SimCalc replacement unit. Analyses found that the teachers' rating accurately predicted outcomes: students designated by their teacher as low-achieving learned less. Of course, the opposite effect would be desirable: if teachers knew which students were low-performing, it would be preferable for those students to receive *more* resources and guidance so that they could learn more.

More broadly, we are investigating a "low-low effect," designated as such because it appeared for low-ranked students in classrooms with low pretest means. We found this effect in both our Seventh- and Eighth-Grade studies, but for brevity we only present the Seventh-Grade data in Figure 4. Three graphs are presented side by side, representing classrooms with low-, medium-, and high-mean pretest scores (based on a tertile split across the treatment group). Each graph plots the teachers' categorization of their students (as low, medium, or high achievers) against the mean of those students' gain scores. The students in the low classroom have a particular pattern: low students in low classrooms had the lowest gains.

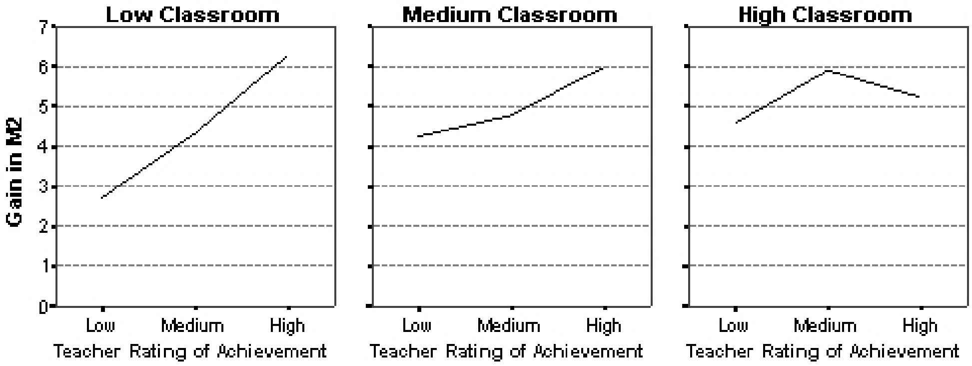

Figure 4. The "low-low effect" in the Seventh-Grade treatment group.

We have built an HLM of this phenomenon, and it is statistically significant in both our Seventh- and Eighth-grade studies. For each study, we ran an HLM of student gains, nesting students within classrooms. We then constructed the model using classroom mean pretest scores as a predictor at the classroom level and indicator variables of teacher-rated student achievement level (low and middle levels, with high level as the reference category) as predictors at the student level. To test for the low-low effect, we examined the coefficient for the interaction between classroom pretest and the indicator for low-achieving student. This coefficient was positive and significant in both the seventh-grade study ($\beta = 0.29$, $p < .05$) and the eighth-grade study ($\beta = 0.40$, $p < .001$), indicating the presence of the low-low effect. We also tested the same model on control classrooms where SimCalc materials were not used and found no presence of low-low effect. This suggests that the low-low effect is specific to the SimCalc materials.

We are in the process of investigating the low-low effect more deeply to examine possible alternative explanations for this phenomenon, including the possibility that it is an artifact of some kind. For example, it could be that only low classrooms have students with extremely low pretest scores. And it could be that students need a certain level of knowledge at baseline in order to engage meaningfully with the curriculum, or that teachers need certain additional skills to use these materials that engage lower-achieving students. For present purposes, the important point is that we see this as an indication of more and less equitable implementations of the SimCalc replacement unit.

## Conjectured Mechanisms of Within-Classroom Equity and Inequity

While our research was not designed to pinpoint particular mechanisms that produce more or less equitable classroom implementations, empirical analyses have produced a number of candidate explanations.

### 1. Blocked Access to Learning Resources during Instruction

One conjecture that has emerged in Empson et al.'s (2009) case studies is that some teachers may block learning resources from students, thus causing inequitable learning opportunities. This grows out of the idea that

SimCalc can work in multiple configurations of learning resources. Full class discussion around a shared simulation display, guided by a knowledgeable teacher, can be one kind of resource. Individual student activities with the software, guided by a workbook, can be another kind of resource. Empson and her team found that Ms. Garfield and Ms. Driver each had classroom implementations which featured different configurations of resources. What was distinctive about Mr. Simmons was that he blocked access to both full class discussion and individual student activities for many students. For example, Mr. Simmons concentrated whole-group discussion on interaction with a small subset of vocal boys, who made over 10 times more contributions than rest of the class. He also curtailed students' interactions with SimCalc by specifying each step to take in running the simulation and by requiring students to frequently turn away from the computers. Blocking access to resources in these ways decreased students' opportunities to engage meaningfully with the content and to make substantive connections on their own.

The pattern of blocking access was also prominent in Dunn's case studies in the Eighth-Grade study (Dunn, 2009). One teacher, "Marilyn," had particularly low student gain scores. She was on the low end of the range in total time allocated to teaching with the SimCalc materials, and she skipped more material than the other teachers. In particular, Marilyn seemed to have a pattern of beginning each day's class with a new workbook lesson, regardless of whether there had been sufficient time to complete the previous workbook lesson in the previous class sessions. As the workbook was designed to build ideas sequentially, skipping material in this way could block coherent development of mathematical ideas. Marilyn also was at the high end of the spectrum for the time spent introducing students to ideas via lecture, with a tendency to "walk" students through significant portions of each workbook lesson, in most cases at the beginning of class. This preempted independent student interaction with these portions, and compromised the time available for subsequent autonomous student work and class discussion/teacher feedback on this later work. This uneven allocation of time and guidance blocked consistent access and, once again due to the sequential design of the materials, may also have blocked coherent development of the unit's mathematical ideas.

The complement to the idea of blocked access is the idea of multiple learning resources and multiple configurations of learning opportunities. It could be that a key design principle for equity on a large scale is to provide multiple means for students to engage with the big ideas within the same intervention.

## 2. Favorable Teacher Discourse Moves

A second major conjecture examines the role of particular types of teacher talk in the classroom – responsiveness to student ideas and how much intellectual work they demand of students. Pierson's (2008) dissertation used HLM to examine teacher discourse across 13 teachers who taught using SimCalc materials. In particular, Pierson analyzed videotapes and transcripts of the same SimCalc lesson for all teachers. She developed the ideas that teachers (a) can be more or less responsive[2] to their students and (b) can demand more or less intellectual work[3] from their students. Using a slightly different HLM model than that described above for the low-low effect, she ran her analysis on student posttest achievement scores, nesting students within classrooms. She used classroom discourse variables as predictors at the classroom level and pretest achievement scores as a predictor at the student level.

There were two findings relevant to this discussion of equity. First, Pierson found that both high responsiveness and high intellectual work correlate with classroom-level *gains*. Second, these factors also correlated with the pretest-posttest slope (see discussion above). Specifically, Pierson found that an *increase* of 10% in highly responsive moves corresponded to a *decrease* in the class's pretest-posttest slope of .29. Interestingly, responsiveness and intellectual work seem to be factors in more equitable classrooms, as shown by a decrease in the impact of pretest scores on posttest achievement.

Although Pierson's study showed good evidence *that* high levels of responsiveness and intellectual work have a positive relationship with more equitable patterns of achievement, we should consider *how* these discursive constructs might be related to equity. We hypothesize the following three more refined mechanisms as possible links between equitable achievement and patterns of discourse.

First, discussions high in responsiveness and intellectual work can act as formative assessments, which research indicates is positively related to student learning (Fennema et al., 1996; Wiliam, Lee, Harrison, & Black, 2004). These types of discourse moves afford teachers opportunities to gather evidence of student understanding in order to adjust and customize instruction, resulting in better learning opportunities for everyone.

Second, repeated patterns of responsiveness and intellectual work in classroom discourse socialize students into specific ways of being. These normative discourse patterns communicate expectations for how to engage with one another (listening to, learning from, and critiquing others' ideas); expectations about learning (mistakes are a natural process in learning; and learning is about thinking, not remembering); and beliefs about one's own abilities. Students, particularly low-achieving students, are likely to develop increased confidence, motivation, persistence, and more positive mathematical identities as their ideas are valued, taken up, and extended.

Third, high levels of intellectual work and responsiveness create classroom cultures that require students to routinely work on cognitively demanding tasks that require argumentation, justification, and cognitive struggle. The teachers' role here is critical in that they must uphold the expectation that all students will generate their own solutions and explain them, position students as capable problem solvers, and carefully orchestrate student involvement in classroom discussions. Creating this type of learning community might benefit students with lower levels of prior knowledge reduce that gap and achieve at levels comparable with their peers at the top of the class.

## 3. Emerging Conjectures in Other SimCalc Case Studies

Other case studies conducted in the context of the Scaling Up SimCalc studies are still underway:

- Work by Michelle McLeese and Deborah Tatar considers the social climate of the classroom. This study is exploring the idea that certain forms of laughter signal a more positive social climate and contribute to better learning outcomes.
- Another study, by Meg Kurdziolek and Deborah Tatar considers the configuration of technology in the classroom. For example, they observed SimCalc implementations in a computer lab, with a laptop cart in the teacher's regular classroom, and with only one computer per classroom. Surprisingly, the implementation in the classroom with only one computer was successful; the teacher found ways to actively involve all students despite the resource limitation. They also have found instances where a classroom has more computers and students work in pairs, but a more dominant partner blocks engagement of a less dominant partner. Likewise, both Dunn (2009) and Empson et al. (2009) observed classrooms with a sufficient number of computers where student activity with the computer was routinely interrupted or blocked by the teacher, leading to poor outcomes. At the very least, this suggests that analysis of equity in relationship to the numbers of computers in a classroom needs to take into account pedagogical adaptations and patterns of student interaction when they work in small groups.
- We are also analyzing workbook materials collected in diverse classrooms, containing student work. Preliminary analysis of these workbooks has found strong correlations from students' pretest scores to the completeness and correctness of their workbooks. This may suggest an equity concern that students who begin with higher math scores are better prepared to use the workbooks. Furthermore, because completing relevant portions of the student workbook is correlated with student gains, providing more support to students who are falling behind in completing the workbook might contribute to more equitable outcomes.

As these additional studies mature, they may contribute more nuance to our concepts of access to learning resources and favorable teacher discourse moves, or may contribute additional equity-relevant constructs.

## Discussion

Equity is an important policy objective and often an important goal in the design of interventions resulting from Learning Science theories and design experiments.

By presenting results from the Scaling Up SimCalc work, we have highlighted a few key ideas:

1. Equity and inequity occur simultaneously on different levels and scales; equity may be present at some levels and absent in others.
2. Classroom implementations of the same intervention can be more or less equitable.
3. A range of mechanisms may contribute to equity and inequities in particular classroom interventions.

With regard to the last point, we identified two relevant mechanisms. First, even the best designed learning resources are not useful if students' access to those resources is blocked. Second, when teachers are responsive to student ideas and engage students in doing public intellectual work, all students seem to benefit, not just those students that the teacher is interacting with. However, findings pertaining to students in the low-low effects cases suggest that additional teacher development may be needed in order for instruction to support lower-achieving students' productive engagement with the content. We need to know more about how the teaching knowledge and practices are involved in being responsive and posing questions with high intellectual demand for these students.

These observations may benefit *design*: if we become aware of different sources of inequity, we may be able to design features into the intervention to mitigate some. For example, we could give teachers more guidance about making SimCalc resources available to students in multiple configurations and giving them time to use the materials autonomously.

The observations may also benefit *method.* We suggest that a mix of large-scale experimental designs with embedded case studies is a particularly fruitful method to ferret out issues of inequity, for a few reasons. Large-scale studies can be designed with a structure that captures data at the multiple levels at which equity and inequity can occur. For example, our designs considered the regional, school, classroom, and student levels. Hierarchical linear modeling can highlight cross-level patterns of inequity; some classrooms may have flatter slopes correlating student pretests to gains (i.e., more equitable outcomes), while other classrooms have steeper slopes (e.g., the rich get richer). Case studies, however, are also important for detecting mechanisms of inequity. For instance, it was far from obvious to us at the beginning of the experiments that we might see one-computer-per-classroom implementations that were more equitable than implementations with multiple computers.

We also suggest that this research could lead to fruitful paths in Learning Science *theory*. Although much Learning Science research looks at discourse, less looks at the implications of various classroom discourse strategies for equity. The finding that responsiveness and intellectual demand may help level the playing field in the classroom suggests that the subject of teacher discourse moves is worthy of further investigation.

Overall, we are encouraged about the range of settings in which we found equitable outcomes and energized by the potential to better pinpoint sources of inequity and to better address them in future design iterations.

## Endnotes

[1] A ceiling effect is unlikely because highest average pretest score for any class in Pierson's study was 9.00 points/problems (out of 18 possible) with the average pretest score across all classes being 5.877 points (*s* = 2.28).

[2] *Responsiveness* is an attempt to understand what another is thinking displayed in how one builds, questions, clarifies, takes up, or probes that which another says.

[3] *Intellectual work* reflects the cognitive work requested from students with a given turn of talk. High levels of intellectual work extend thinking and include discursive moves, such as providing justifications, examples, conjectures, explanations, and challenges; making connections across representations; generating problems and scenarios (contextualizing); or requesting these activities from students.

# Distributed Creativity Within a Community of Student Instructional Designers

**Abstract:** This study explored the development of a Communities of Innovation (COI) framework for understanding distributed creativity within a community of graduate student instructional designers. After presenting distributed creativity as a theory of collaborative creativity based on established principles of distributed cognition, I present the Communities of Innovation framework as a potential representation of distributed creativity. I then discuss a study where phenomenological interviewing (Seidman, 2006) and Critical Incident Technique (Flanagan, 1952), were used to explore the experiences of four members of a graduate community of designers with many characteristics emblematic of COIs. Findings included evidence for the inclusion of some aspects of the proposed COI framework. In addition, I identify challenges and recommendations to establishing a COI within a graduate educational setting and possible new directions for research using a variety of different methods to better understand the nature of COIs and how to effectively develop them.

## Understanding Distributed Creativity

Creativity research has often replicated and adapted the theoretical frameworks and research methodologies of cognitive science. For example, creativity researchers have drawn on cognitive principles such as knowledge and memory structures, representations, interference, and so on (for example, see Smith, Ward, & Finke, 1995) in an effort to try and understand the nature of human creativity. However, when cognitive scientists began exploring the potential distribution of cognition across multiple people, creativity researchers largely remained behind. While some writers explored the relationship between individual creativity and the overall system (Csikszentmihalyi, 1999) or the group or workplace climate (Amabile, Conti, Coon, Lazenby, & Herron, 1996; Anderson & West, 1996), few have studied the creative process in distributive terms. More recently, there has been a stronger emphasis on group, or collaborative, creativity—a trend offering great promise for traits increasingly valued in our society (West, 2009).

In this paper presentation, I first discuss key principles necessary for understanding the theory of distributed cognition. I then extend Sawyer and DeZutter's (2009) application of these principles to the concept of distributed creativity and discuss the Communities of Innovation framework as an example of distributed creativity. Finally, I discuss findings from a study of a community of student designers where distributed creativity was theorized to occur. I conclude with implications from this research for the design and research of distributed creativity within student communities.

## Distributed Cognition

Distributed Cognition theories emerged in the 1990s as companions to situated cognition theories, and in fact bear many similar definitions, constructs, and theoretical foundations (Moore & Rocklin, 1998). Researchers developed this theory as an alternative to traditional information processing models of cognition, which often neglected the impact of social variables, by integrating ideas from anthropology, social psychology, sociology and the Russian cultural-historical school of psychology (Cole & Engestrom, 1993). Salomon (1993) believed there were three reasons for the development of distributed cognition theories: 1) the increasingly important role of technology for intellectual tasks—something that has grown exponentially true since Salomon's original essay, 2) the re-emphasis on Russian cultural-historical theories, and 3) dissatisfaction with the limitations from conceiving of cognition as bounded within individuals.

In the past two decades of theoretical and research-based work on distributed cognition theories, different conceptualizations have emerged. For example, Hutchins (1995) wrote that socially distributed cognition has a parallelism that can't be found in individual processing because multiple complex tasks can be simultaneously completed within a system, but not within an individual. Second, tools (including language) always mediate communication between persons in a system, and this creates a problem of the "bandwidth of communication" (p. 284) between members of the system. Hutchins gave the example of a complex navigation system that had some cognitive processes held interpsychologically between the system members that could "never be internalized by a single individual" (P. 284). Hutchins believed that "all divisions of labor, whether the labor is physical or cognitive in nature, require distributed cognition in order to coordinate the activities of the participants" (p. 176). Nardi (1996) added the understanding of "functional systems" to redirect analysis to the systems level, or the level of individuals and artifacts, and the coordination between these two. He explained that distributed cognition focused on structure, or representations, both inside and outside a person's individual cognition. Another way of conceptualizing distributed cognition might be through the kinds of interactions used to distribute the processing. For example, Hwang, Hsu, Tretiakov, Chou, and Lee (2009) explored the roles of interaction (productive collaboration), overaction (social, off-task, but necessary conversation between people), and intra-action (distributing thinking within one person through note taking, tool use, etc.). They found that intra-action had the strongest relationship with learning outcomes, suggesting the particularly important role that tools and non-human systems can play in cognition.

Moore and Rocklin (1998) summarized distributed cognition as representing two different frameworks. The first, "individual-plus," conceives of cognition as primarily residing within individuals but influenced by, and occasionally distributed among, the interacting social and artifact (tools) systems. Moore & Rocklin explained that this perspective conceptualizes cognitions as "divided among an individual, objects, and other people" (p. 107).

A second framework described by Moore and Rocklin (1998) is that of the "social-only" perspective, which conceives of cognition as so thoroughly distributed that one cannot speak of cognition as an individual process because it resides within the group. This brings a realization that "not only do social and other situational factors have an impact on cognitions that occur in one's mind, but that the social processes *themselves* should be considered cognitions (Greenberg & Dicketman, 2002, p. 19, emphasis in original). Cole and Engeström (1993) expanded this framework with a description of Activity Theory, emphasizing cognition and problem solving as occurring through the interactions between individuals, the environment, and the tools or artifacts (conceptual and physical) of the environment. From this view, the "natural unit of analysis for the study of human behavior is activity systems" (p. 9)—or in other words, the study of cognition within social contexts. Thus, when discussing distributed cognition, there are various interpretations of how distributed the cognitive processes must be, leaving room for additional research and clarification.

## Theoretical Application to Distributed Creativity

Traditionally, the psychological study of creativity focused on individual perspectives, taking its cue from information processing cognition models (Mandler, 1995). A trend towards representing individual creativity with cognitive terms and models has also gained support (Smith, Ward, & Finke, 1995; Ward, Smith, & Finke, 1999). However, beginning in the late 1980s and 1990s, some creativity researchers started describing creativity in ways similar to the "individual-plus" model of distributed cognition. For example, Csikszentmihalyi (1999) developed a systems model of creativity, explaining that individual creativity is influenced and defined by the system in which it resides. Other researchers explored the role of the social climate within an organization that might enable innovation (Anderson and West, 1996; Amabile et. al, 1996), or how knowledge is structured and managed within creative enterprises (McAdam, 2004).

Sawyer and DeZutter (2009) have recently described distributed creativity differently, in a way comparable to the *social cognition* branch of distributed cognition. They argue that "creativity is embedded in social groups" and "significant creations are almost always the result of complex collaborations" (p. 81). They defined distributed creativity as pertaining to collaborating groups that collectively produce a creative product, in either predictable and constrained, or unpredictable and unconstrained, environments. They believe that collaborative emergence, or the unpredictable and unexpected emergence of distributed creativity, occurs when activities have unpredictable outcomes; interdependency within the group such that a person's actions are influenced and constrained by the actions of others; and collaboration (equal member contribution).

A possible framework representing Sawyer and DeZutter's conception of distributed creativity within adult learning and working communities could be that of Communities of Innovation (West, 2009). This framework was developed by combining principles drawn from theoretical and research-based discussions in psychology, social learning theory, and organizational development. It proposes that innovation emerges in communities that have the following characteristics:

- Dynamic expertise, characterized by "continuous efforts to surpass one's earlier achievements and work at the edge of one's competence" (Hakkarainen, Palonen, Paavola, & Lehtinen, 2004, p. 243)
- Group flow, which Sawyer (2008) described as including: 1) a shared goal, 2) close or deep listening to each other, 3) complete concentration, 4) being in control of the group's actions and environment, 5) blending of individual egos, 6) equal participation, 7) members' familiarity with each other, 8) constant communication, 9) elaboration of each others' ideas, and 10) frequent failure (and learning from failure).
- Entrepreneurship and ownership. Innovative communities need to develop the unique type of environment that allows enough structure to keep the community together and focused, but enough flexibility to allow individual members to take ownership over their own projects and ideas (Coakes & Smith, 2007; McFadzean, O'Loughlin, & Shaw, 2005)

- Inquiry. Hakkarainen et al. (2004) found that "all models of innovative knowledge communities . . . highlight the role of problems and questions that guide the process of knowledge creation" (p. 197).
- Group reflectiveness. Hakkarainen et al. (2004) argued that both interpersonal and intrapersonal reflection was important and others incorporated similar ideas in their models (Bielaczyc & Collins, 2006; Engeström, 1999; Sawyer, 2008).
- Diversity. Justesen (2004) described diversity in techne and cognition as so critical that she described it as "innoversity." Others have echoed these sentiments (Bielaczyc & Collins, 2006).
- New community boundaries, visions, and goals. In COIs, it is more likely that members network with persons both within and outside the community (Sawhney & Prandelli, 2000) and are less controlled by management and typical beauracracy (Benton & Giavagnoli, 2006).
- "Hacker"-like motivation. Himanen (2001) and Raymond (2003) explained that hackers care deeply about their work and quality, becoming so intensely motivated by their projects that it becomes almost playful or joyful. Hacker-like motivation can be found in areas outside of computer programming where innovation emerges.

These principles, drawn from these and other sources, were organized into the Communities of Innovation framework, and formed the basis for this study, which was an initial exploration of how robust this framework could be when applied to a higher educational setting.

## Research Questions and Methods

The purpose of my research agenda was to study the nature of distributed creativity from a Communities of Innovation perspective, within student design communities in the context of higher education. Specifically, my research questions for this study were:

1. Do elements of a community of innovation emerge among members of a graduate instructional design studio?
2. If so, how do members of this community describe those elements? If not, what do members report might have impeded the development of a COI in this setting?

### Research Design and Participants

This study combined phenomenological interviewing (Seidman 2006) and Critical Incident Technique (Flanagan, 1952) to study the emerging distributed creativity during one semester of a design Studio for graduate-level instructional designers at a large, Southern university. This Studio consisted of three courses: A beginning course focused on gaining expertise utilizing design technologies; a second course involving an individual design project, and a third course involving a larger, group design project. There were high levels of collaboration among students within each course, as well as students between the different courses as newer students were required to serve as assistants for the more experienced students' projects, and more experienced students were required to mentor newer students in their projects. All three courses met together for general instruction and discussion of design principles each week. From this setting, four students (Jamie, Robin, Boyd, and Lori), representing all three Studio courses, were selected as case studies based on their background and inclination towards collaborating in their creative works.

### Data Collection Methods

A combination of methods were used to explore the nature of distributed creativity within this Studio community. This research study followed Seidman's (2006) strategy for phenomenological interviewing, except for one modification. Seidman outlines a three-interview process. The first interview is designed to understand the participant's background relevant to the experience at hand. I conducted this interview at the beginning of the semester about the participants' previous engagements in creative and collaborative school activities. Seidman then recommends a second interview for specific details about the experience itself, and a third interview where the participant and the researcher co-interpret the experience to understand its significance and meaning.

In lieu of Seidman's (2006) second interview, and in order to better understand the specific details of how ideas developed through group collaboration, each participant recorded a weekly 5- to 10-minute voice memo detailing the "critical incidents" (Flanagan, 1952) of their group design activities. In other words, they explained 1) what happened that week that was significant to their project, 2) who was involved in the incident, and 3) why this incident positively or negatively impacted their project. This method enabled the students to provide more thorough details into their weekly group collaborations than they would have been able to remember in a single interview. This information was triangulated with an analysis of the students' design experiences as reported in their required weekly design journals. I also observed first-hand many of the participants' interactions with their peers.

I then concluded the semester by conducting the third of Seidman's interviews and co-interpreting with the participants how their group actions enabled or frustrated the creative process. In addition to these data sources, I interviewed the Studio instructors in order to understand their rationale, goals, and perspectives on the Studio setting.

## Data Analysis Methods and Rigor Guidelines

Data were analyzed using constant comparison coding techniques for forming categories and theories derived from categories. This analytic method is similar to the form of analysis suggested by Flanagan (1952) for Critical Incident data, which I collected via the student voice memos. Initial categories were derived from the COI model (group flow, hacker ethic, entrepreneurship, etc.). Additional categories were created from the analysis process to describe emerging significant events or patterns in the participants' experiences. Trustworthiness was developed through member checking case study reports with the participants, asking independent coders to analyze uncoded portions of the data to confirm emerging themes, peer review of the theoretical and methodological frameworks, and triangulation of methods and data sources.

## Findings

Findings included the emergence of several elements of the Community of Innovation framework in the experiences of the participants (flow, hacker ethic, and entrepreneurship). In addition, new themes emerged representing additional ideas that could be added to the framework (perspectives on collaboration and mentoring, interactive idea generation, sense of community, learning through design criticism, and idea prototyping). Finally, some COI elements were not found in this study (see Figure 1).

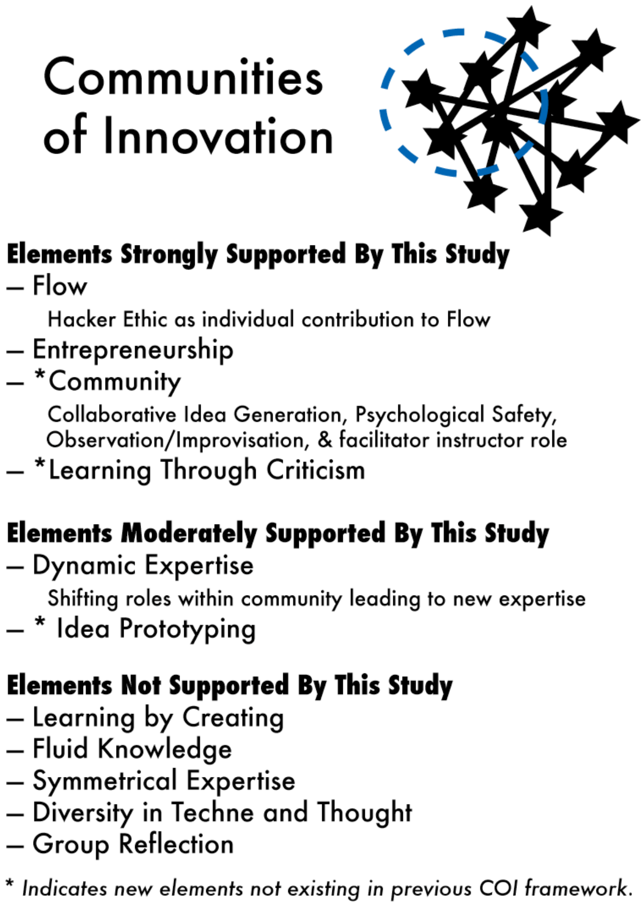

Figure 1. Revised Communities of Innovation framework

### Existing COI Elements Supported by the Data

#### Flow

While Group Flow (Sawyer, 2008) was theorized to be specifically important to COIs, it was difficult to detect Group Flow in this study (12 coded statements). This could be due to the lack of group flow or to the difficulty of capturing it within the questions and self-reports used in this study. However, individual flow (Csikszentmihályi, 1990) emerged as a significant theme (30 statements, found in all four case studies' experiences), and was coded as situations when participants reported being completely engaged to the point of losing consciousness of their surroundings and time, in part because they felt competent to complete the task, understood the bounds and rules of the activity, and found it personally enjoyable. While the flow experience was mostly described as individual, it appeared to be fostered by community characteristics such as project ownership; student agency; and a fertile, creative environment.

#### Hacker ethic

Hacker ethic was coded when statements described the participants' work as interesting, playful, or completed because of a desire for quality or satisfaction rather than a grade, or involving high levels of enthusiasm. From the literature (Himanen, 2001; Raymond, 2003) and this research, I interpreted flow as an experience that happens to people, whereas a hacker ethic is something innate that a person brings to an experience. Data in this study supported this distinction, but participants often indicated that both existed simultaneously. All four participants described having a hacker ethic for learning the skills needed to complete high-quality projects, although Jamie least so (6 coded statements compared with an average of 22 statements for each of the other three).

## Entrepreneurship and autonomy

Entrepreneurship/autonomy was coded when participants discussed the ability to create their own projects, define their own goals, or take ownership in their work. All participants indicated that Studio enabled them to become innovative by allowing autonomy in selecting and designing projects. Boyd remarked, "It [Studio] lets you have your own goals not compared to somebody else" and "they really give you free reign" over tools, learning design/theory, etc. He continued, "Really the only thing that can impede you . . . would just be your own limitations."

## Collaboration and mentoring

"Collaboration," defined as repeated interactions focused on achieving a goal such as developing a project component or learning new skills, was evident in 173 comments. All four participants reported that collaboration was crucial to developing their projects, although they defined collaboration differently and benefited from different kinds of collaborative relationships. The participants often indicated a desire for even more collaboration (32 statements). Interestingly, despite all four participants being very comfortable with Internet technologies and two of them living far away from the university, only Lori indicated collaborating with friends on the Internet, while the others strongly preferred face-to-face collaborations.

Some of the collaborations reported by the participants were minor interactions with other community members that either pulled the participants away from or reinforced a particular decision, or gave emotional support for a chosen action. These small nudges in a particular direction were coded 34 times. Sometimes, however, the participants indicated more dedicated, consistent, and one-on-one collaboration that was coded as mentoring (30 statements). All participants reported some degree of mentoring, usually to support their technical skill development.

## Interactive idea generation

In this study, we flagged every instance where participants mentioned a new idea, and coded these ideas as having originated from the participants themselves, through interactions with others, or from materials such as textbooks or tutorials. In general, participants reported mostly receiving ideas through interactions with others, especially other Studio members (134 coded statements, see Figure 2), as well as from connections outside of Studio (37 statements). Participants also drew ideas from assigned textbooks (8 statements), and from searching on the Internet (41 statements). Mostly they reported their ideas were generated interactively with others. Some of these ideas were related to technical issues and learning new technologies. Most ideas were related to minor design changes, usability issues, and aesthetic improvements. Robin eventually changed the entire template for her project because Boyd, in a desk critique, questioned the viability of her previous design. In return, Robin and others offered ideas to Boyd about adding interactive elements to his Web site and improving his font and color choices. Boyd noted*,* I received some really great feedback, . . . which led directly to changes

**Where Participants Reported Receiving Ideas**

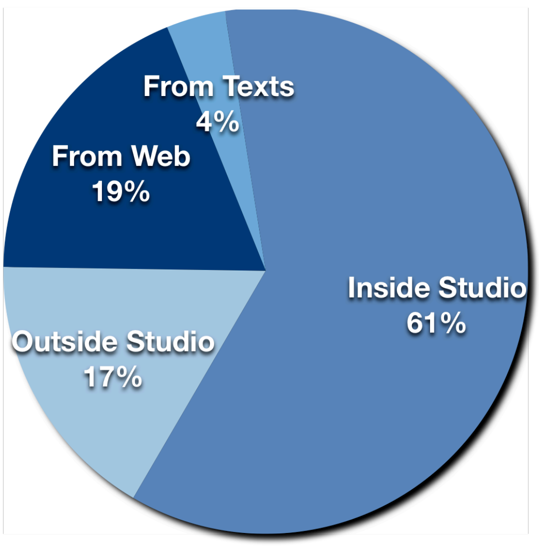

Figure 2. Where participants reported receiving their ideas.

## Sense of community

Sense of community was coded a total of 50 times when participants indicated being emotionally or psychologically connected with, trusting, receiving support and encouragement from, and feeling friendly with their Studio peers. [Note: Although collaboration could be another indication of the strength of a community, I coded collaborative events separately to allow specific analysis of those interactions.]

## Learning through critiquing

Learning through critiquing was coded when participants indicated learning or gaining insights from the peer feedback process or from evaluating other designs, and it was coded 39 times. For example, Lori mentioned that she and a friend sat in on each others' prototyping meetings with their instructor. During the discussion of her friend's prototype, Lori contributed advice that caused her to reflect on her own project: "In just some of the things I suggested to her I was like wait a minute, I could be doing that for my project." She further observed, "so much more happens when you can actually sit and talk about your project."

#### Idea prototyping

Participants discussed the importance of prototyping ideas to facilitate idea generation through observation and improvisation. However, the evidence for including this element in the COI framework is still tentative (13 coded statements in this study). This concept is supported by models of rapid prototyping, which is an approach to design that emphasizes a "rapid, iterative series of tryout and revision cycles . . . until an acceptable version is created" (Baek, Cagiltay, Boling & Frick, 2008, p. 660). Often, rapid prototyping involves users in testing the product, but this study indicated that it was also necessary for engaging members of a COI in developing innovative ideas. Participants suggested that prototyping might be most influential when it begins early in the design process and when sufficient to facilitate one-on-one or small-group discussions about the prototype.

### Challenges to Implementing a COI

From this study, several challenges to implementing a Community of Innovation in an educational setting were evident. First, there was a lack of time for completing the tasks sufficiently, causing participants to often focus solely on completing tasks instead of considering the most innovative or effective way to produce their projects. Another impediment for the students was their lack of technology skills, particularly for Boyd and Lori who had innovative ideas but could not develop them due to limited technical skills. Thus, while Hakkarainen, et al. (2004) noted the importance of dynamic expertise that is adaptable to changing problems, there appears to be a need also for domain-specific expertise as a prerequisite to innovative collaboration and improvisation.

Finally, participants reported receiving ideas, social support, and feedback from peers, but this support was usually superficial unless it came from a member of their close peer group. The clearest example was Lori, who described working closely with a dedicated and skilled mentor, but reported almost no collaborations with anyone else. Robin and Boyd did not have dedicated mentors but instead formed a group with Studio friends that provided quality feedback and support. Like Lori, however, they collaborated little with anyone else. Jamie worked closely with her team members, but reported little interactions outside of her team. Thus, COI support and collaboration may impact innovation only among members of local, helpful peer groups within the community. If so, connecting community members with "innovation champions" (Coakes & Smith, 2007) or developing expert networks (Hakkarainen et al., 2004) may prove especially important.

## Conclusions: Reexamining the Formative COI Framework

In this study, I employed a formative Communities of Innovation framework, an adaptation of theories about communities of learning/practice and creativity research, to describe the innovative potential of adult groups. Not all of the theorized COI elements were evident in the data. Findings included evidence for some aspects of the proposed COI model (flow and hacker ethic, entrepreneurship, collaboration and mentoring, interactive idea generation, sense of community, and learning through design criticism), moderate support for others (dynamic expertise and idea prototyping), and no evidence supporting other proposed components from the previous iteration of the model (West, 2009—developing adaptable knowledge and expertise, symmetrical expertise within the community, community reflection, shifting interpersonal roles, or benefiting from cultural/ educational/skill/other diversity). There was not evidence that these latter components are not important to a COI, only that they weren't evident in this study.

Based on these findings, the COI framework was tentatively revised to differentiate original elements that were strongly and weakly supported by data in this study, new elements supported by the data, and those original elements that were not supported by the evidence in this research (see Figure 1). This distinction is helpful for designing and researching COIs, as it creates priorities for emphasizing specific elements in a given community.

## Implications for Future Research

As Greeno (1997) explained, we need to seek to understand "which combinations and sequences of learning activities will prepare students best for the kinds of participation in social practices that we value most" (p. 9). Because graduates enter a workforce that is increasingly demanding creativity as the currency for success (Banahan & Playfoot, 2004), it is important to continue researching how we can foster effective distributed creativity in higher education in order to best replicate the kinds of social practices and activities graduates will engage in when they fully enter society. The conceptualization of COIs described in this paper is formative. Support for some components was apparent in this study, but several unanswered questions for future research remain, including:

1. What is the nature of group flow and how can it be developed within a community?

Flow was common across participants' experiences, but was usually manifested as individual rather than group flow, which may have been due to methodological limitations. Future research is warranted to delineate the differences between individual and group flow, articulate the nature of individual and group flow, and examine what influences group flow. To address these questions, conversation analysis—a methodology designed to rigorously capture routine, everyday activities occurring in naturalistic settings in a manner that is reproducible and defensible (Sawyer & DeZutter, 2009)—might be used.

2. How do COI designers balance structure and scaffolding with autonomy?

In this study, autonomy and entrepreneurship were key characteristics of COIs. Yet, this freedom created challenges for participants as they struggled to identify the vision for their projects. Future research is needed to understand how to balance structure and scaffolding, especially for novices, and the autonomy needed to promote innovation. Researchers might employ quasi-experimental studies with control and experimental groups to account for varying levels of scaffolding and structure. Results could be compared according to expert judgments of the innovativeness of the final products, or by utilizing a measure of creative potential (Kim, 2007) or divergent thinking (Runco, 1993). Qualitative methods could explore the nature of the scaffolding found to be most effective, and how participants perceived, experienced, and benefited from this scaffolding.

3. What is the nature of community within a COI and how does this compare with other communities?

Research is needed to articulate the nature of the community within a COI and how this differs from other kinds of communities, such as learning communities and communities of practice. These questions could be studied via social network analysis in order to quantify the social capital of relationships making up COIs.

4. How is knowledge and expertise acquired in a COI?

This study provided tentative findings related to how innovation develops through the peer critiquing process and that how dynamic expertise influences innovation. However, research is needed to verify these findings and extend our understanding of these principles. Case study methods could prove valuable for documenting how dynamic expertise is developed, relying on a combination of critical incident recall and close researcher observation with a small participant sample. Video analysis may also be helpful in capturing the nuances of expertise development. Conversation analysis could again be useful in microanalyzing the discourse.

5. What is the value of COIs? Do they produce more innovative ideas or products?

A significant, and largely unanswered, question concerns whether COIs stimulate more innovation than other social structures. Researchers could use historical approaches by first identifying major innovative ideas and working backwards to analyze archival data concerning the social structure surrounding the innovation. Another approach would be for experts to review the products generated by a COI and other kinds of communities to develop a reliable instrument for analyzing the innovative potential of group ideas.

# Students' Meaning Making in a Mobile Assisted Chinese Idiom Learning Environment

Lung-Hsiang Wong, Learning Sciences Laboratory, National Institute of Education, 1, Nanyang Walk, Singapore 637616, lunghsiang.wong@nie.edu.sg
Chee-Kuen Chin, Chee-Lay Tan, May Liu, & Cheng Gong, Singapore Centre for Chinese Language, 287, Ghim Moh Road, Singapore 269623, {cheekuen.chin, cheelay.tan, may.liu, cheng.gong}@sccl.sg

**Abstract:** In recent years, we witness the rise of communicative and contextualized language learning approaches that is concomitant with developments of Mobile Assisted Language Learning (MALL). In this paper, we present a pilot study in MALL that emphasizes "creative learner outputs" and contextualized meaning making. In learning Chinese idioms, students used smartphones on a one-device-per-person basis to capture photos of the real-life contexts pertaining to the idioms, and to construct sentences with them. Subsequently, in-class or online discussions took place, which would enhance the students' understanding in the proper usage of the idioms. The learning design is grounded in the seamless learning model that encompass in-class formal learning and out-of-class informal setting, and personal and social learning spaces. The students' ongoing, open-ended, personal-to-social meaning making process and artifacts have indeed shown some indicators of "seamless language learning" that has the potential of transforming language learning into an authentic learning experience.

## Introduction

A closed system may settle into an undifferentiated state, while an open one is more likely to become animated, and sometimes highly coordinated (Kauffman, 1995). Likewise, in language learning, "closed," mechanical exercises restrict information to only "correct" answers that are unlikely to remain in permanent memory (Stevick, 1996), whereas meaningful and communicative activities build on the classroom to learners' wider knowledge—an almost inexhaustible resource (Bolte & Herrlitz, 1986).

This paper reports on a pilot study of Mobile Assisted Language Learning (MALL) in Nan Chiau Primary School in Singapore. In the study, we facilitated a 5$^{th}$ Grade class to study and apply 29 common Chinese idioms, within the context of learning Chinese as a Second Language (L2). Apart from in-class idiom lessons with contextualized learning activities, the students were assigned with a smartphone each which they kept and accessed 24x7 throughout the nine-week period of the study. They were instructed to carry out photoblogging-like activities by using their smartphones to take photos in their daily lives, and then make sentences with the learned idioms, and subsequently to post them onto a wiki space for sharing and peer review.

The MALL design emphasizes students' proactive association of the contexts that they encounter in the real world with the learned Chinese idioms (a special form of vocabulary). In this paper, we focus on studying the students' individual-to-social learning process, which could be attributed to the process of multimodal, student artifact-focused, ongoing, open-ended meaning making in vocabulary learning. The students' learning processes and outcomes suggest a compelling direction for MALL – seamless language learning.

## Literature Review

### Constructivist Approach in Language Learning

In recent decades, we witness a paradigm shift of language learning theories from behaviorism and structurism to a communicative approach (Salaberry, 1996). The emphasis of the communicative approach is on real-world communication in environment and situation that language learners might actually experience (Hoopingarner, 2009). Under the emerging paradigm, learning is seen not as a passive activity that requires learners to accept pre-packaged information, but as an active process by which learners create their own understanding. This approach meshes well with the constructivist theory of learning (Jonassen, 1991).

Language learning involves active mental activity such as interaction and hypothesis testing (Gass, 1997) and productive output (Swain, 1985). In addition, prior studies in the L2 classroom have brought our attention to the importance of the negotiation of meaning, also known as social meaning making, in L2 development (e.g., Long, 1985). More sophisticated meaning making involves the mutual transformation in the actions, and perhaps the thoughts and moods, of two partners (Locke & Bogin, 2006). However, the social context has been undervalued as an arena for collaborative L2 learning. Where meaning appears fixed, immutable, to be sent and received, what is lost is the collaborative nature of meaning making (Savignon, 1991).

### Vocabulary (Idiom) Learning

As a main component of language learning, vocabulary learning is often delivered in conventional ways, such as providing abstract definitions and sentences taken out of the context of normal use. Such strategies might well lead to simplistic conception of vocabulary (Miller & Gildea, 1987), as they may deprive the students of pragmatic cues and render the process of meaning making harder (Kumaravadivelu, 1994).

Vocabulary can be classified into two categories, context-free and context-dependent vocabulary. Context-free vocabularies, such as nouns, are those which can stand by themselves without depending on sentence contexts (Elliot & Zhang, 1998). Context-dependent vocabularies could either be prepositions, which are not rich in meaning and are better learnt in sentence as their meanings depend on the presence of other words (ibid), or compound vocabulary such as idioms whose complex nature may result in context-dependent appropriateness of their usage (Deng, 2001) – there are many possible real-life contexts where such vocabulary could suitably (or unsuitably but often mistakenly) be used. As contemporary learning theorists argue that language teachers should create the right conditions for students to 'uncover' grammar (e.g., Thornbury, 2001) through active meaning making (Bourke, 2005), we envisage a similar principle for vocabulary learning.

Over the years, vocabulary learning theorists have advocated productive (apart from receptive) learning (Webb, 2005), inductive meaning making (Lewis, 1997), and contextual learning (Sanaoui, 1995), among others. Furthermore, Nation (2001) proposes three psychological processes for successful vocabulary learning: noticing (a word is highlighted as being salient text input), retrieving (repeat encountering of the word) and creative/generative (a previously encountered word is met or used in a slightly different context). The three-stage model stresses the importance of the coupling of receptive and productive learning, and the learners' generative usage of the vocabulary in alternative contexts. All these point to the trend of emphasizing students' self-construction of understanding in vocabulary usage, and this is done most likely through authentic learning.

### Mobile Technology for Vocabulary Learning

As authentic learning (i.e., learning activities that are framed around real-life contexts) comes into the picture of language learning (Widdowson, 1978), MALL becomes a viable solution to the blending of the language learners' learning environment into their real-life contexts. Prior research on mobile learning has shown that the mobility and connectivity of the devices enable students to become an active participant, not a passive receiver, in learning activities (Looi *et al.*, 2009). The recent development of MALL demonstrates a similar tendency.

According to a survey by Kukulska-Hulme & Shield (2007), prior MALL studies could be divided into two categories: content-based (formal learning-oriented; developing learning materials for mobile access) and design-oriented (informal learning-oriented, out-of-class, often authentic and/or social learning activities). Most of the MALL studies in the context of vocabulary learning have conformed to content-based design, whose systems work in the way of pushing of relatively static learning materials or quizzes to the device learning (e.g., Thornton & Houser, 2002; Levy & Kennedy, 2005), which could be attributed to behaviorist learning despite having the advantage of anytime, anywhere. Ogata, Akamatsu & Yano's (2004) design moves one big step by incorporating context-aware technology, as their system enables the learners to use their handhelds to detect the RFID-tagged objects and retrieve their names (vocabulary) and explanations. All the above-stated designs are however still restricted to receptive learning and are usually (not always) only suitable for learning context-free vocabulary. Learning context-dependent vocabulary with the above designs may result in learners' understanding of the general definitions but not necessary the proper usage of them.

### Seamless Learning and Language Learning

Recognizing both the importance and the limitation of formal, in-class language learning, language learning theorists have been advocating the integration of formal and informal language learning (which could be dated back to the pre-MALL days, e.g., Titone, 1969). MALL becomes a solution to the blending of the language learners' learning environment into their real-life contexts. The handhelds which could function as a personal "learning hub" creates the potential for a new wave of evolution of technology-enhanced learning. This evolution is characterized by "seamless learning spaces" and marked by continuity of the learning experience across different environments, and emerging from the availability of one device or more per student ("one-to-one") for 24x7 access (Chan *et al.*, 2006). In particular, the integration of individual and social learning could be further enhanced by blending mobile and Web 2.0 technologies to bring to the students the situated mobile learning experiences that take into account both the students' everyday tasks and socio-constructivism (Winters, 2007). Such integration can be expected to balance and bring out the best of both individual and social learning.

The integration of technology-assisted informal learning into the students' lives does not imply the elimination of school-based formal learning. Instead, it becomes more challenging for teachers to inspire students' learning in both formal and informal settings by modeling the seamless learning process (Zhang *et al.*, 2009). In this regard, we are keen to tap on the seamless learning framework to carry out the modern language learning pedagogy for the e-generation. Such framework favors contextualized learning, the integration of formal and informal learning, and, more importantly, the integration of receptive and productive learning.

## Study Description

Our one-and-a-half-year study, "Move, Idioms!" (成语，动起来！), consists of a pilot study and a full-scale intervention, in July-September 2009 and in January-October 2010 respectively. This paper focuses on the design, implementation, and our analysis on the students' artifacts of the completed pilot study.

In facilitating the pilot study, we designed a learning process to engage students in ongoing Chinese idiom learning and writing (sentence making) activities. A class of 40 Primary 5 students participated in the study. Each of them was assigned a HTC TyTN II smartphone with built-in digital camera, Wi-Fi access, internet browser and Chinese text input. Furthermore, we used PBWorks (http://www.pbworks.com/) to create the wiki space for photo/sentence sharing and peer reviews. Apart from standard wiki features such as multi-user content editor and page history, an online forum-style comment tool is incorporated on each wiki page. In addition, mobile-optimized animations that depict the meanings of idioms can be accessed by students anytime, anywhere. The animations are sponsored by our research partner, a digital content developer based in Taiwan.

Figure 1 depicts the process of our learning design. The four-activity process is iterative and encompasses formal and informal learning spaces, individual and social learning spaces, receptive and productive activities, and the use of both mobile and Web 2.0 technologies (that is, learning takes place in both the physical world and the cyberspace). The processes of the four activities are described below:

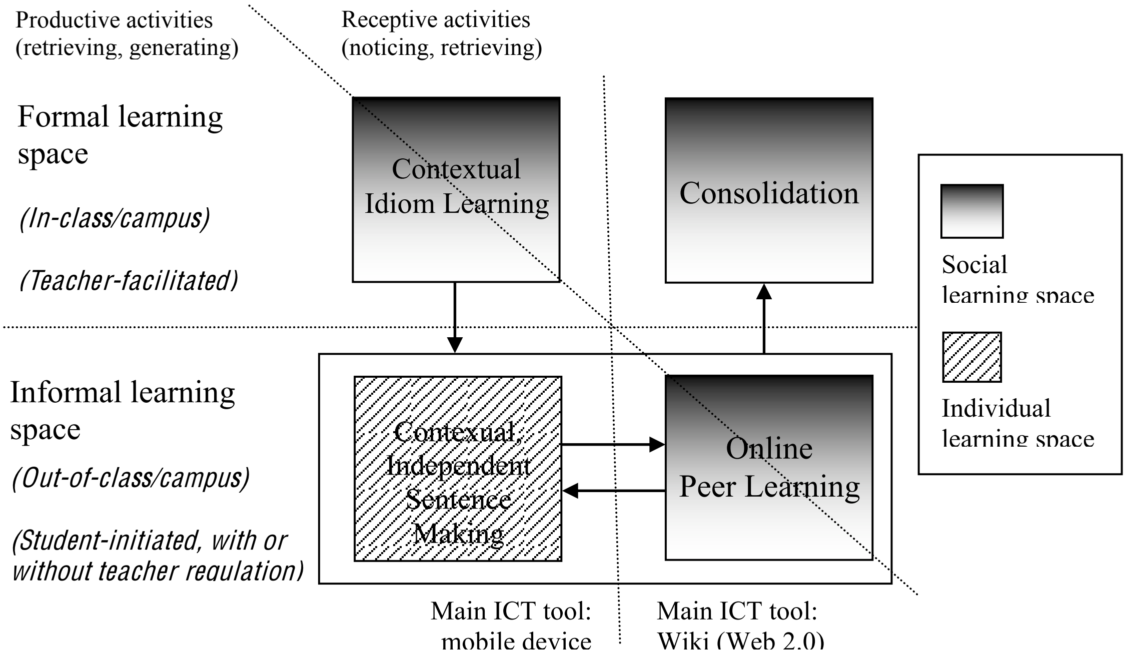

Figure 1. The mobile-assisted idiom learning process.

Activity 1 – In-class contextual idiom learning: The classroom/in-campus activities, to be designed in the form of lesson plans, are conducted with the aim of carrying out the "noticing" and "retrieving" processes in Nation's (2001) framework as well as preparing students to engage in subsequent out-of-school activities ("generating"). During each lesson, a new set of "idiomatic animations" is shown to the class (also accessible by the students after school). The teacher then conduct contextualized learning activities, such as creating linguistic contexts, for instance by providing context-rich images, inviting students to discuss about relevant idioms, and even "mobilizing" the students to take photos in the campus to illustrate the idioms and upload them to the Web.

Activity 2 – Out-of-class, contextual, independent sentence making: students carry the phones assigned to them 24x7. Apart from watching the animations repeatedly, students are instructed to identify or create contexts in their daily lives which could be associated with any learned idiom. They then take photos, make sentences that contain the idioms to describe the photos, and post them onto a class wiki space. In the wiki space, we create one wiki page for each idiom covered in the class for students to post their photos/sentences. This offers convenience for comparing various student-identified contexts pertaining to the same idiom.

Activity 3 – Out-of-class, online peer learning: students are encouraged to perform peer reviews on the wiki by commenting on (with the PBWorks comment tool), correcting or improving their peers' sentences (by making direct modifications on the sentences posted on the wiki pages with a different font color). During the pilot study, they carried out these activities with PC's at home, not the phones, due to technical constraint.

Activity 4 – In-class consolidation: Possible activities include class or small group discussions on selected sentences made by the students, or polls for "the most popular photo/sentence" on each "idiom page".

During the nine-week period of the pilot study, the teacher conducted five "idiom classes" (Activity 1) in the first five weeks with roughly one-week intervals. In the first three classes, the students were required to enact some of the idioms for peers to take photos within the classroom. In the last two classes, the students captured images to illustrate idioms within the campus. In between, the students were encouraged to carry out Activity 2 and 3. The teacher then facilitated Activity 4 in the seventh week. Students worked in groups of five, with each group being assigned an "idiom page" to discuss and identify erroneous uses of idioms with respect to the contexts in the photos or the sentences made, and to provide recommendation in correcting or improving the sentences. The students returned the phones to the school upon the completion of the study.

The data collected and analyzed for project evaluation consists of: (1) Pre- and post-quizzes; (2) Pre- and post-questionnaires; (3) Pre- and post-interviews with two high-, two medium- and two low-ability students (in terms of their academic performances in Chinese class) selected by the teacher; (4) Field notes taken during the in-class activities; (5) Student artifacts and online interactions. Due to space constraint and since we focus this paper on the analysis of the students' meaning making process, we will not go into the details of (1)-(4).

## Findings

### Constructivist Approach in Language Learning

Within the nine-week period, the 40 students contributed a total of 481 photo/sentence sets, revised (corrected or modified) sentences for 124 times, and posted 134 comments. However, the variation in the statistics of individual students' contributions was huge (mean = 12.0, SD = 25.9), as the top contributor posted 151 photo/sentence sets (or 31.9% of the entire class's postings) while 70.0% of her peers contributed less than 1 photo/sentence set per week in average. On the other hand, the students' participation levels were more consistent in offering sentence revisions (mean = 3.1, SD = 7.3) and comments (mean = 4.5, SD = 3.4).

Our observation and our interactions with the teacher and the students throughout the pilot study and our post-study interviews with six students had helped us to identify the challenges that had resulted in the widely varied levels of participation among the students, which are listed below:

- Affective issue: Many students showed great engagement during the in-class Activity 1 but when it came to the after school informal setting, they did not treat the smartphone as a learning tool but more a new toy. As what we have found out from the interviews and casual chats with the students, after enthusiastic exploration of the smartphone functionalities available in the initial period, many of the students had resorted to play online or installed games from time to time apart from carrying out the instructed activities. When being questioned about how they could and whether they had used their phones for other out-of-school learning activities, their common reply was: "no idea", except for a student who claimed that he had occasionally checked an online English dictionary with his phone in doing school assignments.
- Technical issue: Some students intermittently encountered and were frustrated by the technical problems in posting photos and sentences to the Web via their handhelds.
- Parental attitudes: Fearing of misplace or damage, most of the parents forbad the students to bring the phones out of their home except for bringing them to school, thus defeating the purpose of 24x7 seamless learning and severely narrowed the contexts that the students could associate the learned idioms with. Indeed, 83.2% of the contributed photos taken outside campus took place within the students' home.

As a learning design informed by the seamless learning framework, which implies the necessity of changing students' belief and, it is unrealistic to expect a significant breakthrough in the students within a nine-week period. Despite all that, after analyzing the student artifacts and their peer learning process, we found that they have shown great potential and promise, which we shall elaborate in the following sub-sections.

### Student Artifacts

While the earlier activities – teacher's explanation and students' viewing of the idiomatic animations – would be attributed as "transfer of encoded meanings" of the idioms, it is not the end of the students' learning journey and should instead serve as starting points for the students' subsequent "ongoing, open-ended meaning making" (Hedley, 1992) with the aim of rectifying, internalizing and enriching their understanding of the idioms.

From their artifacts, the students demonstrated their creativity by making up contexts that associate with specific idioms. We analyzed all the 481 photo/sentence sets posted on the wiki and classified them into 12 categories with respect to two dimensions, namely, "types of physical setting" and "types of meaning making". "Types of physical setting" refers to the sources of the physical setting captured by each photo ("natural setting", "physical object manipulation", "human enacted scenario", or "previously published materials" such as book illustrations or TV screenshots). "Types of meaning making" refers to how the associated sentence reflects the student's personal meaning making on the photo (i.e., the relationships between the photo content and the sentence content), which could be "literal meaning making", "extended meaning making" (deductive interpretation) and "creative meaning making" (twisted, creative interpretation). Table 1 features examples of different types of photo/sentence set with the idioms underlined in the original Chinese sentences. To benefit the readers, we translated the Chinese sentences into English with the translations of the idioms underlined.

Here is how we distinguish the personal meaning making types: (1) *Literal meaning making*: The sentence demonstrates a direct interpretation of the photo context – all the elements stated in the sentence are visible in the photos. (2) *Extended meaning making*: The sentence demonstrates a logically deductive interpretation on the photo context – there are elements in the sentence which are invisible in the photos but they are logical deductions from the photo context. For (E), (F), (G), (H) the additional elements are sports games, scoring full marks, a theft, and catching a fish, respectively. (3) *Creative meaning making*: The sentence demonstrates a twisted, perhaps creative re-interpretation on the photo context (i.e., other photo viewers may not interpret the photo in the same way). For example, in photo (I), there is no sign of feeding and eating in the photo and yet the student made up the "plot" of feeding the geese. Sentence (J) turns the photo of two mouse devices into a metaphor as the student imagined that they were animals which collided with each other.

Table 1: Various types of photo contexts and students' meaning making.

| | Natural setting | Physical object manipulation | Human-enacted scenario | Previously published materials |
|---|---|---|---|---|
| Literal meaning making |  (A)这里有两只一模一样的螃蟹。 These two crabs are as alike as two peas. |  (B)那些车横冲直撞，真是不知道他们怎么驾车! Those cars are romping about. I am doubtful about the driving skills of the drivers. |  (C)小青正在睡觉，小蓝不想吵到小青所以她轻手轻脚地走了过去。 Xiaoqing is sleeping. Xiaolan passes her by quietly so as not to disturb her. |  (D)老板怒气冲冲地样子好可怕。 The boss looks fierce when he is in a rage. |
| Extended meaning making |  (E)哥哥平时不爱运动可是却可以在小学的运动会上一鸣惊人地得了第一名 。 My brother does not like sports activities. Yet he excels unexpectedly and came in first the Primary School Sports Meet. |  (F)小明手舞足蹈因为他得了一百分。 Knowing that he scored full marks, Xiaoming dances with joy. |  (G)小明偷了伟德的钱包，伟德火冒三丈对小明拳打脚踢起来。 Knowing that Xiaoming has stolen his wallet, Weide beat Xiaoming up in his rage. |  (H)明明抓到鱼儿时就眉开眼笑。 Mingming grinned from ear to ear when he managed to catch the fish. |
| Creative meaning making |  (I)鹅们津津有味吃我们给的面包。 The geese enjoyed eating the bread we provided with relish. |  (J)它们俩横冲直撞，最后意外发生了! They were romping against each other and in the end resulted in an accident. |  (K)看到工人这样做，非常危险。所以，我一言不发，怕惊吓到她。 Seeing the worker doing a risky act, I tried to be quiet so as not to frighten her. |  (L)整个小岛绿茵环抱，鸟语花香，吸引了很多游人前来度假。 Surrounded by green plants and joyous sceneries, the tiny island has been attracting plenty of tourists to spend holidays there. *(photo source: http://www.pconline.com.cn/)* |

The variety of artifacts reflected the students' greater attention to their surroundings and their more conscious attempts to associate their daily life with the idioms – be it in the school, at home, during family outings, when they read books or watched TV. Their sense of the lack of "natural" contexts for them to take idiom-related photos was compensated by their creativity in manipulating physical objects, enacting situations, or appropriation of relevant published materials. In addition, the post-questionnaire results indicate that the students may have extended, perhaps sub-consciously, their mental "habit" of Chinese-idiom-and-real-life-context association beyond the pilot study, as 75.0% of the students "agree" or "strongly agree" that "after participating in the Chinese idiom learning activities, I think of Chinese idioms more often in my daily life."

### Peer Learning Activities

Besides producing their artifacts, the students carried out two types of peer learning - "learning from peers" and "learning with peers". In terms of "learning from peers", we argue that when a student visits or posts a photo/sentence set on one particular wiki-based "idiom page", she is likely to go through the photos/sentences pertaining to the same idiom made by her peers, which might lead to a mental comparison of the contexts and the grammar among the sentences. That is, the student would either learn from better sentences, or identify and correct her peers' grammatical errors or wrong use of idioms. This may lead to "learning with peers" activities where students comment on and discuss about their peers' contributions. As the statistics presented above indicate the students' more consistent levels of participation in peer learning activities (sentence revisions and comments) as compared with artifact contributions, students who had been less active in sharing photos and sentences may have still engaged in peer learning activities (in the forms of "negotiation of forms" [grammar] and "negotiation of meanings" [idiom usage]) and therefore achieved learning objectives to different extents.

Nevertheless, the students' asynchronous online discussions on the idiom usage were relatively trivial in general. We believed that the lack of training in this aspect was the main reason, as we merely presented a few mock-up photo/sentence artifacts and discussions generated by ourselves to the class at the beginning of the study. As such, we (the researchers and the teacher) applied some online forum facilitation strategies (e.g., Wong & Looi, 2010) by tactfully commenting on student artifacts at the right time and in right ways in order to give space for the students to engage in meaningful discussions. We also advised the teacher to promote class-wide discussions on selected student artifacts during "idiom class" 3 and 4, and eventually conduct in-class consolidation (Activity 4) in the 7$^{th}$ week. The students performed much better when they carried out small-group discussions in Activity 4 as they managed to identify most of the erroneous uses of the idioms on the "idiom pages" assigned to the respective groups and offered good recommendations to improve the sentences. The finding seems to imply that small-group face-to-face discussions would yield better outcomes as compared with asynchronous online discussions and class-wide discussions if the students have not yet acquired the skills of peer reviews – with their relatively low linguistic ability and efficacy being two other possible factors.

We take the idiom page of "东倒西歪" as an example. Table 2 features selected student artifacts posted on the page.

Table 2: Four student artifacts posted on the idiom page of "东倒西歪".

| | | | |
|---|---|---|---|
| <br>(L)这个橱柜上的东西摆得东倒西歪。<br>The objects in the cupboard are rickety. | <br>(M)我的水壶东倒西歪，翻倒了<br>My bottle is rickety and lied down. | <br>(N)哥哥的书柜的书东倒西歪，非常乱！<br>The books in my brother's bookcase are rickety and disorder! | <br>(O)哥哥把书桌弄得东倒西歪。<br>My brother makes his study desk rickety. |

Kovecses & Szabco (1996) define idioms as linguistic expressions whose overall meaning (known as figurative/idiomatic meaning) cannot be predicted from the meanings of the constituent parts (known as literal meaning). For some of the Chinese idioms, however, their applicable contexts have to take the literal meanings into account. "东倒西歪" is one of them. The idiom figuratively means "rickety" or "shaky", and literally means "leaning eastward (right-hand side) and tilting westward (left-hand side)" (usually referring to multiple objects leaning toward multiple directions). When the students discussed about the four photo/sentence sets in Table 2, they agreed that (L) was a correct use of the idiom (there are objects leaning toward both left- and right-hand sides in the cupboard) while (O) was wrong (the paper was messily left on the table, but not "rickety"). Some students proposed a correct alternative idiom "乱七八糟" (messy; at sixes at sevens). On the other hand, both (M) and (N) had generated some debates. In (M), a student argued that it was a wrong use of the idiom as the bottle has already lied down on the table and therefore it is no longer "rickety" or "shaky". However, we re-examined the associated sentence and deduced that it could mean "the bottle had been rickety and now finally lie down", and the photo merely shows the consequence, not the previous state of ricketiness. We found this artifact acceptable, though it is necessary to explain to the students that the idiom does not apply to what the photo itself depicts. Finally, we found the books in photo (N) either stand still or lean toward only one direction (not "eastward and westward"), thus questioning the suitability of applying the idiom. All in all, this is a visual-oriented idiom. The students' photos have helped us in visualizing their understanding (or detecting their misconceptions) in the meaning and applicable contexts of the idiom – something that the conventional ways of assessing them by, for example, sentence making, may not thoroughly achieve. Indeed, we noticed that some of the student artifacts offer seemingly error-free sentences, if they are read independently, but their corresponding photos suggest otherwise (misconceptions in the applicable contexts).

The students' meaningful face-to-face discussions showed that they were on the right track to carry out social meaning making – to bring forward their "individually made" meanings on the idioms in-class and during photo-taking/sentence-making activities to their learning community. Compared with conventional idiom instruction where teachers provide general explanations and demonstrate idiom usage in limited contexts, this personal-to-social meaning making process has effectively pushed the boundary of the learning materials as the students' self-identified contextual uses of the idioms (many of which have caught us by surprise as we have never thought of using the idioms in such contexts) have become a rich resource for the students to perform (essentially inductive) constructivist learning on the idioms.

## Discussion

Researchers have been investigating the facilitation of improvisation and/or creative learner output of various forms as a potentially effective means of language learning (e.g., Hodson, 2008). The mobile technology may support *in situ* improvisation and creative output such as taking appropriate pictures in contexts to illustrate the idioms under study. In our study, while such language learning activities could be carried out without technological support, it is the mobile affordance of *in situ* data collection (in particular, the camera function) that offers them the ease of generating their artifacts and helps others to visualize their idiom-and-context associations. As sharing and "rising above" the shared artifacts are the key to achieve students' deep learning of the idioms, the incorporation of the Web 2.0 (wiki) technology further enhances their social learning space by "affording" them rapid artifact revisions and interactions.

This learning process design is grounded in several existing learning language approaches and yet with some novelty. It is inductive vocabulary learning, yet not entirely based on teacher-supplied resources (e.g., Mishan, 2004), but student-generated ones, which are more authentic to the students' daily life. It is language learning by meaning making, yet not through reading or conversational comprehension (e.g., Donato, 1994) but students' idiom-context associations. It emphasizes contextual learning, productive outputs and socio-constructivism. In addition, it reinforces a principle of learning – make errors work for the students and not against them (Rubin & Thompson, 1982). In our study, an "idiom page" that contains both the correct and ambiguous (or erroneous) idiom usages would turn out to be an excellent venue for student discussion. The teacher should hold back his corrective comments to encourage debates among students on diversified views.

The pilot study has also informed us that pertaining to personalized learning, the student artifacts show some indicators of personalized seamless learning, i.e., students' proactive association of what they have learnt in-class with what they are experiencing in daily life, and perhaps with further enactment, reflection and personal meaning making. Pertaining to peer learning, the rich results of the social meaning making practice had facilitated ongoing student discussions and inductive comparisons of varied student-identified contexts. Together with the activities of watching idiomatic animations, this seamless language learning process fulfils Nation's (2001) three-stage process for (essentially personalized) vocabulary learning, and even extends it to involve social learning, and turns the language subject into an authentic learning experience.

On the other hand, the challenges faced in our pilot study have helped us in identifying the implementation. Our original intention of leveraging on general digital natives' eagerness to share their real-life experiences 'on-the-fly', mediated by Web 2.0 (Prensky, 2004) and mobile devices, did not take off. The students were keener on game-playing than blogging. The findings will trigger us to apply additional strategies to prepare the students who will involve in the full-scale study in the following year.

## Conclusion

In this paper, we report a pilot study within the MALL paradigm that is both creative learner output-centric and seamless learning-inclined. These two areas, which promised great educational potential, have been seriously untapped in prior MALL studies. In our study, from artifact generation to peer learning activities, we observed a trajectory of noticing-retrieving-generating process, and personal-to-social meaning making among the students, which we wish to analyze further in order to unveil its relation with Chomsky's (1986) distinctions between Internal- and External-language learning, and the general thinking skills involved (such as that with respect to Bloom's Taxonomy). While the results of the study are promising, much work need to be done to ensure the students' learning motivation and enthusiasm at the in-class mobile assisted learning could be extended to their off-campus time when they are assigned handhelds 24x7. Still, with proper design and implementation of seamless language learning, we envisage the potential of MALL to revolutionize language learning by using mobile devices as individual students' personal "learning hubs", and further synergize the formal (in-class) and informal (real-life), as well as the personal and social language learning spaces.

# Group Micro-creativity in Online Discussions: Effects of New Ideas and Social Metacognition

Gaowei Chen, The Hong Kong Institute of Education, Hong Kong, China, gaoweichen@gmail.com

Zhan Wang, The Hong Kong Institute of Education, Hong Kong, China, janjanwang@gmail.com

**Abstract**: This study examines how group members' new ideas and social metacognition in recent messages (micro-time context) affected a current message's micro-creativity (correct, new idea) during online discussions. Dynamic multi-level analysis was used to model statistically 894 messages by 183 participants on 60 high school mathematics topics from one of the world's largest mathematics problem solving website (www.artofproblemsolving.com). Results showed that new ideas (correct, new ideas and justifications) and social metacognition (correct evaluations and questions) in recent messages increased the likelihood of a current message's micro-creativity. Applied to practice, these results suggest that teachers might increase students' micro-creativity by encouraging them to post more correct, new ideas, justify their own ideas, evaluate others' ideas carefully, and ask more questions during online discussions.

## Introduction

Students are increasingly using online asynchronous discussions for learning (Tallent-Runnels, Thomas, Lan, Cooper, Ahern, & Shaw, 2006), in part because online discussions are more accessible and more equal compared to traditional face-to-face (FTF) discussions (Harasim, 1993). Also, online discussions allow more time for students to prepare, do higher order and critical thinking, and search for extra information before posting a message in the discussion (Pena-Shaff & Nicholls, 2004). By understanding how online discussions evolve message by message, educators can improve their quality and facilitate students' online learning.

Past studies of face-to-face (FTF) discussions have shown that recent group processes (micro-time context) can affect the likelihood of a current speaker's creation of correct, new ideas (*micro-creativity*). In this paper, creativity refers to the "small c" creativity of ordinary people in daily life, not the "big C" creativity of new knowledge or products that substantially affect society (Gruber & Wallace, 1999). Hence, micro-creativity is defined as an expressed *correct, new idea* relative to the group members' experiences during a discussion.

Chiu (2008) showed that recent speakers' justifications and correct evaluations of one another's ideas aided a current speaker's micro-creativity. This raises the issue of how recent phases and messages (local message context) affect a current message's micro-creativity during online discussions. As micro-creativity is central to correct solutions and problem solving success, understanding the group processes that affect micro-creativity can help educators improve students' online discussions.

Most previous studies of online discussions examined the *individual* properties of each discussion message from course related forums (e.g., Hara, Bonk, & Angeli, 2000). Their results showed that many students processed course information at high cognitive levels during online discussions, supporting the claim that online discussion can promote students' micro-creativity. However, researchers have not systematically examined the *relationships* among messages to characterize online moment-to-moment creative processes.

In this study, a step is taken in this direction by examining how new ideas, justifications, social metacognition, and individual characteristics in recent messages facilitate or hinder a current message's micro-creativity during online mathematics problem discussions. This study contributes to the research literature in three ways. First, we introduced hypotheses regarding how new ideas, social metacognition, and individual characteristics help create a local message context that might influence micro-creativity during online discussions. Second, we explicated a new statistical discourse analysis method to model multi-topics of online conversations (Chiu & Khoo, 2005). Lastly, we applied this new method to analyze 60 high school-level mathematics topics from a non-course related forum in one of the world's largest mathematics problem solving website (AoPS, www.artofproblemsolving.com). By understanding the group processes that affect micro-creativity, group members can work together more creatively during online discussions.

## Theoretical Perspective

In this study, several hypotheses are introduced regarding how local message context might influence micro-creativity, which in turn might affect problem solving success during online discussions (see Figure 1). In this paper, "E-poster" is defined as the author of an online discussion message.

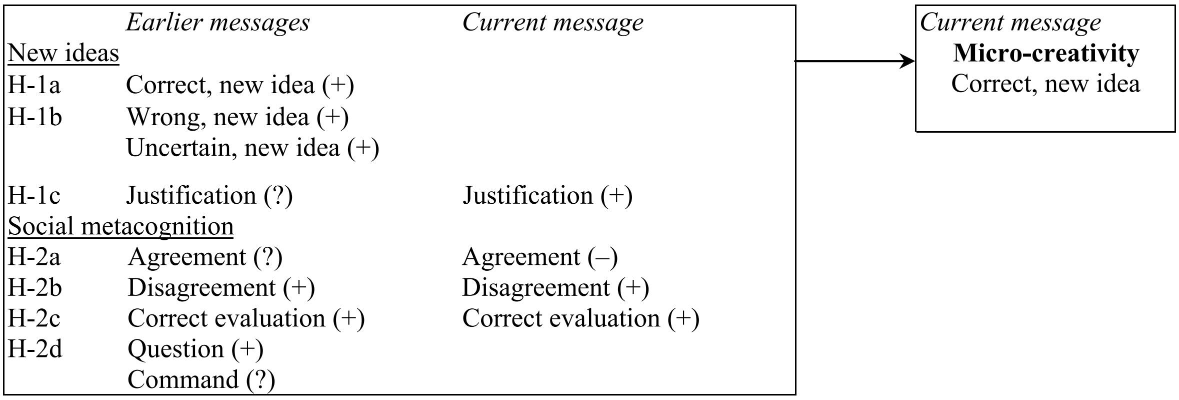

Figure 1. Model of recent messages' effects on the outcome variable micro-creativity in a current message. (Symbols in parentheses indicate the expected direction of the relationship with the outcome variable: positive [+], negative [–], or unknown [?]). H = hypothesis.

## New Ideas

In FTF or online discussions, group members often have diverse perspectives and sources of knowledge (Swann, Kwan, Polzer, & Milton, 2003). Capitalizing on this diversity, heterogeneous group members often contribute new ideas that have not been mentioned earlier in the discussion. Like FTF discussants, e-posters' new ideas can be correct, wrong, or uncertain in many contexts (e.g., high school mathematics). Suppose a group is working on a mathematical problem (e.g., "What is 7 times 9?"). An e-poster's new idea can be correct if it does not violate any mathematics or problem constraints ("7 times 9 is 63"), wrong if it violates at least one mathematics or problem constraint ("7 times 9 is 64"), or uncertain if its validity cannot be determined by considering mathematics or problem constraints ("I'm not sure, but this link might help, [hyperlink]").

Ideally, e-posters build micro-creativity directly on previous micro-creativity. For example, in responding to a micro-creativity message, "7×9 = 7×[10-1]", an e-poster might continue the thread and build new micro-creativity: "7×[10-1] = 7×10-7×1 = 70-7 = 63." Or, e-posters might not be able to build micro-creativity directly based on previous micro-creativity. Instead, they might test the previous micro-creativity against their established facts, existing cognitive schema, or personal experience, especially in online discussions fostering critical thinking (Gunawardena, Lowe, & Anderson, 1997). By testing the micro-creativity, group members are likely to identify the obstacle(s) in it. Then, they can either use questions (e.g., "Could you explain the steps further?") or disagreements (e.g., "I don't think your steps are complete") to express the obstacle and invite further elaborations or justifications (Perturbations; Piaget, 1985). Then, in responding to the questions or disagreements, group members are likely address the obstacle and make micro-creativity (e.g., "Here are the full steps, 7×[10-1] = 7×10-7×1 = 70-7 = 63"). Hence, micro-creativity might spark micro-creativity in subsequent messages.

E-posters might also post wrong, new ideas during online discussions. A group of e-posters' diversity and increased critical thinking might help them detect flaws, modify these wrong ideas, and make micro-creativity (De Lisi & Goldbeck, 1999). However, wrong, new ideas might also lead a group astray, so the effect of them on micro-creativity is unclear.

Lastly, as online discussants are often from different cities or countries, they are likely to have diverse views and sources of knowledge, thereby increasing the likelihood of presenting uncertain, new ideas, which can be uncertain resources ("I'm not sure, but this link might help, [hyperlink]"), tentative suggestions ("There might be a general way to solve such problems"), and personal preference ("I think this method is easier to understand"). The useful part in these uncertain, new ideas might help elicit micro-creativity. However, like wrong, new ideas, these uncertain, new ideas might also lead a group astray. So the effect of them on micro-creativity is unclear as well.

E-posters' ideas might or might not be justified. A justified idea demonstrates that the proposer has tried to justify his or her claim (e.g., "7×9 is 63") by linking it to data/warrants (e.g., showing reasoning/evidence, "because 7×9 =7×[10-1] = 7×10-7×1 = 70-7 = 63"), backings (e.g., "we can solve it by converting multiplication to addition"), or a combination of them (Guiller, Durndell, & Ross, 2008; Toulmin, 2003). A justification argues that an idea is reasonable and can often improve the validity of it (Lindow, Wilkinson, & Peterson, 1985). Furthermore, justifying an idea in written form might help identify errors and provide clearer and more precise steps. Hence, justifications support the validity of an idea and can increase micro-creativity.

H-1a. Earlier correct, new ideas facilitate micro-creativity.
H-1b. Earlier wrong, new ideas and uncertain, new ideas facilitate micro-creativity.

H-1c. Justification in a message facilitates its micro-creativity.

### Social Metacognition
Successful group problem solving often involves social metacognition in the problem content space (Roschelle, 1992). Whereas individual metacognition is monitoring and controlling one's own knowledge, emotions, and actions, social metacognition is group members' monitoring and control of one another's knowledge, emotions, and actions (Chiu & Kuo, 2009). Group members use social metacognitive strategies to evaluate one another's ideas (agreement, disagreement, or neutral), recognize problems, and invite audience participations (question, command, or statement).

In responding to a previous message, a responder might have supportive information, conflicting information, or both supportive and conflicting information. With supportive information, the responder is likely to agree with the proposer's idea and post a supportive message (e.g., "Yes, you are right, I got the same answer"). In such cases, a new idea, which might conflict with the old one, is less likely to be voiced. Hence, an agreement is less likely to aid micro-creativity.

Or, a responder might have conflicting information, which often indicates an inconsistency in understanding of terms, concepts, or schemas (Carson, Butcher, & Coleman, 1988). Then, the responder is likely to disagree with the proposer's idea and respond with a conflicting message (e.g., "No, you are wrong, 7×9 is not 64") to identify the inconsistency. According to *socio-cognitive conflict theory* (Piaget, 1985), the disagreements might aid micro-creativity, either immediately or in subsequent messages.

Lastly, an e-poster might have both supportive and conflicting information toward a previous idea. In online discussion reduces face concerns and allows delayed responses, which likely free an e-poster to provide the conflicting information as well. In such cases, the responder is more likely to disagree with the proposer's idea on at least one point (e.g., "Yes, your answer is correct, *but the method is too complex*"). Again, according to socio-cognitive conflict theory, the disagreement is likely to aid group members' micro-creativity.

Group members' evaluations of one another's ideas can be correct or wrong. Correct evaluations support previous correct ideas by providing supportive information ("Yes, 63 is right") or identify flaws in previous wrong ideas by providing conflicting information ("No, 7×9 is not 64"). In contrast, biased evaluations reject correct ideas ("Nope, 7×9 is not 63") or accept flawed ones ("I agree, 7×9 is 64"), embedding flaws in their partially shared understandings. Group members using these wrong, shared understandings might carry these flaws into their new ideas, resulting in more wrong ideas and fewer correct ones (Chiu, 2008).

H-2a. Agreement in a message hinders its micro-creativity.
H-2b. Disagreements in the current and earlier messages facilitate micro-creativity.
H-2c. Correct evaluations in the current and earlier messages facilitate micro-creativity.

Online discussions can promote e-posters' thoughtful questions and micro-creative answers through its asynchronous discussion mode and increased critical thinking (Gunawardena et al., 1997). The question-answer interactions, when enhanced by critical thinking, are more likely to generate thoughtful questions and micro-creativity. Unlike questions, commands stop or demand stop or demand audience participation and typically begin with verbs. Compared to FTF commands, online commands' effect on group members' micro-creativity is likely smaller. The anonymous nature of online discussions helps reduce a command's face threat. As a result, the target e-poster is less likely to retaliate emotionally and more likely to respond rationally to the command (e.g., "Explain your steps!") and create a new idea (e.g., "Here are my steps…"). Thus, commands might or might not reduce micro-creativity in online discussions.

H-2d. Earlier questions facilitate micro-creativity.

Other factors such as individual characteristics (online displayed gender, past posts, initiator of topic), message # (greater # indicates later posting) and message length (the number of words per message) were entered as control variables.

## Method

### Participants
In this study, 183 e-posters discussed 60 mathematics problems in the High School Basics (HSB) forum. About 80% e-posters were 13- to 18-year-old high school students in grades 9-11 from all around the US (calculated approximately from the participants' displayed personal information). The other 20% e-posters were from countries worldwide. The HSB forum is a free, non-course-related forum from the *Art of Problem Solving* website, which is among the world's largest mathematics problem solving websites.

## Data

Sixty problems were randomly selected from the HSB forum of AoPS, excluding problems with less than 4 reply messages. The 60 problems covered the subjects of algebra, geometry, number theory, and counting. Every problem had definite, correct solution(s). The number of responses to the 60 problems ranged from 6 to 26 and the discussion durations of them ranged from 4 to 285 hours.

Each problem and its reply messages were linked to one another by multiple threads, single connections, and quotes of previous messages. See Figure 2 for example relationships between a problem and its 12 responses. The left side outlines the positions of the problem and its 12 responses on the web page. The right side shows their relationships. The number "0" denotes the initial problem; "1" through "12" indicates 12 reply messages in the order of time, where "1" means the earliest reply, "12" the latest.

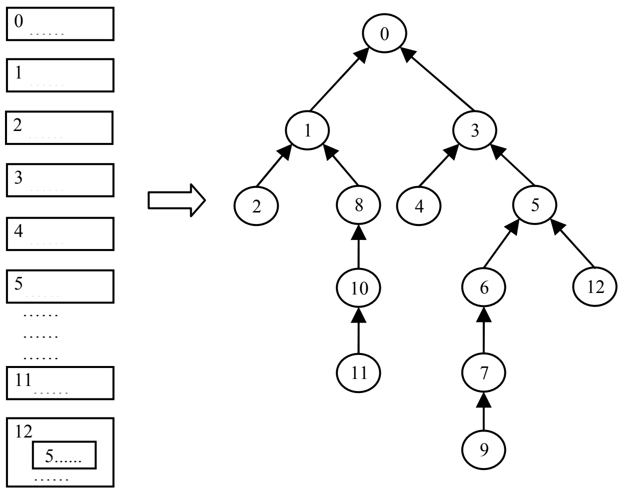

Figure 2. The relationships between a problem and its reply messages.

*Multiple threads*. The problem and 12 reply messages occurred along five discussion threads: (a) 0→ 1 → 2, (b) 0 → 1 → 8 → 10 → 11, (c) 0 → 3 → 4, (d) 0 → 3 → 5 → 6 → 7 → 9, and (e) 0 → 3 → 5 → 12. Messages in each thread were ordered by time, but they were not necessarily consecutive. In thread (d) for example, message #9 followed message #7 (not #8) and message #5 followed message #3 (not #4).

*Single connections*. All reply messages were linked together by single connections. The forum's interface design constrained each message to respond to only one previous message, which helped form clear multiple discussion threads and avoid ambiguous relationships among messages. For example, message #9 only responded to message #7.

*Quote of previous messages*. For two messages that were not consecutive along each single connected thread, the reply message automatically quoted the message to which it responded. By doing so, both messages can be read at the same place. As illustrated in Figure 2, message #12 quoted message #5, with the latter enclosed in the indented rectangle. For two consecutive messages that can be read at same computer window, the reply message did not necessarily quote the previous one.

## Variables

Variables for a single message included the e-poster's past posts, message #, message length, and the following binary variables: micro-creativity (correct, new idea), wrong & new idea, uncertain & idea, justification, repetition, agreement, disagreement, correct evaluation, question, command, masculine, feminine, and initiator of the discussion topic. The analyses use two sets of variables: *current variables* measuring properties of the current message (0) and *lag variables* measuring properties of earlier messages in the same thread (-n, where n = 1, 2, 3, 4, …).

## Coding

Two students coded each message separately. Then, they settled all coding disagreements by consensus. All 894 messages in the transcript were included and coded. Krippendorff'sα (2004) was used to compute the inter-rater reliability. Unlike other inter-rater reliability measures, Krippendorff'sα applies to any number of coders, any number of categories or scale values, any level of measurement, any sample size, and incomplete data. Its values range from -1 (maximum disagreement) to 1 (perfect agreement). A value near 0 indicates chance agreement among the coders, and a value of 0.7 or higher indicates satisfactory agreement.

The web server automatically recorded each e-poster's number of past posts and each message's # and length. Other variables were coded as binary variables. A message's variable (-n) was coded as the values of the variable of the message n connections prior. For example, in Figure 2, the value of wrong & new idea (-1) for message #9 was the same value of wrong & new idea (0) for message #7, since #7 was #9's previous message.

## Analyses

*Dynamic multi-level models* (Chiu & Khoo, 2005) separate unexplained error into message (level one) and topic (level two) components, thereby removing the correlation among error terms resulting from messages nested within topics. For the outcome variable micro-creativity, we first added *s* topic level variables as control variables: algebra topic, geometry topic, and number theory or counting topic (**S**). We then added *t* current message variables (0) as control variables: masculine, feminine, past posts, initiator, message # and message length (**T**). As the likelihood ratio test for significance of additional explanatory variables was not reliable for this estimation method, Wald tests were used. Non-significant variables and interactions were removed.

We then added *u* current message variables (0): justification, agreement, disagreement, and correct evaluation (**U**). Likewise, we repeated the procedure for **T** on **U**. Then, we tested for interaction effects among pairs of significant variables in **U**. Non-significant variables and interactions were removed from the specification. Next, we tested if the *u* regression coefficients (($\beta_{uj} = \beta_{u0} + f_{uj}$) differed significantly at the topic level ($f_{uj} \neq 0$?). If yes, we kept these additional parameters in the model. Otherwise, we removed them.

Next, we tested the hypotheses by entering lag variables measuring the property of earlier messages (-n), first lag variables (-1), then lag variables (-2), lag variables (-3), and lastly, lag variables (-4). First, we added lag variables (-1) at the message level: message length (-1), masculine (-1), feminine (-1), past posts (-1), initiator (-1), correct, new idea (-1), wrong & new idea (-1), uncertain & new idea (-1), justification (-1), repetition (-1), agreement (-1), disagreement (-1), correct evaluation (-1), question (-1), and command (-1) (**V**). Likewise, we applied the procedure for **U** on **V**. Then, we repeated the procedure for lags -2, -3, and -4 of the variables in **V**.

We used an alpha level of .05 for all statistical tests. Benjamini, Krieger, and Yekutieli's (2006) two-stage linear step-up procedure was used to control for the false discovery rate. We used Higgins and Thompson's (2002) $I^2$ index, which assesses both the statistical significance and the extent of heterogeneity simultaneously, for testing serial correlation in the residuals of the regressions for all topics.

Based on the multi-level analysis results, the path analysis estimated the direct and indirect effects of the significant explanatory variables separately to compute their total effects (Kennedy, 2003). To facilitate the interpretation of these results, we converted the total effects of each predictor to odds ratios, indicated by the percentage increase or decrease (+ X% or – X%) in the likelihood of an outcome variable (Judge, Griffiths, Hill, Lutkepohl, & Lee, 1985).

## Results

Coding of each dimension showed high inter-rater reliability. The inter-rater reliabilities as measured by Krippendorff's α for knowledge content, evaluation, and invitational form were 0.85, 0.89, and 0.92 respectively (corresponding percentages of agreement were 90%, 94%, and 97%). The multi-level variance components analysis showed that e-posters' micro-creativity did not differ significantly across topics, so single-level analyses at the message level were adequate. No interaction effects were detected in the analyses.

As variables measuring earlier messages required data from preceding turns, some messages could not be used, leaving fewer messages available for analyses. As a variable measuring messages up to two turn prior was significant (i.e., correct, new idea [-2]), 501 messages by 137 e-posters were included in the final analyses.

Correct, new idea in the previous message (-1) reduced the likelihood of micro-creativity (–5%: 9% → 4%; when a previous correct, new idea did not occur, micro-creativity occurred 9% of the time; when a previous correct, new idea occurred, micro-creativity occurred 4% of the time; see Table 1 and Figure 3), whereas correct, new idea two messages prior (-2) increased it (+11%: 9% → 20%), supporting H-1a. Justifications aided micro-creativity (+48%: 9% → 57%), showing that a justified, new idea was more likely to be correct, supporting H-1c.

Table 1: Total effects of each explanatory variable on micro-creativity and explanatory variables.

| Explanatory variable (E) | | Target (T) | P(T│E) (%)[a] | P(T│~ E) (%)[b] | Effect (%) |
|---|---|---|---|---|---|
| (1) | Past posts (0) | Micro-creativity | 11 | 9 | +2[c] |
| (2) | Initiator (0) | Micro-creativity | 4 | 9 | –5 |
| (3) | Justification (0) | Micro-creativity | 57 | 9 | +48 |
| (4) | Correct evaluation (0) | Micro-creativity | 30 | 9 | +21 |
| (5) | Question (-1) | Micro-creativity | 21 | 9 | +12 |
| (6) | Correct, new idea (-1) | Micro-creativity | 4 | 9 | –5 |
| (7) | Correct, new idea (-2) | Micro-creativity | 20 | 9 | +11 |
| (8) | Question (-1) | Justification (0) | 43 | 22 | +21 |

| | | | | | |
|---|---|---|---|---|---|
| (9) | Question (-1) | Correct evaluation (0) | 15 | 36 | –21 |
| (10) | Correct, new idea (-2) | Question (-1) | 55 | 25 | +30 |
| (11) | Correct, new idea (-2) | Correct, new idea (-1) | 19 | 39 | –20 |

[a] Probability that the target occurs, given that the explanatory variable does occur.
[b] Probability that the target occurs, given that the explanatory variable does *not* occur.
[c] The +2% effect is explained by a 100% increase above the mean of e-posters' past posts.

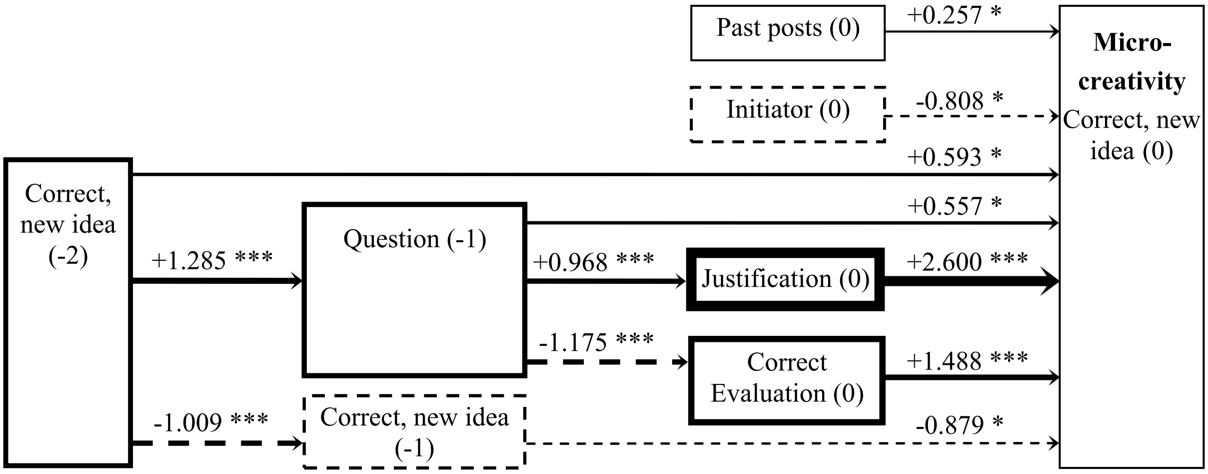

Figure 3. Path analysis of significant explanatory variables of micro-creativity using two-level Logit. Values are standardized parameter coefficients. Explanatory variables inside solid boxes indicate positive overall effects, while those inside dashed boxes indicate negative overall effects. Solid arrows (→) indicate positive direct effects, while dashed arrows (---→) indicate negative direct effects. Line widths indicate effect sizes according to the percentage changes in Table 1.

Correct evaluation (0), i.e., a correct evaluation in the current message, increased micro-creativity (+21%: 9% → 30%), supporting the first half of H-2c. If evaluating a previous idea correctly, either agreeing with a correct idea or disagreeing with a wrong idea, an e-poster was 21% more likely to show micro-creativity.

A question in the previous message (-1) increased micro-creativity (+12%: 9% → 21%), supporting H-2d. Commands in the earlier messages did not affect micro-creativity. As the data had only two commands (out of 501 messages), the statistical power was too low to test their effects.

This Logit model had an 82% accuracy rate for predicting micro-creativity in any given message ($y_{ij}$* vs. $y_{ij}$). The corresponding Probit model produced consistent parameter estimates. Furthermore, the final model' $Q$ statistics and $I^2$ index showed no significant serial correlation of residuals for the 60 topics up to lag 3 ($df$ = 60, 116, 170, respectively; $Q$ = 46.062, 89.786, 106.139, respectively; p>.05 for all; $I^2$ index = 0 for all). So, the time-series model was likely appropriate.

## Discussion

Of all 501 messages, 64% had new ideas, including 31% micro-creativity, 7% wrong, new ideas, and 26% uncertain, new ideas. The high proportion of new ideas is consistent with Heckman and Annabi's (2005) study where 83% online discussion messages and 30% FTF utterances contained new ideas (e.g., analysis, integration). Also, micro-creativity occurred more often than wrong, new ideas or uncertain, new ideas in this study, consistent with Chiu's (2008) study of FTF discussions showing that correct ideas occurred 20% of the time while wrong ideas occurred 10% of the time.

### Correct, New Ideas Increases Subsequent Micro-creativity

Correct, new ideas in earlier messages aided a current message's micro-creativity. Specifically, Correct, new ideas in the previous message reduced the likelihood of a current message's micro-creativity, whereas correct, new ideas two messages prior increased it. Overall, correct, new ideas in earlier messages increased the likelihood of a current message's micro-creativity.

These results suggest that, in responding to correct, new ideas, e-posters were less likely to build micro-creativity directly. Instead, they tended to ask questions (or perhaps use other perturbations) as the path analysis showed that correct, new ideas predicted questions in this study. Then, in responding to these questions, they were likely to address the obstacle(s) in the earlier correct, new ideas and make new micro-creativity. Hence, correct, new ideas helped elicit more micro-creativity in subsequent messages, showing that the chain reactions of micro-creativity might occur in online discussions, thereby supporting the claim that online discussions can promote students' micro-creativity.

The effects of wrong, new ideas and uncertain, new ideas on micro-creativity remained unclear. The useful parts in wrong or uncertain messages might have aided e-posters' micro-creativity (Nijstad, Diehl, & Stroebe, 2003). However, the wrong or uncertain information in these messages might also lead e-posters astray, thereby lowering the efficiency in eliciting micro-creativity.

Together, these results suggest that micro-creativity were more important than wrong or uncertain, new ideas for eliciting micro-creativity in this study, unlike Chiu's (2008) study of FTF discussion showing that wrong, new ideas were more important than micro-creativity for eliciting micro-creativity.

## Justifications Increase Immediate Micro-creativity

Justifications aided immediate micro-creativity, consistent with the studies of FTF discussions (e.g., Chiu, 2008; Goldbeck, 1998; Lindow et al., 1985). Furthermore, justifications had the strongest effect on micro-creativity (+48%), larger than the combined effects of all other predictors. This result highlights the importance of justifications in aiding micro-creativity during online discussions. The process of justifying a new idea might help identify flaws in each step, obtain precise reasoning steps, and lead to micro-creativity. Hence, e-posters can capitalize on the time flexibility of online discussions to think and search for evidence to justify their new ideas, thereby aiding micro-creativity.

## Correct evaluations Increase Immediate Micro-creativity

Like justifications, correct evaluations also aided immediate micro-creativity. If evaluating a previous idea correctly, the e-poster was likely to show micro-creativity. Controlling for correct evaluations, agreements or disagreements alone did not affect e-posters' micro-creativity. These results show that the accuracy of e-posters' evaluations was more important than the type of evaluations for facilitating micro-creativity in this study. Recognizing the previous ideas as correct or wrong helps e-posters build on them to make micro-creativity (Barron, 2003). Hence, e-posters can take time to evaluate one another's ideas carefully, thereby increasing the likelihood of presenting correct evaluations that aid immediate micro-creativity.

During the online discussions in this study, agreements did not reduce the likelihood of micro-creativity, nor did disagreements increase it, possibly because e-posters used fewer simple agreements and more simple disagreements. Unlike FTF discussions, online discussions do not expect any participant to respond soon or respond at all. Hence, simple confirmations or false agreements without micro-creativity (e.g., the "Uh-huh" or "Yeah" in FTF discussions) are less likely to occur in online discussions. Instead, the reduced face concern and increased psychological distance of e-posters might incline them to disagree more often with others' ideas, even without sufficient evidence for the opposition (e.g., "You're wrong", "I disagree"; Reinig & Mejias, 2004). Hence, simple disagreements without micro-creativity are more likely in online discussions. As a result, the expected negative effect of agreements and positive effect of disagreements on micro-creativity are likely to be mitigated.

## Questions Increase Subsequent Micro-creativity

Questions yielded greater micro-creativity, showing that questions often received satisfactory responses. Questions also increased the likelihood of micro-creativity through inviting justifications (see Figure 3). These results show that e-posters were likely to ask questions that invite explanations or justifications, supporting the view that online discussions can promote e-posters' higher order thinking (Schrire, 2004).

Questions often occurred after micro-creativity and helped elicit more micro-creativity. After micro-creativity, the responders often asked questions inviting further explanations or justifications, which in turn yielded micro-creativity. The "micro-creativity (-2) → question (-1) → micro-creativity" and "micro-creativity (-2) → question (-1) → justification (0) → micro-creativity" effects suggest that e-posters are likely to identify the obstacles in micro-creativity, express them by questions, and use micro-creativity to address the questions. Meanwhile, these effects highlighted the importance of questions in facilitating micro-creativity during online discussions.

## Implications for Teachers and Students

This study highlights the importance of micro-creativity, justifications, correct evaluations, and questions in facilitating micro-creativity during online discussions. To aid students' online micro-creativity and problem solving, teachers can encourage them to post more micro-creativity, justify their own ideas, evaluate one another's ideas carefully, and ask more questions during online discussions.

First, teachers can encourage students to post more micro-creativity during online discussions, which is not necessarily the ultimate solution to the problem. As micro-creativity fostered subsequent micro-creativity, even minor micro-creativity might serve as bases for creating more comprehensive micro-creativity. Second, teachers can encourage students to justify their own ideas and evaluate others' ideas carefully. Supported by a justification, a new idea is more likely to be reasonable and micro-creative. Meanwhile, by evaluating a previous idea carefully, a student is more likely to evaluate it accurately and correctly, and thereby build micro-creativity on it. Third, teachers can encourage students to ask more questions during online discussions. By asking questions that invite explanations or justifications, students can stimulate one another's higher order thinking and micro-creativity. Lastly, teachers can intervene to ask leading questions to inspire students' micro-creativity.

# Concrete vs. Abstract Problem Formats: A *Dis*advantage of Prior Knowledge

Andrew F. Heckler, Department of Physics, Ohio State University Columbus, OH 43210
Email: heckler.6@osu.edu

**Abstract:** Three experiments examine the effects of varying the relative concreteness of physics word problems on student performance. Previous studies have found that concrete representations benefit performance for relatively simple problems, whereas abstract representations are beneficial for more complex problems. These findings are replicated in a physics context. More importantly, a significant disadvantage for concrete representations is identified for some questions. When a problem potentially elicits prior knowledge that is contrary to scientific knowledge, e.g. a scientific "misconception", it is found that the concrete representation invokes incorrect answers more frequently than abstract representations. In addition, an interaction is found between the final course grade of the student and the abstract vs. concrete problem format, with higher grade students performing disproportionally better on abstract problems. This is consistent with previous findings in reasoning and an explanation is provided that involves the cuing of familiar, automatic knowledge and skills vs. explicit deliberate processes.

## Introduction

One truism in education research is that student responses to a particular question depend on the how the question is represented. This idea can be applied in a productive way for the topic of problem solving: while it is clear that student performance on problem solving depends on the representation (or context) of the problem, one can gain a better understanding of the nature of student problem solving by determining *which* dimensions of representational variation matter and *how* the variations affects performance (e.g., Kotovsky, Hayes, & Simon, 1985; Collins & Ferguson, 1993, Zhang, 1997).

This paper builds on a series of previous studies that examine the effects of varying the dimension of concrete vs. abstract problem representations on student performance. These studies indicate that there is often a tradeoff between concrete and abstract representations. In particular, in cases where the problem complexity is substantial, abstract problem representations have been found to be beneficial for problem performance (Koedinger, Alibali, & Nathan, 2008), and have been found to facilitate transfer in problem solving performance (Goldstone & Son, 2005; Kaminsky, Sloutsky & Heckler, 2008).

In contrast, concrete representations can be beneficial because, for example, previous knowledge can facilitate situated reasoning that allows for the use of familiar, intuitive strategies practiced frequently (Kintsch & Greeno, 1985; Carraher, Carraher, & Schliemann, 1987; Nathan et al., 1992; Pollard & Evans, 1987) and provides redundancy that is helpful for avoiding and detecting errors (e.g. Koedinger, Nathan, 2004; Koedinger, Alibali, & Nathan, 2008).

We consider two points regarding abstract and concrete problem representations. First, while grounded or concrete problem representations may produce problem-solving benefits via the cuing of helpful prior knowledge of a specific situation, it may also be the case that the grounded representation can cue knowledge that drives the solver toward an *incorrect* solution path. Potential examples of this are the well known findings of patterned and "incorrect" student answering to simple conceptual questions about physical phenomena (e.g., Pfundt & Duit, 2000). Some have interpreted these findings as evidence of coherent "scientific misconceptions", while others have explained it in terms of the cuing of "knowledge in pieces" or "resources" (diSessa, 1988; Hammer, 2000). In either case, the patterned incorrect answers are a result of prior knowledge of some type.

The second point to consider is that individual differences can elucidate important insights into the nature of the effect of representational variation. For example, in reasoning studies involving the Wason card task, Stanovich and West (1998) provide evidence that both high and low SAT (test score) participants can easily solve the task in some concrete, familiar representations, but in the generic form the task is more difficult and is solved much more frequently by high SAT participants. They argue that concrete, familiar tasks tend to invoke practiced and automatic knowledge that is independent of ability, and abstract tasks require higher order, more deliberate thinking skills.

Therefore in this paper we address two questions. First, if prior knowledge can in some cases include "incorrect" scientific knowledge, then in these cases will concrete, familiar representations tend to cue this incorrect knowledge more frequently than abstract and less familiar representations? Put more plainly, will students display misconceptions more frequently in concrete problems than abstract problems? Second, will there be a significant interaction between ability level of the student and the representational format? A disproportionate increase in performance for high ability on abstract questions students would lend more support for the idea that concrete representations cue familiar and automatic solution methods that are common to all students.

## Experiment 1

The goal of the first experiment is to replicate previous studies which demonstrate that concrete, more grounded problems are more successfully solved than more abstract, generic problems if the problems are sufficiently simple and familiar (e.g., Koedinger et al., 2004; 2008). A simple physics problem is posed in two different contexts: abstract and generic vs. concrete and familiar. In addition, the problem is constructed to include a physical situation which is known to elicit misconceptions.

### Participants

The participants were 170 university students enrolled in the first quarter of a calculus-based introductory physics course at a large research university. They completed this assignment for participation credit as part of their total course grade. Participants were randomly placed in one of two conditions, the abstract (n=92) and concrete (n=78) contexts conditions.

### Materials, Design, and Procedure

Participants were given one of the two physics problems shown in Table 1. They were given 15-20 minutes to complete the task at the beginning of a physics lab class in a proctored environment, and were given credit for participation. The problems are simple mechanics problems that would be typically found in the back of a textbook or on an exam, and are given routinely in homework assignments. The problem is typically solved by determining the two unknowns in the problem (friction and acceleration) via solutions to (a minimum of) two simple equations, one involving the definition of friction force ($F_{friction} = \mu F_{\text{normal}} = \mu mg$) and Newton's second law ($F_{\text{net}} = F_{applied} - F_{friction} = ma$).

While it may not be obvious at first glance, even to the expert, the physical situation described by the problem is somewhat counterintuitive. In particular, the net force resulting from the two horizontal forces on the object (applied force and friction force) is in the direction opposite the motion. That is, the applied force is less than the friction force. Nonetheless, the object can still be moving, just slowing down. It is well-known that many students have difficulty with the idea that the net force can be opposite the direction of motion (Viennot, 1979; Clement, 1982).

Table 1. Question Set 1: isomorphic abstract and concrete versions of a force-motion show-work problem.

| Abstract version | Concrete version |
|---|---|
| A force F is exerted on an object in the positive direction. The object is sliding on a surface in the positive direction toward a mark on the surface. At the very moment the object passes the mark, the force F is 80N. The mass of the object is 32Kg and the coefficient of friction between the object and the surface is $\mu_k$=0.3.<br>What is the magnitude and direction of the acceleration of the object at the moment it passes the mark? | In front of a house, a boy is pulling on a large toy rocking-horse in the direction towards the driveway. The rocking-horse is on the sidewalk sliding toward the driveway. At the very moment the rocking-horse crosses onto the driveway, the boy is pulling it with a force of 80N. The mass of the large toy rocking-horse is 32Kg and the coefficient of friction between the toy and the concrete is $\mu_k$=0.3.<br>What is the magnitude and direction of the acceleration of the toy rocking-horse at the moment it crosses onto the driveway? |

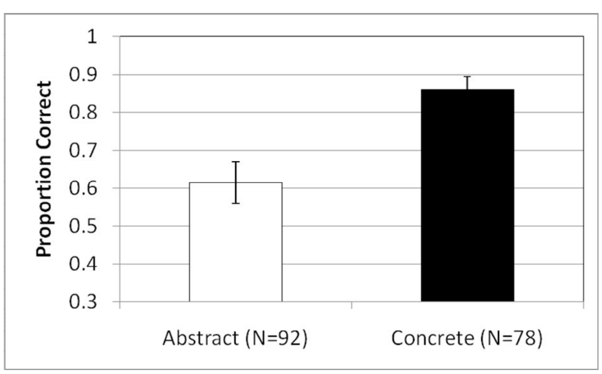

Figure 1. Student performance on Question 1, separated by condition. Error bars are 1 SEM.

## Results and Discussion

As indicated in Figure 1, students were significantly more successful in obtaining a correct solution in the concrete condition (86%) than the abstract condition (62%), $\chi^2(1) = 13.2$, $p < .0001$, effect size $d = .6$. These results are consistent with previous findings that concrete, grounded context results in better student performance compared to the abstract context Further analysis of the solutions supported a previously described explanation for this difference (e.g. Koedinger et al. 2004), namely that the abstract condition inhibits the use of familiar knowledge that may help in understanding and solving the problem. In the abstract condition, the most common errors involved issues of not properly understanding the physical situation described in the problem text. For example in the abstract condition a 10/92 students confused (i.e., switched) the values of the two of the forces provided in the problem (the applied force and the weight, via mass). In addition, 5/92 students in the abstract condition ignored friction. In contrast, none of the students in the concrete condition made these errors; the most common error in the concrete condition was a simple algebraic error. Therefore, these results suggest that students in the abstract condition were less able to understand the physical details of the problem, and this lack of physical understanding could in turn inhibit them in their solution to the problem.

However, responses from a small number of students suggest that in some cases the concrete context can interfere with success in solving the problem as well. In particular, the common conceptual error that an object must be moving in the direction of the net applied force was made by a small number of students (4/78) in the concrete condition. For example, one of these students wrote, "Because net force is less than zero, static friction was not overcome and acceleration is zero". In contrast, *none* (0/92) of the students in the abstract condition made this error. However, the elicitation of this misconception may have been minimized in the particular concrete context given, as the friction force (large toy on concrete) is fairly salient compared to the force in the direction of motion (via a boy). This may partially explain why only a small number of students displayed the misconception.

## Experiment 2

Experiment 1 replicated the finding that the concrete condition provides benefits to problem solving. However, there was also an indication that more concrete contexts can cue misconceptions more frequently. The purpose of Experiment 2 is to determine more directly whether a concrete context cues a misconception more frequently than an abstract context. We elicit the same misconception as in Experiment 1, namely the student belief that the direction of the net force on an object and its velocity must be in the same direction.

### Participants

Two hundred and fifty-two participants were enrolled in the first quarter of a calculus-based introductory physics series at a large research university. They completed this assignment for participation credit as part of their total course grade.

Table 2. Question Set 2: isomorphic abstract and concrete versions of a force-motion conceptual question.

| Abstract version | Concrete version |
| --- | --- |
| At a particular instant of time, there are several forces acting on an object in both the positive and negative direction, but the forces in the negative direction (to the left) are greater. Which statement best describes the motion of the object at this instant?<br>a) it is moving to the right<br>b) it is moving to the left<br>c) it is not moving<br>d) both a and b are possible<br>e) both a and c are possible<br>f) a, b, and c are possible | A force sensor is attached inside a soccer ball that is used during a match. The force sensor measures the forces acting on the ball. At a randomly chosen instant during the game, the sensor detects that there is only one horizontal force on the ball, and that force is directed toward the home-team goal. Which statement best describes the motion of the ball at this instant?<br>a) the ball is moving toward the home team goal<br>b) the ball is moving away from the home team goal<br>c) the ball is not moving<br>d) both a and b are possible<br>e) both a and c are possible<br>f) a, b, and c are possible |

Note: For both questions, answer *f* is the correct answer.

### Materials design and Procedure

Experiment 2 is a within-subject design. Participants completed the multiple choice questions shown in Table 2 in a quiet, proctored room. These two questions were part of a larger set of multiple choice questions and the design was counter-balanced for question order (no reliable differences in order were found). The validity and reliability of the multiple choice questions was verified through extensive testing and interviews (Rosenblatt, Sayre & Heckler, 2008). These two questions are designed to elicit student beliefs about the relationship between the direction of net force on an object and the direction of its velocity[1].

The final course grades of the students were also collected. The student were then categorized as the High grade students (n =123) and Low grade students (n = 119), indicating whether they were in the top half or bottom half of the class as measured by the final course grade.

## Results and Discussion

While both questions were difficult overall, students answered the Abstract question correctly more often (20%) than the Concrete question (9%), McNemar's test $p < .001$, effect size $d = 0.32$. Figure 2 shows the proportion of students choosing the correct answer choice separated out by High and Low Grade students. Inspection of Figure 2 reveals that High and Low grade students perform similarly (poorly) on the Concrete question and the High Grade students perform significantly better on the Abstract question than the low grade student. A repeated measures analysis, with question type as the repeated measure and grade rank as the between student factor, reveals significant main effects of question type ($F(1) = 18.4$, $p < .001$), and rank ($F(1) = 4.5$, $p = .035$), and there is a reliable interaction between question type and grade rank, $F(1) = 8.0$, $p = .005$. This interaction is mainly due to the High Grade students choosing the correct answer more often for the abstract question (26%) than for the concrete question (10%), McNemar's test, $p < .001$. There is no significant difference in choosing the correct response between the concrete (12%) and abstract (8%) question for Low grade students, McNemar's test $p = .5$.

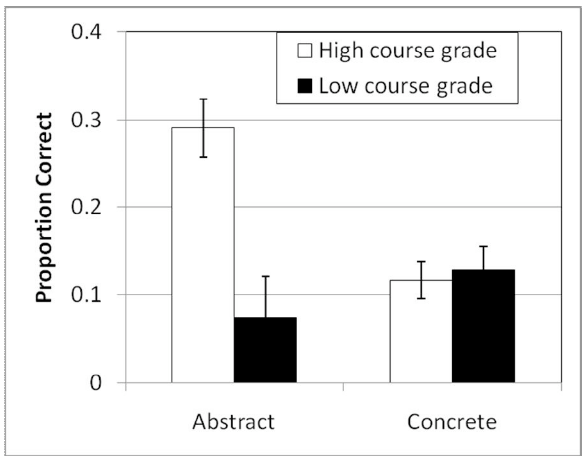

Figure 2: Student performance on Question set 2, separated by High course grade students (n = 123) and Low course grade students (n =119). Error bars are 1 SEM.

## Experiment 3

The purpose of this experiment is two-fold, first it is to replicate the finding that while concrete context help with simple problems, more complicated problems may have increased performance in more abstract problem representations (Koedinger et al., 2008). Therefore, we pose a slightly more complicated problem (involving three rather than two equations and unknowns). The second purpose is somewhat exploratory. Experiments 1 and 2 indicate that everyday knowledge may in some cases hinder problem solving because it may misguide the solver to an incorrect solution path. In Experiment 3, we pose a simple kinematics problem that lends itself to using everyday knowledge, but may also present cues in the concrete context that lead to incorrect assumptions.

### Participants

The participants were 68 university students enrolled in the first quarter of a calculus-based introductory physics course at a large research university. They completed this assignment for participation credit as part of their total course grade. Participants were randomly placed in one of two conditions, the abstract (n=32) and concrete (n=36) contexts conditions.

### Materials design and Procedure

Participants were given one of the two physics problems shown in Table 3. They were given 15-20 minutes to complete the task in a quiet, proctored room. The problems are simple kinematics problems that would be typically found in the back of a textbook or on an exam, and are given routinely in homework assignments. The problems are typically solved by determining three unknowns, the distance that each person travelled and the acceleration of one of them. This involved using three equations: the total distance $d_{tot} = d_1 + d_2$, the kinematic equation for the constant velocity person $d_1 = v_1 t$, and the kinematic equation for the constant acceleration person $d_2 = a_2t^2/2$. Therefore this problem is slightly more complicated than the problem in Experiment 1, which only needed two equations and two unknowns.

Table 3. Question Set 3: isomorphic abstract and concrete versions of a kinematics show-work problem.

| Abstract version | Concrete version |
|---|---|
| Two objects are 60 kilometers apart and move toward each other such that they will meet at a point in-between the original starting positions. The first object travels in the positive direction toward the meeting point at a constant speed of 18 meters/second. The second object begins at zero speed and constantly accelerates in the negative direction toward the meeting point. If both objects meet in exactly 30 minutes, what was the acceleration of the second object? | Two friends, Kevin and Claire, live 60 kilometers apart and decide to meet in a town called "Tristville" in between them. Claire drives eastward toward Tristville at a constant speed of 18 meters/second. Kevin begins at zero speed and constantly accelerates westward toward Tristville. If they both reach Tristville in exactly one-half hour, what was Kevin's acceleration? |

## Results and Discussion

There are three important results from Experiment 3. First, unlike Experiment 1, students were equally successful in obtaining a correct solution in the concrete condition (47%) than the abstract condition (53%), $\chi^2(1) = .2, p = .6$. Second, Figure 3 shows the proportion of students obtaining the correct solution, separated out by High and Low Grade students. Inspection of Figure 3 reveals a pattern similar to the results in Experiment 2: High and Low grade students perform similarly on the Concrete question and the High Grade students perform significantly better on the abstract question than the Low Grade students. A two-way Generalized Linear Model (question type × grade rank) with a binary response analysis reveals a significant main effects of rank (Wald $\chi^2(1) = 9.9, p = .002$), and there is a reliable interaction between question type and grade rank, Wald $\chi^2(1) = 4.1$, $p = .04$. This interaction is mainly due to the High Grade students choosing the correct answer more often of the abstract question (87%) than for the concrete question (57%). While there may be a trend for students choosing the correct response in the concrete condition (41%) compared to the abstract condition (24%) for Low Grade students, the difference is not statistically reliable.

The third result comes from a closer examination of the solution methods which reveals an unanticipated and fairly frequent misunderstanding of the problem. In particular, 28% (10/36) of the students in the concrete condition made the same mistake of explicitly assuming that the two friends in the problem met *halfway* when in fact it is only stated in the problem that they met "in between" the starting points. None (0/32) of the students in the abstract condition made this erroneous assumption. Students' remarks in debriefing revealed that the most plausible explanation for this assumption is that the students in the concrete condition assumed that "friends meet halfway". In the abstract condition, the "friends" are replaced with "objects", and none of the students appeared to be cued to assume that the objects met halfway. Therefore, this is a case in which the concrete context appears to be interfering with the correct solution. It is important to note however, that the fraction of students in the concrete condition making this assumption did not depend on grade rank $\chi^2(1) = .8$, $p = .4$. Therefore, if this "misconception" (which could also be viewed as simply an incorrect assumption) is responsible for the difference in score between the abstract and concrete conditions for the High Grade students, it remains to be explained why the Low Grade students did not have a similar gain in score. It may be that the low grade students are such poor performers that switching from concrete to abstract simply involves switching from one incorrect method to another incorrect method.

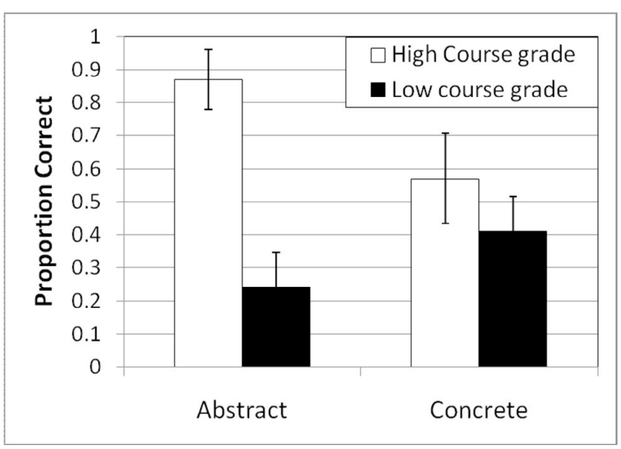

Figure 3: Student performance on Question Set 3. Error bars are 1 SEM.

## General Discussion

There are four main results from this study. First, the advantage of concrete problem representation found in Koedinger et al. (2004, 2008) was replicated for a relatively simple physics problem. This experiment was different from the previous studies in that both of the representations were in "story" format. Nonetheless, the nature of the advantage in the concrete representation, namely better comprehension of the problem appears to be consistent with these previous studies.

The second finding was a significant interaction between abstract vs. concrete problem representation and student course grade for a simple conceptual question that is known to strongly elicit a well-known scientific misconception. In particular, the concrete, familiar representation was likely to elicit the misconception at a similarly high level for both High and Low Grade students; however, in the abstract representation, the High Grade students performed significantly better than the Low Grade students. This result could be interpreted as support for the idea that incorrect answering in the concrete representation is due to cueing of everyday, familiar knowledge common to all students while the abstract representation is less likely to cue such knowledge. The High Grade students may answer correctly more often in the abstract context because they may tend to use explicit reasoning skills rather than on relying on automatic, prior knowledge. Another possible explanation is that both High and Low Grade students began the course at floor on these questions, and the High Grade students have learned the abstract representation simply because the course may have presented more abstract than concrete examples, thus they would perform better on the abstract questions. In contrast, the Low Grade rank students may have simply not learned the material yet, thus they score low on both abstract and concrete questions. Understanding the distinction between these two possibilities is worth further investigation, and it is possible that both may be at work.

The third finding was a lack of difference in class averaged performance of the concrete and abstract representations for a problem that was slightly more complex (as measured by number of equations and unknowns to solve) than the problem in Experiment 1. This is somewhat consistent with the findings of Koedinger et al. (2008) in that they found an increase in advantage of the abstract representation when the problem difficulty was increased.

The fourth finding is similar to the second, but for a quantitative problem rather than a conceptual question. In particular, High and Low Grade students perform similarly in the concrete representation, but High Grade students perform significantly better in the abstract representation. A similar proportion of High and Low Grade students displayed an incorrect assumption in the concrete representation that was apparently caused by the familiar nature of the representation, and no students displayed this assumption in the abstract condition. Once again it is not clear what causes the difference in performance between the High and Low Grade students. The two explanations given above for the second finding remain viable. The concrete representation may be cueing familiar automatic problem solving processes and the abstract may be cuing (in High Grade students) more explicit, deliberative processes. On the other hand, it may be the case that (effectively) only relatively abstract examples are practiced in the course and only the High Grade students have learned them. In any case, it is clear that the concrete representation is cuing knowledge that inhibits the solution process, at least in High Grade students.

In sum, while some advantages of concrete representation have been replicated, this study identifies an important disadvantage for concrete representations: they can cue familiar knowledge that is contrary to scientific knowledge and this in turn can lead solvers to incorrect solution paths. This raises some practical issues about the relative usefulness of concrete and abstract questions as a diagnostic instrument. From a psychometric perspective, the abstract representation would be preferable over the concrete representation because the former is more successful at discriminating between students, at least as measured by final course grade. However, from a pedagogical perspective, the results from this study suggest that both high and low level students are susceptible to misconceptions cued by problems posed in the concrete representation format. Therefore, concrete problem representations are important for determining whether both High and Low Grade students have overcome the relevant scientific misconceptions. Once again, these results highlight the important tradeoffs between problems with concrete and abstract representations.

## Endnotes

(1) Note that the two questions are not exactly isomorphic: the abstract question mentions forces in two directions and the concrete question mentions only one force in one direction. However, in our previous work in constructing items of this type we found that this difference does not reliably or consistently change student answering patterns.

**Abstract**: A central interest in developing professionalism resides in the potential for professionals to learn from and with one another in ways that support transformations of their knowledge practices. However, negotiation between multiple perspectives, interests, practices and traditions intertwines cognitive-epistemic with socio-relational and affective aspects, which may lead to tension and conflict. While tension can disable learning, this paper argues that identifying these tensions should be viewed as a significant source for change and development. The paper reports on a teacher-researcher collaboration at a secondary school which focuses on the co-design of a learning module. It is shown that the identification of tensions during meetings helped participants to focus their efforts on the root causes of problems, which led to a reconceptualisation of the current work practices. This subsequently helped team members to deviate from established norms and improve their practices.

## Introduction

Rapid changes in current networked society present new challenges to human competence and flexibility. Productive participation in knowledge-intensive work requires that individuals, their professional communities, and their organizations develop new practices, advance their knowledge and their understanding as well as produce innovations. This is reflected in developments in professional communities wherein work is increasingly focused on the deliberate advancement of knowledge rather than on the mere production of material objects (Bereiter, 2002; Paavola & Hakkarainen, 2005). In order to cope with the cognitive, social, and motivational challenges of knowledge-based society, tools and pedagogical methods are needed that open up opportunities for enduring and sustained transformation of professionals' knowledge practices.

Based on the works of Engeström (1987), Schatzki (2002) and Reckwitz (2002) we define a knowledge practice as follows: *a social-historically created and shared behavioural pattern consisting of an interconnected and inseparable array of recurrent activities, conventions, rules and norms that play part in the creation of knowledge artefacts.* According to this conceptualization, practices are characterized by their social nature, which means that practices are shaped by and evolve within a knowledge community, ultimately becoming part of the its identity. In addition, the concept of knowledge practice entails stability as well as change. Stability is reflected as routines, procedures, conventions, underlying beliefs and values, epistemological conceptualizations and the set of available tools. At the same time, practices are open to change in that each activity based on this practice is adapted in response to changing contexts and particular circumstances.

The rationale for practice transformations is that newly developed practices and tools aim to overcome the tensions a particular knowledge community identified during certain events in their knowledge work. Practice transformations involve fundamental changes in views, beliefs, ideas and ways of working with knowledge that fulfil a certain need that is relevant for a particular professional community's knowledge work. These transformations lead towards historically new types of practices based on collaborative, tool-mediated knowledge production that takes place as long-term, sustained processes and which ultimately lead to a reconceptualization of the object and motive of the community's knowledge practices to embrace a more diverse horizon of possibilities than in the previous practice.

However, practices are difficult to change, not only because this would imply a negative evaluation of previous socially grounded practices, but also because such transformation involves a period of disorientation while old practices are gradually unlearned and new practices are gradually developed (Eraut, 2004). During this period professionals feel like novices, but without having the excuses or discounts on performance normally assigned to novices. The pain of transformation lies in the loss of control over one's practice when one's tacit knowledge ceases to provide the necessary support; and the emotional dimension is also of considerable importance. In addition, Little (1990) reports that professionals view transforming practices as involving high transactional costs to participatory work in time. According to Argyris and Schön (1978) the central problem for most professionals is that they are intellectually and emotionally committed to espoused theories which describe the world as they would like it to be, but which do not necessarily accurately describe their own activities and constrain possibilities for transforming their practices. Moreover, practices are similar to physical infrastructures in a sense that when everything is working well one does not pay attention to them. Consequently, professionals rely on them even they are not fully aware what constitutes them. Additionally, the practices have been evolved during a long period. According to these authors, these problems can only be solved when professionals step outside their taken-for-granted world and espoused theories to actively search for genuine feedback which challenge the outcomes of their activities.

Although practices tend to remain stable and to reproduce socially shared knowledge, this stability is altered as internal or external disturbances produce various forms of tensions within activity systems (Engeström, 1987, 2007; Hakkarainen, Palonen, Paavola, & Lehtinen, 2004). The notion of developmental tensions as a driving force of change and development is drawn from the premises of cultural-historical activity theory (CHAT) (Engeström, 1987; 1999). CHAT draws upon the works of Heidegger (1962), Dewey (1968) and Leont' ev (1981) converging on the role of tensions and their resolution as a means of revealing the nature of the world around us. In these socio-historical approaches to learning and knowledge, tensions are conceptualized as the conditions that open up opportunities for creative efforts in activity and communication and are as such the driving force behind innovative knowledge practices.

Changes in practices are due to external as well as internal disturbances. According to Engeström (1999a; 1999b), identification of tensions in an activity system helps learners to focus their efforts on the root causes of problems. Barab, Barnett, Yamagata-Lynch, Squire, & Keating (2002) corroborate on this in arguing that tensions and their resolution helps to identify the dynamic forces of change and comprise an important constituent and starting point for investigating such processes. The mechanism behind tensions resolution is that as the tensions of a particular activity system are aggravated, some individual participants begin to question and deviate from its established norms. Learning is accomplished when tensions lead to a reconceptualization of the object and motive of a particular activity to embrace a more diverse horizon of possibilities than in the previous activity. While practices might change when new tools become available or circumstances and contexts shift, they can also be deliberately altered by those carrying out the activities when they invent new strategies of working or activities. In addition, members of a community may experience difficulties in constructing a connection between the goals or their actions and the object and motive of the collective activity, which may give rise to tensions.

For instance, knowledge communities that involve cross boundary practices between different domains of knowledge embody an epistemic collision of activity systems which generates disturbances and conflicts. This involves that in collaborative contexts, negotiation between multiple perspectives, interests, practices and traditions intertwines cognitive-epistemic with socio-relational and affective aspects, which may lead to tension and conflict. As practices inevitably change when concrete activities are carried out, the development and transformations of practices proves to be an ongoing and contingent process. Due to this dynamic nature of practices, the design of a new object might overcome shortcomings of former existing objects, but when they are employed as tools this will restructure the nature of the current practices and will in this manner create new opportunities but also new problems and challenges. According to this line of reasoning, learning or development of practices occurs when members attempt to negotiate about how to adapt their knowledge practices as a results of these disruptions feeding into the shared object.

In general, what is important here is that a group of professionals has to capitalize on the multiple perspectives of its members, that the group creates ownership and commitment towards achieving the common objectives and that members build up on each other willing to learn from tensions. The way to overcome these tensions is to negotiate possible solutions or design hypotheses for new practices or new tools. Eventually these new practices and tools lead to new tensions which leads to an iterative sideways movement. Preconditions for groups to be able to solve tensions to improve their practices are: 1) proactive and continuous creation of common ground, 2) sharing tensions in considerate ways and 3) supporting and recognizing agency (Matusov, 2001). However, what is still lacking in socio-historical accounts and studies of tension resolution as conditions for practice transformations to occur, is a description of patterns of tension resolution that lead to productive changes and development. Moreover, the investigation of trajectories of tension resolution affecting the emergence of new knowledge practices located at several timescales and places has rarely been touched upon in empirical endeavours.

In the present paper, we will present the data of a study in the field of a school-university partnership at a secondary school which shows a particular patterns in the cognitive-epistemic consequences and resolution of tensions. This study focused on the investigation of the practice changes of an interdisciplinary team which focused on the redesign and implementation of a learning module. Meetings of this team served to reflect upon and analyze teachers' prevailing practices, as well as envision and implement changes to the module.

## The Setting and Knowledge Practices of the Investigated Knowledge Community

This study focuses on describing the nature and scope of transformations in teachers' coaching practices that followed from resolutions of developmental tensions that arose in an university-school partnership. This partnership involved the 2-year lasting collaboration at UniC, a secondary school in Utrecht in The Netherlands that was aimed at the redesign of a course module based on knowledge creation principles (Paavola & Hakkarainen, 2005). One central feature of the knowledge creation approach that was taken up in the design was the concept of *mediation* which means that students' activities are directed towards the collaborative creation and advancement of shared knowledge objects (e.g., documentaries, research reports or instructional material) mediated by specific supporting technological or conceptual tools.

At UniC, students are coached towards the national school exam, complementing the focus on knowledge acquisition by stressing development of competencies, skills and personal development. By clever organization of compulsory learning materials students are enabled to develop their own talents and interests in a course module in which they plan and perform projects within or outside of the school context. This means that every week in the curriculum a half day is reserved for these projects for periods each of which last eight weeks. The school supports the students and offers possibilities to carry out their projects.

Within this pedagogical context, teachers' coaching practices traditionally focus on the development of courses and assignments providing guidance to students' self-directed learning process. UniC expressed the aspiration to challenge their students more towards meaningful learning. In addition, the teachers' expressed that their role during these projects was unclear and that they needed more scaffolds to structure their coaching. Therefore, a multi-disciplinary team consisting of educational researchers, teachers, students, dean, process coordinator and pedagogical experts was set up to flesh out the design based on knowledge creation principles which matched UniC's general pedagogical approach and objectives. The collaborative design, implementation and testing of the new course module implied that high demands were placed on coaching practices of the teachers which provide a platform for tensions to arise. For instance, they had to: (a) comprehend the theoretical principles behind the knowledge creation metaphor, (b) apply these principles in their practice, and (c) reflect on their role as a teacher and transform their practices accordingly to scaffold students' knowledge creation processes.

## Method

Multiple, intertwined methodological approaches and various approaches to data collection and analysis were combined to elaborate dynamics of incremental changes which reflect practice transformations resulting from patterns of tension resolution. The study involved ethnographic analyses with participatory observation, a developmental intervention approach, interviews and event sampling to follow the processes towards new practices. Our analyses took tensions in partners' activities as a point of departure. We look for episodes in the material that express problems and materializes as developmental tensions.

Then we can investigate discursive activities between partners (micro level), elaborate on episodes of tension resolutions over time (meso-level) and examine how patterns of tension resolution relate to transformations of practices at the level of trajectories (macro-level). This gives to transformation processes as they play as professionals deliberately extending shared knowledge and mobilize knowledge types embedded in the social practice in their problem solving. For framing the analysis we developed the following approach:

1. Description of the knowledge practices of the investigated professional community;
2. Description of the nature of tensions that occur in these practices. Explore resolutions to the tensions, characterize tension-resolutions and analyze how these contribute to transformation towards new practice over time;
3. Examination of practice transformation including emphasizing the vertical (socialization and internalization) and/or horizontal dimension (boundary crossing and externalization).

The cases in this cluster examine the nature of these tensions that provide an important starting point to explore change and development of knowledge practices. To assess the knowledge practices of the actors involved both studies, we combined data collected from different instruments, namely:

- Material artefacts, such as reports, concept maps, and written comments;
- Pre- and post questionnaires;
- Semi-structured interviews;
- Transcribed recordings and minutes of the meetings.

These instruments were mainly designed to capture critical events during the meetings and to discern how these events are echoed in the ways professionals adapted their practices. Critical events were conceptualized as articulations of developmental tensions and were posteriori checked with the investigated knowledge communities.

## Results

Most tensions were observable on the boundary of the intersecting activity systems showing how team members balanced institutionalized or traditional and newly developed practices. One source for tensions involved the specific organization of teachers' coaching practices to be more in line with the new pedagogical approach and at the same time foster students' knowledge construction processes. The following excerpt exemplifies this tension during an interview with one of the participating teachers:

| | | |
|---|---|---|
| 1 | Teacher3 | I see that an increasing amount of student groups do not have a clear view of what they are doing, that is what I am afraid of, unfortunately |
| 2 | Researcher1 | How do you coach these students then? |
| 3 | T3 | Well, you cannot just leave them, than this would lead to chaos. […] You can divide tasks in the group and think of who is going to do what, but then I would be too directive and I am not sure whether that should be our intention, so therefore I give them more freedom […] |
| 4 | R1 | […] Well you mean that you are still in search of what is expected of you as a teacher. What do you need in your coaching? |
| 5 | T3 | First I need to know more about knowledge creation, what the idea and what the pillars are, so I can eventually adapt my coaching to that […] normally I am very clear in my teaching, but in this pilot it seems that you have to discover what the best ways of coaching are |

*Interview Teacher 3; December 2006*

Teacher3 expresses his concern about his impression that students have not been successful in organizing and structuring their work. When prompted for his ways to cope with this impression in his coaching, he states that he would like to be more directive, saying " .. you can divide tasks in the group" (passage 3). He identifies a tension with what he interprets as the coaching practice which would comply with principles of knowledge creation" but then I would be too directive and I am not sure whether that should be our intention, so therefore I give them more freedom" (passage 3). Eventually, for him to overcome this dilemma, more guidelines for coaching knowledge construction are needed.

Thus, this episode points to a tension between what can be interpreted as top-down instruction at one hand and social distancing at the other. Teacher3 was reluctant to interfere with students' activities too much, since this would be in conflict with his emergent perspective about what is important when fostering students' knowledge construction. Still, this coaching practice added to the problem of students, who reported that they sometimes experienced their teachers' approach as being disruptive in the context of their activities:

| | |
|---|---|
| Researcher3 | What do you think of your teachers' coaching? |
| Student1 | Well, sometimes teachers ask us just too often what we are doing and what our end product will be; what we want to achieve. But in most cases, we had explained that seven times already and they still want us to explain it even further, while we even do not yet know how far we can go, that is quite annoying |

*Interview Student group 4; December 2006*

In this episode student1 reflects on their teacher's approach, mainly involves asking explanatory questions about the nature and status of the group's activities. This is corroborating on what teacher3 stated in the previous episode. Although teacher3 adopted this coaching practice as his interpretation of what is needed to foster students' knowledge construction processes, this caused a conflict with the observed and experienced processes of teachers and students. This point was explicated during a subsequent plenary meeting of the design group:

| | | |
|---|---|---|
| 1 | Teacher3 | […] Well, it seems our students do not have a clear idea of what they have to do |
| 2 | Dean | Students have to know what the assignment entails […] |
| 3 | Ped. Expert | […] So I would suggest that the teachers can focus on helping to students create these structures. […] |
| 4 | Researcher3 | Students could concretize their ideas in a plan |
| 5 | T2 | So I would like to coach them to make it clearer like what the object is and its requirements. So far, we have maybe been too reserved. |
| 6 | PE | That is very important, and then those group members will follow their own work structure. […] |
| 7 | R2 | Still, it is not a bad thing that it going like this, if they first muddle a little, […] |
| 8 | PE | But you shouldn't let that continue too long |
| 9 | T1 | But, what you see now. That we should give a little more |

| | | |
|---|---|---|
| | | structure |
| 10 | T2 | We can ask students to make a so-called Tabasco planning which they are already used to construct. In this planning they have to specify the activities they are going to perform, what the end objectives are. This can serve as a tool for teachers to monitor students' progress without being too directive or strict […] |
| 11 | Process coordinator | And you could revise this planning, which makes leaves it more open for students […] |
| 12 | T2 | Apparently that is needed |
| 13 | R3 | So, it is our observation that that is needed, yes. |
| 14 | T2 | Well, that is clear by now. This shows that a good start is necessary. There has to be concrete object and once that it is there, it will go well |

*Protocol meeting design team; January 2007*

This episode shows the identification of the issue that is at hand ".. it seems that our students do not have a clear idea of what they have to do" (passage 1), leading to an expression and framing of the tension between teachers' current approach ".. So I would like to coach them to make it clearer like what the object is and its requirements. So far, we have maybe been too reserved" (passage 3), and the more directive approach ".. But, what you see now. That we should give a little more structure" (passage 9). The suggestion that is put forward to overcome this tension is to synthesize both perspectives in a concrete manner, ".. We can ask students to make a so-called Tabasco planning which they are already used to construct" (passage 10). This is accepted and taken up by the others ".. apparently that is needed" (passage 12).

Another issue related to teacher's 3 concern regarding the lack of guidelines for coaching students' knowledge construction, and the contribution and roles of the members of the design team in the coaching practices:

| | | |
|---|---|---|
| 1 | T3 | Nevertheless, it is important get more assistance during work sessions because now we're only with the three of us,. that is my first concern |
| 2 | D | It should be fixed then, we need teachers for this class […] |
| 3 | T1 | Sometimes you [Researchers] are a little blunt It is not criticism but I noticed that you have you own agenda You don't really help us coach, we just have to take care of it. In my opinion that is not really being an actor! |
| 4 | R1 | Well, the idea was that we didn't want to participate as a teacher because we don't have that expertise though we are here to provide you with some advice and answer your questions, if you have any |
| 5 | T1 | […] I am teaching the knowledge creation project on my own which is not an ideal situation, I just want you to think with me. Clearly we don't expect you to teach […] |
| 7 | R1 | Well, I believe that is a good thing to hear, I am glad that this came forward |
| 8 | PE | The researchers are used to stay in the background to be able to observe the process as objectively as possible |
| 9 | T2 | There is a big culture difference because we are used that everyone is involved You are think as observers |
| 10 | PC | It is a type of participation when you are observing […] |
| 11 | T2 | You could divide one group into two groups so that T1 has to coach his own groups but that T4 and T1 meet each other during class to discuss any problems or to ask each other for advice |
| 12 | D | You can then also ask researchers for feedback during coaching […] |
| 13 | R1 | Yes, that would be perfect [everybody agrees] |

*Protocol meeting co-design team; January 2007*

This episode shows a tension between the work traditions of researchers at the one hand and teachers at the other. The issue that was expressed "..it is important get more assistance during work sessions because now we're only with the three of us" (passage 1), opened up for explicating the underlying conflict between the perspectives of researchers and teachers regarding their role during the coaching of students' knowledge creation processes. Utterance s such as "..You don't really help us coach, we just have to take care of it. In my opinion that is not really being an actor!" (passage 3) versus "Well, the idea was that we didn't want to participate as a teacher" (passage 4) illustrate this tension. Subsequently this resulted in a framing of these conflicting perspectives from the view of the traditional work practices of both groups to create common understanding ".. There is a big culture difference because we are used that everyone is involved You are think as observers" (passage9). Eventually, partners provided suggestions to overcome this tension by a division of labor ".. You could divide one group into two groups […] you can then also ask researchers for feedback during coaching" (passage 11).

The abovementioned developmental tensions set the stage for collaborative analysis and for the creation of a shared understanding to overcome them and change teachers' coaching. Eventually, teachers' coaching transformed towards an increasing emphasis in the collective construction of a planning together with students. This would help students to organize their work and offered teachers a tool that enabled them to monitor students' progress during knowledge construction:

**Phase 1 in coaching knowledge creation**
- Do students have a clear plan?
- What are they eventually going to show, what is their object?
- The teacher has a specific role in this process
- 'Go' or 'no go' decision

*Slide taken from presentation of Teacher3; March 2007*

In this artefact, i.e. presentation provided to other teachers at UniC, teacher3 shows that that the significance of a "planning" is echoed in teachers' coaching practices. This theme can be traced from the tension that team members identified and attempted to overcome earlier. Moreover, teacher3 took up this idea and implemented a 'go-no go' decision in his practice. Then students had to negotiate their planning with their teacher before they were allowed to continue with their knowledge creation projects:

R3 How do you see your role as a teacher now, what is most important?

T3 Well. First that students chose a subject and that they construct a planning. And the task of the teacher is to perform a reality check and argue whether students' planning is a good one or not, to give a 'go' or 'no go' decision at the start. There is where the teacher plays an essential role and this planning gives a good tool for me to observe what is happening and to ensure that students keep in a 'flow' towards the end

*Interview Student group 4; December 2006*

In this excerpt, teacher3 reports that he had adapted his coaching to such an extent that he now asks his students to construct a planning and that it is the teacher's task to decide whether students can continue in pursuing their knowledge construction according to this plan or that they have to construct a more realistic or challenging planning.

Tension resolution of conflicting perspectives about division of labor between members of the design team resulted in creation of a joint venture agreement:

For Utrecht University this agreement involves:
- To perform research at UniC in collaboration with teachers and students concerning the concept of knowledge creation and support thereof
- To realize a long-term relationship between research and educational practice, in which knowledge, insights and experiences are exchanged with the aim of learning and capitalizing from each other

For UniC this agreement involves:
- To obtain more insight and tools to experiment with possible solutions for the challenges and issues which structurally occur in educational practice
- To realize a long-term relationship between research and educational practice, in which knowledge, insights and experiences are exchanged with the aim of learning and capitalizing from each other

*Join venture agreement, first version; April 2007*

## Conclusion

A central challenge in transforming practices of teachers resides in potentials for teachers to learn from and with each other in the work place as they create and advance shared epistemic artefacts relevant for transforming their knowledge practices. To advance our understanding of such processes in teachers' practices, we must explore how these practices evolve. This study focused on developmental tensions between members in university-school partnership, and how their resolution points to practice transformations.

The findings illustrate that interaction between different knowledge trajectories occurred on both the individual and collective platform of the design team and how participants stabilized out of flux by changing their practices accordingly. During meetings practical pedagogical enacted knowledge of teachers intersected with social practices of the educational researchers. At this level, developmental tensions surfaced on the nexus of perspectives, agendas and interpretations of the actors involved in the collaborative design in the university-school partnership. The attempts undertaken to overcome the identified tensions involved the creation of artefacts (e.g. the joint venture agreement) that serve to objectify and afford this transformation.

Tacit knowledge (represented as the network of implicit epistemological beliefs, attitudes and knowledge) was explicated during group meetings and ideas expressed were often taken up by the group and integrated within existent practices, or became the driving force behind the development of relatively new pedagogical practices. For instance, the tension between top–down instruction versus social distancing and differentiation of coaching styles was resolved by a collective envisioning and fleshing out of coaching practices. More specifically, more emphasis was placed on employing students' planning as tools to monitor and to scaffold students' knowledge creation.

In sum, the study shows the transitions observed from identification of tensions, the attempts to overcome them by engaging in transformation of coaching and of social practices towards the creation of artefacts that serve to objectify and afford this transformation. Based on socio-historical perspectives on learning and development, we have appropriated the notion of developmental tensions as a driving force of change and development. Although we do not claim that developmental tensions are the sole impetus of transformations of work practices, the investigation of tensions and their resolution helps to identify the dynamic forces of change and comprise an important constituent and starting point for investigating such processes (Barab et al., 2002; Engeström, 1987; Koschmann, Kuutti, & Hickman, 1998; Murphy & Rodriguez-Manzanares, 2008). For the research reported here, the identification of these tensions provides a starting point for investigating and explaining practice transformations in knowledge creation contexts.

Based on the findings reported in this paper, we have derived a generic pattern of managing or resolving tension, namely: identifying, labeling, framing and solving/suggesting:

1. *Labelling the issue:* Often, tensions are not about the issue at hand (e.g., scheduling a meeting) but rather about what it represents, such as the experience of disrespect or the illegitimate exercise of authority. A tension could only arise as the consequence of one of the professionals in the knowledge construction work to describe a particular problem at hand;
2. *Identifying the tension:* as a result of professionals knowing what the issue is at hand, the contradictions in perspectives, knowledge, attitudes or affects come to the fore explicating the problematic features of the practices under scrutiny. These tensions are explicated in the voices of the several professionals in the collaborative knowledge construction work;
3. *Framing the tension:* subsequently, the tension is framed employing the self-created language, norms and rules of the knowledge community. This framing is necessary for creating a shared understanding of the tension and for constructing a representation of the forces acting in preserving and causing the problematic practices at hand. This will eventually enable professionals to adapt their practices to be able to overcome the tension;
4. *Constructing solutions:* Finally, professionals transform their or shared practices, construct new tools and implement them in the ongoing knowledge construction work.

In future research this generic pattern for tension resolution will be tested in other pedagogical co-design settings.

## Acknowledgements

The present investigation emerged in the context of research and development of Knowledge-Practices Laboratory (www.kp-lab.org, FP6-2004-IST-4, integrated project 27490, 2006-2011) project funded by Information Society Technologies (IST) program of European Community.

**Abstract:** Research indicates that people engage in rich mathematical practices in everyday activities, yet little is known about school-aged children's mathematics learning within the family context. This paper reports results of an interview study with 20 families to understand contexts and activities that engage mathematics in the family setting. The results indicate that problem solving is frequent activity, and that mathematics is engaged in accomplishing problem solutions in a range of contexts or situations. We describe features of math engaged problem solving and describe how it is value driven. We see multiple kinds of math and multiple people drawn into problem solving, and we identify socially distributed mathematical practices. These findings implicate the family as an under-recognized, yet rich source of math teaching and learning.

## Introduction

We investigate the diverse contexts and activities in which middle school age learners and their families engage in mathematical practices and problem solving. We describe several features of problem solving for the families we studied, characterizing the structure of their mathematical activities, and analyzing the social conditions and arrangements for their family-based mathematical practices. Several important features of problem solving around the home emerge: (1) the family is a setting giving rise to problems to be solved, which also generate mathematical activity; (2) values steer problem definition, identification, solutions and their judged adequacy; (3) different types of math and math at different levels come into play concurrently; and (4) it is critical to view mathematical thinking and learning as embedded in activity and in a social, historical, and distributed knowledge environment.

We first give some background on our approach and describe our research methods. Then we discuss each aspect of familial problem solving and present one example for each that is characteristic of the feature. We follow the descriptions with a summary and discussion of the significance of this characterization of problem solving with mathematics.

## Background and Perspectives

Understanding mathematical problem solving in the complexity of family life activities is supported by certain orientations to theoretical and analytical approaches. Work on problem solving has had a long history, with significant roots in Gestalt psychological studies by Wertheimer (1945), Duncker (1945) and others, which had direct influences on the cognitive revolution in studying thinking (Newell, 1981; Simon, 1999). The mathematician George Polya in *How to Solve It* was another major contributor to conceptualizing problem solving processes in mathematics (1957). None of these approaches, however, sought to understand the situated nature of mathematical practices in relation to everyday life activities. In the 1970's, spurred by everyday cognition theoretical formulations from Neisser (1976), Bronfenbrenner (1979), and Cole (1971), an ecological orientation to looking at mathematics use *in situ* was developed. It was advanced throughout the 1980's by Lave (1988), Saxe (1988), Nunes et al. (1989), Scribner (1984), and others more recently (Goldman & Booker, 2009; Hoyles et al. 2001; Nasir, 2000; Satwicz & Stevens, 2008; Stevens et al., 2006). We know from such studies that people engage mathematically in the course of everyday activities from dieting to shopping to sports to the work of nursing and dairy order filling.

We take a view of problem solving that recognizes its complexity and finds problems being generated in many life situations. Problems and problem solving are part of the social fabric in peoples' lives, and they are distributed in time, place and across persons. They involve cognitive, social, cultural and physical means in their definition, generation and solutions, and a direct pursuit of both outside constraints and peoples' desires. We are especially interested in the problem-solving that people do during their family-based activities, how it both requires and generates mathematical practices, and how these mathematical problem-solving practices instantiate learning.

We see mathematics practice as ubiquitous in people's family-based activities. We also take a comprehensive view of learning that is based on activity in practice (Lave & Wenger 1991), and consider the family as a little examined yet significant cultural environment for activities and social relations that constitute a sizeable proportion of human experience and involve poorly understood forms of learning (Bronfenbrenner, 1979; Leichter, 1975). In relation to math, Ginsburg and his colleagues document how and what mathematics young children are "taught" at home (Ginsberg et al., 1999). Jackson and Remillard (2005) and Rogoff, Ellis, and Gardner (1984) show that the explicit teaching softens and changes once children enter school. The literature leaves us with a very obscured view of the significant role that families might play in mathematics teaching and learning, yet with the hopes that math engagements might be ubiquitous in familial circumstances and activity. Our work enters the family space to better understand the significance of the family as a setting for mathematics engagement, learning and the development of quantitative literacies (Steen, 2004).

## Methods

The Family Math research project investigates the ways families with middle school aged children characterize their engagement in mathematical problem solving during the course of individual and family activities and events.[1] Our goal is to identify the social, cultural, and material contexts that are relevant to and create opportunities for mathematics learning and practice as well as to characterize similarities and differences in family math situations. We seek to identify the resources family members use for solving problems together, characterize the structure of these activities, describe the resources used in solving math-related problems, and analyze the social conditions and arrangements for family-based mathematics practices. Eventually, these understandings of mathematics of family life will help the field identify and design for points of synergy for strengthening the role of the family in mathematical teaching and learning and to build bridges between math in the home and math and school.

In the results reported here we present data based on two-hour interviews with 20 families providing narrative accounts of math in their daily lives. Narratives provide us with participants' accounts in their own words and allow for us to have records of how people relate stories about their math related activities, including family members self-identifying as African-American (N=5), Latino (N=23), Asian (N=7), Pacific Islander (N=8), Multi Racial (N=6) and white (N=25). The families also represent a spectrum of economic diversity, ranging from low income (children can receive free lunch) to upper-middle income families. The educational levels of the heads of families was also diverse, ranging from high school education through graduate school.

### Data collection

We developed a semi-structured interview to have people discuss the activities they engage in as part of family life, work and school, allowing them to give us particularized versions of how they think about and accomplish their life tasks. The interview gave family members ample space for describing their experiences, while also collecting certain information from all families such as education levels, perceived comfort with mathematics, school attainment, number and description of math classes that parents (and students) have taken, and their attitudes towards mathematics in general and towards school math. The protocol included two segments to provide parity of data across all families. Each family member told a "Math in a Minute" story about an experience of any kind, positive or negative, alone or with others, that they had with mathematics. Each family also was asked to choose a cell phone plan by using brochures from four providers we provided that would meet the needs of the family. This task put the family into action and provided observable, interactive accounts of the family in a problem-solving situation. All interviews were videotaped and took approximately two hours.

### Data Analyses

The analyses of the interviews proceeded through several stages and treatments. Three were particularly critical to the analyses of data for this paper: content logging, identification of talk and interactions involving problem solving, and development of a Math Inventory. These three data examinations eventually became the basis of a database on the intersection of problem solving and mathematics. All videotapes were first content logged to delineate events, turns in conversation topics, stories, events, and sub-topics of interest inside participants' accounts. Analyses of the segments resulted in 14 general categories, such as formalisms, gestures, props, efficiency, (math) avoidance, emotions, division of labor, and values. This paper emphasizes the categories of "problem-solving" and "type of mathematics" so we could better understand the occasions where family members depicted a situation *as creating a problem for them* and for which they engaged mathematics. These categorization processes resulted in a database comprising 315 stories—events that participants described where they were solving a problem using one or more types of mathematical practices.

We also developed a list of 20 categories for "types of mathematics used," establishing definitions with exemplars from our dataset for each. To consider overall patterns in our dataset of problems involving math, we examined the frequency with which the various types of math occurred within the various family activities.

## Findings: Four Features of Math Engaged Problem Solving in the Family

Four aspects of math engaged problem solving are described through vignettes based on our families' accounts of their math engagements. We tell their stories and point out the ways in which they are representative and characteristic of patterns we saw in the larger data set.

### I. Everyday problems lead the math

The most overarching feature of family problem solving is that problems come first, with math following. The complexity of family life and many interactions among family members and other institutions generate many contexts that require problem solving. The problems are complex (a need to renovate a bathroom), involve many steps over significant time periods (training for a race), and often are nested inside larger or connected problems (playing an extended game). Problems are defined and constrained by life imperatives (we must pay our credit card bills).

The knowledge and solutions derived from problem solving must align with situations and real constraints. People generally define their problems, and secondarily consider how to solve them, and then when to use math. Math rarely leads (except when family members directly want to learn or practice math). Single problems expand to fill the space, time and solution resources available. They may branch, with the resolution of one problem spawning new or next problems. People talked of the nesting and cascading of problems to be solved. We saw great examples of this in home improvement projects. People seem to meet up with problems once they start improvements, only to realize they must be solved in coordinated or timed ways. This is not to suggest that all problems are like runaway trains or that every problem facet being solved engages mathematics. It is to suggest that problems to be solved are complex ones that often require shifting attention, coordination of multiple nested activities, and unplanned-for triage processes.

When is mathematics brought to bear on problems in the rough and tumble of problem solving? Sometimes people are aware they are bringing math to the situation; other times they are engaging unawares of their mathematical practice. We had many instances in the database where we coded that the math was inferred—that people could not have accomplished what they told us they did without doing some mathematics. In this way, math could be *sub rosa*. The problems to be solved are often unique and situation dependent, people are generally required to evaluate their own solutions, and if correct, decide if the correct solution is really relevant or appropriate to the particularities of the situation. For example, people described both "doing the math" and "tossing it" when the idealized math did not fit the local situational constraints. We can see some of these characteristics of problems in a family's condo renovation project.

In one family, mom Yali and daughters Vivian and Renee are in the process of renovating a condo that Yali recently bought. Vivian is in law school and Yali recently became a teacher after a mid-career change. They want to save money on the renovations and Vivian likes carpentry, so she is managing the renovations and doing some of the work. Vivian describes how there are so many decisions to make—moldings, the placement and the size of walls, cabinets, which way to place the tub, where to put the sink? Closets, should there be one or two? Vivian discusses how they conceived of the renovation.

> *Interviewer*: Did you use any tools or ways to visualize to make these decisions? How did you actually decide where to put things?
>
> *Vivian*: It was a combination of just paper, like drawing a two dimensional…this is a square that is the kitchen. Where are the things going to be? And then actually showing up on site. I had to go down there a number of times, which was the hardest part, because, you know, we're trying to figure out, okay, we have this space between the tub and the toilet and how much space do you need for your knees? So we would just take the tape measure, and we're like okay, we want the [height of the] bench by the dining table. And we're like, well, how high is the bench by the dining table? There are these various measurements. So we literally took the tape measure and measured our knees from the floor sitting on [the bench]. So then you want to design, okay, what are our options? And you draw those on paper and then you actually show up and then you sit on the toilet. How many inches do I need, if the tub comes to here will I be able to sit down? <Yali laughs> We will, but if we sell the house to someone who's taller, will they? So it was kind of a back and forth.
>
> *Interviewer*: So you used your body for some of that?
>
> *Yali and Vivian*: Oh Yeah…

> *Interviewer*: …And you drew plans. When you drew the plans did you draw them to scale? Or did you just free form draw them?
>
> *Vivian*: I did both. Some things, well I'd mostly draw the free form just to give to the contractor an idea, okay this is what I decided. The tub is going to go here and I'd draw the inches...But I actually got on my computer and found some grid to work with to actually get more of the proportions. I didn't have a ruler in my whole room. So I couldn't even just measure a piece of paper and draw inches myself. I had to do it all online.

The family enjoys that they measured with their bodies, and upon Vivian's telling of the story, they all move around and giggle. Vivian's story on managing renovations reveals how informed critical decision-making is to their home improvement project. Vivian uses math in this work. She draws plans free form, but also draws them to scale in order to communicate with the contractor. The math involves knowing the dimensions of the large fixtures and pieces and the dimensions of the spacing they are being placed in. Drawing the scale version of the plans involves assigning scale units and engaging in proportional reasoning and problem solving. If a bathtub is 60 X 30 inches, how big is that on this particular graph paper? Still, even scaled plans might not be enough, and the women use their bodies to give a reality check to the calculations to make sure what is accurate on the 2D scaled paper plan will also work in the 3D world of real people moving around in the spaces. In the renovation project, daughter Vivian knows not only how to make and use scale models, but also what their limitations are, and when to switch into reality mode. This back and forth cycling of model to reality is interesting, and typical in this type of situation.

The renovation also included a new kitchen and new closets in the entranceway. There was a lot of figuring and fitting going on. To measure for the stone countertop, Vivian entices thirteen year old Renee into realizing she could use the Pythagorean theorem to complete the measurements for the counter in the stovetop corner. There was also clever financial planning around emerging problems as they were discovered, from having to convert from metric to standard measurements to figure out if the cabinets would fit before ordering, to balancing loans for the construction costs against 0% financing on appliances and fixtures, with the projection of a well-paying job when law school was over in a year. The problem space was huge, cascading and needing attention over an extended period of time. The math identified in the renovation story was extensive as well and included arithmetic, comparing magnitudes, geometry, measurement, optimization, unit conversion; proportional reasoning, decimals, unit conversion, formula, measurement, estimation, data representation, and interest rates.

## II. Values steer the problem definition

*Why* engage all of this problem solving? Our analyses revealed that exploring values answered that question. Why bother to take a student loan to help finance your mom's condo renovation and juggle a huge amount of debt for several years? Values also answer the *how* question. Vivian could hire someone to design the new kitchen and bathroom, or she could figure it herself, especially since she had lots of ideas and she thought she knew enough to get started. Values drive some of the decision-making around problem solving, and in volatile emotional moments, steer people into certain practices and solutions (instead of arguing, let's check the figures). Peoples' preferences and their values actually are determinant in whether or not a problem will even be engaged (Pea & Martin, 2010).

When families spoke about their problem solving strategies and gave examples of the kinds of problems that arose in their lives, family members consistently talked about what they valued. Families often had to consider the factors that mattered when making decisions. Was getting the "best" deal most important? Did social relationships play a part? Was time an important consideration? Was it important to make decisions by taking into consideration *all* of the relevant information? Each family's answers to these questions varied, sometimes even from one problem to the next. The answers to these questions often organized the problems to be solved by defining the constraints, the resources, and the criteria by which the outcomes would be judged. Values helped families determine *how* to solve problems once they were identified as such. When one mother wanted a savings plan to pay down credit card debt, she chose a socially regulated solution that traded the "best" financial deal for the power of social commitment and cultural participation.

One family's approach to purchases illuminates not only how values enter into the mathematics of their decision-making, but in this case, the creation of a new kind of value exchange unit (product goods vs. days mother has to work away from home). The dad, Jim, is an analyst and the mom, Liz is a part-time financial consultant. Liz works part-time because she tries to stay at home with the children as much as she can. She does take consulting jobs to keep up with expenses, but she tries to optimize her time at home with what she can earn through consulting gigs. When we asked how they handle the purchase of big-ticket items, they responded by going straight to the importance of their values. Jim said that he and Liz had been thinking about "bigger ticket item" purchases:

> We have got into an interesting concept about what the value of bigger ticket items is to us personally, and value is a very personal thing. Since my wife is a consultant and works on billable hours, we have gotten into this thing of looking at something, and if it is a big ticket item, thinking about how many hours it costs for us to get it. Whatever it is: I have to work three days, or it will cost me three weeks of effort if I want to do this, whatever the big ticket item is. And we sit back and we say, you know: is this really worth three weeks? No. Is this worth three days? No. So it depends – and sometimes – is this worth three days worth of effort? Yes. It's an interesting way of thinking of things, and trying to assess the value, which we do on bigger ticket items… We oftentimes say, you know, it's not worth that to me. I am not going to work five days to get this thing. It's just not worth it to me. It is an interesting value concept that just the two of us think about.

The family actually pits Liz's time at home against their wants, knowing they can have one or the other. Liz's home time usually wins, and the family goes without. This is especially so if the purchase was a flat screen TV. However other kinds of big ticket items, such as paying to offset the tuition for their middle school aged daughter's private school, is considered worth the consulting hours. Jim and Liz went on to tell us that even their children have come to use a similar approach in their own thinking. It started as the children were getting to the ages where they wanted to purchase souvenirs when the family went on a vacation. They decided to give their children $10.00 and let their children budget their own purchases, forcing them to ask the question of whether what they would purchase was worth it.

> Jim: But it has translated down a bit with the kids and the money that we give them on vacation, and we…they have ten dollars, and then they go through this value exercise to say 'do I really want that candy bar for two dollars or not?' And they are starting to make value judgments themselves on what is important to them, and whether or not they are going to spend the money on a particular item, or save it.

What such a structuring of the values undergirding decision making for bigger ticket purchase items exemplifies is that how a family weighs, or creates equivalences between, different categories of resource (incremental earnings, big ticket purchases, family time), affects the decisions that they make in how resources are allocated. In turn, features of the ideology, as well as of the mathematical practices, can serve as a model that the children emulate in their own age-relevant versions of the adult problems. For example, the math involved in Jim and Liz's purchase to consulting hours trade off includes unit conversion, arithmetic, and proportional reasoning. As the parents discuss family purchases, the children are exposed to mathematical reasoning involving these concepts, as well as the value considerations their parents consider important.

## III. Different maths engaged in service of problem solving

Two findings relating to the math family members engaged while problem solving are of special interest. The first is that a number of problems in our database indicate that people engaged multiple maths on the way to problem resolution, even when we exclude simple arithmetic or computation from the data set. The second is that, even for the same problem, family members approach problems with different ways of bringing math to the solutions. There are several conditions for multiple maths to co-occur. People in the family sometimes approached the same problem in different ways. In some of the cases, they knew the way of another family member, but chose to use their own. In a few cases, this led to circulation of a problem from one person to the other, and in these instances, we found family member playing to perceived expertise of others.

Engaging multiple kinds of math to problem solving is a very interesting and positive aspect of family mathematical practice, and we see it in stark contrast to how problem solving is taught in school math. In school, the approach to math most preferred is a development-sequential one. Math in school tends to concentrate on learning and practicing one kind of math at a time, and this is generally the case, even when problems are of an applied nature. In school, the applied problem is often designed to practice a singular math concept; at home, the problem is generally designed to accomplish a goal that is desired and sought, often with the engagement of a variety of math practices for accomplishment. The family offers children the opportunity to develop mathematical practice under conditions that matter to them.

For one middle school boy, Ravi, a pre-algebra student, opportunities to apply his new problem-solving skills abound at home. His mom talked about how he constantly enjoyed trying to calculate the best deal. The family told the story of Ravi's part in helping them decide what car to purchase. The family was looking at various Toyota models, and they were considering a number of factors in making the decision. Ravi compared the options and saw gas mileage as the deciding factor:

> *Ravi*: Yeah, uh, so we were considering between a Toyota Corolla, a Toyota Camry, and a Prius. And I said that we should buy a Prius because my mom drives a lot of miles [Mom &

Son laugh]. And so, uh, with a Prius, uh, you get, uh, I believe you get some tax benefits, car, auto insurance [Mom & Sister smile].

*Dad*: [returns, sits down and pats son on the back while smiling and laughing] You don't need to know that.

*Ravi*: … and, a Prius, um, is better for the environment also.

While Mom and Dad would also take the tax benefits into account, they knew Ravi was not yet ready to weigh those benefits. Still, he was intent on making a case for the mileage in terms of environmental effects along with cost savings at the pump and at income tax time. He had figured the differences and savings for his parents and argued for the ways the pump and environmental impact savings would even out the extra purchase price. His interest in optimizing was balanced by his knowledge of his mom's commute and a general appreciation in the family for thoughtful, mathematical arguments. Ravi demonstrated how he put what he learned in school to work for him on the Prius problem:

*Ravi*: Yeah, like um, usually in the car, like uh, for the Prius, like miles per gallon. When you see 50 miles per gallon, that means if you drive, you will use 1 tank of gas if you drive 500 miles. That means, if you fill up your tank you can drive from here to LA in that tank.

In Ravi's example, he set up a problem and argumentation for his choice that would put the mileage benefits of the Prius into perspective. He knew he could make it from Palo Alto to LA on a 10-gallon tank. It is important to recognize what drives Ravi to set up a proportional calculation. He wants to find the best of three car options for his family's needs. His interest in optimizing gas mileage to get his family the best financial deal while making a responsible environmental decision works nicely with his penchant for math problem solving generally. The car purchase context sets up the opportunity for Ravi to draw on several types of math problem solving at once. The car purchase demonstrates the way Ravi is able to draw on his school knowledge inside a relevant family context. He tackles everything from arithmetic and measurement to optimization and proportional reasoning in order to support his argument.

## IV. Mathematical thinking as activity in distributed knowledge environments

The stories that families told us indicated that math engaged problem solving was most often a social affair. This was so even when we asked an individual for a story. Children often mentioned how siblings, parents, grandparents, or friends were part of their math stories. Adult problem solving often involved others, even if they did not always involve children. Social, historical and cultural practices were deeply embedded in problem solving. Playing math games with a grandfather, working on puzzles as a family, inventing fantasy businesses for play, and saving money and managing debt were all deeply social and distributed across persons, time and setting. When math was involved, it became entwined with the persons in activity. Math engaged events, like other learning situations, were embedded and distributed among people, artifacts, activities and settings (Gonzales et al., 2001; Pea, 1993). Individual accounts of how the math practice was distributed differed, yet we found only few instances in family-based activities where math engagements were isolated or individual.

Mathematics during a road trip plays out in one family for whom mental math is key, particularly for the father, Steve. Throughout our interview, Steve's use of mental math to figure out problems is a common theme recognized by the rest of the family and becomes a source of amusement. For example, Steve describes doing "nutrition math" around each meal to stay on the *Zone* diet and also decrease the amount of cholesterol he and his wife consume. Such activity involves calculating protein grams, different forms of carbohydrates, and fat per meal, as well as the amount of cholesterol and total number of calories. According to Steve, "you almost need a computer to do the nutrition analysis of each meal at this point. So, I have this much saturated fat, so if I use olive oil instead of this oil…a lot of [calculations like] that." However, rather than using a computer to keep track of the calculations, Steve says he adds up the different quantities in his head as he builds a menu. His comment - "I do it in my head" - causes laughter from his wife, Sharron, and daughter, Elise. Sharron jokingly asks us: "Do you see a theme here?" - referring to the father's focus throughout the interview on doing calculations in his head. Sharron and Elise also figure cholesterol, but with different methods—one cooks with no fat, since "zero times zero is zero", and the other computes cholesterol with paper calculations.

The focus on mental math is not only important to Steve, but it is also passed down to Elise, with the involvement of the whole family. Elise describes a game she played in the car on a trip with her parents:

*Elise*: We were coming home across the Golden Gate Bridge, and I wanted to see if I could hold my breath across it. Our guidebook said it was 2 miles long, and at 45 miles/hour, so we had to figure out how long I had to hold my breath, and it ended up being 3 minutes. And that's a long time, so… I didn't hold it for the whole entire time.

*Sharron* (chimes in laughing): We drove faster!

> *Steve* adds: We realized we'd have to change some of the physics in order for this to work, since 3 minutes was too long. So we drove faster and shortened the span to just the part that was kind of out there. She figured out the stuff while we were driving. That was her project to do the math.

This game was initiated by Elise, as holding her breath across a bridge was something she had done on a fieldtrip with her friends. However, it was taken up by the whole family, and became a problem to solve by the family unit. According to Sharron, for Elise to figure out whether she would be able to hold her breath "was a good exercise that took part of the time between Santa Rosa and the Golden Gate Bridge." Once she figured out that she would not be able to hold her breath long enough, the family unit took it on to figure out how to help her succeed, both by changing the constraints of the problem, the factors involved, and what would count as a solution. As a family, they decided that she should not try to hold her breath for the entire bridge, but rather concentrate on a shorter span of the bridge that was more manageable. The father also changed the speed of the car, speeding across a section of the bridge to make it easier for his daughter to succeed. This episode was recounted by the family with enthusiasm, with all members actively chiming in to the description. What started out as a game for the daughter became a challenge for the family to solve.

This family focus on mental math is not new for Elise, and she gets practice in many situations with her parents' help: "There are a lot of times in cars when dad has a problemish thing, like if we're going this fast, how long will it take us to get somewhere." Steve adds, "That's right. And you have to do it in your head. Which is hard, isn't it? But really good practice." At the store, Elise's parents often ask her to help with the "shopping math," asking her to do price comparisons to figure out which is the best value, as well as figuring out the nutritional analysis of foods based on the serving size they actually eat. In talking about shopping math, Steve says:

> They try to teach rounding in the schools obviously, but when [Elise] gets a problem that we would just instinctively round off, because we think, 'I'm never going to calculate 16.3 divided by 8.7' or something, she's instinctively trying, you can see, especially - that's why it's good to try to do stuff in your head – try[ing] in her head to do 16.3 divided by 8.7 (Steve gestures as though writing out a long division problem.) And it's like, 'ok, this is a good time for rounding'. And she's like 'Oh, well then, 16 divided by 8. Now it's easy'. But it's not an instant conclusion that you leap to.

Sharron adds: "probably more than anything, that ability to get common number sense for everyday use for quick, (snaps) quick answers just seems to be really key for her, and she's getting there." Her family is explicit about using rounding as a strategy, as Elise recognizes. She says about Steve: "You do that a lot. I have trouble with a math problem. And then he says, well what if the numbers are this and this, could you figure it out then? Then, it's oh, that's how you do it."

## Summary

Four features of mathematically engaged problem solving were found across our interview data: Mathematics was engaged as people solved problems in their lives; problems that received attention did so because people valued the end goals related to the problem solving; multiple maths were brought to bear on problems; and, math was embedded in the socially distributed learning opportunities. Mathematics followed as people attended to other goals. These features varied across families, situations, and events, to the extent that family position, histories, styles and cultural practices had a lot to do with how and when problems and math were engaged.

These results have several implications. First, rich problem solving in the family is not appreciated, and family mathematics even less so. If mathematical engagements are recognized, they are usually considered to be of less consequence than the more formal math structures taught in schools. Second, the results of our analysis indicate that family mathematics practices are socially embedded in some of the families' most important and valued activities. Family members engage with math because they need to or want to. They support each other through reliance on, and knowledge of, their distributed expertise. Third, children are often witnesses and participants in these vital family problem-solving contexts, and the mathematics engaged is definitely providing learning opportunities—about math and life. Fourth, the mathematics covered has alignment with school math objectives through pre-algebra—another reason why the learning opportunities available in families are rich ones.

## Endnotes

(1) The Family Math Study is conducted as part of the LIFE Center (NSF REC 0354453). Eventually, its results will also inform a range of studies about learning in both formal and informal learning environments (for more about the LIFE Center, http://www.life-slc.org).

## Acknowledgments

We'd like to thank all of the families that participated. They enlightened us about both problem solving and math. Ana Rios and Judit Moschkovich of the NSF CEMELA Center conducted a few of the interviews, as did Ernesto Colin. The findings and opinions are those of the authors and do not represent the opinions of the NSF.

# Transformative professional development: Cultivating concern with others' thinking as the root of teacher identity

Rachel E. Scherr and Hunter G. Close, Seattle Pacific University, Seattle, Washington, 98119,
rescherr@gmail.com, hclose@spu.edu

**Abstract:** At the university level, science education reform is limited by novice instructors who do not share reformers' educational values. The current challenge is to provide professional development (PD) that will be *transformative:* rather than merely exposing participants to reform instructional materials, it will change what future instructors believe is worthwhile in science education. Our view is that professional development is most effective when it enriches the intellectual life of teachers and builds teacher identity by cultivating concern with student thinking. In an example of an activity that originates in this perspective, participants interview peers about physics concepts and conduct structured reflections on the interviewing experience. The activity holds promise for improving participants' abilities to listen and to teach effectively, increasing their esteem for the intelligence that teaching requires, and increasing their interest in K-12 physical science teaching as a profession.

## Major issues addressed

Physics education research has produced a wide variety of high-quality instructional materials for use in introductory university-level courses (Laws, 1999; McDermott & Redish, 1999; Sokoloff & Thornton, 2001; Thornton & Sokoloff, 1997), including tutorials (McDermott, Shaffer, & PEG, 1998). The limiting reagent for physics education reform at the university level is now implementation (Tobin & McRobbie, 1997).

### At the university level, reform is limited by novice instructors who do not "buy in"

Experienced educators and developers are well aware that successful implementation of reform instructional materials includes establishing appropriate norms for learning in the classroom (Henderson, Yerushalmi, Kuo, Heller, & Heller, 2007). At the university level, for example, science education reform has often taken the form of collaborative worksheets ("tutorials") used in recitation sessions. In these classrooms, norms include an emphasis on conceptual understanding (and a concurrent de-emphasis of algorithmic application of formulas); an expectation that this understanding is best achieved through explaining one's own thinking, listening and responding to others' ideas, and constructing arguments; and an acceptance of instructors as facilitators of this process rather than sources of correct answers. The establishment of these norms is "among the most critical and subtle features of implementing these reforms" (Finkelstein & Pollock, 2005).

From the students' point of view, the graduate teaching assistants (TAs) and/or undergraduate learning assistants (LAs) who lead each tutorial section are important arbiters of these norms and expectations. The development of these norms by these novice instructors is thus a critical task of tutorial implementation Instructors who "buy into" tutorials are more likely to convey their respect for the material and the tutorial process to the students, as well as learning more themselves. This development is nontrivial: although graduate and advanced undergraduate students may be presumed to be more sophisticated learners than introductory students, they are in some cases more thoroughly embedded in traditional teaching practices. Prior research by the authors on tutorial implementation has provided examples of how lack of buy-in by an individual TA can undermine the effectiveness of tutorials (Goertzen, Scherr, & Elby, 2009).

Lack of buy-in can have roots in impoverished beliefs about the intellectual life of teachers In our culture, the work of a science teacher is not regarded as that which requires the great power of a creative and analytical intellect. Novices who believe that an instructor's job is merely to "check that students get it" may be frustrated with tutorials, in which instructors are expected to facilitate student exploration of a variety of solution paths. The public perception of science teaching as minimally intellectual work diminishes the interest the next generation of talented thinkers might have in doing the work: talented, intelligent students want to grow up to do something that they believe requires talent and intelligence, and teaching is not usually considered to be one of those things. Novice instructors' lack of appreciation for the intellectual rigor and creative opportunities in teaching impedes science education reform.

### Typical professional development rarely helps instructors value reform instruction

TAs and LAs receive various forms of professional development (PD) associated with their teaching responsibilities. While these programs may provide novice instructors with necessary information and general skills, few help them recognize the worth of reform instruction. Some novice instructors participate in workshops and seminars focused on classroom management, grading, facilitating discussion or learning questioning skills (Gilreath & Slater, 1994; Hollar, Carlson, & Spencer, 2000). These types of PD are oriented toward providing instructors with specific skills and information, and are not specific or sustained enough to have much effect on their values. In a tutorial program, the most common form of professional development is a weekly session aimed specifically at preparing instructors for the coming week's instruction. The primary activity is usually to complete the tutorial worksheet as if they were students. This specific preparation is surely necessary to effective instruction. However, research indicates that it is not sufficient to help the participants appreciate the power of tutorial teaching. In particular, the social and environmental context of the tutorials – including classroom, departmental, and institutional levels of implementation and support – has been shown to strongly affect whether TAs buy into tutorials, and probably outweighs the influence of the typical preparation activities that we prepare for them (Goertzen et al., 2009).

Some novice instructors take courses that offer instruction in pedagogical content knowledge and constructivist learning theories (Hammrich, 2001; Ishikawa, Potter, & Davis, 2001; Lawrenz, 1992; McGivney-Burelle, DeFranco, Vinsonhaler, & Santucci, 2001; Otero, Finkelstein, McCray, & Pollock, 2006) Where pedagogy courses are offered, there is more potential to help instructors value reform teaching, because the courses address models of teaching and learning directly for a sustained period of time. A pedagogy course is particularly likely to be effective when there is good alignment between the learning theories presented in the course and the practical teaching experiences that the instructors have: if the instructors learn constructivism in the pedagogy course, but are permitted or requested to teach by telling in the classrooms that they lead, they are less likely to appreciate constructivist teaching methods. Assessment of professional development that includes a pedagogy course should thus include systematic observations of the participants' classrooms, not only surveys or interviews.

## Potential significance of the work

The current challenge for university physics education reform is to provide professional development (PD) that helps instructors to appropriately value reform instruction. Such PD will be *transformative:* rather than merely exposing participants to reform instructional materials, it will change what future instructors believe is worthwhile in science education. We take the perspective that this transformation is a *philosophical* and *epistemic* one, involving a change in what is thought to be worth knowing.

### Transformative professional development enriches the intellectual life of teachers

In the transition from Plato's philosophy of the natural world to Aristotle's, phenomena of the natural world were promoted in epistemic status. In Plato's philosophy, the actual world is not something that is worthy of study in and of itself; it consists instead of a variety of imperfect copies or images of ideal principles These ideals are the "real" things of concern, and the proper subject of contemplation and analysis, while their shadows and distortions (of which the world we experience consists) are not. In contrast, Aristotle's philosophy (which followed shortly thereafter) granted a new and higher status to the world of phenomena, as we experience it. This world is populated with all sorts of things that are themselves worthy of study, as they are. On this, Aristotle says (Aristotle, c. 350 B.C.):

> *It is the business of experience to give the principles that belong to each subject I mean for example that astronomical experience supplies the principles of astronomical science; for once the phenomena were adequately apprehended, the demonstrations of astronomy were discovered. Similarly with any other art or science.*

An Aristotelian might see the Platonist who does not care to pursue truth by first studying the instantiated world as fixated on the world as it should be, rather than the world that is.

A similar dichotomy of perspective exists for novice instructors learning to think about student thinking. Most of these instructors are very (and rightly) concerned with understanding physics as it *should be* understood. This is not to suggest that there is only one way to think correctly about physics; surely, there is not But novices are usually very aware that they have ways of thinking that they may want to avoid, and ways of thinking that they strive to use more consistently and reliably. They are right to recognize that they have not yet mastered basic physics (though they probably also underestimate how long it takes most physics instructors to do so). Thus, initially, novice instructors are generally *fixated* on correct understanding in physics – on their own part, on the part of their peer instructors, and on the part of the students that they would teach. This is not to say that their attention is so focused on correct understanding of physics that they always understand clearly for some bit of instruction what the target understanding is; it means that correct understanding is their primary *concern* during teaching. They are fixated to the point of failing to understand expressions of student thinking in physics as phenomena worthy of study and explanation, as they are, and not only secondarily, as they fail to match up with correct understanding in physics. In this way, beginning instructors are Platonists when it comes to alternative ways students have of thinking and knowing. The most important thing to observe (according to the beginning instructor) about student thinking when teaching is how that thinking is wrong, and since this is teaching, an activity in which the student (we assume) is supposed to be changed by the interaction, the most important action is to fix the wrong thinking as soon as possible.

The key Aristotelian insight, that observable things are worth studying as they are, may be applied in extreme fashion to teaching. According to an excessively Aristotelian view of studying student thinking, we physics instructors might be happy each day to ask our students questions, listen to their answers in detail, write down some observations, and thank the students for their time before inviting them to come back tomorrow. Later we would return to our notes and try to figure out what deeper truth was expressed in all those instances of student expression. But at no point would we distract ourselves from our scientific task with thoughts of what all that student thinking ought to have been. It is easy to see that such an extreme view is not appropriate for a classroom, because it leaves no place for student learning. Thus, neither philosopher's approach to nature is sufficient if it is applied to teaching, for in one, the reality of student thinking is neglected, and in the other, there is no role for instruction. If attention to student thinking is necessary for effective instruction, then the teacher is performing a complex, hybrid intellectual task of understanding clearly both where the students are, and where the teacher wants them to be. To prepare physics instructors is to prepare them to perform all the components of this hybrid task. We believe the greater task for those who prepare physics instructors lies in helping the instructors to understand the Aristotelian component.

Fortunately, however, establishing this Aristotelian component in the understanding of the instructor is not only a task of great effort, but also a great gift to the instructor. Through the recognition that teaching includes the work of making observations about student thinking and making sense of those observations, the instructor's vision opens into an entirely new realm of phenomena of infinite variety. And a scientist takes pleasure in observing and thinking about wonderful new things, as they are.

### A teacher solves puzzles of student thinking and learning

As if the news about a fascinating new class of phenomena weren't good enough, there is even more: the instructor also has the pleasure of *figuring out* puzzles of transforming student thinking from state A to state B, and then to state C, *etc.* Thus, teaching has a natural science component (understanding student thinking) and an engineering component (shaping student thinking to become more functional). These puzzles are as numerous as the instructor wishes, and include at least the number of students multiplied by the number of specific learning goals set forth by the instructor. A template for such a multi-part puzzle might look like "How can I better understand how [student name] thinks about [specific topic]? Once I understand well enough, how can I get [student name] to understand [specific aspect of specific topic]? How will I know if it worked?"

Kuhn described how it was this sort of intellectual pleasure that keeps scientists wanting to come back to work each day (Kuhn, 1962):

> *The challenge of the puzzle is an important part of what drives [the scientist] on… What then challenges him is the conviction that, if only he is skillful enough, he will succeed in solving a puzzle that no one before has solved or solved so well.*

Surely these words apply equally well to the science teacher, provided that the science teacher conceives of the job as providing a steady stream (really, a fire hose) of this sort of puzzle material. The main obstacle to conceiving of the job in this way, we believe, is merely the fact that those talented and intelligent people who might love to do such a job are not aware that the possibility exists. The lack of awareness is due in part to how such an approach to teaching has been modeled for potential future instructors by so few, and the other part, perhaps, is due to the lack of explicit instruction in professional development about how to approach teaching in this way.

## Theoretical perspective: Resources and framing

While teachers are making observations about student thinking, they are also making sense of what they observe: that is, they are inevitably (and probably implicitly) forming theories of what knowledge is and how learning takes place. This epistemological change is at the heart of transformative professional development. We assume that the cognitive processes underlying epistemological change are similar, in some respects, to the cognitive processes underlying conceptual change.

### Resources vs. (mis)conceptions

We take a *resources-based* rather than the more common *conceptions-based* view of the prior knowledge students bring to bear in physical science (Hammer, 2000; Smith, diSessa, & Roschelle, 1993/1994). In this view, learners (whether they are students or beginning teachers) have ideas that are activated by particular situations. People use these activated resources to construct knowledge and guide their behavior. These ideas are not categorically wrong or right, but rather are appropriate or inappropriate for the particular situation (Hammer, Elby, Scherr, & Redish, 2005; Russ, Scherr, Hammer, & Mikeska, 2008). Such a framework provides an explanation for how novices become experts: they begin to use resources from other contexts, adding new ones and building up a more coherent structure of ideas (Smith et al., 1993/1994). Smith et al. characterized such a framework as one that "emphasizes knowledge refinement and reorganization, rather than replacement, as primary metaphors for learning." (p. 116).

To see how the distinction between a conceptions-based and a resources-based cognitive framework plays out in interpreting learner epistemologies, consider a hypothetical introductory physics student named Dan. Even when a tutorial tries to elicit his intuitive ideas, Dan answers in terms of remembered facts and equations. Why? According to the conceptions-based framework adopted by most epistemology researchers (Hofer & Pintrich, 1997; Schommer), Dan's behavior probably stems from an epistemological *belief* that physics knowledge comes from authority, or that physics knowledge consists largely of facts and formulas (Hammer, 1994). In that case, changing Dan's behavior would likely involve an arduous attempt to confront and replace his epistemological "misconceptions" with more productive beliefs.

The resources-based framework provides an alternative interpretation and instructional strategy. In our view, Dan's focus on facts and formulas probably arises not from a stable epistemological *belief*, but from the context-sensitive activation of finer-grained *epistemological resources.* We see evidence of these resources, including resources regarding the source of knowledge, even in small children. When asked how she knows what's for dinner, a child might respond "Daddy told me," reflecting the activation of the resource *knowledge as transmitted stuff* (Hammer & Elby, 2002). The same child, when asked how she knows Mommy got her a present, might reply, "I figured it out, 'cause it's my birthday and I saw her hiding something." This answer reflects the activation of the resource *knowledge as fabricated stuff*, corresponding to the view that knowledge is built up from "raw materials" such as prior knowledge about birthdays and observations of sneaky parental behavior. Along these same lines, we can interpret Dan's behavior as stemming from the inappropriate over-activation of resources such as *knowledge as transmitted stuff* – resources that are useful when learning state capitals, but not as useful when learning physics concepts.

According to this framework, we can change Dan's approach to tutorials without introducing new epistemological beliefs "from scratch." Instead, we can help him activate epistemological resources *he already possesses* and applies in other contexts. For instance, Dan may rely on his common-sense ideas when explaining wave phenomena he sees at the beach, or when having a classroom discussion about psychological (rather than physical) phenomena. As instructors, we would try to help Dan "find" those resources and activate them in physics class (Hammer & Elby, 2003).

## Epistemological framing

A learning context such as a lecture or a tutorial can trigger a locally coherent set of epistemological resources, a set that explicitly or implicitly answers the question, "What counts as knowledge and learning in this context?" We call such a set of resources an *epistemological frame*, acknowledging the sociolinguistics literature that helped us formulate this perspective (MacLachlan & Reid, 1994; Tannen, 1993). Examples include *remembering stuff from authority* and *intuitive sense-making*. When Dan frames an activity as *remembering stuff from authority*, he "believes" – in that moment – that knowledge comes from authority and that solving a problem is a matter of finding the right knowledge. But in another context, Dan could frame problem-solving as *intuitive sense-making* and act as if he believes knowledge is constructed from everyday ideas and experiences. In a resources framework, neither of those frames is Dan's "true belief," because he doesn't have a single, universal belief about the nature of problem-solving.

When we study (and try to affect) the epistemologies that novice instructors exhibit while learning and teaching, the distinction between the conceptions/beliefs and resources models – and particularly, the notion of frames – becomes especially important. Instead of assuming that instructors *have* stable epistemological beliefs that they apply consistently and universally, we assume that different contexts can trigger different epistemological frames. For instance, when an undergraduate LA we'll call Lisa does her own advanced physics homework, she may fall – consciously or unconsciously – into manipulating symbols without trying to make sense of the underlying physics. When addressing "brainteaser" physics problems posed in her LA pedagogy class, however, Lisa easily enters an *intuitive sense-making* frame; she tries to make sense of the qualitative physics concepts and doesn't want to be told the answer, realizing that jumping to the answer is detrimental to her learning process. In that context, Lisa "knows" that learning physics is largely a matter of making sense of it for yourself, rather than just hearing a clear explanation or manipulating symbols. Nonetheless, when Lisa got into an introductory physics classroom as an LA, she acted as if she thought her students' learning is mostly a matter of hearing clear explanations and manipulating symbols. Our point here is that instructors' epistemologies appear to display context dependencies best analyzed in terms of resources and frames rather than beliefs.

Fostering epistemological development, in this framework, consists largely of helping novice instructors become more reflective about which frames they're using in which contexts (including when they teach), and eventually to "crystallize" their productive epistemological frames into well-thought-out epistemological beliefs about how people learn (Hammer et al., 2005). With Lisa, for example, we might try to create contexts in which she can observe students engaged in making sense of physics concepts, reflect on the similarities to (some of) her own most satisfying learning experiences, and consider how she might foster such learning experiences in the classrooms in which she is an instructor. This approach embeds our philosophical perspective: By posing student thinking about physics as an observable phenomenon, we support novice teachers in strengthening the Aristotelian component of their understanding of teaching Excitingly, we sometimes find that "once the phenomena [of student thinking] are adequately apprehended," novice instructors spontaneously draw valuable conclusions about cognition. Lisa, having thoughtfully observed students express a variety of ideas about force and motion, might express a new conviction that people hold multiple, perhaps contradictory ideas at the same time, or that people hold ideas that are neither right nor wrong but rather are applicable in certain contexts.

Our framework embeds a deep respect for novice instructors' existing beliefs and prior experiences, seeing them as the essential material from which expert conceptions of teaching are constructed The physics education community has long taken this perspective regarding learners' physics ideas, with the benefit that we can help students identify ideas that can be the basis for effective constructivist instruction (Hammer & Elby, 2003). Our theoretical framework extends this fruitful perspective to professional development We also go one step further by explicitly entrusting novices with the cognitive ability to figure things out: not only do they possess the building blocks of cognition, but also, we believe, they are capable of doing the building. This is in contrast to a view in which students need to be led step-by-step through a logical sequence prescribed by an expert.

## Methodology for facilitating and understanding transformative professional development

Our view is that professional development is most effective when it enriches the intellectual life of teachers and builds teacher identity by cultivating concern with student thinking. We are in the early stages of a project with two mutually supporting purposes: (1) to provide novice instructors with professional development that shapes what they value in science education, and (2) to better understand novice instructors' experiences of potentially transformative professional development.

### Design and implementation of transformative professional development

We have selected undergraduate Learning Assistants (LAs) as our initial target population because Learning Assistant programs can be centerpieces of university science education reform. LAs are talented undergraduates who work with faculty members to make large-enrollment courses more collaborative, student-centered, and interactive. Research has shown that LA programs improve undergraduate performance in physics courses, facilitate multi-disciplinary collaboration among faculty, involve more faculty in teacher preparation efforts, and recruit talented science majors to teaching careers (Otero et al., 2006; Pollock & Finkelstein, 2008). That is, a quality LA program is at once a mechanism for course transformation, for teacher recruitment, and for TA and faculty professional development.

LA programs integrate content, pedagogy, and practice and produce documented improvement in all three areas (Otero et al., 2006; Pollock & Finkelstein, 2008). LA programs are effective partly because LAs take a low-credit pedagogy course that instructs them in the nature of teaching and learning and introduces them to interactive teaching techniques. (TAs are usually not required to take a pedagogy class, partly because their typical course load is already very high.) Thus, in an LA program, university educators have the opportunity to shape participants' perceptions of teaching. LAs whose pedagogy class helps them appreciate the worth of reform instruction are a valuable resource for their institution and for science education reform generally.

Our design and implementation work is focused on the most flexible and most potentially innovative component of the LA program, which is the pedagogy session. The over-arching goal of these sessions is to provide LAs with a sense of the intellectual depth that a physics teacher can experience and enjoy by thinking deeply about student thinking. One promising activity that we have piloted is the Physics Interview Project (PIP). In this key example of an activity that originates in our theoretical perspective, participants interview peers about physics concepts and conduct structured reflections on the interviewing experience The activity holds promise for improving participants' abilities to listen and to teach effectively, increasing their esteem for the intelligence that teaching requires, and dramatically increasing their interest in K-12 physical science teaching as a profession.

In the PIP, each LA interviews a peer in order to study that person's thought process about some physical system. LAs perform three interviews throughout the academic year; the protocol for the first one is designed by the LA program director (HGC), and the later protocols are designed by individual LAs. After conducting each interview, LAs transcribe part of it and perform it in class, explaining why they thought the selection was interesting. They write a reflection paper that includes a characterization of the interviewee's thinking and the LA's thoughts on the difficulty and value of the experience. The PIP puts LAs face to face (literally) with the phenomena that are the subject of physics education research, and thus provides a particularly compelling entry point into that research. Importantly, LAs are exposed not only to the *refined results* of physics education research (as they might be in other LA programs) but also to the *raw data.*

## Research on participants' professional development experiences

The research arm of the project documents and analyzes individual instructors as they work together in preparation for teaching, as they teach, and in reflective interviews, with the goal of understanding transformative experiences they may have and learning about the processes by which novice instructors develop into intelligent and talented educators.

### Data sources

The aim of data collection for this project is to enable rich representation of individual LAs' experiences in the course of the program. To this end, we document novice instructors in all three environments that directly relate to their teaching: their pedagogy course (1.5 hours biweekly), their preparation course (1.5 hours weekly), and the classes in which they are instructors (2-4 hours weekly for each focal LA). Because the nature of the activity that people perceive themselves to be engaged in affects how they interact (Bateson, 1972; Goffman, 1986; Goodwin, 2000; MacLachlan & Reid, 1994; Tannen, 1993), we keep the recording subordinate to normal classroom practices. The approach has served us well in other projects (Goertzen et al., 2009; Goertzen, Scherr, & Elby, accepted (2010)).

In addition to the naturalistic videotaping, we conduct twice-yearly clinical interviews with a protocol similar to the one described in Goertzen et al, 2009, in which the primary question is "How is [name of course] going?" Open-ended prompts such as this have been shown to initiate conversations that result in epistemologically rich responses; participants volunteer which aspects of the course they judge to be successful, which aspects are lacking, what features they believe should get more emphasis, and otherwise reveal their values and expectations for instruction and their views about how students learn (Hammer, 1994).

### Analytic framework

The primary research activity of this project is to develop rich case studies of individual LAs' experiences in our professional development program, with the goal of understanding transformative experiences they may have. Case studies are particularly powerful for this project in that they get at the *mechanisms* by which our program may affect LAs. Fortunately, the increasing ease of video recording offers new opportunities to create richly detailed records of classroom activities. These recordings call for research methodologies that balance generalizability with interpretive validity.

*Classroom behavior as the primary data source.* When developing a case study, we use video recordings of LAs' classes as the primary source of data. We watch video episodes of LAs teaching and/or working together in the pedagogy and preparation courses and seek to provide plausible framings that might explain their classroom behavior. Transcriptions of the interviews are used to support or contradict the conclusions we develop while watching video episodes. This contrasts with many studies of TAs and teachers, which attempt to first understand the instructor through interviews or surveys, and then (in some cases) compare these assessments to actual behavior (Hammrich, 2001; Ishikawa et al., 2001; Lawrenz, 1992). We consider interviews to be secondary data because we conduct them with the intent of understanding LAs' overall beliefs and attitudes about tutorials, and thus they are unlikely to reference particular teaching situations (Goertzen et al., 2009). Depending on such interviews to fully explain TAs' framing would be attributing more consistency within an individual than we have argued is warranted.

*Insight-oriented analysis.* The primary purpose of "insight-oriented" analysis is to identify and richly describe the events in an episode as they unfold in the interaction among the participants. "Coding-oriented" analysis, in contrast, aims to generate categories that will be used to document the frequency and distribution of events of interest. (Of course, insight-oriented analysis may generate a coding scheme, and coding may lead to deeper insights.) The backbone of video analysis as we conduct it is collaborative analysis of short episodes of classroom activity. Having selected an episode, we play the video for a multidisciplinary analysis group, and members of the group call to stop the playback whenever they see something they want to discuss. We often benefit from replaying the video multiple times. In many cases, we do not approach the data with pre-conceived categories of interest. Rather, the goal of the group work is to progressively deepen our understanding of the participants' activities and to challenge the biases of individual analysts. There is a constant effort to ground assertions in the evidence of the video episode, and to limit proposed hypotheses to those for which the video episode (or others like it) could provide confirming or disconfirming evidence. The resulting discussion is often a lively, multidimensional conversation reflecting the diverse interests of the participants as well as the focal interest of the project.

### Observational methodology

The challenge presented by our theoretical perspective is to identify the ways that LAs frame their teaching and learning. No meter measures framing; instead, we infer people's sense of the nature of their activity primarily through their behavior, and secondarily through explicit statements in interviews. Participants' understanding of the nature of the activity in which they are engaged — i.e. their framing of the activity — guides their selective attention, provides cognitive structure for interpreting events, and manifests itself in their observable behavior.(Hammer et al., 2005) To the extent that framing is an interpretation based on previous experience, it is informed by an individual's broad history and experience with related events and systems. In the moment, though, participants mutually construct their sense of shared activity by means of verbal and nonverbal interactions, including linguistic signals, prosodic features, and body language (Bateson, 1972).

When we analyze LAs' teaching and learning behaviors, we use evidence such as how much they talk, the types of questions they ask, the conversational pace, their body positioning, gestures, and register (word choice, syntax, pitch, etc.), to infer how they are framing the situation. We look for additional support for these analyses from the ways LAs reflect on their teaching and learning in interviews. While we use LAs' stated beliefs to corroborate our ideas about how they frame, we are careful not to assume that these beliefs will necessarily match their actions. We also do not attribute framing solely to the LA: negotiations with students either support or undermine the instructor's sense of what's going on, so that together they construct a shared framing of the activity. (This is not to say that participants always have the same framing: mismatched framing is common, and can lead to humor or conflict depending on whether the participants recognize that they are framing in different ways (Goffman, 1986).)

## Findings

The main goal of our present work is to illustrate the fruitfulness of our theoretical and philosophical perspective rather than to demonstrate empirical results. That said, preliminary observations of the LAs' experiences with our professional development program include:

- LAs initially find it very difficult to ask questions to learn about another person's thinking. Their urge to guide them to a particular conclusion is so strong as to almost preclude thoughtful listening.
- LAs grow to understand the superficiality of questioning about vocabulary and trusting in answers in which proper vocabulary conceals the quality of understanding.
- LAs learn that people do not necessarily say what they really think, even if they are not trying to deceive.
- LAs come to recognize that the complexity of a real person's thinking is much greater than is indicated in summaries of research about tendencies in student thought.
- LAs learn that people who have no formal education in physics often have some surprisingly productive intuitions.
- LAs find that people can make a surprising amount of intellectual progress simply by having the opportunity to reason things out.
- LAs find the PIP valuable for relating to people in general, because of the practice with listening for understanding without imposing your own point of view.

The PIP seems to us to be extremely promising for transformative professional development. We look forward to learning more about the details of what happens in the interviews that the LAs conduct, and to better understand how the experience is meaningful to the LAs.

# Scaffolding Children's Understanding of the Fit Between Organisms and their Environment In the Context of the Practices of Science

**Kathleen E. Metz, UC Berkeley**
**Stephanie Sisk-Hilton, San Francisco State University**
**Eric Berson, Uyen Ly, UC Berkeley**

**Abstract:** This research project applies the learning progression perspective to the teaching of the conceptual underpinnings of evolution for 2nd and 3rd graders. We frame the progression from the epistemic perspective that understanding a scientific idea encompasses *using* that idea, in prediction, interpretation and explanation of the natural world. The progression foregrounds the question of the fit between organisms and their environment. This paper reports on the first step of the project, our teaching of the curriculum in an urban summer school and the analysis thereof. We analyze students' reasoning during prototype instructional activities and in comparison of pre- and post-interviews. We have had success scaffolding children's understanding of differential survival advantage of different traits. While we have existence proofs of children coming to understand the impact of this differential on changing distributions across generations, this next step of understanding appears to be much more difficult.

Evolution remains widely misunderstood at all ages. Preschoolers and adults alike manifest teleological reasoning in thinking about the biological, *albeit* with changing cues as to when it is applied (Keleman, 1999; Lombrozo & Carey, 2006). Across this same wide age-span individuals manifest 'biological essentialism", assuming that a species is determined by a defining essence (Gelman, 2003; Medin & Atran, 2004), while ignoring the within-species variation so crucial to understanding the mechanism of natural selection (Shtulman, 2005). Indeed even earlier biologists fell prey to these same misconceptions, as reflected in Ernst Mayr's (1988) tracking of teleological reasoning across the history of biology and Stephen Jay Gould's (1996) attribution of early evolutionary theorists' devaluing of within-species variability to their "essentialist tendencies".

In this continuity of challenges to understanding evolution, we envision an intriguing potential of starting instruction about the conceptual underpinnings of evolution at the second and third grade level. While these findings indicate that these conceptual challenges are robust and difficult to transcend for students of all ages, this continuity in the conceptual challenges leaves open the possibility that some form of early intervention might have an advantageous impact. We make no claim that these conceptual issues could be easily resolved if addressed much earlier in the K-12 curriculum. Rather, in accordance with the idea of *learning trajectory*, we posit that strategically taking up the conceptual underpinnings of evolution at this level could support a basic understanding of some facets of the theory and enable a deeper understanding of evolution at subsequent grades.

This research agenda accords with the new NRC report, *Taking science to school: Learning and teaching science in grades K-8* (Duschl, Schweingruber, & Shouse, 2007). This report emphasizes the fundamental importance of the interplay of instruction, experience, and maturation in the competence that children can achieve. Its conclusion that "*what children can do is in large part contingent on their prior opportunities to learn"* points to the key role of the learning trajectory in instructional design and analysis of children's capabilities. Finally in place of the problematic dichotomy of content and process, it recommends framing K-8 science learning in terms of four interrelated strands: *a)* Know, use and interpret scientific explanations of the natural world; *b)* Generate and evaluate scientific evidence and explanations; *c)* Understand the nature and development of scientific knowledge; and *d)* Participate productively in scientific practices and discourses. This research is grounded in this conceptualization of science learning.

This paper reports on our project, striving to scaffold young children's understanding of the fit between organisms and their environment. We present the instructional approach through description of the learning progression and design principles that informed the construction of the curriculum. We analyze the children's understanding of the fit between organisms and their environment and how this changed over time, through: *a)* comparison of pre- and post-test one-on-one interviews; and *b)* children's thinking wrestling with the targeted ideas in the context of prototype lessons. The research is small scale, limited to two cycles of research within a summer enrichment program (over which the team will have complete control of student placement and instruction) and two years of the classes of three second and third grade teachers in a diverse, urban school (reflecting the complex environment to which any viable intervention must adapt). This paper reports on the first cycle of the summer enrichment program.

## The Scaffolding of Children's Understanding

### The Learning Progression

Above and beyond consideration of where children begin and the long-term end-point in the conceptualization of a learning progression, we aimed to conceptualize the conceptual terrain of the progression such that it supports increasing explanatory power *from the students' perspective*. Most elementary school science curricula violate this criterion, with content that will only prove to have some explanatory power when linked to concepts reserved for older grades – a curricular pattern that fails to reflect the power or purpose of science or the heart of its practices. We aimed to construct the learning progression in evolution in such a way that the concepts within this grade-band have explanatory power in and of themselves, while also strategically grounding more powerful and complete explanatory models to be taught in subsequent grade levels.

The learning progression is framed in terms of *increasingly powerful explanations of the fit between organisms and their environment.* We focus on phenomenology and change at the time scale of microevolution. An ecological perspective is limited to that needed to understand this relationship; *e.g*., the survival value of different inheritable traits of a population within a particular environment. The cellular level is excluded, as well as speciation and genetics above and beyond the idea of inheritance.

Our current version of the learning progression consists of seven levels. We assume that children will come to school with some understanding of the two most basic levels: the simplistic idea that organism*s Live where they belong* (Level I) and the more adequate idea that organisms *Live where they can get what they need* in Level 2. While children come to school with some ideas about what organisms need, the curriculum aims to develop these understandings. Variation in organisms' structures/ limiting factors embodies the idea that organisms are able to get what they need in very different environments --- with different limiting factors --- due to variation in their structures. At this level we can build on some understandings that children have of structure/ function, but also need to substantially elaborate the structure/ function idea and the scope of the context to which it is applied. *Survival value of specie's trait* (Level 4) conceptualizes fit between organisms and environment in terms of the survival value of a particular trait (e.g.; the survival value of the Grey Whales' migration between Baja and the Arctic or the ridge on the male crickets' wing that enable them to chirp). Whereas survival value or cost-benefit analysis may be intuitive at some level and some contexts (*e.g.*; is it worth trying to get my ball back now from the playground bully), we doubt children have ever considered animal or plants' traits from this perspective. *Within-population variation and differential survival advantage* (Level 5) takes up the idea of differential survival advantage of different traits of the same characteristic within a given environment. *Natural selection* (Level 6) is conceptualized as the idea that, over many generations, inherited traits that help organisms' chances to survive and reproduce in that environment become more common there. Traits that hurt their chances become less common. The traits that hurt its chances become less common. The last level (Level 7) encompasses the outcome of the mechanism of natural selection, namely *Organisms well-adapted to where they live.* A secondary progression, supporting understanding of life cycle, resemblance of parent and offspring, and inheritance supports the primary progression building increasingly powerful explanations of the fit between organisms and their environment.

### Pedagogical Design Principles

Given space constraints, we present the pedagogical design principles here in brief:

1) Understanding a scientific concept entails *using* the concept in the practices of science, including interpretation of the natural world, making prediction, and developing explanations.
2) Build children's conceptual understanding through a range of scientific knowledge-building practices, including thought experiments, field-based and laboratory-based empirical inquiry, and text-based research.
3) Immerse children in exploration of a phenomenology and the puzzling patterns therein *prior* to introducing the corresponding explanatory abstraction.
4) Leverage strategically selected in-depth cases of phenomenology and their interpretation as a basis to build generalizations and abstractions.
5) Capitalize on fruitful preconceptions.
6) Build from contexts that we anticipate will be less likely to evoke buggy reasoning before having students apply these new ideas to contexts that we anticipate will be vulnerable to buggy reasoning.

7) Emphasize the metaconceptual and metacognitive knowledge that support children's understanding of the power of the targeted ideas in explaining the fit between organisms and their environment.

### The Curriculum Modules

We have developed two curriculum modules, to scaffold children's advancement on the learning progression, in accordance with these design principles. One of the modules develops these ideas in the children's study of botany, the other in the realm of the children's study of the animals and their behavior. Each module is approximately 30 hours in length, about the length of a relatively long "replacement unit".

## Measures of Student Understanding

### Pre- and Post-Interviews

We developed a structured interview instrument to measure student progress on the learning trajectory. In accordance with our conceptualization of what understanding of a concept entails, items elicited children's using the targeted ideas in predicting, interpreting and explaining biological phenomena. The instrument consisted of 7 extended items. One item was framed in terms of one of the particular organisms the class studied (Brassica rapa on the part of the botany class and crickets for those in the animal class). All the others were transfer items, a characteristic of the instrument that we realized made it extremely difficult. The instrument included items without any kind of scaffolding, as well as two items with dynamic scaffolding and two items with what we conceptualized as empirical scaffolding, in the form of empirical feedback following the children's generation of a prediction and the explanation thereof. The instrument assessed the conceptual terrain through: *a)* two items involving children's thinking about why particular organisms (otters and kelp) lived where they lived and consideration of where else they could or could not live; *b)* four cases of microevolution, involving predictions and explanations about a population after an environment change, followed by explanation of what actually happened (*e.g.*; changes in the coloration of male guppies, following arrival of predators); and *c)* explanation of change in a characteristic over time (e.g.; the question, drawn from this research literature, of why cheetahs today are so much faster than their ancestors).

### On-Line Student Negotiation of Curricular Activities

Above and beyond analysis of gains in understanding from before and after the instructional intervention, we are also interested in understanding how the curriculum functioned to support conceptual development and how we might iteratively improve it for these purposes. For the purpose of analyzing the interplay of instruction and learning, we videotaped all instruction and developed a complete database of student written work and easel pad record notations from class discussions (used in place of the white board to support the inclusion in the written artifact data base.) We also designed embedded assessments into the curricular plan.

## Analysis of Children's Understanding

We conducted structured one-on-one interviews with almost all of the 40 children in the summer program. These interviews were videotaped to enable close analysis. We are currently formalizing the coding process to apply to the full set of interviews. While we will report statistics about all 40 children and their changes from pre- to post at the conference, the results we report are only preliminary and formative, and based on the 13interviews we have studied to date. (These * are all the children from the animal behavior class who participated in all days of the program, minus one child with Down's syndrome who did not participate in the post-test interview.

### Advancements From Pre- to Post-Test and Enduring Conceptual Challenges

Even before the curriculum, the majority of the children we have analyzed (9 out of 13) had some understanding of the differential survival value of some traits, at least in the relatively straightforward and familiar instance of camouflage; *i.e*., organisms that stick out in an environment with a predator, as opposed to those that blend in, are more likely to be eaten. This in-coming level of understanding emerged in our framing of an item based on the classic case of the shifts in peppered moth coloration following severe pollution due to industrialization, as well as another item based on Endler's (1980) study of microevolution of male guppy coloration as a function of the presence of predator fish. For example, in an item asking children to make predictions and explanations thereof of the color of moths following heavy soot darkening their landing places, most of the children realized the survival value of dark coloration. For example: "They [the birds] can find the light ones because they're not camouflaged. But the dark ones, they're camouflaged. But they won't find the dark ones."

In the single non-transfer item, 12 of 13 children reflected some degree of conceptual advancement from pre to post-test. Thus, for example, the animal curriculum cohort had studied a case of microevolution of crickets on Kauai (Tinghitella, 2008, 2009): the appearance in the island cricket population of a slightly different wing structure such that cricket could not make a chirping sound, followed by arrival of maggots that lay their eggs in crickets that they can locate through their chirping. Post-instructional intervention, 92 % of the children in the animal curriculum cohort analyzed to date not only appreciated the differential survival advantage for the particular population currently living *( i.e;* those crickets that chirped were more likely to be found by the maggots and thereafter soon die from the development of the maggots in their body), but also considered the impact of this differential survival value -- combined with some rudimentary understanding of inheritance-- on the relative frequency of the trait in the next generation. For example, Ellen appropriately predicts an increase in the proportion of non-chirpers, but qualifies her prediction with noting that chirping is both a risk and an advantage. On the one hand, she views chirping as a survival disadvantage, in her words, "The fly will only go for the chirping cricket". On the other hand, she also notes the survival value of chirping, "They [indicating male crickets with changed wing structure] don't chirp, so that mates won't be attracted to them." As she explains her prediction of an increase in non-chirpers and decrease in chirpers (as represented in iconic symbols for chirpers and non-chirpers in the next generation), "a lot of the chirping crickets got eaten by the fly, the fly. And then most of these guys [non-chirpers] gave some birth to offspring."

Analysis of the transfer items revealed that 69% of the children also considered the impact of the shifts in survival value of traits to changes in the relative frequency of the traits in subsequent generations to contexts they had not studied in class. For example, consider Wally's post-test reasoning about the case of microevolution of male guppy coloration post arrival of predator fish. He predicts there will be more "black" or "grey ones" (camouflaged) and fewer "yellow ones" (colorful), on the grounds that:

> The black guppies can blend in more than the golden guppies... The yellow ones are getting eaten, because they can't blend in so good. And the gray ones... most of them, they can survive and then they give babies. There will be more and more gray ones... The yellow guppies, they'll get eaten so when they give babies, they won't have as much, and when they get eaten, there will be less and less.

In short, these interviews documented second and third graders' wrestling with questions of microevolution. The post-instruction interviews revealed conceptual advancements on the part of many students in a context they had studied, success on transfer tasks on the part of some, as well as multiple enduring conceptual challenges. In the sections below, we consider the functioning of the curriculum vis à vis these challenges.

## On-Line Student Negotiation of Curricular Activities and Embedded Assessments

### Children's Thinking in the Context of the Botany Curriculum

The botany curriculum included an instructional sequence of an empirical investigation followed by a thought experiment designed to support the children's wrestling with several ideas central to the learning progression, including within-kind variation (LP5), differential survival advantage (LP5) and a change in the prevalence of traits in subsequent generations (LP6). These investigations engage students in applying these ideas in the context of making predictions and developing explanations. Students are also immersed in a phenomenology to establish the basis from which to reason scientifically. The investigations build on prior investigations to develop these abstract ideas in a phenomenology that is familiar to students.

This instructional sequence begins with the students' close analysis of a population of aster seeds, identifying subtle differences between seeds. Students noticed that some seeds were slightly bigger than others and some had slightly bigger parachutes. They made predictions about which of these differences might matter for the distance that the seeds might travel in the wind. Students developed an experiment to test their predictions, comparing the distance bigger seeds and smaller seeds traveled.

To extend their empirical exploration of traits that support dispersal potential, we designed a thought experiment to scaffold students thinking around differential survival value and subsequent generations. We adapted the thought experiment from a case in the research literature of microevolution of the aster seed structure following the arrival of the seeds on ocean islands (Cody & Overton, 1996). As part of the thought experiment, we asked students to make predictions about the survival advantage of different aster seeds on the island and the distribution of size within the population of aster seeds in future generations. In this limited space, we focus on the interplay of instruction and evidence of students' thinking along the learning progression as reflected in the thought experiment.

We framed the microevolution thought experiment in terms of a population of aster seeds (large and small) that landed on an island. In this thought experiment, students (a) made predictions about where the next generation of seeds might land; (b) explained their predictions in terms of the survival advantage of the seeds that land on the island; (c) made predictions about future generations of seeds on the island and their differences with respect to size; and (d) compared their predictions to empirical data from the scientist. The students worked together as a class on each part of the thought experiment, but recorded their own predictions and explanations separately on written templates functioning as independent, instructionally embedded assessment. An analysis of the classroom video of the thought experiment and written assessments reveal that most children had some understanding of survival advantage of the larger seeds and that the larger seeds would be more prevalent in the next generation (LP6).

Consider the interplay of task and student thinking in the context of this thought experiment. Shown a sample of seeds that landed on the island, the teacher challenged the class to make predictions about where the next generation of seeds might land (Figure 1). As part of the classroom discussion, many students shared similar predictions. For instance, "What I think will happen is that most of the heavy seeds will land on land and the light seeds will likely land on water" and "What I think will happen is that the light seeds will be more likely to land in the water because they fly farther." Based on analysis of student work, all of the students represented more heavy than light seeds in their predictions of which seeds would land on the island in the next generation.

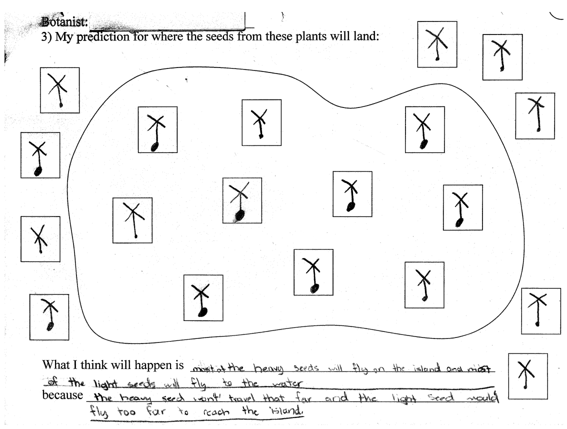

Figure 1. Sample of prediction of regarding where seeds with different traits will land.

The teacher asked the students to explain their prediction in terms of survival advantage, using a written template to scaffold their explanations. Analyses of these assessments reveals that 12 of 17 students appropriated the class discussion about the impact of seed size on distance traveled and used this as a rationale for explaining the differential survival advantage of heavier seeds. These students explained that the heavier seeds had a survival advantage relative to the lighter seeds. They reasoned that the lighter seeds tended to travel too far and would land in the water, whereas the heavier seeds didn't travel as far and would be more likely to land on the island, e.g.:

> [*Written prompt:* The heavy/light (circle one) seeds will have a survival advantage because…] …[circled "heavy" above]… the big ones will travel on land and the light ones will travel too far so they might fall in the water.

Students subsequently made predictions about what the scientist saw when she went to study the seeds on the island, many years after the seeds first arrived. Many students noted that while there will likely be MOSTLY bigger seeds on the island, there may still be some smaller seeds, for example:

> I predict that most of the…there won't be that much little ones that will be on the island. But I think the heavy ones will be on the island, because they have the advantage because they are heavier and they don't go as far…

In the final part of the thought experiment, the teacher presented the students with empirical data from the scientist and asked the students to explain what the scientist saw, how that might have happened and how their predictions matched what the scientist saw. Consider, for example, how one student compared her prediction to the empirical data (below). After summarizing the scientist's observations, the student explains these observations by reasoning that the lighter seeds were less plentiful because they had flown off of the island. She then concludes that her prediction fit with the scientists' observations based on a relative distribution of small to big seeds.

> *What did the scientist see?* A bunch of big seeds and a few little.
> *Why do you think that happened?* All the little seeds flew off the island.
> *How does your prediction fit with what the scientist saw?* That my prediction fit in because I drew three small seed and a lot of big seeds.

Note she appropriately predicted a decrease in light seeds and an increase in big ones, she may not fully attend to the generational nature of the mechanism over long periods of time.

Analysis of students' work indicates that 12 of 17 students demonstrated an understanding of survival advantage (LP5). However, generational thinking was still problematic for many. Nonetheless, by immersing students in the seed phenomenology and by engaging in the practices of science under these instructional conditions, students were able to reason about the differential survival value of traits and how the value can change with the change in the environment (arriving on the island.) The curriculum subsequently built on this emerging understanding to further develop student reasoning along the learning progression. In subsequent investigations, students continued to build on these ideas in a more independent context of partner work focused on using empirical data from their plant populations growing in the classroom to make predictions about plant characteristics in future generations following an environmental change.

### Children's Thinking in the Context of the Animals and Their Behavior Curriculum

The idea of multiple generations also proved particularly difficult for students as they reasoned about shifting survival advantage of a trait in relationship to an environmental press in the context of the animal behavior curriculum. In the Kauai crickets thought experiment, the first point at which the curriculum scaffolded students to work through the process of natural selection most students (88% based on analysis of individual students' worksheets)readily worked into their repertoire the idea that a particular trait could have *survival value* for an individual (LP 4), and also that within a population, individuals with a certain trait could have a *survival advantage* over those members of the population without the trait (LP 5). Likewise the idea that offspring usually had traits similar to the parents was non-problematic according to students' comments in the class discussion and as shown universally on student workseets (although students over-attributed identical traits to offspring, since the curriculum did not explore genetics). Some students were able to use these ideas to reason about the likelihood of a trait being passed from one generation to a single subsequent generation. For instance, at the beginning of the Kauai Crickets thought experiment, Maria explained the ideas of her partner, Carlos, regarding which type of male crickets had a survival advantage: "the chirping ones because um, the chirping ones could find a mate, and then when they had their babies they could also chirp." However, almost all students encountered significant difficulty in reasoning about the impact of an environmental press over many generations. In their written records, 23% predicted that variation would simply cease to exist in the next generation (the trait with survival advantage would be present in all individuals), 29% predicted an increase in the population of non-chirpers but were unable to describe their reasoning, and 23% were unable to construct a response at all. Of the 23% who predicted an increase in the population of non-chirpers and gave a reason, all focused on the fate of an individual or a single generation, for example, "the chirping crickets get caught by the fly." Students had difficulty creating a chain of reasoning that moved beyond the second generation and considered the impact of differential survival value *survival, reproduction, and traits present in subsequent generations.*

In the animal behavior curriculum, a single external representation used multiple times throughout the series of investigations appeared critical in scaffolding children's multi-generational reasoning (see figure 2). Evidence suggests that this form, in the context of the curriculum's thought experiments, helped students develop evidence-based predictions about the shifting distribution of a trait over many generations. The representation was first used in the Kauai crickets thought experiment, where it did not have an obvious impact (see above). However, in subsequent thought experiments, when students returned to the representation they were better able to make generational predictions. For instance, in students' final projects, in which student pairs predicted changes to a population of an animal of their choosing in response to a real environmental press, the teacher observed only 2 pairs reasoning about a potential shift in trait distribution due to differential survival based on traits. Upon bringing back a version of the generational chart seen in figure 2, all pairs were able to construct such an explanation (with differing degrees of direct teacher intervention). The generational representation scaffolded students' development of a multi-generational prediction regarding shift in the distribution of a traitin three key ways, discussed briefly below in the context of the Kauai crickets example.

First, the representation *required students to represent the members of a population as individuals with or without a key trait and on this basis make predictions about whether they were likely to survive and reproduce.* After students discussed the survival value of chirping for male crickets prior to the arrival of a predator, the teacher presented a small sample population to represent the initial trait distribution, in this case 10 male crickets in which 7 were chirpers and 3 were non-chirpers. The teacher then described the arrival of the predator fly, and several students co-constructed the idea that non-chirpers, previously at a disadvantage in attracting a mate, now had a survival advantage because they would be less likely to be victims of the fly. However, the seemingly simple question of "would there be more or fewer chirping crickets in the next generation" met with little response. The teacher then asked students to predict using actual numbers: out of the 10 crickets represented on their page, which five would survive and reproduce. Underneath the first representation were 5 boxes in which to place the reproducers. They then filled in connected boxes to show the traits of their offspring. Students repeated this process for two subsequent generations before making predictions about the population 15 generations later. Manually "moving" representations of individuals from members of the population as a whole into a sub-group of those that reproduced allowed students who were unsure of the question when initially asked to develop well-reasoned responses. For instance, Tyrone, who adamantly insisted that neither chirpers nor non-chirpers had a survival advantage when the predator fly arrived, when forced to make a decision about which individuals to place in the "reproducer" boxes, placed more non-chirpers than chirpers, and wrote [italics refer to provided prompt]: "*Now I think* the non-chirping *male crickets have a survival advantage because* the fly would not eat them." In class conversation and on his representation sheet, he contended that 15 generations later, there would be *no* chirpers. While this is not entirely accurate, his reasoning showed a move from not accounting for survival advantage to predicting individual survival based on a trait to making predictions about trait distribution in the population as a whole.

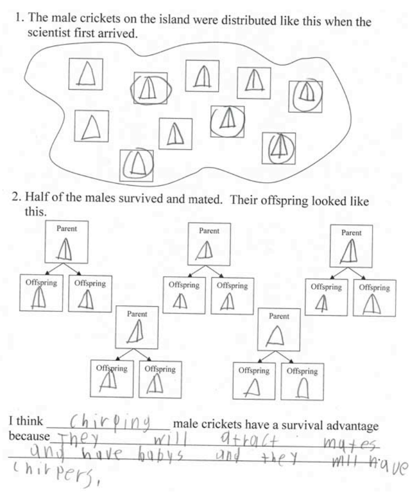

Figure 2. Sample of simplified visual representation of shifting distribution of a trait over generations.

Second, this format provided a simplified representation of *next generation as involving the offspring of organisms present at the onset of the investigation.* The representation physically linked traits of offspring to traits of parents. Students then transferred only the offspring into a new box labeled "Generation 2." Of course, this is a simplification in many ways. The representation limited offspring per parent, mandated number of reproducers in a generation, and assumed offspring always had the same trait as the represented parent. Most importantly, the representation prompted students to reason about the fate of individuals, although the goal was to get them to reason about the shifting distribution of a trait within a population. However, for many students, as in the example of Tyrone above, reasoning at the level of the individual appeared to be a necessary step to move from the claim that it was impossible to predict future distribution toward reasoning that accounted for differential survival advantage resulting in some members of a population being more likely than others to survive and reproduce in each generation (LP 6).

Finally, the generational representation provided a simplified visual that scaffolded students' understanding of the *shifting relative concentration of a particular trait in a population across generations.* By looking at the scattered icons representing the predicted population by trait in each generation, students easily discussed the shift in prevalence of a trait over multiple subsequent generations. Some students described the shift using the actual numbers of the greatly simplified population drawing, for example, "here there's seven that chirp, but now there's just four so there's more that don't." Others were able to make more generalized statements about how traits become more or less prevalent across generations, still referring to the simplified representation. For instance, Martin stated, "[in generation 15] there'll be mostly non-chirpers because if they had to mate… and if they had babies, then they'd have to be non-chirpers." Many students continued to need this representation to scaffold their predictions and explanations for the remainder of the curriculum, even those who were able to construct more generalized explanations of shifting trait distribution. As discussed above, 7 of the 9 student pairs used the representation in constructing an explanation for their final project in the curriculum.

## Conclusions

The understanding of evolution poses challenges for high school and colleges students. Our project aims to support understanding of this key theoretical frame by beginning early: with second and third graders. We have conceptualized a learning progression in terms of steps of increasing power and complexity in explaining the fit between organisms and their environment. Analysis of structured interviews, classroom discussions, and instructionally embedded assessments reveal children wresting with key aspects of natural selection in cases of microevolution. Predicting changes in relative frequency of a trait from one generation to the next appears to pose less substantial challenge than extrapolating shifts in distributions across a broader scope of generations and time.

We have three more rounds of the educational design experiment, including a second summer school with many of the first summer's second grade participants as third graders in the other domain (switching from study of botany to animals and their behavior or visa versa) and two semesters in regular school year classrooms. This gives us the opportunity to continue to rework the curriculum to more adequately scaffold the conceptual issues that prove most difficult. Our goal is to iteratively refine the instruction, as we closely examine the power and limitations in children's understandings of evolution that emerge under these instructional conditions. This process will best position us to try to differentiate robust limitations of children this age from limitations due to suboptimal learning opportunities.

# Learning physics as *coherently packaging* multiple sets of signs

Kristine Lund, Karine Bécu-Robinault ICAR Research Lab, CNRS, University of Lyon
ENS-LSH, 15 parvis René Descartes, 69007 Lyon, France
Email: Kristine.Lund@univ-lyon2.fr, Karine.Robinault@inrp.fr

**Abstract:** This paper studies the multimodal reformulations that teachers and students make when they talk about and do physics experiments in class. Using the framework of semiotic bundles, we show that reformulating aspects having to do with physics knowledge while moving between talk, gestures, drawings and manipulations is done differently by experts and novices. Analysis of video excerpts illustrate that teachers are able to coherently package multiple sets of signs throughout their discourse and actions in the classroom, but students who are learning physics have specific problems that this framework makes evident. In particular, successfully reformulating from one semiotic resource to another implies that the first resource be correctly constructed. In addition, specific *tool affordances* hinder students in their attempt to coherently package multiple sets of signs while this is not the case for teachers. We conclude by suggesting ways in which teachers can ease students' difficulties in constructing semiotic bundles.

## Introduction

Our research team has many years of experience in designing teaching sequences for upper secondary school in physics and chemistry (e.g. Buty, et al., 2004). These groups are based on the collaboration of practicing teachers and researchers in which instrumental and theory-oriented approaches are combined (Brown, 1992). One main hypothese stemming from research on the design of these teaching sequences is that the modeling activities of students in relation to an epistemological point of view concerning physics' functioning must be taken into account (Bécu-Robinault, 2002). In addition, other theoretical underpinnings are taken into account, such as the role of social interactions in learning (e.g. Doisy & Mugny, 1984) and research results concerning misconceptions (cf. Duit & Von Rhöneck, 1998 for a meta-review). Since 1997, we have developed a range of teaching-learning sequences, concerning learners aged from 15 to 18 all of which have been implemented in classrooms and evaluated from teaching and learning perspectives. Our results show that teachers are able to use the teaching-learning sequences and associated documents and they also perceive improvements in student learning. Despite this, evaluations also show that, unexpectedly, a variety of teachers devote a great deal of time to the reformulation of the ideas in the elaborated documents (Lund & Bécu-Robinault, forthcoming). We know teachers have a fixed duration to teach their class and do not purposefully waste time, so we hypothesize that this phase is important for helping students grasp the knowledge to be taught. In this study we explore the implicit reasons for which teachers may perform such a reformulation activity and this prompts us to look more closely at the initial lessons of a particular physics teaching-learning sequence.

In what follows we will present our theoretical framework, describe our empirical study, present our analyses and results and conclude with perspectives for further work.

## Theoretical framework

Physics learning in the classroom is a complex activity that is both cognitive and social where teachers and students use talk, gestures, drawings and the manipulation of objects to co-construct physics concepts. It has been shown that embodiment through gesture plays a role in learning new concepts (Goldin-Meadow, et al, 2009) and Roth & Pozzer-Ardenghi (2005) propose that for understanding communication in everyday settings, one must take into account not only words and gestures but also all other semiotic resources co-participants produce or find in the setting. In this paper, we choose to address students' conceptual difficulties in the particular case of learning electricity through the study of multimodal reformulation as a tool to co-construct discourse (De Gaulmyn, 1987; Apotheloz, 2001; Lund, 2007), thus taking into account all the semiotic resources that co-participants do. We will use the notion of semiotic bundles as a method for explaining students' difficulties (Arzarello, 2004) and illustrating teachers' expertise. In the sections that follow, we present these notions and set the scene for showing how reformulating aspects of one particular semiotic resource into another one is an expert activity for teachers but fraught with difficulties for students.

### Multimodal reformulation

The term multimodal is often used to signify the medium in which a particular message can be expressed, for example text or graphics (e.g. Pineda & Garza, 2000). The authors Kress & Van Leeuwen, (2001) distinguish between modes and media: modes are the abstract, non–material resources of meaning-making whereas media are the specific material forms in which modes are carried out. The mode of gesture is carried out in the media of movements of the body. Different media afford different kinds of meaning (Dicks, et al. 2006), e.g. expressing an idea in writing or speech affects what is conveyed. Here, we use the term multimodal to describe the addition of non-verbal human face-to-face interactive phenomena such as gesture, gaze, posture, object manipulations, etc. to speech, studied extensively as a phenomenon in its own right by researchers such as Kendon (2004), Cosnier, (2000), McNeal (1992) and Brassac, et al. (2008).

Many interactive situations whose objective is learning presumes a dissymmetry of knowledge between interlocutors. This dissymmetry calls for adjusting discourse so that interlocutors reach mutual comprehension and common ground. Teachers' discourse does not escape from these adjustments and they often occur as reformulations; what learners say is put by the teacher into more conventional words (Chouinard & Clark, 2003). In this study, we borrow a different focus for the definition of reformulation, elaborated in the context of collaborative writing (Apotheloz, 2001). This is an oralo-graphic situation that articulates two different modes, speaking and writing. For Apotheloz, cooperation during such a task consists in "continuously exhibiting, that is at each step, the manner in which what is formulated articulates with what has already been formulated" (p. 62, our translation from French). We study this same phenomenon of reformulation, but in a situation where there is a plurality of multimodal activity: teachers and students speak, write, gesture, draw and manipulate objects and we see that the reformulations between modes that are carried out by teachers and those that are carried out by students differ greatly in how such a reformulation provides for the construction of meaning.

### Semiotic Bundles

We use Arzarello's (2004) semiotic bundle to interpret such multimodal reformulation, originally defined to analyze interactions around mathematics learning. A semiotic bundle is a collection of semiotic sets and a set of relationships between the sets of the bundle. A semiotic set is composed of three elements. The first component is a set of signs that may *be produced* with different intentional actions (speaking, writing, drawing, gesturing, handling an artifact). The second component is a set of modes *for producing* the signs and possibly transforming them. The modes can be rules or algorithms, but can also be more flexible action or productions modes, such as the modes referred to in the previous section, comparable to the intentional actions of Arzarello (speaking, writing, drawing, gesturing, handling an artifact). The third and final component is a set of relationships among the produced signs and their meanings embodied in an underlying meaning structure. A semiotic bundle is a dynamic structure changing over time due to the semiotic activities of the participants who are constructing it.

Our research questions focus on describing how expert teachers and novice students reformulate aspects having to do with physics knowledge while moving between talk, gestures, drawings and manipulations of physical objects. We hypothesize that experts and novices will reformulate differently and that the theoretical concept of the semiotic bundle is useful for understanding students' difficulties in physics while illustrating how teachers' expertise in multimodal reformulation can potentially be leveraged for helping students.

## Empirical study

This study has been carried out in the context of a research-action group that designs teaching sequences for physics (Bécu-Robinault, 2007; Buty et al, 2004). All the teaching sequences have been co-elaborated by researchers and practicing teachers, implemented in classrooms and evaluated from teaching and learning perspectives. In this presentation, we focus on the electro kinetics sequence, lasting 3 months, for grade 7 in the French school system. The teaching and learning of electricity has been the object of many investigations in science education. From international research results, we know that students encounter deep-level conceptual and reasoning difficulties in understanding introductory electricity. The main difficulty concerns notions of current, electric current and energy that are not differentiated by students (Psillos et al., 1988). Many teachers spontaneously use analogies, such as a water analogy, to teach electricity. Indeed, using analogies in teaching is thought to provide learners with tools that facilitate science understanding and promote conceptual change. We thus chose to introduce an analogy, in order to predict and interpret phenomena without using any formal concepts and to help students to develop an understanding of electricity and energy concepts (cf. Scott et al., 2006). This analogy relates these concepts to familiar every day objects (loaves of bread represent energy, delivery vans in motion represent the current, the bakery and the supermarket are respectively the analogues of the battery and the light bulb). The analogy is intended to help students to differentiate the concepts of current and energy. The lesson is set up so that questioning why a battery has a life span prompts thinking in terms of energy while questioning how a bulb lights up prompts thinking in terms of current.

### Short description of the lessons studied

In the French curriculum, electricity at grade 7 is taught through a phenomenological study of electrical circuits. In this presentation, we will focus on the first two lessons dedicated to the study of the simple circuit (how to light a bulb with a battery) and to the introduction of an analogy used for teaching (differentiation of current and energy, although we will not focus on energy in our examples). The first lesson is a necessary preliminary, in order that students understand how to handle electrical devices, identify the different terminals, and have no choice but to build a loop with the battery, wires and bulb. To understand how a simple circuit functions, students are asked to draw their experiment before handling electrical devices. This lesson begins with the presentation of a well-known object, a Maglite™ flashlight. Students usually question a battery's freshness and this cannot be interpreted in terms of current so the second lesson addresses this concern. With the help of the analogy, we suggest that the current implies thinking with a circuit perspective and that energy implies thinking with a chain perspective. Students are thus asked to connect each term of the analogy and its corresponding physical object in the world and use a variety of semiotic resources (modes producing signs).

## Methodology

Video recordings and partial multimodal transcriptions of one pair of students and a teacher involved in the research-action group were made and written documents distributed by the teacher were collected. The transcriptions (cf. Atkinson & Heritage, 1984) were done according to the following conventions (cf. Table 1).

Table 1. Conventions for multimodal transcriptions

| |
|---|
| Multimodal transcription conventions |
| ^ : rising tone |
| ‘ : falling tone |
| [ : overlapping speech |
| a : underlining words implies insistence |
| : ou ::: : a sound is drawn out |
| = : immediate chaining with next utterance |
| (.) : micropause |
| (3 s) : pause in seconds |
| (...) : a cut in the recording |
| (inaudible) : inaudible passage |
| ** gestures are described and shown in relation to the discourse that was spoken when they were performed |

Verbal and non-verbal behavior of the teacher and students were analyzed in relation to the classroom production. Written teaching-learning materials were used to define what type of resources students had at their disposal to build semiotic sets and bundles.

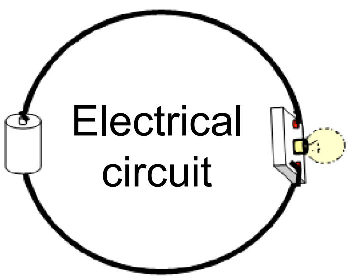
## Analyses and results

We present three short video extracts and their corresponding analyses. Before the third extract, we describe three groups of students' drawings. The first extract corresponds to the presentation of the analogy: the teacher defines each term and correspondence. In the second, the teacher constructs an experiment (lighting the bulb by connecting two wires to a battery) that corresponds to a physical object, a drawing of that object and a drawing of the experiment. In the third, the students attempt this same experiment.

### A teacher's complex yet coherent semiotic bundle

The first extract (second lesson) concerns an integration of two semiotic sets into a coherent semiotic bundle. The first semiotic set contains the model of the electrical circuit (Figure 1, left) and the second contains the analogy of the electrical circuit, built around a bakery that delivers bread to supermarkets (Figure 1, right).

Model of the electrical circuit



Analogy built around a baker delivering bread

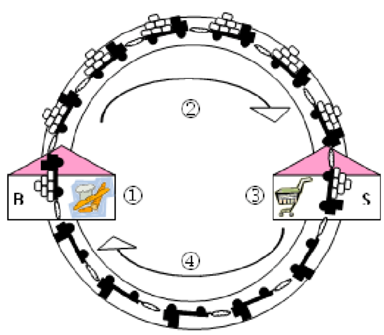


Figure 1. Two semiotic sets: the electrical circuit and the bakery analogy.

The elements of the analogy are presented below; each numbered element corresponds to the circled number on the figure at the right.

1. Each bakery always loads the same number of loaves of bread at into each delivery truck.
2. All delivery trucks move at the same speed. The speed of the delivery trucks is adapted to the demand of each supermarket.
3. The delivery trucks arrive at the supermarket where the loaves of bread are delivered, transformed and then sold to clients. All of the delivery trucks delivery all of their loaves of bread.
4. After delivery, each truck returns empty to the bakery in order to get a new load of loaves of bread.

The relations allowing the coherence of the semiotic bundle are provided by teacher's talk and gestures concerning each semiotic set and by written documents distributed at the beginning of the lesson (cf. Table 2 where T stands for teacher and S for student).

Table 2. Teacher discourse and gestures during her presentation of the bakery analogy.

| Time | Discourse | Gestures |
|---|---|---|
| 7'33 | T: the electric current can can circulate | traces a circle with her hand, then traces another |
| | Ok and this electric current what is it in the | rapidly traces a smaller circle with her hand |
| | delivery truck analogy^ | raises her right hand in order to indicate the change from the domain of electricity to the analogy |
| | S: the delivery [trucks | |
| | T: [why yes ^ | points her finger at a student |
| | S: the lineup of delivery trucks= | |
| 7'43 | T: =the lineup of delivery trucks very good | traces a circle with her hand |
| | it's the lineup of delivery trucks | traces a circle with her hand, then traces another circle |
| | uhh it's the fact that | traces a circle with her hand |
| | it's the circulation of the delivery trucks | traces a half circle, pauses at the bottom |
| | the trucks | finishes her circle |
| | are moving | traces a half circle with her hand, pauses between the bottom and the top, finishes her circle |
| | so the electric current circulates | traces a circle pauses between the bottom and the top |
| | ok it's all of the trucks that circulate very | traces a circle that is almost complete with her hand |
| 7'52 | good | |

Our videotape shows that gestures are identical when the reference domain changes (from electrical circuit to bakery analogy). The teacher makes a circular gesture to mimic both circulation of electricity (first semiotic set) and traffic of delivery trucks (second semiotic set). This circular gesture is repeated eleven times (cf. Figure 2), in association with the verbalization "circulation of delivery trucks" or "circulation of current". The rhythmic gesturing emphasizes the continuous aspect of the electrical circuit (delivery trucks) and allows the teacher to insist upon the systemic point of view. Moreover, she makes pauses corresponding to the positions of the supermarket (bulb) and of the bakery (battery). We argue that these similar gestures within two separate semiotic sets help students to integrate the analogues in a single and coherent semiotic bundle.

Figure 2. Teacher gesturing in order to make the link between circulation ofdelivery trucks and circulation of current.

However, problems begin for students at a much earlier stage. This paper's aim is to show that building complex semiotic bundles such as this one can be difficult for students unless each semiotic set they add to their bundle under construction (indeed each semiotic resource that they add to their set) is done in a coherent way. In order to illustrate this, we look at the bundle at an earlier stage, before the analogy has been introduced, when the objective is to build a simple circuit. In this context, a first semiotic set will consist of a drawing, written comments on that drawing, gestures about that drawing and a verbal description of that drawing, all done by the students. A second semiotic set will consist of handling the experimental apparatus, talking about handling it, performing gestures to show objects, all mostly done by the students alone. Having said that, semiotic sets and bundles can be co-constructed between teachers and students, adding to the complexity of our analytical viewpoint.

## A teacher's initial coherent semiotic bundle

Figure 3 shows an example of how an expert teacher is able to construct a coherent semiotic bundle from a variety of physical objects and functional representations of those objects (following her own instructions given to the students during the first lesson, as stated below):

1. Do a drawing that represents what happens inside the flashlight when it is turned on and is shining (a photo of this object is given – it's a familiar object for all students).
2. Draw diverse experiments with the proposed objects that will permit you to verify what happens inside the flashlight when it is shining.
3. After the teacher gives permission, ask for the necessary objects and perform the experiments.
4. Is your drawing for question 1 correct? If it isn't, do another one that shows what is happening inside the flashlight when it is shining.

Figure 3 shows that it is easy to link each part of the drawings with the experimental apparatus, because aspects and locations of objects (battery, bulb) are similar. These relations are also facilitated because drawing and experimental apparatus are built on the basis of the electrical diagram the teacher has in mind (far right of Figure 3). The teacher is thus able to move from one mode to another while maintaining coherency and building meaning. We also notice that the teacher does *not* draw the clamps of the crocodile clips in her drawing of the experiment, as they are not relevant to carrying out the experiment. As an expert, she is able to model the physical objects in a way that is pertinent for the experiment she will be carrying out, only paying attention to the characteristics that are relevant for that objective (see discussion on affordances in the next section).

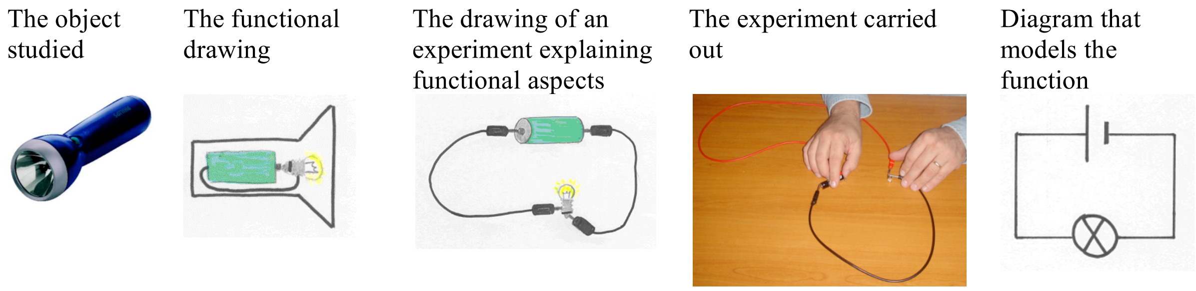

Figure 3. An *a priori* didactical analysis of multimodal and polysemiotic coherence for the simple circuit

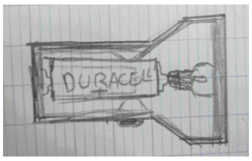
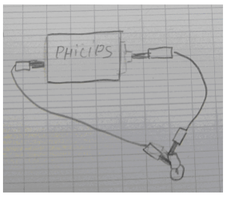
## Students' difficulties in constructing the initial semiotic bundle

We first show an analysis of three different student groups' drawings in order to illustrate the range of difficulties students have when they propose experiments that fit to their representation of what happens inside the flashlight when it is turned on and is shining (cf. Figure 4). One of the first difficulties students experience while building the semiotic bundle is connecting the experimental apparatus to the initial 'thought objects' that represent the flashlight parts in their drawing. From an expert point of view, the real object (the flashlight), the drawings and the experimental apparatus as well as discourse and gestures about these, form one semiotic set. On the other hand, we see that students already have difficulty relating these elements to each other, *within the semiotic set itself*, so adding another set to this one (e.g. the bakery analogy) to make a semiotic bundle seems, at this stage, to be out of these students' reach.

| Group# | The functional drawing | The drawing of an experiment explaining functional aspects | Comments |
|---|---|---|---|

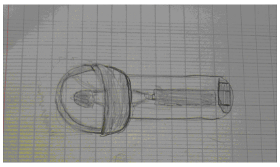
1

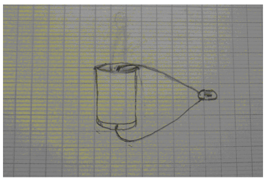




There is no wire in the functional drawing. Names of batteries are different from one drawing to another although the battery is the same. However, the drawing of the experiment is correct.

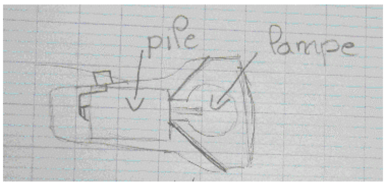
2

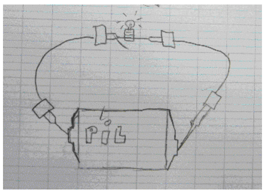




Students use one wire to connect either the battery to the bulb or the battery to itself. They tell their teacher that there is a button they can press to initiate battery functioning.

3





The functional drawing reproduces the general look of the bulb.
The drawing of the experiment takes into account the objects students have to use and the physical affordances of their experimental apparatus are evident in their drawing, even though this is not pertinent.

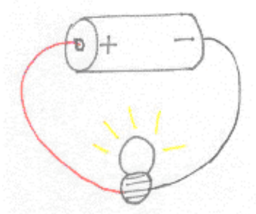
Figure 4. Example of students' polysemiotic incoherencies for the simple circuit.

The second extract (cf. Figure 5) concerns two students (Pierre and Jacques) who experience many difficulties in attempting to perform the simple circuit experiment as described above. Firstly, the students' drawing of the experiment is not correct. In order for the bulb to light up, one wire must be touching the very end of the bulb and the other wire must be touching the middle part (cf. the teacher's drawing in Figure 3).

So in this case, Pierre and Jacques are attempting to create coherency within an underlying meaning structure between two modes while trying to respect a drawing that will not help them. Secondly, the physical affordances of the crocodile clips (not shown in their drawing, but visible in the photo), entice the students to clamp them onto something, but the bulb does not allow clamping. Instead, one must just maintain the clamps stable (without trying to open them) so that they are touching the correct parts of the bulb and battery (cf. the teacher's experiment, above). According to Suthers, et al. (forthcoming), a given medium offers particular affordances (potentials for action in relation to the actor, following Gibson, 1977) of which salient affordances are expected to be the most pertinent (Norman, 1999). In this case, the crocodile clips were salient, but their function was not pertinent. Contrary to instructions, Pierre and Jacques do not redraw the experiment in an attempt to focus on how the electrical connections must be made, although this could have helped them.

The object studied

The drawing of an experiment explaining functional aspects



The experiment carried out a first time

Figure 5. Analysis of two students' multimodal and polysemiotic *in*coherence for the simple circuit.

6

Later on, another student shows Pierre and Jacques how to light the bulb with one wire. On this basis, they make several trials and suddenly, it works. Pierre says "it's magic!", but since he hadn't drawn any new representation of the experiment, this event remains at the level of the magic trick for him, because it is not integrated into the semiotic bundle. This interpretation is also illustrated by a final trial made with the teacher that does not work either. Figure 6 and Table 3 with the associated discourse of the teacher shows that Pierre has not yet understood how to hook the wires up to the battery. In fact, Pierre and Jacques followed their drawing, but this did not result in a lighted bulb and so they were stuck.

Table 3. Teacher discourse when a student helps him to hold the experiment.

| Time | Discourse | Gestures |
|---|---|---|
| 32'44 | T: no, not really here well we'll see that later on but it should not be placed on the same area of the bulb, | points to the wire on the bulb |
| | it should be on this area and on the contact | points to the lower side of the bulb and the bottom of the bulb |

Figure 6. Pierre is called upon to help the teacher hold the experiment.

## Conclusions and further work

In this article, we have used the notions of multimodal reformulation and the semiotic bundle to describe how meaning-making occurs when students and teachers speak, gesture, draw and manipulate objects. Choosing to look at meaning-making through the construction of such semiotic bundles allows us to meet two goals. Firstly, we render explicit teachers' expertise (i.e. their ability to seamlessly change modes, to select the appropriate characteristics of experimental apparatus to model in relation to a known objective and finally to coherently construct a complex semiotic bundle). Secondly we pinpoint where difficulties appear for students. In particular, if students erroneously construct a particular semiotic resource (e.g. the drawing for the experiment), they won't be able to build an underlying structure of meaning between it and the next semiotic resource they reformulate into (e.g. experimental apparatus). Secondly, the physical affordances of experimental materials (e.g. the crocodile clips) can hinder reformulation between a semiotic resource in one set and a semiotic resource in another (e.g. between drawing and experimental manipulation). Finally, although we did not show the data in this paper because of lack of space, some subsequent student interventions indicate that the multimodal reformulations produced by the teacher in order to broaden the semiotic bundle facilitate the understanding of the electric circuit: students reproduce similar gestures to those of their teacher and they discuss new metaphors based on the systemic point of view. We can conclude that it is useful to consider teaching sequences from the viewpoint of the *complexity* of the semiotic bundle that is being built. Each new semiotic resource and set that is added to the bundle must be constructed without error so that students are able to reformulate a given resource into another mode. Physical objects to be manipulated must be carefully chosen so as to not mislead students by material affordances that are not relevant to the task at hand. In sum, each step of the construction of each semiotic set that makes up a semiotic bundle can be seen as a checkpoint for student understanding. Future work will include the documentation of additional examples of representational mode changing and semiotic bundle building, both by teachers and students. We will also further explore how students can appropriate teachers' expert multimodal reformulation practices and the extent to which this affects their learning.

We would like to thank the students and teachers who were filmed for this study and the educational administrators who accepted that such research be carried out in their school.

# Digital art-making as a representational process

Erica Halverson, UW-Madison, 1086 Educational Sciences, 1025 W. Johnson, Madison, WI 53706, erhalverson@education.wisc.edu

**Abstract:** In this paper, I take a distributed cognition framework to analyze the tasks of artistic production in terms of the external representations produced. Using data collected through case studies with four youth media arts organizations (YMAOs), I ask how the digital art-making process can be understood in terms of the construction of external representations and what function these representations serve in art-making. I analyze data on the process of making digital art in terms of the macro and micro tasks performed (Spillane, Halverson, & Diamond, 2001) in order to highlight external representation construction across organizations. Then I describe one micro task in depth to unpack the role the representations created serve in sensemaking. I find that digital art-making as structured in YMAOs seems to provide a robust, authentic environment for the construction of process-based external representations which has implications for content domains that value representation as a learning goal.

## Introduction

> I think that's what artists do. They struggle with their pieces, with what their pieces are about. They struggle with who they are and how they're going to show themselves (Street Level participant, 09.08).

Producing external representations that demonstrate mastery of a topic is often the desired outcome of participation in a constructivist-oriented curriculum. Performance-based assessment is predicated on the idea that the products of a learning process accurately represent what learners know and can do. While curriculum and assessment designers often struggle to construct tasks that afford learners the opportunity to engage in authentic production, art-making is fundamentally a representational task (Eisner, 2002; Langer, 1953). In producing art, we always strive to represent an idea, a feeling, a story to an audience using the tools of artistic media. In this paper, I describe how structured artistic production experiences provide adolescents with the opportunity to engage in a series of complex representational tasks. These representational tasks are consistent with a broad framework demonstrating the importance of external representations in sensemaking (Cox, 1999; Reisberg, 1987) as well as our understanding of the role of representation in creativity (Hasirici & Demirkan, 2007) and the artistic production process (Eisner, 2002).

The use of external representations for sensemaking in the context of schooling has thus far been situated in research on mathematics (e.g. Zhang & Norman, 1994) and science (e.g. Puntambekar & Goldstein, 2007). Philosophers of art (Langer, 1953) and scholars who describe the arts and cognition (Gardner, 1973; Eisner, 2002) take engagement with complex external representations to be a core part of artistic production. Despite a common emphasis on creating external representations as a method for students to demonstrate mastery, there is virtually no connection across research on artistic production activities and core subject areas. One reason for this may be the lack of common language for describing the value of representation for sensemaking in classroom-based academic tasks and in artistic production. The ability to evaluate and construct representations in physics, for example, is considered a high-level skill, and one that is essential for students to master. The arts, on the other hand, are often considered "extra" activities that, despite their direct parallels with scientific investigation (Gardner, 1973), do not warrant the same prestige. Understanding the role external representations play in artistic production processes can demonstrate the ways learning art and learning science are alike, breaking down the artificial separation between core and "extra" academic subject areas.

In order to understand the role of external representations in artistic production, I take a distributed cognition framework to analyze the tasks of the art-making process in terms of the external representations produced. Using data collected through case studies with four youth media arts organizations (YMAOs), I ask how the digital art-making process can be understood in terms of the construction of external representations and what function these representations serve in art-making. I analyze data on the process of making digital art in terms of the macro and micro tasks performed (Spillane, Halverson, & Diamond, 2001) in order to highlight external representation construction and use across organizations. Then I describe one micro task in depth to unpack the role the representations created serve in sensemaking. I conclude with reflections on the important role digital art production can serve in student learning and development with implications for content domains that value representation as a learning goal.

## The Role of External Representation in Sensemaking

Understanding the role of external representation in sensemaking begins with a distributed cognition perspective on thinking and learning (Hutchins, 1995; Salomon, 1993). Distributed cognition shifts the "locus of knowledge" from inside the individual to within and among actor-tool-activity networks (Salomon, 1993).

Understanding how people interpret and construct external representations using available tools over the course of systemic activity is a core task of research on distributed cognition (Cox, 1999; Zhang & Norman, 1994). Hutchins (1995) describes this research as, "the examination of the role of material media in which representations are embodied and in the physical properties that propagate representations across media" (p. 266).

In a distributed cognitive system, external representations function both as tools to think with (Norman, 1993; Zhang & Norman, 1994) and as tools for expressing complex ideas (Norman, 1983). Cox (1999) distinguishes between external representations that are provided for learners to assist in their understanding (presented or pre-fabricated) and the representations that learners construct to demonstrate their own understanding or to assist their own learning (self-constructed). While much of the research on the role of external representations in distributed cognitive systems has focused on learners' use of presented representations, Cox (1999) argues that constructing representations are of vital importance to understanding learning: "This activity represents more than a simple translation, for as Vygotsky observed, when signs (language, diagrams, etc.) are included in an action, they do more than facilitate manoeuvres that are impossible in the absence of the sign system. They fundamentally transform action" (p. 347). Reisberg (1987) described external representations as both *aides memoires* – expressions of understanding that extend human cognition – and *aides pensées* – tools with which to develop new understanding. In both cases, "one can learn by turning one's [internal] representations into stimuli – i.e. by externalizing them" (p. 288). How learners construct external representations of complex ideas and the value of this activity in building robust understanding is of great interest to educators and researchers who value a constructivist approach to learning.

### External Representation and the Arts

Artistic production provides a rich context for understanding distributed cognition and the role of external representation (Eisner, 2002; Gardner, 1973). Eisner (2002) describes artistic production as, "[the] transformation of a material to a medium. Materials *become* media when they mediate…[and] to convert a material into a medium is an achievement" (p. 80). Like any representational domain such as mathematics or writing, "getting smart" in the context of producing art, "means coming to know the potential of the materials in relation to the aims of a project or problem" (Eisner, 2002, p. 72). Art-making is fundamentally a creative process, and creativity is intimately tied to the production of external representations (Csikszentmihalyi, 1996). Hasirci and Demirkan (2007) describe mental images and external representations as "essential in investigations of creativity" (p. 262). Hayes (1989) describes the capacity to build the right representation in the right situation as a marker of creative expertise. There are strong parallels between the role external representations play in creative acts in art and in science. In both domains, creativity requires convergent and divergent thinking; the ability to construct representations that are both unique and recognizable is the marker of an accomplished artist and scientist (Gardner, 1973).

Artistic production is about the creation of representations. Creating art mindfully, that is learning how to construct and critically evaluate these representations, requires scaffolded instruction. In youth arts organizations, participants are engaged in authentic artistic production tasks, yet they are guided in these authentic tasks by explicit pedagogical practices. Eisner (2002) describes student artists in the context of formal instruction as, "work[ing] meaningfully on the creation of images" (p. xii). Research on artistic production in youth arts organizations has demonstrated that youth are highly invested in the meaningful construction of images with explicit attention to how these products will be received by a public audience (Heath, 2000; Soep, 2006). In my research, I am interested in how youth learn to engage with and create external representations over time. I follow this process in youth arts organizations because they offer youth explicit instruction (much like schools) toward the goal of the public sharing of art (much like professional artists). It is in this context of these organizations that I take up questions of external representations and artistic production.

## Research Methods

Broadly, I am interested in the role self-constructed external representations play in learning, particularly in the arts. While seminal research on arts-based learning has broadly considered the importance of representations in art-making (Eisner, 2002; Gardner, 1989), this research has not taken an explicitly distributed cognition perspective on the art-making process in order to understand how representations are constructed and the functions they serve. To initiate this research trajectory, I posed the following research questions: (a) What are the representational tasks involved in producing autobiographical digital art? (b) What function do those representational tasks serve emerging art-makers in youth media arts organizations as they create products to share with a public audience?

### Data Collection

To address these questions, my research team conducted four instrumental case studies (Stake, 2000) with YMAOs across the United States. Youth arts organizations work in a variety of media including live theatre, radio, digital story, film, and spoken word poetry. While all of these media afford youth the opportunity to engage in the representation of self through art, we chose YMAOs that work in the digital media arts, with a focus on film. This allowed us to hold the representational medium constant as we explored how youth constructed and used external representations. Table One briefly describes the four organizations.

Table 1: Four case study organizations.

| | Location | Production cycle length | Type of program | Time of data collection | # of youth participants |
|---|---|---|---|---|---|
| Appalachian Media Institute | Whitesburg, KY | 3 months | Summer internship | Summer 2008 | 12 |
| In Progress | St. Paul, MN (headquarters) | Varied | Ongoing | Summer 2007 | 10 |
| Reel Works Teen Filmmaking | New York, NY | 6 months | Semester | Fall 2007 – Spring 2008 | 12 |
| Street Level Youth Media | Chicago, IL | 3 months | Summer internship | Summer 2008 | 12 |

At each organization, we traced one production cycle – from participants' initial entry into the organization to the final presentation of their work. In identifying a production cycle as the frame for our cases, we created further consistency in our data collection not by the amount of time we spent with each organization but by the organizational structure provided for participants to produce their digital art (Table 1). In order to capture the production cycle at every organization we collected a variety of qualitative data:

- *Documentation of the process in action*. Most of this documentation was in the form of ethnographic observation, though we also obtained video documentation at various points across the production cycle.
- *Artifact collection*. We collected all artifacts youth created around the digital production process including application essays, journals, group brainstorming sheets, worksheets, edited/unedited video footage, and blog entries. We also collected curricular materials used by organizational leaders and individual workshop facilitators.
- *Interviews* with participants, organizational leaders, facilitators, and mentors.

Data collection was iterative; we employed a constant comparative method across our case studies (Glaser & Strauss, 1967). We began with two open-ended case studies (*Reel Works* and *In Progress*) and then returned to the field a year later to conduct two more directed case studies (*AM*I and *Street Level*) based on our initial interpretations. In our open-ended case studies, we participated in as much of the production cycle as we could, and collected all artifacts that seemed relevant. While we did not initially conduct a full analysis of all representations produced, we did identify when and where opportunities for construction occurred to inform the design of our second round of case studies. In this second round, we directed our efforts towards capturing youths' representation construction – both the process of constructing and their use of these representations in the context of the production cycle. We also asked organizational leaders more pointed questions about the relationship between identity and representation in our second round of interviews.

## Data Analysis

In a distributed cognitive system, the way actors make sense of their work can be analyzed in terms of the tasks they must complete and the artifacts generated in the completion of these tasks. In this analysis, I employ Spillane et al.'s (2001) analytic method for understanding distributed cognitive tasks, breaking down the digital art-making process into macro and micro tasks. In my previous work, I have documented autobiographical artistic production as a "dramaturgical process" – the telling, adapting, and performing of narratives of personal experience (Author, 2007, in press). Using an open-ended coding process (Corbin & Strauss, 2008) of observational data, interviews and artifacts created during the production cycle across all four case studies, I coded all the representational tasks we captured as one of three macro tasks: (a) Telling stories and/or figuring out what story to tell; (b) Adapting stories into filmic representations or; (c) Presenting products to an outside audience.

Once I classified all data that concerned the building of an external representation into these three categories, I conducted a second round of grounded coding where I assigned the data to a "micro task" within one of these macro tasks. Since tasks demonstrate the distributed interrelationships among actors and artifacts in sensemaking (Spillane et al., 2001), I considered an activity a micro task if participants had to create a unique external representation as an integral part of the activity. Having identified these micro tasks, I explored them further in analysis by identifying relevant properties and dimensions (Corbin & Strauss, 2008) of these micro tasks across organizations and by building theoretical conceptual matrices that highlighted analytic points of interest across the data.

## Findings: Representational micro tasks in digital art-making

Given the central role artifacts play in analyzing distributed cognitive tasks, my analysis affords opportunities to see these cognitive processes as representational tasks and to understand the tasks at a level of depth previously unexplored in cognitive analyses of artistic production. In this section, I first describe the representational tasks youth engage in as they created digital art at the four YMAOs. Table 2 provides a summary of all the micro tasks and their prevalence across organizations. In the narrative sections below, I reference the names of tasks by an individual data citation (field note, interview, journal entry, worksheet) though multiple forms of data demonstrated the prevalence of these tasks and their relevant artifacts. I then describe one representational task in depth: the pitch. In doing so, I analyze the role this task and accompanying external representations serve in sensemaking.

Table 2: Micro tasks in the process of digital art production.

| Type of task | Format(s) | AMI | IP | RW | SL |
|---|---|---|---|---|---|
| *Macro task: Telling stories* | | | | | |
| Application essay | Written text | √ | | √ | √ |
| Application interview | Oral conversation | | √ | √ | |
| Warm-up ideas | Written text; Multimodal | √ | √ | √ | √ |
| Pitch | Oral presentation<br>PowerPoint or other supplementary text | √ | √ | √ | √ |

| Final video | Multimodal | √ | √ | √ | √ |
| Artist statement | Written text | | | | √ |
| Public showing | Multimodal; Oral conversation; Written text | √ | √ | √ | √ |

### Telling Stories

In the context of producing digital videos, "telling stories" as a macro task is accomplished when filmmakers are ready to begin shooting footage for their films. Across all four organizations, there were five different micro tasks that youth participated in.

*The application essay*. In three of the four organizations youth were required to submit a written application. Applicants were given a series of guiding questions to respond to, including questions about what stories they might like to tell with film, as well as reasons for wanting to join the program.

*The application interview*. Two of the four organizations required youth to participate in one-on-one interviews with the program's directors prior to beginning the process. At Reel Works, youth had also written applications so the interviews were supplementary. At In Progress, interviews were the director's opportunity to talk with youth prior to their beginning the process about their goals and film ideas.

*Warm-up ideas*. While some youth came to the organizations having already decided what film they want to make, many had not. Youth produced a variety of artifacts that were "warm-ups" for their final product including short essays in response to questions such as, "Why do you like art and making stories? What are you going to do this year" (IP FN 07.31.07) or writing prompts such as, "I really miss…" and "My greatest passion in life [is]…" (RW Journals Fall 2008). Participants also produced more focused representations based on guided worksheets. Alternately, youth produced mini-films in a short production cycle such as "community-based interviews" (AMI FN 06.08) or "past assignments" (SL FN 07.01.08). The resulting artifacts were multi-modal, video-based projects that were accomplished in a short period of time and are given feedback by the adult facilitators.

*Pitch.* Across organizations youth were required to "pitch" their ideas to a critical group, either within their community or to some outside group. Youth produced a wide variety of artifacts during the pitch, depending on the nature of the task as structured by the organization. The pitch is described in greater depth below.

*First treatment.* Before participants began shooting their films, they created a representation of their plan – referred to as a "first treatment," (RW FN 07.20.07) "shot list," (SL Journals 07.08) "essays," (IP FN

08.01.07) and “proposals” that include who they will interview, shot list, b-roll footage, why they want to make the film and its importance (AMI Interview 04.08).

## Adapting Stories

To distinguish between the “telling stories” macro task and the “adapting stories” macro task, I divided the work by representations that were created before and after footage for the final product was shot. In some cases youth used footage they created in their “warm-ups” for their final product, blurring the line between the two macro tasks. Additionally, films that were heavily interview-based had a clearer distinction between pre-/post-shooting artifacts since none of the dialogue was crafted in advance. For films with narrative elements, some of the adaptation work was accomplished in advance of shooting. Despite this messiness, there were two micro tasks unique to the adaptation function.

*Prose script.* Participants at *Reel Works* generated scripts for their films after they shot the majority of their footage, giving them a roadmap for how to edit their films and a broad sense of how the final product would look. *AMI* had their participants create “paper edits…where you write down what you think your video will look like and what each part’s going to be like. Like some people do it minute-by-minute or just in minute chunks…like what scenes are going to look like and what each character’s going to bring” (AMI Interview 07.16.08).

*Rough cut.* Participants produced one or more “rough cuts” before they presented a final product. Typically, these rough cuts were used in critique sessions with peers and/or mentors. Rough cuts are multimodal since they represent the film to that point – they may be missing certain key modes (such as soundtrack) or they may contain all modes in basic form.

## Presenting Products

A core component of any performance-arts production process is the final presentation to an outside audience. Since audience is a critical component of artistic production, all of the micro tasks in the presentation function focused on creating a sharable product that can be communicated to outsiders. Three unique representational tasks emerged.

*Final video.* All participants produced a video, either alone or with a group. The final video is the ultimate external representation – the permanent instantiation of how an individual or group of youth chose to share their story with an audience. In other work I describe how these final products can be analyzed as standalone multimodal representations (Halverson, in press).

*Artist statement*. At *Street Level* youth created “artist statements”, written text that accompanied their videos describing who they are and what their piece is about.

*Public showing.* In addition to completing a video as a standalone piece of work, youth participate in a variety of public events where they have an opportunity to engage in a discussion about their work with audience members, either in the form of a gallery opening (Street Level) or a screening with a post-show “talk back” (other three organizations).

## One Micro Task In-Depth: The Pitch

While the above description outlines the representational tasks involved in producing digital art, I am also interested in the role these representations serve in helping youth to understand the art-making process. In order to explore the role representations serve art-makers, I chose one task and its accompanying representations to analyze in further depth. Table 3 provides a more detailed breakdown of “the pitch” at each organization.

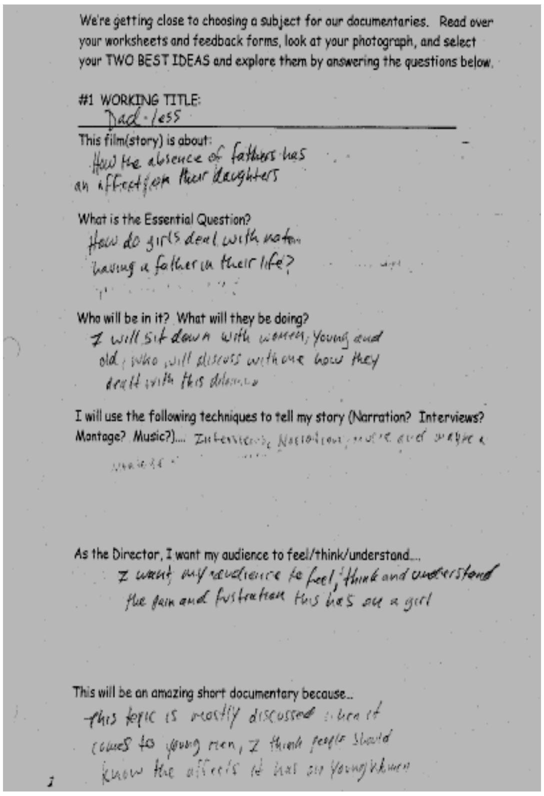
Table 3: Pitch micro task across organizations.

| | Micro-task | Artifacts produced | People involved |
|---|---|---|---|
| AMI | Brainstorming session | Ideas on butcher block paper<br>Oral presentation<br>List of ideas to vote on<br>Vote tally for project ideas | Participants<br>Instructors<br>Mentors |
| In Progress | One-on-one meeting | Journal notes | Participants<br>Director |
| Reel Works | Formal story pitch | Pitch worksheet<br>Oral presentation | Participants<br>Instructors<br>Mentors<br>External experts |
| Street Level | Group presentation | PowerPoint<br>Oral presentation | Participants<br>Instructors |

The artifacts generated for these pitch sessions provide opportunities for youth to engage with their film ideas by a) expressing textually and orally what story they want to tell and why and b) engaging with experts and peers through reflective critique. The differences in task and artifacts created are isomorphic representations that are implementations of the same abstract goal (Zhang & Norman, 1994).

The *Reel Works* pitch process is the most traditional example of "pitching" movie ideas to sell to outsiders. Youth participants traveled to Time-Warner studios in New York City to share their ideas with their peers, mentors, and directors, and a panel of professional producers. Youth were instructed to treat this meeting as if they were selling their movie ideas to producers, providing a context for their presentations. In addition, they were given a worksheet to guide their thinking about the development of their ideas (Figure 1). Some youth used the worksheet directly, filling in responses to worksheet questions and using these responses to give their pitches. Others used the questions on the worksheet as guidelines for the construction of a narrative description that they created in a journal. Youth used these artifacts to read from as their delivered their pitches, though they also answered questions from the audience extemporaneously.

The worksheet provided space to reflect the content of the story – e.g. "*This film(story) is about*: The life of my grandfather; Through good times and bad. How I handled the ups and downs." It also provided space to think about the representational medium of film – e.g. "In this film, I would be the narrator. I will also interview my parents and other artists who appreciate the art of photography like I do. There will definitely be music in the beginning of this film." Finally, participants reflected on the meaning of their film: "*As the Director, I want my audience to feel/think/understand*…where I'm from, try and put theirselves [sic] in my situation, be inspired at the end of my film. I want people to go out and change their situations, my film should be influencial [sic]." The questions posed on the worksheets encourage youth to think about the content of their film, their use of film as a medium, and why their film is important. This explicit attention to content, structure, and impact resulted in external representations, in the form of written statements on their ideas, how they will be carried out and the functions they may serve.



We're getting close to choosing a subject for our documentaries. Read over your worksheets and feedback forms, look at your photograph, and select your TWO BEST IDEAS and explore them by answering the questions below.

#1 WORKING TITLE:
Dad-less

This film(story) is about:
How the absence of fathers has an affect on their daughters

What is the Essential Question?
How do girls deal with not having a father in their life?

Who will be in it? What will they be doing?
I will sit down with women, young and old, who will discuss with me how they dealt with this dilemma

I will use the following techniques to tell my story (Narration? Interviews? Montage? Music?)....

As the Director, I want my audience to feel/think/understand....
I want my audience to feel, think and understand the pain and frustration this has on a girl

This will be an amazing short documentary because...
this topic is mostly discussed when it comes to young men, I think people should know the affects it has on young women

Figure 1. *Reel Works* pitch worksheet.

The oral presentation afforded youth the opportunity to engage in reflective critique that pushes these ideas further. These critique sessions focused on both practical issues of filmmaking and about the function of film as a medium in communicating a complex idea. For example, in pitching *Rupture,* the film about absentee fathers referenced in Figure 1, the filmmaker, instructor, mentor, and an external expert have an extended exchange about how to construct this piece so that it shows certain universal themes yet maintains her individual experience. As the instructor describes: "your story is one that many, many people have experienced but when you bring us through the story through your eyes, of walking through those doors, of what you were thinking and then of what your mother was thinking as you came through those doors" (RW pitch meeting, 03.08).

In contrast, at AMI*,* the focus of the pitch is for youth to sell their ideas to one another. Since films are made in groups, the pitch session serves as an opportunity to select three ideas they will choose to make. Youth engage in an extended brainstorm session where they generate their film ideas and try to draw connections across ideas (Figure 2). Every person has a chance to contribute their ideas, to describe the idea they contributed to the brainstorming session, and to indicate which of the ideas are their favorites. The butcher block paper is used to generate ideas and to draw connections across stories.

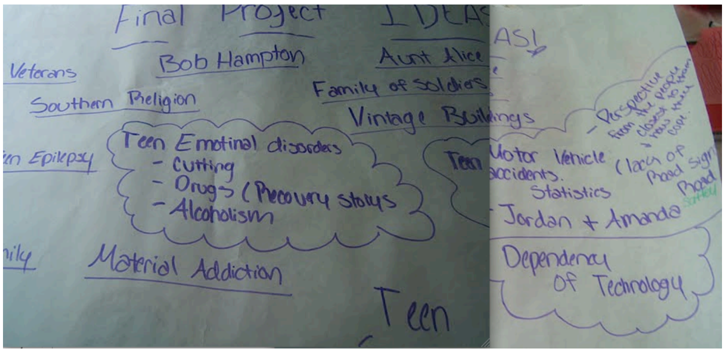


Figure 2. Final project brainstorm at *AMI.*

Once three ideas have been selected through a blind voting process, and youth are assigned to groups based on their own interests and mentors' construction of productive teams, these new groups devise a "proposal" for their film. The proposal consists of basic structural ideas, whom they will interview, a preliminary shot list, and a description of the film, as well as an assessment of who the audience for the film will be. Similar to Reel Works*,* AMI participants are given a series of questions to answer about their prospective film; they use "sample proposals" as models to construct their own (AMI FN, 06.27.08).

While the content of the pitches are constructed representations of participants' ideas, the structure for the representations is created by the organizations. By prompting youth with questions to answer, models to follow, and formats to fit ideas into, the organizations provide a structural scaffold within which participants can craft representations of their ideas. The pitch happens relatively early in the process, usually about one third of the way through the production cycle. At this point, youth are likely still struggling with core questions around why their ideas matter and whom these ideas may reach. Structuring the representational task in this way facilitates youth engagement with these questions and requires that they construct external representations, in the form of text and oral presentations that describe their emerging understanding of the value of their ideas and how these ideas can be communicated to outsiders. Across the pitch meetings, instructors and mentors used participants' pitches to help youth think in depth about the generalizability of their individual narrative ideas.

## Discussion: External representations in art-making and beyond

Analyzing the micro tasks embedded in the telling, adapting, and performing of narratives of personal experience demonstrates that learning to make art in the context of YMAOs is fundamentally a distributed, representational endeavor. YMAOs structure opportunities throughout the process for participants to create artifacts - written, oral, and multimodal – that demonstrate youths' evolving understanding of the story they want to tell and how the medium of film affords them the opportunity to represent this idea. Building these representations provides opportunities for sensemaking and reflection both in the representations themselves and in the discourse generated around these representations. Each microtask results in an external representation that affords the opportunity to explore the relationship between the idea and how the medium of film can express this core idea. The films themselves are multimodal representations of sophisticated ideas (Halverson, in press); seeing the microtasks from initial conception to final product allows us to understand how the final representation comes to be and whether and how youth are mindful of what their artistic representation conveys.

This type of distributed, representational system is not limited to digital art-making. Artistic production is a representational act, and learning to create art in an organizational context allows emerging artists to understand how representation affords reflection on art and meaning. The representational tasks scaffold the art-making process for youth to become reflective artists also look a lot like the representational process we want our students of science and mathematics to engage in.

## Educational Significance

Understanding artistic production in terms of external representational tasks is significant to researchers, practitioners, and designers who are interested in constructivist, project-based learning environments, especially those that engage learners with 21st Century skills. A decade ago, Cox (1999) described the growing importance of representation construction in progressive learning environments: "As educational technology becomes more and more integrated into the curriculum and as the variety and sophistication of data visualization and external representation techniques proliferate, the issue of training students to use ERs effectively is likely to increase in importance" (p. 360). Digital art-making as structured in YMAOs seems to provide a robust, authentic environment for the construction of process-based external representations.

Constructing external representations of process over time is a crucial component of YMAOs as designed environments. Despite this, research on the design of learning spaces that promote the development of complex external representations has been left to the sciences particularly physics, engineering, and the biological sciences. My analysis confirms Eisner's assertion that we need to allow artistic production to enter the conversation around external representations, complex cognition and the design of learning environments: "the tasks that the arts put forward – such as noticing subtleties among qualitative relationships, conceiving of imaginative possibilities, interpreting metaphorical meanings the work displays, exploiting unanticipated opportunities in the course of one's work - require complex cognitive modes of thought" (Eisner, 2002, p. 35).

Finally, narrative media such as digital art-making may be especially potent for adolescents and emerging adults who are involved in a psychosocial identity development process. Identity development has been described as the negotiation of a relationship between cultural and personal narratives (Hammack, 2008) – explicit engagement with these narratives through the dramaturgical process could facilitate positive developmental outcomes for participants. Artistic production that focuses on autobiographical experiences opens up opportunities for the representational process to engage youth in identity exploration. Future work will focus on how constructing external representations over time is intricately connected to identity development.

# Kindergarten and First-Grade Students' Representational Practices While Creating Storyboards of Honeybees Collecting Nectar

Joshua A. Danish, David Phelps, Indiana University, 201 North Rose Ave, Bloomington IN, 47405
Email: jdanish@indiana.edu, davphelp@indiana.edu

**Abstract:** A productive approach to studying the role of representations in supporting students' learning of science content is to examine their representational practices. The current study examines kindergarten and first-grade students' representational practices in a similar context—the creation of storyboards—both before and after a curricular intervention in order to highlight those aspects of their practices that changed while engaging in a superficially similar task. Analysis of the students' storyboards reveals considerable improvement after the intervention. Analysis of the students' practices as they changed over time is also presented by examining the students' interactions, with a focus on their discussions of the science content and the representations themselves.

There is no doubt that students' ability to create representations such as drawings and graphs is central to their ability to learn science in school (DiSessa, 2004; DiSessa, Hammer, Sherin, & Kolpakowski, 1991; Lehrer & Schauble, 2006). One reason for the centrality of representations in science classrooms is that specific representational forms can help students more easily engage with and communicate complex ideas (Roth & McGinn, 1998). For this reason, representations are also instrumental in the work of professional scientists (Latour, 1988; Lynch, 1988), and thus many attempts to teach students how to engage in authentic science necessarily include helping them to create representations. After all, students do not always create representations that are immediately productive for learning and expressing science content. Rather, students need support in order to create productive and accurate representations regardless of whether they are being asked to create canonical representations (i.e., graphs) or invented representations (i.e., drawings or diagrams from observation). One method that has been used to examine the way that the students' context can support their creation of representations is to study students' *representational practices* as they engage in creating and refining representations in science class. The practice approach highlights the relationship between students' representational actions, their knowledge of the content, and the features of the context that enable and constrain those actions (Danish & Enyedy, 2007; Hall, 1996; Roth & McGinn, 1998).
