Prior examinations of students' representational actions from a practice perspective have proven effective in several accounts of how representational practices contribute to or explain student learning within science and math (c.f., Cobb, Stephan, McClain, & Gravemeijer, 2001; Danish & Enyedy, 2007; Hall, 1996; Hall & Rubin, 1998; Roth & McGinn, 1998). However, there are two key gaps in the current literature that this paper aims to fill. First, examinations of students' representational practices typically focus on the way that these practices change in different contexts. This is, in part, to examine how students' movement through a range of representational activities supports them in learning new content. While this is a fruitful approach, it does not allow for a systematic comparison of students' practices as they change over time with respect to a single representational form. Second, this literature largely overlooks the representational practices of early elementary school children (for some exceptions see Danish & Enyedy, 2007; Lehrer & Schauble, 2000). Rather than neglecting the representational practices of young children, we argue that they are a crucial population to study because the practices that students develop early in their school careers will be important in supporting their later science and representational activities. Moreover, early elementary students spend a great deal of time learning by drawing, sculpting, and enacting their ideas in science class, and so it behooves us as a field to better understand these processes in order to inform research and teaching with representations.

This paper aims to begin filling these gaps in the literature by documenting the representational practices of 42 kindergarten and first-grade students in service of learning how honeybees collect nectar. The students were asked to create storyboards at two points in time: before and after a curricular intervention where they learned about honeybee content and were also encouraged to request and provide representational feedback (for the larger study upon which this analysis draws see Danish, 2009a; Danish, 2009b). First, to ground our discussion of the students' representational choices, we present a brief analysis of their representations (the storyboards) to highlight the fact that these did in fact improve over the course of the study. Then, video of students' interactions were analyzed to document the students' representational practices by identifying what their discourse revealed regarding the issues that they saw relevant in their representational practices. Specifically, their talk was coded along multiple dimensions to identify the prevalence and circumstance of talk about the science content and the representations themselves.

## Representational Practices

Simply put, practices refer to the patterned way of acting that people develop over time (Lave & Wenger, 1991). More specifically, Hall and Rubin (1998) further define *representational* practices as "making, using, and reading conventional representational forms," (p. 228). Hall and Rubin also caution us that these representational practices are "less stable and more detailed than many textbooks or studies of instruction presume" (ibid). The present study responds to this concern by documenting the details of students' representational practices as well as examining the process through which these practices change.

## Examining Representational Practice.

One hallmark of the practice approach to studying students' actions is that it recognizes the importance of context in shaping those actions (c.f., Roth & McGinn, 1998). To this end, most accounts of students' practices tend to at least implicitly recognize that there are features of the practice that are relatively stable across moments, and features that are highly dependent upon the moment being observed.

*Stable aspects of students' representational practices.* There are two ways of explaining stability, or observable patterns in students' representational practices. The first is to recognize that there are local social patterns, or norms that are stable within a particular setting. The second is to assume that individual participants "carry" the necessary knowledge across moments. Cobb et al. (2001) refer to the social aspect of this equation as norms, and the individual aspect as a psychological correlate, and argue that the two are mutually co-constructed and cannot be separated. Simply put, each individual has certain beliefs and knowledge about the practices and the content to which they refer, which include an understanding of the social norms surrounding it. At the same time, the social norms have grown out of and account for individual knowledge of the local participants. By definition norms are non-deterministic; students may or may not selectively follow them though one can typically identify norms by the way that participants mark their violation (Cobb, et al., 2001; Danish & Enyedy, 2007; Hall & Rubin, 1998).

In related research, diSessa and his colleagues identified "meta-representational competencies" which refers to students' understandings that apply across multiple representational forms, such as a belief in the need for parsimony (DiSessa, 2004; DiSessa, et al., 1991). Furthermore, these competencies, they argue, develop over time as students engage in representing in school (and other) contexts (Sherin, 2000). While these two approaches to locating stability in students' representational practices—the one focused on the social norms, and the other upon individual competencies—come from different theoretical perspectives, the result is the same; they describe patterns in how students engage with representations and suggest that these patterns, which are learned over time, have important implications for what students do with the representations that they encounter. Thus, it is important to document the patterns in students' representational actions, regardless of whether or not they appear to originate in social norms or individual preferences and competencies.

*The role of context in representational practice*. Of course, students' representational practices are also defined by their context of use, which may be defined in terms of the nature of a specific representation, of the task, or even of the other people present (DiSessa, et al., 1991; Hall & Rubin, 1998; Roth & McGinn, 1998). For example, students may not assume that a representation needs to be self-explanatory when they know that their teacher will allow them additional time to explain it further (Danish & Enyedy, 2007). There is, however, a reciprocal relationship between practices and context; individuals are presumed to see the context differently as a result of their changing practices. In fact, many of the studies described above rely on this to examine how students developing practices, combined with new contexts, can lead to key content learning. Therefore, in order to document students' representational practices, we attempt to identify those aspects that are relatively stable, the representational context, and the interaction between the two.

## Documenting Representational Practices

Traditionally, examinations of representational practices have focused on how they change over time along with shifting instructional activities. Researchers then identify students' practices by examining talk (and actions) as the students engage in creating, debating, and modifying representations. Hypotheses are then developed regarding what types of behavior are normative. These are vetted against the corpus of data to look for seeming violations of those norms (for an in-depth description of one such approach see Cobb, et al., 2001). This approach makes sense, given that the goal of these prior studies was to understand how specific practices, when paired with specific instructional exercises, resulted in students learning about the content being studied. Unfortunately, a side-effect of this approach is that these studies provide considerably less guidance to researchers and teachers whose aim is to support more general representational activities across a range of content domains. Furthermore, while patterns in the practice are described, it is difficult to distinguish patterns from the context in which they are visible for the very reason that the researchers are shifting those contexts in order to pursue specific instructional goals. For these reasons the present study aims to examine students' representational practices in a relatively stable context—the creation of storyboards. Of course, as students' practices shift students may be expected to relate in different ways to a superficially similar context. However, by holding the task stable, we are able to gain a richer understanding of the inter-relationship between the students' changing practices and the context of their use. Finally, by shifting our focus away from the process through which students' representational practices support (or not) their learning of specific content topics, we are able to more thoroughly document the entire range of their practices.

### What do we know about young children's representational practices?

Well before entering kindergarten, students are able to produce representations and understand their symbolic functioning (DeLoache & Burns, 1994). Studies have also shown that young children are aware of the context of their representational choices, and can adjust their interpretation or creation of a representation in response to their audience and the context (Callaghan, 1999). In fact, it was even demonstrated that kindergarten and first grade students appeared to recognize and balance between multiple competing influences on their representational choices including individual preferences, local norms, and the affordances of the immediate context (Danish & Enyedy, 2007). Furthermore, it has been demonstrated that young students are able to develop a rich sense of the requirements of a model for scientific activity, and to adjust their models accordingly as they engage with learning new content (Lehrer & Schauble, 2000). In short, there is reason to believe that young children are capable of rich and elaborate representational practices, and that these practices influence the role that representations play in supporting young students in learning about science content.

## Methods

The data presented in this paper comes from part of a larger study known as the BeeSign study, a 10-week curriculum intervention described in detail elsewhere (Danish, 2009a, 2009b). However, the prior analyses examined student content learning based on pre- and post interviews and primarily focused on the classroom intervention. The present study extends this work by examining the storyboard activity administered before and after the larger study. The study as a whole, and the storyboard in particular, will be described below.

### Participants

This study took place with two mixed-age kindergarten and first-grade classrooms (most of the students were between 5 and 7 years old) in a progressive California elementary school. The school as a whole has a range of family incomes from $35,000 or less per year to $250,000 or more per year with a demographic composition of approximately 47% Caucasian, 27% Latino, 13% African American, and 13% Asian. There were 42 students who consented to participate in the study (22 boys, 20 girls).

### Procedures

The students in this study participated in the BeeSign curriculum as their science curriculum for over 10 weeks. There were typically two one-hour-long sessions per week, for a total of 19 sessions. Over the study, the students were taught about how honeybees collect nectar through a series of inquiry and representational activities. In the representational activities, the teachers encouraged the students to provide and solicit feedback from their peers.

The students began the study by engaging in a pre-test, followed by the storyboard activity to be described below. They then engaged in the curriculum activities, followed by a final storyboard activity and then a post-test interview. The interviews were scored in terms of students' understanding of honeybees in terms of the structure, behavior, and function of the system based on the work of Hmelo-Silver and colleagues (2004) who had documented that novices tended to focus on the superficial structures and behaviors of a system at the expense of the functions. The students in the BeeSign study showed statistically significant gains from the pre- to post-interview in terms of the structures, behaviors, and functions that they described (Danish, 2009a, 2009b).

#### The storyboard activity

The present analysis focuses on the storyboard activity that took place both before and after the curricular intervention. During this activity the students were divided by the teachers into small groups of 3 to 6 students who sat together at a table. One half of the groups remained stable from the pre- to post- test, and the other half did not because one of the two teachers chose to allow the students to form their own groups in the post-activity. At both time points the students were asked to draw a storyboard about "how bees get food" and were shown how to use a storyboard to represent a series of steps in a process. The students were given a template that included 4 boxes in which to draw the storyboard, with several lines beneath each box in which they could write descriptions of the images. The students were allowed to talk and solicit feedback from their peers. However, the teachers did not actively request this (as they had during the curriculum intervention) in order to capture how frequently the students did this of their own accord. There were 6 groups videotaped at each time point, but only 10 of the groups (5 in the pre condition, and 5 in the post) had audio and video that was of high enough quality to analyze the students' work. On average, the students took 40 minutes to complete the task.

Students' talk during the storyboard activity were transcribed and coded along several dimensions for a total of 2361 unique utterances. An utterance was defined as one breath group, or roughly one sentence. The science content codes identified honeybee structures, behaviors, and functions (Hmelo-Silver & Pfeffer, 2004). The other coding categories (described below) were developed from student talk using a grounded approach. Inter-coder reliability reached 85% agreement for 24% of all coded utterances.

To analyze the actual storyboards that the students created, a list was made of structures and behaviors based upon the pre- and post-interview-scoring rubric. We then amended this list by adding any additional structures or behaviors that were consistently mentioned in the storyboard videos, such as the fact that bees have 6 legs. Credit was given either for clearly identifiable visual features, or for references in the writing that students had included beneath the images. Two researchers coded each storyboard independently, and then compared their codes. Differences were negotiated until resolved so that the storyboard scores represent 100% agreement. These scores did not include a number of implicit features that were present in many of the post-storyboards, such as a pattern of showing the bee flying to the flower and then back to the hive. While these were technically accurate, it was difficult to attribute them to a deep understanding of the content. Also, we did not deduct points for inaccuracies such as a bee being labeled as a King bee, which primarily happened during the pre-test. Therefore, any reported gains are actually quite conservative.

## Results

### Storyboard Results

The mean score for a storyboard increased from 1.20 points to 5.55 points from the pre- to the post-activity (N=34 due to student absences). This increase was statistically significant: $t(34) = 11.115$, $p < .01$, two tailed. Some of the most common features that students were given credit for were the inclusion of 3 distinct body parts, the inclusion of 6 legs, and the presence of the proboscis. Figure 1 depicts representative bee drawings from the pre and post-test storyboards. The bee on the left would not have received any points while the bee on the right would have received points for having three body parts, a stinger, six legs, a clearly identifiable proboscis, a clear compound eye, and the pollen basket. Combined with the interview results referenced earlier, these findings suggest that not only did the students learn about how honeybees collect nectar over the course of this study, they also demonstrated this learning in their storyboards. With this learning as a backdrop, we now present the analysis of student talk while creating the storyboards. In particular, we will focus on several of the shifts in talk from the pre- to post-test condition as they coincided with these dramatic increases in what features the students incorporated into their storyboards.

Figure 1. An example of a bee from the pre-test (left) and from the post-test (right).

### Representational Practice Results

The first analysis we performed was to determine how much of students' talk throughout this sequence of activities related to the content being studied (either science talk, or the representations themselves). Each utterance was then coded as belonging to one of four categories: Science and Representation, Instrumental and Procedural, Spelling and Heading, and Off-topic (see Table 1 for descriptions and frequencies).

Table 1: Student utterances while creating their storyboards

| | Science and Representation | Instrumental and Procedural | Spelling and Heading | Off-topic |
|---|---|---|---|---|
| Description | Talk about the science content (honeybees) or the representation. | Talk about the procedure and materials such as crayons, or the storyboard template | Sounding out letters, or asking someone how to spell words | Talk about lunch, clothes, parents, pop-culture, etc |
| Utterances (N=2361) | 869 (36.8%) | 802 (33.9%) | 211 (8.9%) | 479 (20.2%) |

While our analytic focus for the remainder of this paper will be on the 36.8% of the talk where the students discussed the actual science content of the curriculum unit, or their ongoing representations, it is important that we not dismiss the fact that there remains an additional 42.8% of talk which was on-topic, and central to the students' work. This is important because we do not want to give the impression that the students were silent except when addressing the content. Nor should one consider a noisy classroom, in which many students are discussing issues other than the content being covered, problematic. Rather, much of this talk may be central to students' ability to engage with their ongoing work. Furthermore, we often noted that even when silent or discussing off-topic issues, students were frequently seen drawing. In other words, despite being quite revealing about students' understanding of content, on-topic talk is not the only predictor of how effectively the students were creating their representations.

## What aspects of the science content do students discuss as they create their storyboards?

In order to better understand the relationship between students' social practices while representing and the content being studied, we examined the science content of their talk. We first coded the students' science talk in terms of whether it referred to the structures, behaviors, or functions of how honeybees collect nectar. Our hypothesis was that students would talk primarily about structures and behaviors as this mirrors previous findings that describe students' performance when examining complex systems (Hmelo-Silver & Pfeffer, 2004). Furthermore, we hypothesized that there would be a significant increase in student talk about these features during the post-test as the students learned the content. Note that utterances were only coded if they represented a unique idea within an episode. Episodes consisted of groups of utterances around a similar topic. In other words, if a student mentioned the proboscis, and then discussed it for 5 utterances with their peer, this was only coded once in order to avoid inflating our results. Some utterances were also coded simultaneously for a structure and a behavior, or for more than one structure. Finally, note that the percentages refer to percentages of on-topic utterances in each condition, and so do not sum to 100 as there were also on-topic utterances related to representations and other issues to be discussed below. Frequency counts and examples are presented in table 2.

Table 2a: Students' science talk across time.

| | Structure | Behavior | Function |
|---|---|---|---|
| Examples | Bee, hive, proboscis (e.g. "This is a bee hive.") | Searching for flower, getting nectar, performing a dance (e.g. "They're going to drink nectar from the flower.") | Survive the winter, collect nectar more quickly (e.g. "They do a dance to tell others where the honey is.") |
| Pre (N = 367) | 106 (28.8%) | 86 (23.4%) | 11 (3.0)% |
| Post (N=502) | 113 (22.5%) | 34 (7.9%) | 2 (0.4%) |

As can be seen in table 2a, the most common type of science talk related to structures, as hypothesized (28.8% in the pre- and 22.5% in the post-condition). However, we were surprised at the fact that the percentage of on-topic science talk decreased from the pre- to post-storyboard. This decrease was statistically significant for unique counts of structure ($\chi^2(1, N = 869) = 4.56$, p = .03), unique counts of behavior ($\chi^2(1, N = 841) = 40.90$, p < .001), and unique counts of function ($\chi^2(1, N = 869) = 9.71$, p = .02). We will return to this point after first presenting some follow-up analyses.

To assess the quality of this science talk we applied three code modifiers, marking each science content utterance for whether it was scientifically inaccurate or not, anatomically detailed or not, and topically extraneous or not for the given science prompt: how do honeybees collect nectar. Note that, as before, these codes represent unique ideas within a given episode, and so these counts are somewhat conservative and again do not add up to 100% (See Table 2b).

Table 2b: Quality of students' science talk across time.

| | Inaccurate | Detailed | Extraneous |
|---|---|---|---|
| Examples | Flowers contain honey, there is a king bee (e.g. "This is the king and queen bees.") | Head, thorax, abdomen, proboscis, pollen basket, (e.g. "The pollen basket's right there.") | House, trash-can, jetpack, chairs (e.g. "This is how I make a person in a chair.") |
| Pre (N=367) | 11 (3%) | 0 (0%) | 19 (5.2%) |
| Post (N=502) | 1 (0.2%) | 24 (4.8%) | 8 (1.6%) |
| $\chi^2(1, N = 869)$= | 12.18, p < .001 | 18.04, p < .001 | 9.04, p = .003 |

Table 2b presents a somewhat different picture of students' science talk as it moves from the pre-test to the post-test, and may begin to explain why students' discussion of structures decreased despite our prediction that they would increase. While the percentage of talk featuring science structures decreased from the pre- to post-activity, the talk in the post-activity contained significantly fewer inaccuracies, more details, and fewer extraneous features than talk in the pre-activity (See Table 2b). This may also partially explain why the storyboard products in the pre-activity often contained inaccuracies, minimal details, and extraneous features, whereas the storyboard products in the post-activity presented fewer inaccuracies and many more details. In short, students' talk in the post-test was far more refined, focusing on accurate and relevant details.

To further explore the role of science talk in the students' representational practices, we then addressed the question, *How do the patterns of student talk change with respect to audience?* Despite a concerted effort to limit teacher interaction with students during the storyboard activity, students often addressed the teachers or responded to very high-level questions from teachers or other adults with very specific information. The results are summarized in table 3.

Table 3: Students' science talk across audiences.

| Audience | Structure | Behavior | Function |
|---|---|---|---|
| Peer (N = 503) | 99 (19.7%) | 33 (6.5%) | 5 (1.0%) |
| Adult (N = 293) | 87 (29.6%) | 83 (28.3%) | 8 (2.7%) |
| Self (N = 68) | 30 (44.1%) | 9 (13.2%) | 0 (0%) |

Students were more likely to explicitly mention science structures in comments made out loud to their selves (44.1%) or to adults (29.6%), than when speaking to their peers (19.7%). Similarly, students were more likely to explicitly identify honeybee behaviors when talking out loud to their self (13.2%), or an adult (28.3%), than when conversing with a peer (6.5%). Further, students were more likely to discuss functions relevant to nectar collection when speaking with adults (2.7%), than with a peer (1.0%) or out loud to themselves (0%). This highlights the importance of the teacher in soliciting content-rich discussion from the students given that these predominated even when the teachers were intentionally limiting their discussion with the students.

## What aspects of the representations do the students discuss?

To answer this question, students' representational talk was coded in two specific ways. First, it was coded in terms of whether the students were discussing what to represent, how to represent it, or why it should be represented in that way. These three categories were designed to capture the nuances of students' representational talk, and whether it engaged students in simply discussing the features of their specific representations, the method of implementing those features, or the underlying motivations and reasons behind them (Danish, 2009a).

Our grounded approach generated two further coding categories: Unspecified and Progress. Unspecified comments present an indiscriminate or vague subject (e.g. "Look at this" or "I'm doing something cool") and Progress comments refer to the students' current state of completion (e.g. "I'm on my third one," or "I'm almost done"). With respect to unspecified comments, note that while we could frequently determine the feature that the students were addressing by looking at the video, it was unspecified whether they were referring to the inclusion of the feature (the What code) or how it was represented (the How code). Prior analyses (Danish, 2009a) indicate that students focus on "what" was represented when drawing (as opposed to skits or simulations where students are more likely to discuss the "how" or "why" of their representational choices). Our hypothesis based on prior analyses is that students will primarily focus on the "what" features of representations during the pre-activity, but will shift to discussing the "how" and "why" of their storyboards more often in the post-activity. As predicted, the majority of students' talk in the pre-activity related to "what" was represented ($\chi^2(1, N = 869) = 47.13$, $p < .001$), whereas in the post-activity this talk shifted significantly to the "how" ($\chi^2(1, N = 869) = 25.47$, $p < .001$) and "why" ($\chi^2(1, N = 869) = 28.76$, $p < .001$) of the representations (see Table 4).

Table 4: Students' representational talk across time.

| | What | How | Why | Unspecified | Progress | Other |
|---|---|---|---|---|---|---|
| Pre (N = 367) | 232 (63.2%) | 27 (7.3%) | 13 (4.3)% | 35 (9.5%) | 6 (1.6%) | 46 (12.5%) |
| Post (N=502) | 199 (39.6%) | 98 (19.5%) | 73 (14.5%) | 45 (9.0%) | 36 (7.1%) | 49 (9.7%) |

As with students' science discourse, our goal in this analysis was to move beyond simply documenting the content of students' talk to capture the role that it played in their practices. Therefore, we further coded students' representational talk in terms of how it supported their interactions. Specifically, similar to prior work (Danish & Enyedy, 2007) we noticed that students typically engaged in assessing or critiquing each other's work. Therefore, we coded students' utterances in terms of the various ways that assessments played a role in shaping the students interactions: (a) Assessment-Seeking, (b) Assessment-Giving, (c) Assessment-Warranting, and (d) Assessment-Responding (see Table 5 for descriptions, examples, and frequency counts). Note that while we are reporting incidences of student talk in table 5, these comments often played a role in shaping students' representations, causing them to add, remove, or change the features of their drawings in response to the issues raised, even when the student making the change was not directly addressed (for similar examples see Danish & Enyedy, 2007).

Our statistical analysis reveals that students are significantly more likely to engage in assessment related interactions during the post-activity than in the pre-activity for our first three coding categories: (a) Assessment-Seeking ($\chi^2(1, N = 869) = 3.88$, $p = .048$), (b) Assessment-Giving ($\chi^2(1, N = 869) = 18.41$, $p < .001$), and (c) Assessment-Warranting ($\chi^2(1, N = 869) = 6.58$, $p = .010$). Assessment-Responding increased marginally from pre- to post-activity ($\chi^2(1, N = 869) = 3.01$, $p < .082$).

Table 5: Students' evaluative interactional moves over time.

| | Assessment-Seeking | Assessment-Giving | Assessment-Warranting | Assessment-Responding |
|---|---|---|---|---|
| Description | Directly requests evaluation of their storyboard | Explicitly appraises their storyboard or their peer's. | Augments their appraisal with a reason or example | Replies to the given feedback |
| Example | "What do you think of this?" | "it doesn't have wings," or "you forgot legs." | "the stinger is suppose to be a straight line" | "I forgot to include it" or "I'm waiting to draw it" |
| Pre (N=367) | 2 (0.5) | 6 (1.6%) | 2 (0.5%) | 4 (1.1%) |
| Post (N=502) | 11 (2.2%) | 42 (8.4%) | 15 (2.9%) | 14 (2.7%) |

## Discussion

This study aimed to document and describe the development of a group of kindergarten and first-grade students' representational practices as they related to drawing storyboards about honeybees collecting nectar. To highlight the change in students' practices, they were examined in a similar context (creating a storyboard) both before and after having learned about the content (how honeybees collect nectar). Our goal in doing so was to examine how the practices changed over time despite the fact that the task was, ostensibly, the same. We do not claim that the participants experienced the practice as the same at both time points. In fact, our theoretical assumption is that students' knowledge of the content and representing, and their shared practices for representing have shifted, which in turn shifts the way that they engage in representing at these two time points. In other words, the students learned new practices—which include an understanding of the content, how to represent it, and how to assess representations of it—and those new practices influenced how the students responded to the stated task of showing how bees get food using a storyboard.

Our results reveal that students' representational practices include a great deal of time talking about the task requirements (instrumental talk), some off-topic talk, as well as discussions of the content and how it should be represented. Initially, we were surprised to find that the students' talk included a higher percentage of unique ideas regarding science-related structures and behavior in the pre-activity than in the post-activity. However, further analyses revealed that those ideas were less accurate, less detailed, and were more likely to include non-essential structures (e.g. ladybug, house) to the science being represented. Furthermore, students were more likely to request and give assessments during the post-activity than during the pre-activity. These are important changes in representational practices that cannot be derived simply from counting the amount of structure and behavior talk.

A practice-oriented, and heavily contextualized analysis of students' representational acts defies, by definition, generalization of the specific findings. In other words, we would not expect to see this same pattern of talk in every kindergarten and first-grade classroom. However, we believe that some aspects of this analysis are, in fact, crucial to understanding and supporting other students and contexts. First, we have shown that there may be some value in examining the set of students' representational practices as they change over time instead of simply focusing on how they relate to the microgenesis of specific content knowledge as prior studies have. Had we not taken such steps, we might have overlooked the fact that students actually talk less about the content as they continue to master it—an important finding to consider when engaging in formative assessment of students' ideas through representational activities. This kind of analysis is supported, in part, by examining tasks that appear to be similar, rather than attempting to examine a shift in practices and context at the same time. Second, we hope that by documenting the breadth of student talk as they created their representations, we have helped practitioners and other researchers to recognize the fact that even students who have moved through a curriculum in a rather successful manner do not limit themselves to discussing the content accurately and consistently. However, one shift in student practices that appears to help correct for student mistakes and persistent misconceptions is the increase in critiques and other forms of assessment followed by students adjusting their representations accordingly. Future work should look more closely at the role of such critiques in supporting students as they create representations, and examine processes for encouraging more of them.

In sum, we have attempted to provide a robust and realistic picture of the kinds of talk that students engaged in as they created representations. Our hope is that this is a starting point for additional studies of students' representational practices which aim to look beyond the microgenesis of specific content ideas to a full description of the relationship between students' representing, the content, the context, and how these all shift over time.

## Endnotes

(1) Cobb et al., actually separate this discussion into several nested levels of analysis. However, for brevity, we compress them into the two components for our present discussion.

## Acknowledgments

We would like to acknowledge the teachers and students who so kindly participated in this study. We would also like to thank Noel Enyedy, William Sandoval, Frederick Ericson, Charles Goodwin, and Candy Goodwin who provided feedback on early versions of this analysis. Portions of this work were supported by the Spencer Foundation Dissertation Fellowship, and by a UC Regents Dissertation Fellowship.

# When Students Speak, Who Listens? Constructing Audience in Classroom Argumentation

Leema K. Berland, University of Texas, 1 Univ. Station, Austin, TX 78712, leema.berland@mail.utexas.edu
Andrea Forte, Drexel University,3141 Chestnut St, Philadelphia, PA 19104, andrea.forte@drexel.edu

**Abstract:** Does a speaker craft an argument carefully if no one will hear it? Does an engineer design structures without reflecting on the individuals for whom her creations will have meaning and utility? Learning sciences research often explores such creative activities as meaningful opportunities for learning—inherent in these acts of creation is the concept of audience. In this paper, we draw on the philosophical and science studies literature to further unpack the role of audience in argumentation and examine three different ways that educators have addressed the problem of creating an audience for student work. We discuss how these approaches can challenge existing classroom structures and present evidence from empirical studies that demonstrate some of the outcomes.

## Audience: What and Who is It?

> *…the gathering of those whom the speaker wants to influence by his or her arguments.*
> (Perelman, 1982, p. 14), emphasis is his.

The word "audience" often conjures images of a crowded theater or lecture hall—the "gathering" referred to in Perelman's above quote. In reality, audience might be dispersed across continents and across centuries or may only exist in the mind of a speaker, writer, or artist. Walter Ong stated that, for writers, audience itself is a fiction, invoked by the arguer in order to organize and contextualize her communication (Ong, 1975). In addition, he suggests that the audience itself responds to a text by adopting an expected role—for example, the role of reviewer or the role of student—and participates in constructing meaning rather than simply receiving it. Whether real or imagined, listening or reading, live or in absentia, audience plays an important role in defining the context in which argumentation takes place.

Audience is complex. Understanding the nature and impact of audience plays a central role in the vast literature on rhetoric and argumentation. Whether written or oral, arguments are situated in a rhetorical space that is constructed by both the audience and the speaker or writer. Tindale described how audience plays an active role in determining the nature of an argument:

> The rhetorical audience is not a passive consumer of arguments, as some logicians seem to think; it plays an *active* role in the argumentation. The nature of the audience sets the terms of the premises, which are formulated in light of theses accepted by those to be addressed. The audience contributes assumptions to the reasoning… And the audience can interact with the argumentation in the mind of the arguer or in dialogue with the arguer… (Tindale, 1999, pp. 85-86)

Argumentation, then, is not simply a matter of constructing a logically coherent series of statements, it is a socially situated event designed by the arguer to satisfy the demands of a particular context. Thus, understanding audience in the classroom is critical for understanding how constructing arguments can be an effective learning activity and how to best design such experiences for students.

In this paper, we explore the role of audience when fostering scientific argumentation in classrooms. To support our analysis of audience in the classroom, we draw not only on the science studies and rhetoric literature, but on four years of empirical classroom studies that examine argumentation in both spoken (Berland, 2008, submitted; Kuhn, Kenyon, & Reiser, 2006) and written forms (Forte & Bruckman, 2006; Forte & Bruckman, 2007; Forte & Bruckman, under review). These different contexts for argumentation give rise to different understandings of audience in the classroom. We begin by exploring the role of audience in argumentative discourse, we then move to examine the implications for classrooms.

## Argumentation and Learning: Audience Influences the Goals of the Argument

The first order of business between an arguer and her audience is agreeing on a goal. Is the audience to be persuaded? Is a compromise sought? Are the parties mutually engaged in solving a problem? The goal of the interaction must be established. Even when the audience is present, this is typically done implicitly; in the case of written communication, the arguer may invoke an audience based on her knowledge of communicative norms for a particular genre of writing. Determining the goal is an important first step because different goals result in different argument styles. In fact, philosophers have identified multiple forms of arguments. For example, Walton (1998), drawing from work such as Aristotle (1955) and Locke (1961 [1690]), has identified six possible argumentative dialogues each of which is "a goal-directed conventional framework in which two [or more] speech partners reason together in an orderly way….Each type of dialogue has distinctive goals as well as methods that are used by the participants to achieve these goals together" (p. 3). Work such as this suggests that argumentative discussions vary broadly based on the participants' goals. Table 1 both summarizes Walton's dialogue types (as he describes them) and identifies the instructional goals emphasized by each dialogue type.

Table 1: Walton's dialogue types and implied instructional goals (Walton, 1998)

| **Dialogue type** | **End result** | **Implied Instructional Goals** |
|---|---|---|
| Critical | Individuals are persuaded of a single claim | Criticizing counter-arguments |
| Inquiry | Claims are proven to be true or false | Collaborating to draw conclusions from premises/data |
| Negotiation | A "good deal" is reached | Bargaining and compromising |
| Information-seeking | An individual gains information | Asking questions and collecting information |
| Deliberation | A practical problem is solved | Debating possible courses of outcomes by predicting their outcome |
| Eristic | Opponents are defeated | Quarreling through aggressive tactics (including insults, emotional attacks etc.) |

As seen in Table 1, each of these dialogue types has a different end result and suggests different kinds of pedagogic goals. For example, the critical dialogue is used to persuade people and involves the goals of understanding and refuting counter-arguments, whereas the inquiry dialogue is a way to construct a single claim that is irrefutably supported by evidence and entails collaborating to use data in order to draw conclusions.

The first author has examined argumentation in science classrooms (Berland, submitted a) in which students engaged in whole class arguments in a way that aligned with the critical dialogue of Walton's scheme (1998). Each of these is characterized by the various discourse moves receiving different emphases. For example, in the critical dialogue, students were likely to negatively evaluate one another while mustering evidence to disprove counter claims, while in the information-seeking dialogue the students questioned one another but rarely compared across their contrary claims in order to acknowledge or reconcile their disagreements. In addition, the first author witnessed students engaging in a form of argumentative discourse that did not align with Walton's scheme. In particular, the students engaged in "information sharing" in which they presented previously constructed arguments without attending to the arguments of others or receiving feedback on their own. Jimenez-Aleixandre, Rodriguez, & Duschl (2000) describe these interactions by saying the students are "doing school" rather than "doing science." They are characterized by a focus on procedures, the teacher's expectations and school culture (i.e., expecting the answer include one concept that is predetermined). In these dialogues, the often-implicit goal is to quickly get an answer to the question at hand. In other words, the goal is to construct an acceptable claim.

This information sharing dialogue generally does not align with expectations for argumentation—that is probably why it is not accounted for by Walton's scheme. However, we include it here because it reveals the importance of having an authentic audience: In these interactions the implied audience is invariably the teacher as students attempt to meet the requirements of the assignment. An audience of classmates or an external body might help move these students from the their focus on teacher expectations to the strength of their arguments.

Features of these dialogue types also surface when students invoke an audience for written work. The second author has examined students' writing practices in high school science classes when they are asked to publish a real science resource on a wiki. Students who wrote on the wiki also adopted the dialogic style of "information sharing." At first glance, it seems unlikely that one would find other forms of dialog in a written performance—if one is writing about science rather than discussing it, then it seems natural to present finished arguments. Yet, social media like wikis support discursive forms of written interaction as collaborators deliberate over the content they wish to present as well as the form of their argument. Although inquiry and negotiation dialogues such as these are common on other wikis, like Wikipedia, this kind of dialogue was rarely observed among students and was not encouraged by teachers (Forte & Bruckman, 2007).

These studies also revealed that, even when writing in an online public venue, students frequently adopted traditional standards for written school genres. These standards assume that the student's written performance is ultimately intended to be assessed by the teacher, not to persuade or inform others and not as a starting point for collaborative inquiry. Performative standards motivate student engagement in information-sharing rather than more critical or inquiry dialogues. Moreover, in this case, the students saw information-sharing as being in competition with other more argumentative dialogue types: students frequently reported invoking an inexpert audience to help them organize their arguments, and several students explained in interviews that the teacher as audience competed with their potential readership online (Forte and Bruckman, in press). Ultimately, they attended to both audiences as they constructed their texts.

> What do people want to know about [this disorder]? That's kind of like what I was thinking about. Like what would I be interested in if I was trying to look at one of these sites? And I wouldn't say I'd be really interested in the biochemistry but since it has to be included, it shall be included. – Sara

Combining our empirical studies with the philosophical and science studies literature emphasizes the importance of argumentative goals—and the role of the audience in determining these goals. In particular, we see in the work of both authors that the teacher-audience often worked to disrupt the students' focus on goals that align more directly with argumentation and sensemaking. This suggests that one challenge facing classroom communities as they work to engage students in argumentative discourse is the creation of contexts in which students are able to engage in argumentative dialogues and the goals implied by them.

## Audience Influences How the Goals are Achieved

Beyond influencing the dialogue type—or argumentative goal—the audience influences the content of the interaction by impacting the criteria by which the argument will be judged. As stated by Tindale, "….depending on the circumstances, their [arguers'] arguments will seek different results and will use methods appropriate to the purpose of the discourse as well as to the audience to be influenced" (Tindale, 1999). In other words, arguers must change the content of their argument to meet the expectations of their audience. If this alignment does not occur, the argument will fail because the audience will judge it on different criteria then the author used.

In terms of scientific argumentation that occurs in classrooms, we have seen the students' criteria for evaluating arguments range from superficial (i.e., evaluating the appearance of the graphs; assessing arguments based on assumed expertise of the authors) to more content-based (i.e., aligning the claim to an answer in a text book) to scientific (i.e., examining the alignment between the claims and the evidence presented in defense of those claims). If the criteria that audience members use influence the content of the argument, then we would expect these different criteria to result in different arguments. For example, if the audience is focusing on superficial criteria, the arguers have little reason to articulate the evidence that supports their claims. Similarly, if the audience is focused on whether the claim makes sense or aligns with a textbook answer, the arguers have little reason to do more than identify outside sources that validate their claims.

The relationship between the expectations of the audience and the content of the argument is made most obvious in discussions in which the arguer's approach to supporting a claim differs from the expectations of the audience. For example, in an earlier study (Kuhn, et al., 2006) the first author observed a group of students arguing about their explanations regarding why the majority of Galapagos Finches died in the mid 1970s. One pair in this group (correctly) thought that a drought killed the finches' food (plant seeds) while the other pair believed it was torrential rains. The torrential rain pair defended their claim using logic and personal experience with drowning plants while the pair that believed it was a drought relied on evidence of the rainfall decreasing. After being unable to meet their demands for empirical evidence, the group that believed that torrential rains killed the plants revised their claim to align with the available evidence: a drought killed the birds' food. In interactions such as this, you see the substance of the argument changing to account for the audience's expectations. In this case, the claim changed because the arguers could not meet their audience members' demand for empirical evidence that supported the original claim.

The second author found that, when writing, audience awareness was a constant feature of students' process for constructing a text that would be acceptable to both their teacher and to a broader readership. In general, students adapted their writing to fulfill the perceived expectations of their Internet audience (Forte & Bruckman, in press). Some commented on the sense of responsibility they felt toward their readership: "It's like 'oh my gosh, I have a huge responsibility now' even if nobody actually uses this. It's still there, somebody *could* use it so everything has to be exactly right." Comments like this demonstrate the student authors attending to a non-teacher audience. Moreover, these different audiences for the students' work demand different kinds of information and different forms of presentation. In fact, as students reconstructed their writing process in interviews throughout the school year, they described different strategies for constructing texts and citing their sources depending on whether they were attending to their Internet or in-school audience (See Table 3).

Many students explained that, in order to present scientific information to a broad audience, they had to simplify the complex vocabulary they found in scientific journals so that their readers would understand their assertions. In order to do so, students reported that they needed to engage deeply with content and they frequently looked up additional explanations and definitions to get things right. One student described his process for researching his topic as 40% "collecting information. 60% was actually trying to understand what on earth are we talking about." Another noted that:

> I had to take words and I mean, I wanted to make it readable for people too, because I knew other people were going to look at this, so I was not going to use, like, huge words, just kind of make it simple. - Lina

This same student also described consciously choosing to follow her teacher's suggestions even when they conflicted with her sense of the Internet audience's needs:

> Well, 'causes.' I was like, well, if someone was to look at this, it would be like 'causes of the disease'… and then Dr. Baker was like, 'Well, you are supposed to find the *etiology* of the disease.' I was like, 'Okay, I am going to use the word 'etiology'. - Lina

In this example, Lina ended up mirroring her teacher in order to perform for assessment purposes. The extra work that students had to do to develop their ideas for a less knowledgeable audience supports and explains Gunel, Hand, & McDermott's finding that writing science for the teacher is associated with lower post-test scores than writing for peers and younger students (2009). They similarly found that students tended to use "big words" to impress their teacher on the assumption that the teacher would already understand them.

Table 3: Student Strategies for Constructing a Science Text on a Wiki (Forte & Bruckman, in press)

<table>
<tr><th></th><th>Teacher as Audience<br>Goal: Meet Assessment Criteria</th><th>Broad Internet Audience<br>Goal: Provide Credible Science Resource</th></tr>
<tr><td>Crafting Content</td><td rowspan="2">• Follow directions<br>• Look at others' work<br>• Apply conventions from other classes<br>• Seek feedback</td><td>• Simplify scientific language<br>• Invoke an inexpert reader<br>• Use existing sources as a model<br>• Reflect on own experiences as a reader</td></tr>
<tr><td>Sourcing Content</td><td>• Same strategies, different rationale:<br>o Ensure credibility<br>o Defer responsibility</td></tr>
</table>

Beyond the clarity of their explanations, these students placed a different emphasis on citation as a criterion for successful arguments when thinking about their external audience. In fact, as these students wrote online for a broad audience, some explained that citation was an important part of presenting their work in public, because of the responsibility to their audience:

> All the information I put up had sources, had everything, had a credible background to it. So I think if it's going to be so open for other people to use, your work should be credible. – Jerry

The work of the first and second authors demonstrates that the students' sense of their audience influences the content and justification of their arguments. Moreover, the second author's work revealing that the students' shifted their criteria as their attention shifted from a teacher-based audience to an external readership demonstrates the impact of the teacher on their argumentation. In particular, we see that, as with their argumentative goal, the criteria that students apply to their arguments differ when they work to satisfy an authentic audience who might be persuaded by their argument rather than a teacher who seeks to assess whether they achieved the desired answer.

## Implications for Designing Learning Experiences

The intertwined relationship between audience and student engagement with the science content suggests that a primary challenge when engaging in argumentative discourse in science classrooms is to *create situations in which students have an authentic audience for their arguments*. Moreover, the corollary to the philosophical focus on how the audience can shape the form and content of an argument is that the audience has a role in the argumentative discourse. That is, although a fictional audience might be invoked, an audience that is present should be providing feedback and engaging actively in the construction of the argument. From the perspective of the audience, this suggests that the listeners and readers have a key role in the argument process. Thus, the audience members must learn to play that role: They need to ask questions, evaluate arguments and offer alternatives. Whether in the classroom or in mediated online environments, these practices may need to be actively introduced and cultivated.

In order to serve as an authentic audience in argumentative discourse, students must see one another's ideas as worth responding to and must value the feedback provided by their peers in addition to that provided by their teacher. In an examination of power in a middle school science classroom, Cornelius and Herrenkohl

(2004) found that the typical "evaluation" phase of the triadic-dialog (Lemke, 1990) or IRE (Mehan, 1979) exchange can limit student ownership of ideas. Similarly, Tabak and Baumgartner (2004) found that triadic dialogues limit students' need and motivation to substantively engage with their classmates' understandings. Analyses such as these indicate that the prominence of teacher feedback in class discussions can limit students' ability to engage with one another's ideas because it removes their authority and motivation to evaluate and question them. In order for students to be audience members for one another's arguments, classroom norms must change to enable such interaction.

In addition, if students are to act as an audience for one another, they must reach agreement about the goal of their interaction. As described in the first section, this agreement is often achieved implicitly and is restricted by the context and content of an argument; however, traditional school norms may conflict with goals of specific forms of discourse such as scientific argumentation. In an analysis of classroom communities' adaptations of scientific argumentation, the first author and colleagues (Berland, submitted a) found that each classroom adapted the discourse practice differently. Moreover, the students in that study never explicitly discussed their goals with one another—instead the goal was made clear in the students' interactions. Their apparent agreement in argumentative goal could be attributed to their existing classroom culture (Berland, submitted b). That is, the goals with which they argued were similar to the goals of their non-argumentative, more typical class discussions. For example, in the class that argued as a form of critical dialogue, the goal was to critique counter arguments in order to prove that they knew the right answer. During non-argumentative class discussions, these students also seemed focused on demonstrating that they knew the right answer. Similarly, the class that focused on information seeking during the class argument was frequently engaged in similar interactions with their teacher when not arguing. This work demonstrates that the goals that typically govern classroom practices influence how students engage in argumentation. Thus, creating an environment in which it is sensible for students to engage with their audience to negotiate goals and criteria for meeting those goals involves a transformation of social norms in the classroom.

## Transforming the Classroom Norms

Learning sciences research has a strong tradition of exploring transformative social arrangements in the classroom that cast students as responsible, generative participants in their educational experiences. For example, the literature on knowledge building communities suggests that students can function much like a community of scientists by proposing, debating and building on one another's ideas to further the knowledge of the class as a whole (Scardamalia & Bereiter, 1991). To support this goal, the software Knowledge Forum helps students identify possible discourse moves in a knowledge building exchange. Developing such a community requires a fundamental cultural shift in schools from what Scardamalia and Bereiter call a first-order learning environment, in which there is a static set of knowledge to be learned, to a second-order learning environment in which the state of knowledge is always changing and participants must continuously adapt to the ideas and suggestions of their peers.

Brown and Campione (1996) addressed this challenge by explicitly transforming the goals and criteria of the classroom activities. They did this by making students responsible for learning the ideas under study and then creating situations in which students were accountable to one another for those understandings. These expectations helped create a "community of learners," in which the students had authentic reason and opportunity to engage with one another's ideas through scientific discourse practices. However, these solutions required changing the entire community. This transformation is difficult, and possibly unrealistic in traditional classroom settings.

The first author built on this work with a focus on scientific argumentation: she designed activities in which the explicit goal was for students to convince one another of their ideas such that they had to attend and respond to one another's ideas rather than the teacher's. However, engagement in the goal of persuasion seemed to limit student motivation or willingness to engage in sensemaking (Berland, submitted a). This is an example of how changing a portion of the classroom norms—in this case, the interaction patterns—without changing the other expectations—such as the goals—resulted in an incomplete adoption of the scientific practice. This reinforces the systemic requirements put forth by the Brown and Campione (1996) and Scardamalia and Bereiter (1996) studies, but returns us to the question of how we can foster these sorts of interactions in more traditional classrooms.

Looking across the literature, we have identified three approaches to addressing this challenge.

1. Introducing an outside audience
2. Recasting student roles
3. Creating a fake audience

Each of these approaches has implicitly or explicitly created situations in which students had an authentic audience with whom they could negotiate the goals and criteria for their discussions. In the following sections, we will draw on the literature and our own empirical work to exemplify each of the three approaches.

## Approach 1: Introducing an Outside Audience

Science fairs, band concerts, and student journals are all examples of traditional ways that educators have sought to "break down" the barriers between the classroom and outside communities in order to introduce an external audience for student work. Recently social media and "Web 2.0" have brought about new opportunities for student interactions with outsiders (Ellison & Wu, 2008: Wheeler, Yeomans, & Wheeler, 2008). In addition, learning sciences researchers have a relatively long tradition of exploring the potential for students to interact with distant peers, mentors, and subject matter experts via the Internet. Kids as Global Scientists (KGS)/Biokids (Songer, 1996), CoVis Mentor Database (O'Neill & Gomez, 1998), and Bos and Krajcik's online writing research (1998) are all examples of early learning sciences projects that created opportunities for students to engage with and present ideas to distant audiences through networked technology.

Because these interactions are mediated through educational software, the goals of discourse and the criteria for achieving these goals may be influenced by the design of the communication environments themselves. For example, in an implementation of KGS, students used an interface that structured activities by allowing them to see weather data, ask questions of remote peers, and answer questions from remote peers and local graduate student mentors (Songer, 1996). This configuration supported an "inquiry" style dialogue (Walton, 1998) by encouraging specific kinds of interactions such as reviewing data and asking questions. In other cases, such as in the work of the second author, who studied students writing a science resource on a wiki, the communication tools themselves are relatively versatile and lend little structure to the interaction. In such cases, it is critical to structure learning activities in such a way that students have a model of how they are expected to engage in with their readership in order to develop the goal and criteria for those interactions (Forte & Bruckman, in press). This may be done by explicitly structuring assignments, or, in exceptional cases such as the Math Forum project, it may be done through the development of an online community with cultural norms and expectations for social interactions among members (Renninger, Shumar, Barab, Kling, & Gray, 2004). This ideal can be difficult to achieve when both students and teachers can easily fall back on "default" classroom interaction styles that place the teacher back in the position of primary audience.

As discussed above, if expected to join in a particular mode of discourse, audience members also need to understand their role in the interaction. This can be a particularly challenging aspect of introducing an outside audience—engaging in specific forms of argumentation and providing useful feedback is not always easy. Even when the interactive environment helps structure classroom interactions, it can be difficult for outsiders to know what is expected and how to take on the role of audience productively. Songer (1996) provides an example of effective mentoring in which a KGS mentor "seeds ideas" among students; they note that mentors were not always so effective and were coached to engage with students in specific ways. O'Neill and Gomez (1998) developed the CoVis Mentor Database based on their research with science teachers who orchestrated online mentoring experiences for their students and likewise note that both mentors and students "needed substantial guidance concerning the kind of help they should provide and expect" (p. 327).

## Approach 2: Recasting Student Roles

In the previous section, we discussed the use of an external audience to help transform classroom interactions. Another approach to changing the experience of audience is to recast students as audiences for one another. This can be done in more structured ways, such as assigning explicit roles, or less structured ways that encourage student engagement with one another's ideas in a more or less spontaneous fashion. Herrenkohl and Guerra (1998) took a highly structured approach in a study of participant structures in argumentation among elementary school science students. They identified three distinct intellectual roles in argumentative discourse: predicting and theorizing, summarizing results, and relating evidence and results to theory and prediction. They assigned students to these roles and, in a comparison group, also assigned audience roles to students. They found that when audience roles were specified, the class engaged in more whole-class inquiry activities and students took more leading roles.

Other researchers have had success assigning students less explicit roles. For example, in a study with undergraduate students, Forte and Bruckman (2006) found that assigning students to be reviewers of one another's work created a situation in which students tailored arguments to convince their peers. After reviewing their peers' arguments, students revised position papers to be more convincing to an audience that might not share their point of view. Still another form of audience role assignment that can implicitly encourage specific discourse practices is asking students to role-play with one another. For example, Pitts and Edelson (2004) ask students to adopt the role of scientists and interact with one another as such to solve environmental science problems. Although discourse roles themselves are not made explicit, students draw on their understandings of what scientists are like and what they do to organize their interactions with one another. Finally, a still less-structured approach is to give students a common goal to encourage knowledge-building interactions, such as Peters and Slotta's (2009) studies of students who construct a science resource for one another online.

When discourse roles are assigned, interactions can be far more structured than in the first approach and the problem of agreeing on argumentative goals and criteria is less difficult to resolve. The assigned roles should support students in meeting argumentative goals, which are often made explicit upon assignment. In the first example above, Herrenkohl and Guerra (1998) made highly specified role assignments based on scientific discourse practices. In this case, the activity was sufficiently structured to circumvent confusion about the goal of discourse and the means of achieving this goal. In the case of Pitts and Edelson's (2004) role-playing scientists, or Peters and Slotta's (2009) wiki writers, discourse is less highly structured and students must draw on their understandings of scientific practices to come to an agreement on the best ways to pursue their goals.

### Approach 3: Creating a Fake Audience

When it comes to scientific reasoning and argumentation, encouraging students to role play and engage with a fake audience (and even to believe such an audience exists) has been used to motivate and organize learning activities and to connect science learning with students' experiences outside of school. Elaborate cover stories are used in problem-based and project based learning projects such as *Blueprint for Success*, which places students in the position of designing a playground for an imaginary architecture firm (Barron, et al., 1998). In the *Mission to Mars* project, students designed model rockets to learn about physical science (Petrosino, 1998). After observing that students did not engage in inquiry learning while building their rockets, Petrosino introduced the idea that an audience would evaluate their designs and found that the introduction of a critical audience helped students organize their own activities in a goal-directed fashion cited in (Petrosino, 1998 cited in Barron et. al., 1998).

Once again, advances in educational technology have brought about opportunities for innovative ways to connect students with audiences—in this case, imaginary audiences. Goal-Based Scenarios (GBS) are a form of problem-based learning that engages students in an imaginary problem scenario (Schank, Fano, Bell, & Jona, 1994). The educational software *Sickle Cell Counselor* and *Broadcast News* are GBS's that encourage learners to develop arguments based on a dataset and present them to fictitious audiences who provide feedback and questions to direct further inquiry. These audiences are not real audiences that can be affected and persuaded by learners, they are computational agents that provide "canned" responses designed to elicit reflection. Because the audience does not exist, agreeing on an argumentative goal and on the criteria for successfully reaching that goal is a matter of coaxing students into the "right" frame of mind.

## Discussion

Comparing various educational reform efforts reveals that learning scientists and science educators have long been working to create situations in which students work to engage audiences in an authentic fashion. Examining each of these designs in light of the philosophical and social sciences work on argumentation and audience suggests that a key challenge connecting these studies lies in the students' interpretation of the audience: are they constructing arguments or designing artifacts for their teacher to assess for accuracy or for an audience that they can hope to influence? Each of the studies discussed above has created ways to make the experience more authentic by creating a sense of audience that was external from the teacher.

This analysis has also revealed the importance of attending to whether and how the students negotiate their goals for their interactions and their criteria for success with their audience. Is this something that comes from the teacher or as a natural outcome of their interactions? The second author's work suggests that having a teacher-imposed goal and criteria may be in competition with the natural goals and criteria that emerge through the interactions. However, the teacher needs a way to influence these interactions in order to help students stay focused on activities and discussions that will help them move towards the learning goals. Our work suggests that creating this balance should be a focus of future work in supporting students as they engage in argumentation as a learning activity.

# "Ideas First" in Collaborative Second Language (L2) Writing: An Exploratory Study

Yun Wen, Wenli Chen, Chee-Kit Looi
Learning Sciences Lab, National Institute of Education, 1, Nanyang Walk, Singapore 637616
Email: yun.wen@nie.edu.sg, wenli.chen@nie.edu.sg, cheekit.looi@nie.edu.sg

**Abstract:** Drawing from sociocultural perspectives, this paper argues for the necessity of distinguishing the activity of "brainstorming ideas" from the activity of "generating words/phrases" in collaborative L2 process writing. We designed a series of Chinese writing lessons based on the online collaborative learning software GroupScribbles (GS) to explore students' participation and performance with "ideas first" versus "words/phrase first" activity designs. Quantitative data collected from an analytical tool reveal that students engaged more actively in the "ideas first" collaborative L2 writing than in the "words/phrases first" approach. Our research findings suggest that "ideas first" supported by the affordances of the GS tools a viable approach for collaborative L2 writing.

## Introduction

Collaborative learning has been considered to be one of the effective instructional strategies in language learning. It "has a 'social constructivist' philosophical base, which views learning as construction of knowledge within a social context and which therefore encourages acculturation of individuals into a learning community" (Oxford, 1997, p 443). As an approach based on this notion, collaborative second language (L2) writing is a recursive, bottom-up process that requires participants to collaboratively contribute words/phrases or ideas, and eventually compose their compositions in individuals or groups. Although brainstorming as the fundamental pre-writing activity has been emphasized in various models of the writing process, almost all the models are established based on work in first language (L1) writing. Brainstorming is considered as an idea-generating technique which is an enabler for creative thinking. When models incorporating brainstorming are utilized to guide L2 writing, there is a salient contradiction between L2 writers' ideas expressions and their limited target language proficiency. Some researchers propose the model for collaborative writing process with vocabulary first at the initial step (e.g., Wong, et. al., 2009). In practical collaborative L2 writing activities, the teacher typically encourages the students to write down as much as they are able to without foregrounding ideas or words/phases contributions. In fact, for L2 writers, their low proficiency of the target language often requires them to focus primarily on vocabulary and grammar, and hence hampers ideas generation and expression (Scott, 1996; Stapa & Majid, 2009).

Ideas could take the form of arguments or evidences for an argumentation; they could be inspirations or original thoughts for a narration as well. We use the term "Ideas first" to refer to a particular design of the writing activity which foregrounds the content of ideas rather than their expressions or representations in some language. Students are encouraged to express own ideas related to a general topic in multimodal ways. For Chinese language learners, not only Chinese characters, but Hanyu Pinyin (Chinese phonetics) and even drawings can be accepted. Figure 1 (left) shows examples of artifacts manifesting "ideas" in this type of activity for the topic of: "Adolescent smoking is an increasing serious problem; discuss reasons for that". Figure 1 (right) shows the artifacts manifesting in "words/phrases" for the same topic. The "words/phrases first" activity foregrounds and requires knowledge of the target language, thus emphasizing more on rhetorical structures and grammar. Students are encouraged to contribute Chinese idioms or proverbs related to the topic, or proper nouns or terms or vocabulary which can be used in the given context, or various adjectives or verb phrases helpful for composing more precise and vivid expressions. For a student with higher target language proficiency, she or he may more automatically think of words related to the topic or the context. On the contrary, low proficiency students have a high propensity for weak or no participation. Therefore, it seems that the "ideas first" pedagogy should be distinguished from the "words/phrases first" pedagogy, to enable active participation at the beginning stage of the L2 collaborative writing process.

We propose that "ideas first" is a more effective approach to engage L2 learners in collaborative writing activities. Our study sets out to investigate students' participation in the "ideas first" activities and "words/phrases first" activities respectively. It involves four L2 writing lessons with two different pedagogical designs: two writing lessons involve "ideas first" activities and another two lessons involve "vocabulary first" activities. All the collaborative activities are enabled on a software platform named GroupScribbles (GS), which can facilitate peer online communication and ideas/vocabularies brainstorming and sharing.

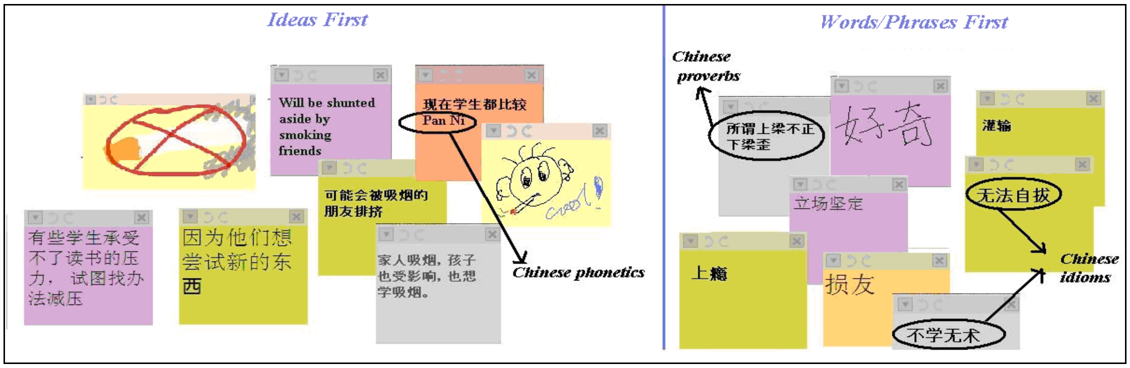

Figure 1. Examples of artifacts from “ideas first” vs. “words/phrases first” activities

## The Viability and Importance of “Ideas First”

Many psycholinguists or neuropsychologists hold the view that a person’s knowledge of vocabulary is stored in his or her mental lexicon (Harley, 2008), whereas ideas may be stored as concepts and images not yet formulated in words, and can be represented in any form of language. From this theoretical perspective, it seems that the capacity for ideas generation could be separate from language proficiency. When describing their classical model for cognitive process writing, Flower and Hayes (1981) argue that the process of converting ideas into words on paper is analogous to translating, demanding writers to put abstract thoughts through the technical aspects of writing such as grammatical structures. When cognitive load is not expended on vocabulary and language structure, the enthusiasm and capacity of L2 writers to engage in writing and group work participation could be enhanced. Hence, when “ideas first” approach is adopted, there can be more opportunities to exploit participants’ creative potential.

Traditionally, writing is regarded as a ‘‘non-linear, exploratory and generative process whereby writers discover and reformulate their ideas as they attempt to approximate meaning’’ (Zamel, 1983, p. 165), and ideas come from stored knowledge and experiences directly related to the writing topic. However, this traditional cognitive approach is too narrow in its understanding of social, historical and political contexts of writing (Prior, 2006). Today, with the sociocultural theory being more pervasive in the field of second language learning, there are more concerns over the role of social interaction in students’ cognitive development and language learning. A central hypothesis underpins the sociocultural theory of human development whereby higher-order functions develop out of the social interaction of an individual with the external social world (Tharp & Gallimore, 1988) that includes people, objects, and events in the environment. In this view, language as one of the most crucial human artifacts is thought to be socially constructed rather than internally intrinsic (Thorne, 2000). The participation metaphor of learning has been widely accepted, which refers to learning as a process of participation in shared learning activities and social process of knowledge construction (Sfard, 1998). Accordingly, rather than interpreted as internal mental processes solely by the individuals, language learning is viewed as a semiotic process attributable to participation in social activities (Block, 2003; Lantolf, 2000; Lantolf & Thorne, 2006). Therefore “ideas” that can be expressed and shared do play a bigger role and is critical to the creativeness of a learning community. The production and continual improvement of ideas that have value to a community is based on the premise that what the community accomplishes will be greater than the sum of individual contributions and part of broader cultural efforts (Scardamalia & Bereiter, 2003).

Collaborative writing should be seen beyond being just a mere instructional strategy with the obvious advantage that “two heads are better than one”. The collaborative writing process could be regarded as a process of meaning-making in which language learning and cognitive development occur in the sociocultural activities of participants’ community. This is aligned with the emphasis of Scardamalia and Bereiter’s (1987) process writing model that makes the transition from knowledge telling to knowledge transforming.

## An Intervention Study

### Participants

The study described here is part of a 3-year project to introduce rapid knowledge building practices to primary and secondary schools in Singapore (Looi, Chen & Ng 2009). We co-designed and implemented GS-based collaborative lesson activities with school teachers for students’ Science, Mathematics and Chinese language learning. In our work, we investigated useful pedagogies and teaching strategies that tap on the affordances of GS. This paper focuses on the collaborative L2 writing lessons with two types of pedagogical designs by using GS in secondary 3 (grade 9, 15-year old) normal Chinese language learning. In Singapore schools, English as the first language (L1) is the main teaching language in schools, whereas Chinese is taught as a second language (L2) for the Chinese ethnic students. In this study, the Chinese language class consists of 29 students. The students were organized into 7 groups (each group has 4 students, except a group with 5 students) in order to participate in the GS activities. Before the GS-based writing lessons, this class had been involved in our project for more than half a year (one GS lesson per week), and so they would have been enculturated with the GS environment and collaborative practices enabled by it (Looi, Chen, & Patton, submitted).

## GS interface and affordances

The lower pane is the user's personal work area, or "private board", with a virtual pad of fresh "scribble sheets" on which the user can draw or type (see Figure 2). Scribble sheets are the digital equivalent of small sticky notes that enable a lightweight scribbling to be made on the note. The essential feature of the GS is the combination of the private board where students can work individually and group boards or “public boards” where students can post the work and position relative to others’, view others’ work, and take items back to the private board for further elaboration. Students can choose any mode they feel comfortable to express their ideas through typing, writing by stylus or even drawing on the pad, and then post the pad onto the group or public board to share with others. A student can select any group board by clicking the board number on the right-top, and browse all other groups’ postings posted on the public board. GS hence promotes and facilitates intra- and inter-group sharing of ideas/information.

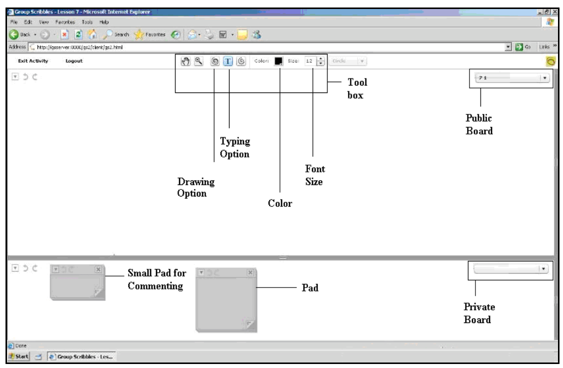

Figure 2. The user interface of GS with a two-paned window

GS is designed for students’ collaborative generation, collection and aggregation of ideas through a shared space based upon individual effort and social sharing of notes. Our research work seeks to tap the potential of GS for supporting L2 learning. In language learning, the task posed for collaborative activities does not focus on problem-solving, but it may be targeted towards enriching students’ vocabulary and proficiency in language expression, developing their thoughts and writing through cogitating with new words, vocabulary and sentence construction (Looi, Chen & Wen, 2009). When exploring the affordances of GS for Chinese language learning, we find that the affordance of “lightweight participation” fits L2 learners very well. For L2 learners, it is not only difficult for them to express themselves in complicate long sentences, but also difficult for them to extract main points from long paragraphs in a short period of time. By ‘lightweight’ we mean each student’s contribution or post can be composed (written, sketched, or typed) quickly in a small size of scribble sheet. Both fragments of ideas and diversified words/phrases can be represented in scribble sheets. They can be shared democratically, organized conveniently and improved continuously.

## Lesson design

This study examines the differences of “idea first” pedagogy and the “words/phrases first” pedagogy in students L2 collaborative writing. Four GS-based Chinese writing lessons (each of 70 minutes) were co-designed by the teacher and researchers. The topic for the lessons 1 and 2 was “why do Singaporeans feel discontented?”, and the task for lessons 3 and 4 was to make a story based on the context that “when you see your classmates Xiaowei and Xiaoli whispering at the school gate, what will you think of?” The topics are designed to be relevant to the students’ daily life.

In lesson 1, students were required to start collaborative L2 writing by first brainstorming ideas on the GS platform. In lesson 2, students first organized their ideas and then selected a few good ones to be further developed into paragraphs through GS. In the “ideas first” activity, they were reminded that any mode of expressing ideas is acceptable. Every student could have an equal opportunity to participate in collaborative writing, including not only generating and sharing ideas, but also improving these ideas by negotiating with others.

One week later in lesson 3, the students were asked to start collaborative L2 writing by generating words/phrases related to a new topic to explore story plots. In lesson 4, they wrote the main paragraphs with the collected words/phrases in lesson 3. In the "words/phrases" activity, students were encouraged to contribute suitable Chinese words/phrases that could be adopted directly in the final writing. In the process of interacting with others, students could enlarge their vocabularies and equip themselves with better understanding of the collected words/phrases.

In lessons 1 and 3, students were given examples about ideas on the story and words/phrases related to the topic respectively before the GS activities. For lesson 1, students might be able to come up with more ideas as they were not bogged down by the confusion between linguistic information and ideas on the topic (Scott, 1996). During each lesson, a short duration of time (around 20 minutes) was allocated for the students to do a "virtual gallery walk" via scanning the boards of other groups in GS. Each student could proffer comments or "borrow" or build on good ideas/words from other groups. After lessons 2 and 4, the teacher printed out each group's final products (GS screen capture) for the students who were then required to individually write the composition.

## Data Analysis

The analysis of this study includes two parts. In the first part, the GS analytic tool is deployed to probe the students' engagement levels within a lesson. This analytic tool is a program developed by us to extract quantitative information which serves as a proxy for the participation levels of each student in the GS activities. The second part focuses on examining group performance differences under the two pedagogical approaches.

Figure 3 and 4 show the students' participation in GS activities in lesson 1 ("ideas first" activity) and lesson 3 ("words first" activity) respectively. The horizontal axis represents the time of the class period using an interval of 6 minutes. The vertical axis is the aggregate count of all students' actions (including typing, drawing, moving postings etc) on the GS boards. When examining the students' GS actions in the first 6 minutes, we found that students had more participation in the GS based collaborative L2 writing in the "ideas first" activity than in the "words first" activity. There were a total of 10030 actions in lesson 1 and 9851 actions in lesson 3. The data perhaps does not mean that the class students posted a larger number of scribble sheets in the ideas first activity, but it implies that there were more students' participations or interactions via GS. They might contribute more actively, or click on other postings and modify the postings of their peers more frequently.

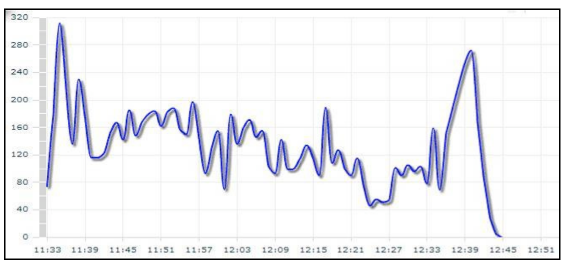

Figure 3. Count of whole class's actions on GS board in lesson 1 "ideas first" activity

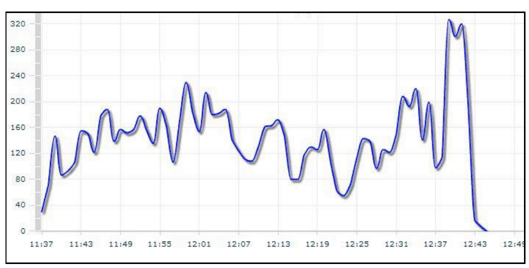

Figure 4. Count of whole class's actions on GS boards in lesson 3 "words first" activity

We further analyzed the data from two groups, namely, group 1 and group 6 (See table 1), to investigate different Chinese language proficiency groups' performances in the same activity. Both groups had a homogenous team composition with 4 students, and the team members were chosen based on their Chinese subject exam results before using GS (class average score was 57). The students' Chinese language proficiency in group 1 (with an average score of 51) is much lower than the students from group 6 (with an average score of 62).

Both groups reported good intra-group collaboration. In their post-lesson reflections, students from group 1 wrote that "my group can collaborate well and complete a task together…can communicate well…

correct each other mistakes and try to improve each other's Chinese". Likewise, students from group 6 considered their group as "a good one" and "a quite efficient group". Students' comments on their group collaboration are consistent with the judgment of the researchers based on the classroom observation.

Table 1. The information of two target groups

| Target Group | Group Configuration | | | Group culture of collaboration |
|---|---|---|---|---|
| | Division | Group members | Proficiency in Chinese | |
| Group 1 | homogenous | 4 (2 girls and 2 boys) | Low | Good |
| Group 6 | homogenous | 4 (3 girls and 1 boys) | High | Good |

Figure 5 compares the participation levels of two groups in the "ideas first" activity and the "words/phrases first" activity. We note that the difference in language proficiencies has impact on the participation levels of two groups. Group 1 student (an average of 20 actions per 6 minutes) seems to be more active in the "ideas first" activity than group 6 students (an average of 17 actions per 6 minutes) though group 1's members have lower language proficiencies than that of group 6. The difference in participation levels between the 2 groups in the "words/phrases first" activity was not prominent (both on the average 18 actions per 6 minutes). It seems that compared with students from high language proficiency group, low language proficiency group students were more active in "ideas first" activity. A plausible explanation is that they were less limited by language proficiency in "ideas first" activity since they were allowed to use drawings or their first language to express their ideas.

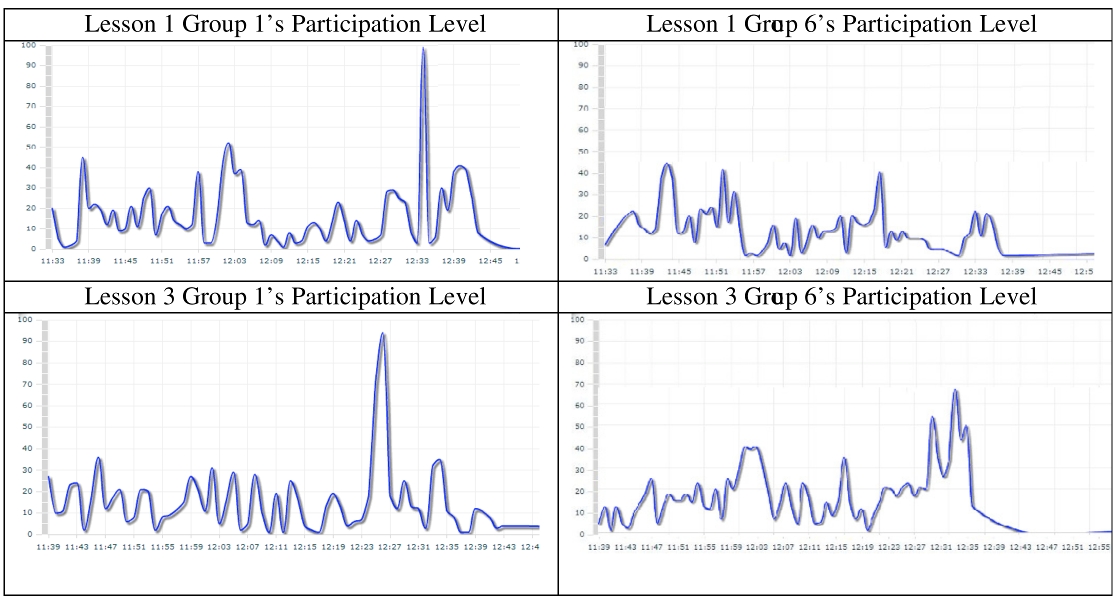

Figure 5. Group participation in "ideas first" activity *vs* "words/phrases first" activity

As shared by the teacher, the weaker ability groups typically had very low motivation to participate in Chinese writing activities. However, after the implementation of the "ideas first" activity, she said "I did not expect the weaker ability groups could complete the task well". The final GS artifacts of group 1 (Figure 6) were better than the artifacts from other higher ability groups in the "ideas first" activity in terms of richness of ideas and the logic of the ideas. The upper section of the screen shows three arguments for the topic "why do Singaporeans feel discontented?" (circled in dotted lines). The lower section shows three solutions to explain the issue at hand (highlighted by dotted rectangles). Other scattered postings were the comments given by other groups when they were visiting group 1's board. On the whole, after the activity of idea generation and modification in lesson 1, the final GS product of group 1 was well-organized, although some sentences were expressed in an awkward style.

The group selected specific individual ideas and developed them further through idea refinement and group negotiations into arguments why Singaporeans feel not contented. For example, the contribution of "税太高（too high tax rate）", referring to the sales tax, was first mooted by group 1 but was never been mentioned by other groups before the gallery work. In the activity of brainstorming ideas, a girl in the group first generated it in English, and then a boy translated it into Chinese. Later with the help of teacher, they posted "太多税要给

（too much taxes to pay）". Finally in lesson 2, they generated the argument which we highlighted by the dotted ellipse at the right-top of the Figure 6, namely, that "Singaporeans always worry about the high tax rate as high taxes made it less affordable to eke out a living." When challenged by other groups to explain why reducing the sales tax would make people feel contented, they clarified that "if the government reduces the tax, it becomes more affordable for the people to make purchases".

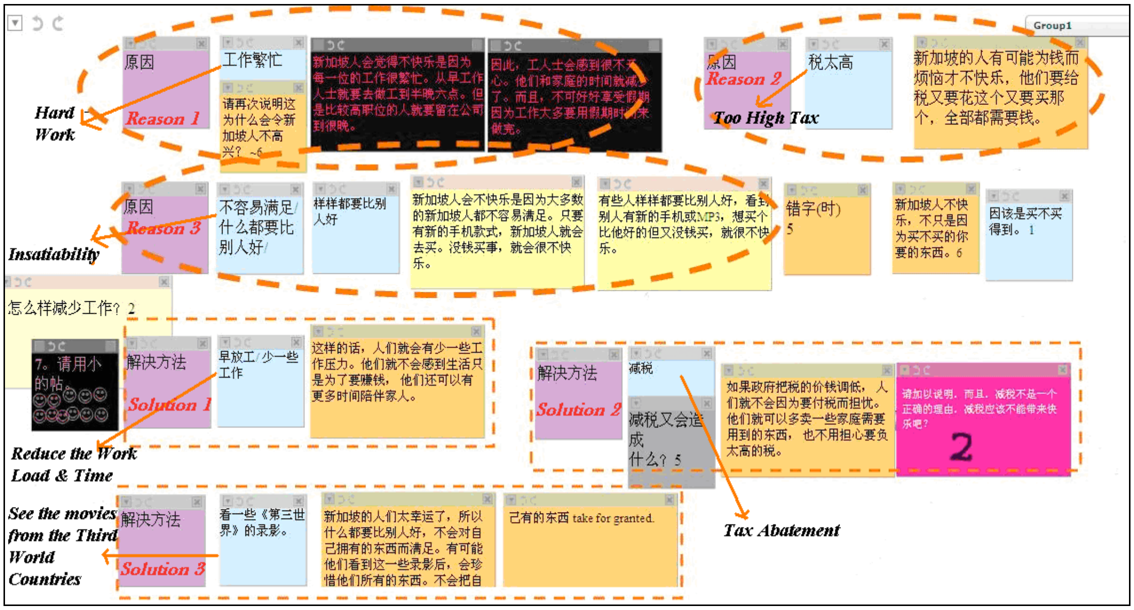

Figure 6. GS screenshot from Group 1 after the "ideas first" activity

In the "words/phrases first" activity, the weakness in language proficiency of group 1 became evident when they were generating words in lesson 1. Figure 7 displays the products of the two groups at the end of the words/phrases contribution phase. The left side of the figure shows the words and phrases generated by group 1, and the right side shows those from the higher ability group. For the benefit of the reader, we circled and translated some simple words posted by two groups, and highlighted comparatively complicated words and idioms within rectangles. Words and phrases from group 1 were much simpler than those from group 6. From a scan of the notes' colours (different students posted in different colours), we found that for both groups, the activity of posting words and phrases were dominated by one group member who had higher language proficiency in the group. In this type of activity, it was difficult to achieve democratic participation within the group collaboration as some students were restrained by their individual language proficiency. In lesson 4, during the process of extending words and phrases into paragraphs, little creativity could be identified from the students' work. This was despite the fact that teacher had constantly reminded the students: "I would like to see more creative stories… do not give me the same stories." Six groups of students wrote similar love stories which were rather cliché.

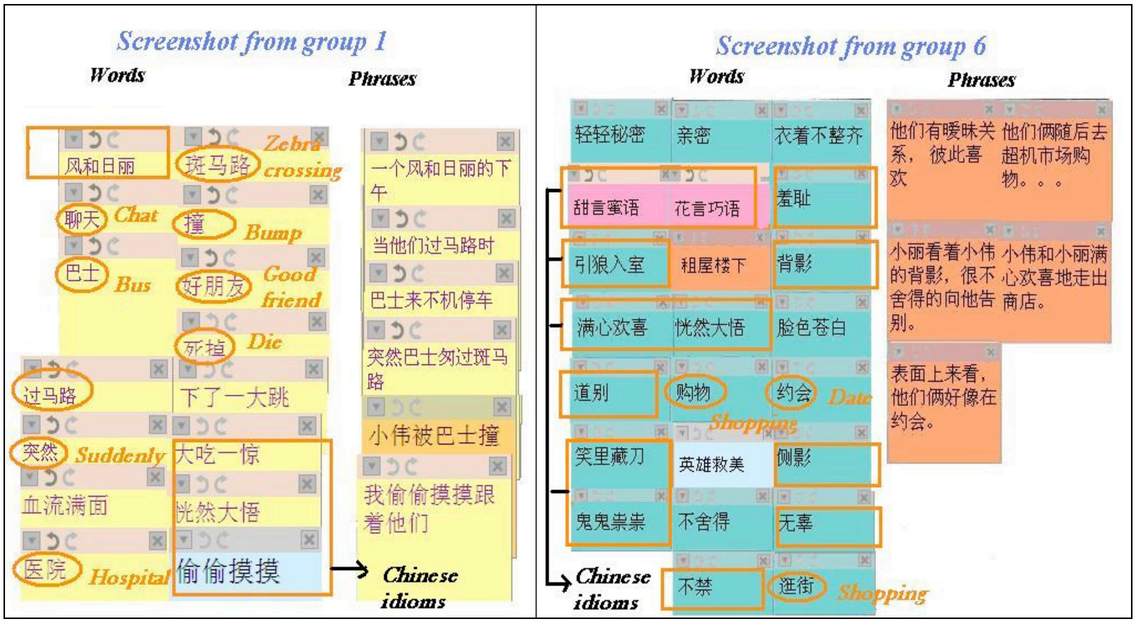

Figure 7. The GS screenshot of two groups in the "words/phrases first" activity

## Discussion & Conclusion

The collaborative L2 writing is a complex process which can be affected by various factors. This paper focuses research effort on the role of ideas generation in collaborative L2 writing. Two GS-based Chinese writing lessons, with the "ideas first" and "words/phrases first" activity designs, are compared. The findings suggest that the "ideas first" activity is a viable approach for collaborative L2 writing. Students especially those who do not have good language proficiency more actively participated in the collaborative L2 writing "ideas first" activity. GS artifacts arising from the two different learning activities also provide evidences that the "ideas first" activity encouraged more symmetric participation from students, and engendered more creativity in their writing

The affordances of GS, "multimodal expression" provides the students more modalities to engage in the "ideas first" activities, whereas in the "words/phrases first" the opportunity of participation is "reduced" to words, and which may generally result less contributions on the GS board. In addition, "lightweight participation", plays an important role in students' collaborative L2 writing. Due to the size limit of scribble sheet, students have to use brief and recapitulative phrases or sentences to express their ideas in the GS environment. It does not matter if the ideas are not mature. The smallness of scribble sheet encourages every individual to think and share actively, by emphasizing "ideas" rather than language proficiency. Furthermore, the students do not need to worry about the organizations of the ideas at the beginning. In a mature learning community, diversified forms of expression could be transformed and organized at the later stage of the learning activity. During this process, new ideas are generated, refined and improved continuously. As the GS activity supports inter-group interactions, ideas could be spread throughout the whole class. A number of studies (e.g., Lockhart & Ng, 1995; Nelson & Carson, 1998) have shown that when students are involved in L2 collaborative writing, they tend to edit the vocabulary or grammatical errors of their peers. Thus, initial representations of ideas do have the opportunities of being continuously polished, and that enables students to write better individual compositions eventually. On the contrary in the "words/phrases first" activity, the students have to rely much on their language proficiency. Even though L2 learners can participate in the group work anonymously, they may not be able to generate words/phrases effectively due to their low language proficiency. Thus students' symmetric participation in the learning activities may still be hindered when the writing activity starts from the words/phrases contribution.

This study is exploratory in nature. Our school-based research is still ongoing and we plan to explore further how the ideas or words spread and are improved upon within and across different student groups in the collaborative L2 writing activities.

# Large Scale Analysis of Student Workbooks: What Can We Learn About Learning?

Nicole Shechtman, SRI International, nicole.shechtman@sri.com
Jeremy Roschelle, SRI International, jeremy.roschelle@sri.com

**Abstract:** As Learning Science–based innovations are studied at scale, traditional Learning Sciences methods such as video analysis and classroom observation become impractical. Yet Learning Scientists want to know more about student misconceptions, the connections between writing and conceptual understanding, and classroom practices than pretests and posttests can reveal. In this paper, we discuss an exploratory posthoc analysis of 765 workbooks from 48 classrooms that implemented SimCalc. These classrooms participated in a large-scale experiment in which we found that students learned more advanced mathematics in classrooms that implemented SimCalc. A team of three master teachers coded the workbooks for completeness, correctness, and other impressions. We found characteristics of students' work that predict gain scores, including the first evidence that classic SimCalc activities—writing stories and drawing graphs about motions—impact student learning. We discuss potential implications for large-scale Learning Sciences research.

## Introduction

Although much Learning Science research is conducted at a small scale (e.g., within a handful of classrooms per research study), most Learning Scientists want to have a large impact on potentially hundreds or thousands of schools. When going from one scale to another, more variance will inevitably occur. Classrooms are complex places and differ in myriad ways. Some variations in classrooms and in implementation may have dramatic consequences for the effectiveness of a design that was successful in smaller scale trials. Ann Brown, for example, famously highlighted the potential for "lethal mutations" that could undermine the effectiveness of an otherwise promising innovation (Brown & Campione, 1996). Thus, a key part of the scaling-up process is research on implementation (e.g., Cohen & Hill, 2001)—seeking to understand what kinds of variation in implementation occur and which variations matter for desired outcomes.

Research on implementation can entail the collection and analysis of a variety of different types of data, including video recordings, field observations, teacher logs, surveys, and artifacts from the classroom. At the scale considered in this work, involving implementation in 48 classrooms in the same school year, researchers face difficult tradeoff decisions in choosing what data to collect. One key tradeoff is between the *cost* of collecting data and the *quality of inferences* the resulting data can support. For example, video recordings are very expensive to collect and analyze but support in-depth analysis of a type that many Learning Scientists prefer. It can be much less expensive to collect and analyze a survey, but inferences from such data may be more circumscribed.

In this paper, we consider the potential value of collecting student workbooks in implementation research at scale. Student workbooks provide a potentially useful tradeoff. On the one hand, they are quite inexpensive to collect; we have found that teachers are willing to put them in a prepaid mailer, eliminating the need for a researcher to visit the classroom. On the other hand, workbooks directly exhibit student work, which can be a rich source of insights into students' misconceptions, for example. We report what we were able to learn from an exploratory, posthoc analysis of 765 workbooks.

We consider two kinds of research questions, some that are general to the method and some that are specific to the SimCalc intervention.

We asked three *method questions*:

1. How long does it take to code 48 classroom sets of workbooks for a 2–3 week intervention?
2. Can suitable interrater reliability be achieved?
3. Could raters accurately detect indicators of high-achieving and low-achieving classrooms?

With regard to the SimCalc intervention, the program developers espoused the beliefs that students need to be actively engaged in using the materials in order to learn (e.g., rather than just watching a teacher lecture with the materials). It is difficult to collect evidence of active engagement of all students in 48 classrooms. However, workbook completion does reveal the extent to which students were engaged in doing the work, especially because the curricular workbooks required students to use the software in order to answer various questions. Furthermore, because students drew graphs and wrote stories in their workbooks, we were able to consider the impact of student engagement with these forms of representation on learning.

Consequently, we asked an additional two *research questions*:

4. Does the completeness of student workbooks, as a proxy for students' active engagement in doing mathematics during the course of the replacement unit, predict student learning gains?

5. Does the correctness of details in student explanations, drawings of graphs, and telling of stories about graphs predict student learning gains of advanced mathematical concepts?

In addition to a specific focus on these research questions, we will report some additional anecdotal insights about what we learned from the analysis of workbooks.

## Background: Analyses of Student Work

In some ways, analysis of student work is ubiquitous in the Learning Sciences. Many published articles show artifacts from the classroom—including students drawings, calculations, graphs, and tables—to provide evidence for their arguments. Student work is often useful, for example, for identifying student misconceptions in graphing (Clement, 1989). However, most analyses are in the context of case studies. Few involve quantitative comparisons of students' prior knowledge and learning outcomes.

One notable use of student work in larger scale research was in the work of the Consortium on Chicago School Research, which collected samples of teacher assignments and student work in 12 Chicago schools at three grade levels and both in mathematics and in language arts (Newman, Lopez, & Bryk, 1998). The researchers found that when teachers gave more challenging assignments (i.e., that required a higher level of intellectual work), students were more likely to exhibit high level work and to have higher achievement outcomes.

Analysis of student work is also featured as a method of teacher professional development and improvement of instruction. For example, in Cognitively Guided Instruction, the entry point for teachers into students' cognition is through examining examples of student work (Fennema et al., 1996). Student work has also been the subject of research related to the benefits of portfolio assessments (Wolf, 1989). The purpose of such work is to form an alternative outcome measure to conventional testing. Although this is a different purpose from the present research—we seek to use student work as an implementation measure, not an outcome measure—one useful commonality is the technique of developing rubrics to score student work.

## Background: Scaling Up SimCalc

The Scaling Up SimCalc Project (Roschelle et al., in press) implemented two randomized controlled experiments (with one embedded quasi-experiment) designed to address the broad research question, "Can a wide variety of teachers use an integration of technology, curriculum, and professional development to increase student learning of complex and conceptually difficult mathematics?" There were two interventions, one for seventh grade and one for eighth grade. Each intervention integrated the representational technology SimCalc MathWorlds, curriculum workbooks, and teacher professional development organized around a 2-3 week replacement unit on rate, proportionality, and linear function. The replacement units incorporated the following hallmarks of the SimCalc approach to the mathematics of change and variation:

1. Anchoring students' efforts to make sense of conceptually rich mathematics in their experience of familiar motions, which are portrayed as computer animations.
2. Engaging students in activities to make and analyze graphs that control animations.
3. Introducing piecewise linear functions as models of everyday situations with changing rates.
4. Connecting students' mathematical understanding of rate and proportionality across key mathematical representations (algebraic expressions, tables, graphs) and familiar representations (narrative stories and animations of motion).
5. Structuring pedagogy around a cycle that asks students to make and compare their predictions.

The main effects of the treatment in the three main studies were positive, with student-level effect sizes of .63, .50 and .56; classrooms that used a SimCalc replacement unit had students who learned more advanced mathematics. This article focuses on data from the 48 treatment classrooms in the first experiment, which centered around seventh-grade students, teachers, and mathematical content.

SimCalc's developers have always espoused the view that students must be actively engaged with doing mathematics in order to learn; the software is a representational infrastructure that supports doing mathematics (Kaput, Hegedus, & Lesh, 2007). We confirmed this view, albeit weakly, in the larger quantitative data set by a finding that the number of days in the computer lab (a proxy for the level of student use of the software) correlated with overall learning gains. Case studies conducted within the Scaling Up SimCalc research provided further opportunities to examine this view within varying classroom implementations. Empson, Greenstein, Maldonado, and Roschelle (2009) examined differential student learning in three different classrooms, each with a different style of implementation. The analysis highlighted access to or blocking of learning resources as critical to students' ability to participate in the classroom as cognitively engaged learners. When a teacher significantly blocked students' autonomous use of SimCalc software and workbooks, by frequently interrupting the students' independent work, the classroom learning gains were lower. Likewise, Dunn (2009) found one low performing teacher spent much more time than the average teacher introducing and demonstrating ideas and much less time allowing students to work with the computer and workbooks. Analysis of student workbooks provides an opportunity to go beyond these case studies by examining connections between student completion of workbooks (and hence their level of engagement in doing the mathematics) with student learning.

SimCalc's developers have also always emphasized the activity of asking students to construct stories about graphs and motions (Kaput & Roschelle, 1998). These stories are seen as valuable because they evoke student engagement when they focus students on mathematically relevant details. For example, whether a students' story is about a race or a soccer game is irrelevant; whether a students' story describes speed and direction of motion is relevant. An emphasis on connecting linguistic and graphical forms of meaning is broadly consistent with the "Multimedia Principle" (Fletcher & Tobias, 2005). However, to date, there has been no empirical confirmation of this principle specific to SimCalc. Likewise, SimCalc developers believe that asking students to draw graphs and to explain motions are valuable activities. Analysis of student workbooks provides an opportunity to code these aspects of student work and to examine correlations to learning gains.

## SimCalc Workbooks

The seventh-grade curriculum, entitled *Managing the Soccer Team*, was designed to be used daily over a 2- to 3-week period to address central concepts of proportionality. Speed as rate is developed through a sequence of increasingly complicated simulation-based activities. The workbook is 59 pages long and has a total of 20 lessons. Lessons progress through representations—from graphs to tables to equations—aiming to teach students to translate among representations and to connect each concept to verbal descriptions of motion or other real-world contexts.

## Data Collection

Teachers were recruited for the Scaling Up SimCalc experiments from several regions of Texas. Recruitment and sampling in the overall experiment is described in Roschelle et al., in press. The seventh-grade treatment sample consisted of 796 students in 48 teachers' classes (for each teacher we collected data for one randomly selected class). The student ethnic breakdown was 48.5% White, 44.3% Hispanic, 4.2% African American, and 1.5% Asian. The mean campus-level percentage of students qualifying for free or reduced-price lunch was 54%, with a range of 1% to 94%, indicating a wide variation in campus poverty levels.

We asked all teachers participating in the Scaling up SimCalc experiment to return student workbooks to us and provided a prepaid express mail shipping box for them to do so. For the seventh-grade treatment teachers, we received boxes of workbooks from all 48 teachers, resulting in a collection of 765 workbooks (overall, 3.9% of the student workbooks were missing). Before analysis, each workbook was assigned the identification number that cross-referenced all other student-level data.

In addition to the workbooks, other data collected included: (1) unit pretests and posttests, (2) student and teacher demographics, (3) teacher mathematical knowledge, and (4) teacher daily implementation logs. Instrumentation and findings for these data are described extensively elsewhere (e.g., Roschelle et al., in press).

## Coding Protocol and Process

Based on a pilot workbook analysis, we designed a coding protocol that would be implemented by experienced math teachers. Teachers coded workbooks grouped by class so that they could observe patterns that may emerge within a class. There were three parts to the protocol.

1. For each workbook, the coder reviewed each of the 20 lessons and applied criteria to determine the level of completeness of the activities in the lesson (no attempt, low, medium, high). Coders did not make judgments about the quality of the work, but rather the presence of any attempted work.
2. For each workbook, the coder reviewed a subset of six key lessons to code the written work for correctness. The research team selected the six activities that seemed most central to the development of students' conceptual understanding. Four of these lessons entailed students' construction of stories from linear and/or piecewise linear graphs or construction of linear and/or piecewise linear graphs from stories. To capture the specificity of mathematical detail for each of the constructed stories and graphs, the coding protocol entailed a checklist of all possible correct mathematical details.
3. After coding a classroom for completeness and correctness, the coders made a holistic guess about the prior achievement level and learning gains in the classroom. The coders made written documentation of the indicators they used to make these judgments and recorded misconceptions that they observed.

We hired three master teachers who had not participated in the experiment to serve as coders during their school summer break. All were mathematics teachers, with one working at the high school level and two working at the middle school level. They all had little or no experience in conducting research.

The coders were trained on a set of 20 workbooks. They coded 5 workbooks together with one of the researchers and then 15 on their own. Interrater reliability on Parts 1 and 2 was sufficiently high for coders to then begin coding the full corpus. Within each class, two workbooks were randomly selected to be double-coded for Parts 1 and 2 to check for the maintenance of reliability.

## Analysis

We report our data analysis by each research question.

### 1. How long does it take to code workbooks?

We found it took the three teachers about 2 months working roughly half time to code 765 workbooks, including 3 days for training and 1 day for debriefing. The approximate time per workbook was 10–20 minutes, which translates to an average of about 4 hours per classroom, for classrooms implementing a 2–3 week long curriculum workbook. This was a relatively inexpensive task in the context of a multimillion dollar project.

### 2. Were we able to achieve adequate interrater reliability?

Interrater reliability was high. The index that we used was the intraclass correlation between each of the coder's ratings. Among the completeness and correctness ratings, there was a total of 26 ratings. The intraclass correlations for 20 of these ratings was over .90, 5 were between .80 and .90, and 1 was .66.

### 3. Could raters accurately detect indicators of high-achieving and low-achieving classrooms?

As shown in Figure 1, we found that coders were somewhat accurate in their holistic guesses about classrooms' average prior achievement levels [$t(33) = 2.5$, $p < .05$]; however they were not accurate in their holistic guesses about classrooms' average learning *gains*. We assume this is indicative of the characteristics of the student work, not these particular teachers' ability to detect learning gains.

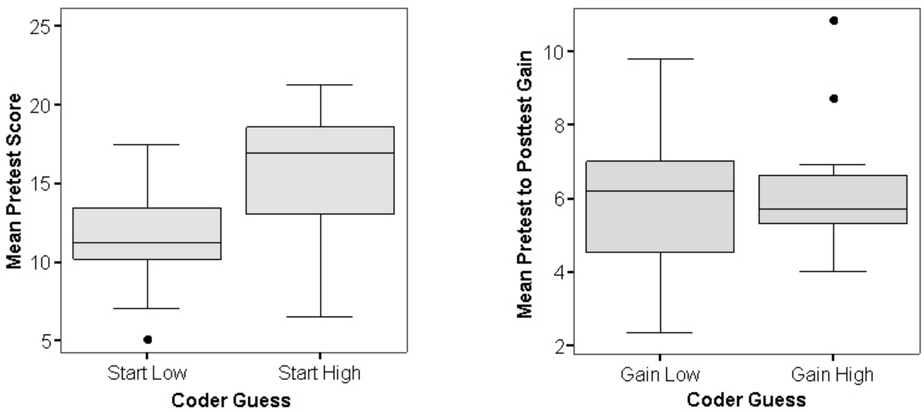

Figure 1. Actual classroom-level means distributed over coders' holistic guesses of achievement levels.

As summarized in Table 1, we debriefed the coders after completing this task to ascertain the qualities of student work that were salient to coders as they made these judgments. In addition, teachers were asked to collect misconceptions they observed in the workbooks. We found they detected a wide range of common misconceptions for this mathematical subject matter, including:

- Confusion between miles and mph—not paying attention to the fact that these are different.
- Distance interpreted as speed and speed interpreted as distance.
- Interpreting an object moving at a constant rate as increasing in speed.
- Confusion regarding which runner is the winner of a race based on reading a position graph.
- Confusion between dollars and decimals (e.g., "0.80 cents").
- In a position graph representing two races, the graphed line "on top" is more.
- Iconic interpretation of graphs as a picture (e.g., "the runner went up" describes a positively sloped position graph).
- In a piecewise linear function, two segments interchanged or confused on graph.
- Incorrect use of conventions (e.g., "13-50" as the ordered pair (13,50)).

Table 1. Qualities of student work that were salient to coders in judging student prior achievement and learning.

| Indicative of High Achievement | Indicative of Low Achievement |
|---|---|
| • Used pencil and erased when they made a mistake.<br>• Attention to correcting their work.<br>• Students were allowed to work on their own. The stories within a classroom were very different from each other, compared to classes where all the kids had the same stories verbatim.<br>• Indication of testing predictions with the software. Say that they saw their prediction was wrong.<br>• Quantified statements, rather than just saying "faster."<br>• Graphing was detailed. For every hour they would plot a point. Paid attention to precision, making sure they ended at the right point on the graph. Used straight edges.<br>• Stories included mathematical observations from the graph. Wrote a lot and were very specific (not simply a creative story).<br>• Evidence of teacher feedback and modeling. | • Sloppy handwriting, incomplete answers, poor spelling, reverse letters, graphing without a straight-edge, wrote in pen, did not correct answers.<br>• Lack of detail, not paying attention to answering questions completely.<br>• A lot of absences—large numbers of pages with missing work.<br>• Struggled with math vocabulary and writing skills. Could not accurately describe motion because they had poor word choice. "The van caught up" instead of "the bus slows down" was very important.<br>• Stories tended to be more creative but were missing a lot of mathematical detail.<br>• In some classrooms, all students had the same incorrect answers. This suggested a teacher error or misconception. |

## 4. Does completeness of student workbooks predict learning gains?

Overall, we found that the mean completion of student workbooks was 75% (SD = 17%), which suggests that most teachers really did implement the SimCalc intervention. As Figure 2 shows, there was considerable variation in workbook completion, both within and across classrooms. The figure shows classrooms in rank order of the classroom median for student completion of workbooks. About two-thirds of the classrooms completed 75% or more of the workbooks. Of the remaining third, three classrooms completed 50% or less of the workbook.

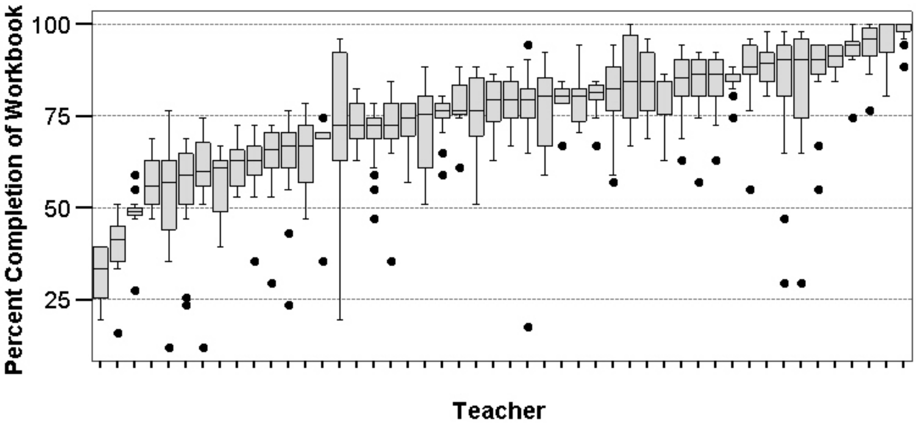

Figure 2. Distributions across classrooms of completion of workbook (teachers ordered by class median).

We then tested whether workbook completion predicted pretest to posttest learning gains, using a hierarchical learning model (HLM) to correct for the nesting of students within classrooms. We examined the "$M_2$" subscale of our assessment, which focuses on more advanced mathematics. We chose to focus on this scale because classrooms that used SimCalc had particularly large gains on this scale; hence, it is sensible to look at this scale when considering the value added by the SimCalc intervention. As Figure 3 shows, there was an overall correlation between student completion of workbooks and mean classroom learning gains [$z = 4.3$, $p < .001$]. Using HLM, we determined that on the 21-point $M_2$ scale, students on the average gained 1 $M_2$ point for every 13.3% of the workbook that was completed.

We then examined completion of each of the 20 lessons individually. We found that the completion rate was uniformly high for the first half of the workbook (with the exception of a section intended for homework); declines in workbook completion occurred in some classrooms in the second half of the workbook. We found a high alpha (0.83) among completion rates for all activities, suggesting that whether a student

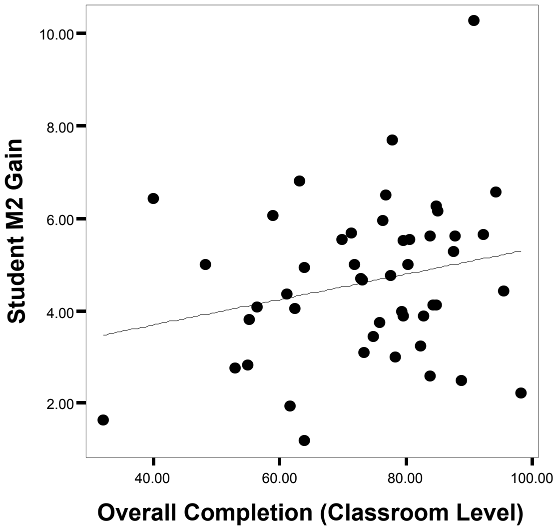

Figure 3. Workbook completion and student learning gains.

completes one activity is a good indicator of whether they will complete other activities. With respect to learning gains, we found correlations between completion of most activities in the second half of the curriculum and learning gains. This may be due to the fact that the second half of the workbook covered the material most relevant to the $M_2$ scale and/or had the most variation in completion.

We then examined factors that might predict completeness of the workbooks. The best predictor of workbook completeness was students' pretest score. The pretest had 30 items. For every 10 additional items correct, students on average completed an additional 6% of the workbook [$z = 5.92$, $p < .001$]. The other statistically significant predictor was gender. On average, girls completed 1.8% more of the workbook than boys did. The other variables that were not significant included: geographic location, student ethnicity, school poverty level, teachers' years-of-experience, teachers' level of mathematical knowledge, how often class was conducted in the computer lab, and the number of days spent implementing the unit. Clearly workbook completion is not a proxy for computer use.

We also used the number of days the unit was implemented in conjunction with the completeness to examine the *pace* with which the class did the unit. Overall, workbook completion was independent of the time teachers' spent doing the unit. However, we did find that classrooms with a higher mean pretest score completed the workbooks faster [$r(48) = .42$, $p < .01$]. Teachers may be purposefully taking more or less time with the workbooks depending on the incoming level of their students, which suggests that most teachers managed implementation to substantially complete the workbooks rather than to occupy a fixed amount of time.

## 5. Does correctness of details in workbook answers predict learning gains?

Figure 4 shows examples of two students' written stories in response to the graph depicted in the workbook. As we found throughout the workbooks, students varied in how much mathematical detail they provided and whether the detail was correct. In the top story, the student provides little detail about speed and describes the wrong vehicle as stopped. In the bottom story (which is still relatively incomplete compared to other stories we saw), the student describes the constant speed of the bus until it stopped. (The scores "-30" and "-10" were written by the teacher and not part of our coding scheme.) We see that the student in the top story has also made notes on the task: "explain lines using speed, location, time; explain motion." One lesson we learned from reviewing workbooks is that the task may not have been clear to most students and teachers; this teacher may have given the students more information on what they were supposed to do. In a revision of the materials, we would consider more specifically prompting students to focus on mathematical detail.

Overall, we found that the level of mathematical detail and correctness in all six activities predicted student learning, either significantly or marginally significantly. Also, as with the completion rates, we found high intercorrelations between correctness for each lesson (alpha = 0.70). Hence, our ability to argue that doing any specific learning activity is important to learning is limited. However, on a whole this finding does suggest that the activities that focus on drawing graphs and writing stories are valuable for student learning.

As was the case for completeness, student pretest scores predicted correctness in the workbook. No other variable predicted correctness, including student gender, geographic location, student ethnicity, school poverty level, teachers' years-of-experience, teachers' level of mathematical knowledge, how often class was conducted in the computer lab, and the number of days spent implementing the unit.

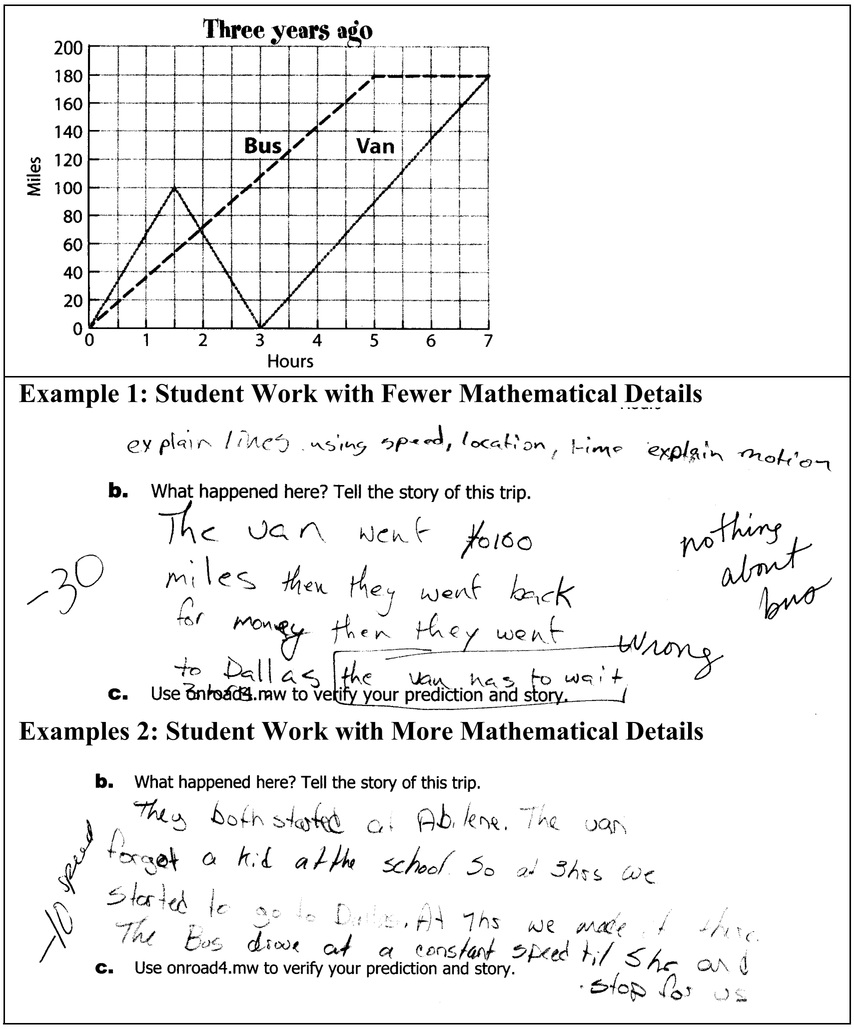

Figure 4: Two contrasting student responses to a story writing task.

## Discussion

Our analysis of the first two research questions suggests that analysis of student workbooks is a viable technique for measuring implementation of a Learning Sciences–based innovation at scale. Workbook coding is reasonably cost effective and time efficient, especially relative to methods requiring field observations or video recordings of classrooms. Furthermore, we were able to achieve suitable interrater reliability. Workbook coding has the advantage that it makes it possible to examine the work of the majority of the students in a classroom, whereas field observations or video recordings often have to be focused on just a few students.

The third research question looked at the connections between coders' holistic judgments and students' actual knowledge and learning. We found that coders could detect with some accuracy which classrooms had lower mean pretest scores. However, they did not tend to detect which classrooms had lower or higher mean learning gains. This suggests that coding specific activities for completeness and correctness provides important analytical information that cannot necessarily be obtained through teachers' holistic judgments.

We did find that completeness of student workbooks predicted student learning. This is important because it suggests that having students do the mathematical work is important to student learning, a core tenet of SimCalc program developers. Although this may seem obvious, it is not obvious to all teachers who implement SimCalc—some prefer to focus on teacher demonstrations using the SimCalc software. Indeed, case studies provide evidence of some classrooms in which teachers blocked student independent work; this work confirms the conjecture arising from those case studies that the workbooks are a valuable learning resource and that low use of the workbooks was a factor in lower student learning gains. A corollary finding was that pretest scores predicted completeness. This is an indication of an advantage that students with higher prior knowledge have in learning the content of this unit. This suggests the necessity for additional supports for students who start the unit with lower prior knowledge, a point that could be addressed in teacher professional development to improve implementation.

We also found that the level of detail in student work and the correctness of the detail predicted student learning. We particularly focused on details in students' construction of graphs and stories about graphs. This is the first empirical confirmation that these activities, long part of the SimCalc approach, have an impact on learning.

Of course, because the workbook is designed for and used in a variety of ways as part of the many resources in the classroom (i.e., not as an assessment instrument), inferences about the work must be made with caution. For example, it is possible that students can be actively engaged in doing simulations with the software or having mathematical conversations with the teacher or peers yet not write extensively in their workbooks. However, while these limitations do exist, we believe the methodology does provide an important window into students' cognitive engagement across a large-scale study that would otherwise be unavailable.

Overall, we would recommend that Learning Scientists who are scaling up their curricular designs consider designing workbooks and other student work artifacts that can be collected and analyzed for evidence of the quality of classroom implementations. Relative to field observation or video recording, analysis of student work is relatively cost effective, while preserving the opportunity for detailed insight into how teachers and students are using materials. This form of data collection may be particularly useful in examining the relationship of constructive activities, such as drawing graphs and writing stories, to students' learning gains.

festner.dagmar@f-bb.de

**Abstract:** Should the construct 'motivation to transfer' used in human resource development and management research be also used in learning research? The current study revisited motivation to transfer on a sample of 128 participants of occupational health training. Confirmatory factor analysis and partial least squares-based path modeling were used to test the hypothesized dimensions and relationships among variables including social and affective cues on training transfer. Based on a combination of the theory of planned behavior, expectancy theory, and self-determination theory, we validated three dimensions of transfer motivation: autonomous motivation to transfer, controlled motivation to transfer, and intentions to transfer. Results indicate that autonomous motivation was affected by attitudes toward training content and utility reactions; controlled motivation was affected by utility reactions, supervisory support, and social norms. Intentions to transfer mediated the effects of autonomous motivation on transfer three months after training. Implications of a multidisciplinary perspective combining learning sciences and human resource development are discussed.

## The Noe Model Revisited

In 2006, in a discussion on how motivation influences transfer, Pugh and Bergin (p. 155) recommended adopting the construct motivation to transfer from the human resource development (HRD) literature to the learning sciences; their recommendation was published in a highly influential journal in the field, *Educational Psychologist*. Twenty years earlier, Raymond Noe coined the term 'motivation to transfer' that Pugh and Bergin were referring to as "the trainees' desire to use the knowledge and skills mastered in the training program on the job" (Noe, 1986, p. 743). His work was published in a highly influential journal in the field of management and HRD, *Academy of Management Review*. It is argued here that it would be fatal if learning scientists followed Pugh and Bergin's advice to adopt the construct from HRD research to learning research. This is for five reasons. First, motivation to transfer currently is a one-dimensional construct that is too coarse to adequately reflect motivational states and traits in the transfer process. Second, motivation to transfer currently is not, and was not, adequately grounded in motivation theories. Third, there is poor empirical evidence in the HRD and management literature on how motivation to transfer affects transfer of learning. Fourth, motivation to transfer currently is a static construct, only measured immediately following an intervention. Finally, Noe (1986) said little in his original conceptualization about the social origin of transfer motivation; this reflected the zeitgeist of the 1980s epoch. Learning researchers now can be thoughtful in adopting a more balanced view.

It is argued further that motivation to transfer does indeed play a central role in the transfer process; there is enough theoretical (and common sense) backdrop to expect that learners who are motivated to apply training content from training to work, or from the classroom to out-of-classroom use, are more likely to be successful than learners who are not motivated. Yet, in its current form, motivation to transfer seems to be a construct powerless to account for intentional transfer processes. Transfer, from a human resource perspective, is defined as the successful application of newly trained knowledge, skills, and attitudes to the workplace (Noe, 1986; Burke & Hutchins, 2007). Hence, we argue that before following Pugh's and Bergin's recommendation, Noe's model of motivation to transfer must be revisited in several significant respects: dimensionality, theoretical grounding, empirical evidence, measurement time, and social nature of motivation.

On revisiting dimensionality, motivation to transfer has been measured as a one-dimensional construct in empirical training research over the past twenty-five years or so (Noe & Schmitt, 1986; Velada, Caetano, Bates, & Holton, 2009). In our recent review on motivation to transfer (Gegenfurtner, Veermans, Festner, & Gruber, 2009), we found that all 31 studies on transfer motivation reported in international peer-reviewed journals from 1986 to now used a one-dimensional scale to assess the construct, ranging from one item to eleven items. This is a paradox since motivation researchers have explored numerous dimensions of motivational processes in human actions. To name just a few, we know of intrinsic and extrinsic motivation; conscious goal intentions and unconscious implementation intentions; expectancies, instrumentalities, and valences; various types of motivational regulation and mindsets; and we differentiate motivation, volition, and emotion. All contribute to our understanding of the many facets and colors that motivation has. Motivation to transfer potentially goes in concert with all of the dimensions just mentioned. It can be argued that motivation to transfer has remained a one-dimensional construct to date because it lacks a clear grounding in motivation theories.

On revisiting theoretical grounding, Noe (1986; Noe & Schmitt, 1986) made no explicit statement as to which theoretical framework the idea of motivation to transfer is based; although there are references to Bandura, Latham, and Vroom in their original papers, the associated motivation theories refer not to transfer motivation but to other aspects of the papers. Hence, motivation to transfer lacked from the start, and still lacks, a solid foundation in motivation theories. In an attempt to provide a first step toward resolving this situation, we conducted two studies in which the theory of planned behavior (Gegenfurtner & Gruber, 2009) and expectancy and self-determination theory (Gegenfurtner, Festner, Gallenberger, Lehtinen, & Gruber, 2009) were tested as a basis for transfer motivation scales. In short, these studies indicate that motivation to transfer has several dimensions: autonomous motivation to transfer, controlled motivation to transfer, and intentions to transfer. These are the first steps, and more efforts are needed to validate the construct's theoretical grounding for human resource development beyond.

On revisiting empirical evidence, it is a likely explanation that the one-dimensionality and the lack of theoretical grounding account for the current state of poor evidence on the intention-behavior relationship in training transfer. Correlation coefficients ranging from 0.04 (Tziner, Haccoun, & Kadish, 1991) to 0.63 (Machin & Fogarty, 1997) suggest that the relation between motivation to transfer and transfer of training needs further elaboration. Again, we believe that a starting point for this elaboration is a reconceptualization of Noe's model of transfer motivation. This may help to form new research practices with respect to the multidimensional nature of transfer motivation, its groundwork in valid motivation theories, and its measurement time.

On revisiting measurement time, our review of transfer motivation (Gegenfurtner et al., 2009b) indicated that, in 30 of 31 cases, the construct was assessed at the immediate end of training. Only Leitl and Zempel-Dohmen (2006) measured transfer motivation at the immediate end *and* at a later point in time, three months after the intervention. We believe that motivation to transfer in particular, like motivation for action in general, dynamically changes over time. Hence, assessment of transfer motivation at a time when the learner has had time to explore opportunities to use training in out-of-classroom applications may provide a very different picture than the assessment of transfer motivation at a time when the learner is just about to leave the classroom. Yet, empirical examinations at a different time than at the immediate end of training are almost non-existent.

On revisiting the social nature of motivation, there is large consensus that motivation is intrinsically social in nature (Hickey, Moore, & Pellegrino, 2001; Järvelä, Volet, & Järvenoja, 2010; Vauras, Salonen, & Kinnunen, 2008). We argue that this holds equally for transfer motivation. Especially when trainees spent some time at the workplace and could test the training content about its usefulness, social cues might affect formation and persistence of motivational states to transfer training. Arguably, the generation of more stable motivational traits is also influenced by factors such as social norms, feelings of relatedness, or control beliefs that are based on environmental (working) conditions emanated in social interaction. Noe (1986) constructed his model of transfer motivation at a time in which the social nature of motivation was not on the agenda yet. Reconceptualizing the Noe model can account for this development in motivation research.

## Present Study

The present study had a dual goal. First, it aimed to test the multidimensionality of motivation to transfer. Multidimensionality was achieved by using a combined motivation theory approach. Specifically, there was a combination of a validated framework from educational psychology, self-determination theory (Baard, Deci, & Ryan, 2004), and a validated framework from management research, expectancy theory (Vroom, 2005), to conceptualize autonomous and controlled motivation to transfer. Expectancy theory as a cognitive-choice approach and self-determination theory as a need-motive-value approach can complement each other in predicting and explaining human performance in the workplace (Kanfer, 1990). Thus, instrumentality and valence items reflecting externally prompted reasons to transfer were used to assess controlled motivation. Conversely, instrumentality and valence items reflecting internally regulated behaviour were used to assess autonomous motivation. Autonomous motivation to transfer is defined here as an internalized desire to transfer learning that is initiated and governed by the self (i.e., regulated by identification or by integration with one's values), and controlled motivation as a desire to transfer learning that is not initiated and governed by the self (i.e., regulated by external rewards or sanctions). In addition to autonomous and controlled motivation as measures of motivational traits, intentions to transfer are also included as measures of motivational states. This is because contrary to motivational traits, intentions represent a more activated, situation-specific motivational state. We used Ajzen's (1991) theory of planned behaviour, a well-validated framework from social psychology, to conceptualize intentions to transfer.

The second goal was to test a hypothesized path model, shown in Figure 1. The model explored a motivational sequence. Effects of autonomous and controlled motivation on training transfer are mediated by the more situation-specific state of transfer intentions; at the same time, situational but distal social (relatedness, support, control, and norms) and affective (attitudes and utility reactions) cues on transfer intentions are mediated by more stable motivational traits, i.e., autonomous and controlled motivation to transfer. It can be argued that motivational traits act like filters. For example, supervisory support may or may not lead to activated intentions, depending on the motivational trait. The model has a range of hypothesized relationships; these are based on theory or past empirical evidence. Specifically, the hypothesis, based on self-determination theory, predicted that relatedness (RE) at work would foster internalization of external regulations and would thus be positively related to autonomous motivation to transfer (Baard et al., 2004; Gegenfurtner et al., 2009a). Supervisory support (SU) was shown to have mixed empirical results on motivation, depending on whether support was perceived to be instrumental or not; we thus expected relations to both autonomous and controlled motivation. Based on the theory of planned behavior (Ajzen, 1991), it was hypothesized that perceived behavioral control (PBC) promoted trainees' feelings of autonomy and would thus be more important for autonomous motives; at the same time, social norms (NO) were hypothesized to have stronger effects for those trainees with controlled motivation. Past research showed that attitudes toward training content (AT) were related to both autonomous and controlled motivation (Gegenfurtner et al., 2009a). Utility reactions (UT) were hypothesized to affect self-determined feelings of autonomy; however, due to their instrumental nature, it was speculated that they could also affect controlled motivation.

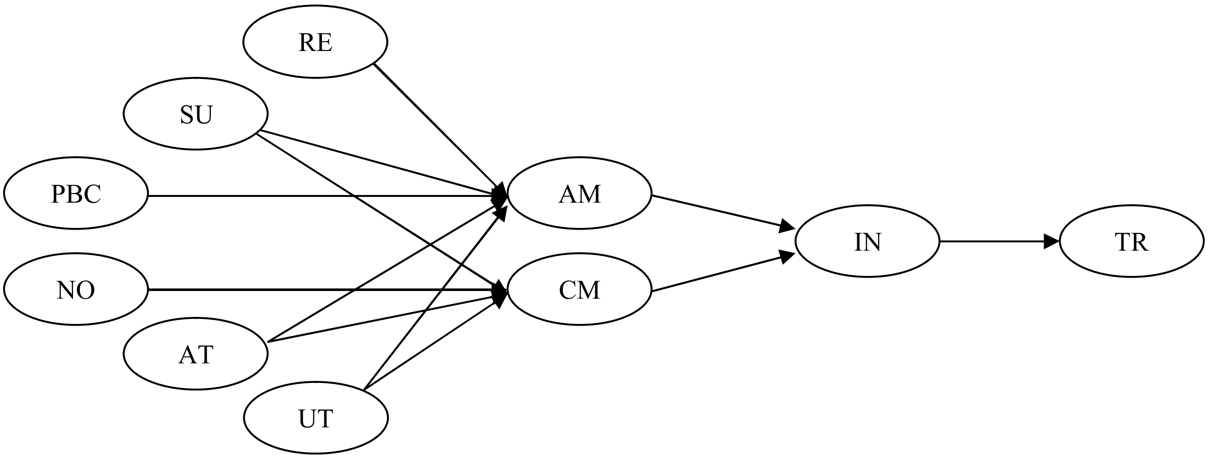

Figure 1. Hypothesized path model.

# Method

## Participants and Procedure

The participants in the study were 496 employees who attended one of the 23 training programs on occupational health and safety following German statutory accident insurance regulations. Three months after the training, trainees received a paper-and-pencil questionnaire sent to their workplace. The questionnaire collected self-report data that, despite the known problems (e.g., leniency, self-serving bias), seemed adequate to use because a major interest was trainees' self-perceived attitudinal and motivational states. One hundred thirty-one trainees (26.4%) completed and returned the questionnaire. Deletion of three multivariate outlying cases ultimately yielded a final sample size of 128 trainees. The majority of the participants was between 41 and 50 years old (43.1%) and has worked with their current employer for up to five years (25.0%); the average organization size was between 100 and 199 employees (68.8%). There was no statistically significant difference between respondents and non-respondents. Participation in the study was voluntary, with informed consent forms signed by the trainees. Anonymity and confidentiality were guaranteed for all responses.

## Instruments

Unless otherwise indicated, a 5-point response scale was used for all items, with 1 = *strongly does not agree*, 2 = *does not agree*, 3 = *partly agrees*, 4 = *agrees*, and 5 = *strongly agrees*. All scales were pilot-tested; minor revisions in expressions and the ordering of items were reflected in the final version of the instrument. Table 1 presents internal consistency values of each scale.

### Demographic and Organizational Membership Characteristics

Demographic and organizational membership characteristics were measured to establish nomological validity. One of each item was used to assess organizational tenure ('How long have you worked with your current employer?'; 1= up to 5 years, 2=6-10, 3=11-15, 4=16-20, 5=21 years or more), organization size ('How many people are employed in your company?'; 1=1-9 employees, 2=10-19, 3=20-49, 4=50-99, 5=100-199, 6=200-249, 7=250-349, 8=350-549, 9=550-999, 10=1000-1999, 11=2000 employees or more), and age (1=up to 30, 2=31-40, 3=41-50, 4=51-60, 5=more than 60 years old).

## Independent Variables: Social and Affective Cues

This study used social and affective cues as independent variables. First, social cues were measured with scales on relatedness, supervisory support, perceived behavioral control, and social norms. To assess relatedness, five items were used based on the Basic Psychological Needs Scale at Work (Baard et al., 2004; Gegenfurtner et al., 2009a); the items measured the extent to which trainees felt connected and respected in their organizations (e.g., 'People at work care about me'). To assess supervisory support, five items were used that measured support associated with goal-setting and feedback (e.g., 'I try to achieve preset goals by applying what I have learned in training on the job'). To assess perceived behavioral control, we included five items that measured participants' perceived capability of and confidence in transferring the training to their workplace (e.g., 'I feel capable to apply the training content at work'). To assess social norms, five items were used that reflected the degree to which participants perceived social normative pressure from referents important to the trainees to perform or not to perform a certain behavior (e.g., 'My boss sets a high value on applying the training content at work').

Second, affective cues were measured with scales on utility reactions and attitudes toward training content. To assess utility reactions, items developed by Tai (2006) were used that measured the affective experience on whether the training has been useful during the last three months (e.g., 'Today, I judge the usefulness of the training as: 1=very low, 2=low, 3=average, 4=high, 5=very high'). To assess attitudes toward training content, five items were used to measure cognitive and emotional/affective aspects of attitudes towards occupational health and safety (Ajzen, 2001; Eagly & Chaiken, 1993; Gegenfurtner et al., 2009a). Sample items were as follows: for cognition, 'I easily come up with at least five reasons for complying with safety and health regulations', and for emotion, 'I feel responsible for health and safety in my working area'.

## Mediating Variables: Motivation to Transfer

Motivation to transfer was measured with three distinct scales specifying autonomous motivation to transfer, controlled motivation to transfer, and intention to transfer (Gegenfurtner et al., 2009a; Gegenfurtner & Gruber, 2009). For autonomous motivation, two pairs of items were included to measure instrumentality and valence of autonomous motives for training transfer. Sample items were as follows: for instrumentality, 'While applying training at work, I can learn a lot', and for valence, 'This learning is important to me'. For controlled motivation, two pairs of items were included to measure instrumentality and valence of controlled motives for training transfer. Sample items were as follows: for instrumentality, 'Successful application of the training content will probably result in a materialistic reward, such as a financial bonus', and for valence, 'This reward is important to me'. A five-item scale was used to measure intention to transfer (e.g., 'I have tried intentionally to apply the training content to my workplace, regardless how well it actually worked').

## Dependent Variable: Transfer of Training

To assess transfer of training, five items described in Festner and Gruber (2008) were used to measure self-perceived change in knowledge, skills, and attitudes toward the training content, occupational health and safety (e.g., 'Today, I engage more in health and safety than I did before the training').

# Data Analyses

A two-stage procedure was adopted for data analysis. First, the factorial validity of the revisited construct of motivation to transfer was assessed. This was done using confirmatory factor analysis (CFA). Given an appropriate level of communality, CFA was considered meaningful (MacCallum, Widaman, Zhang, & Hong, 1999). Based on the EQS 6.1 (Bentler, 2005) software, three first-order CFA models designed to test the multidimensionality of the theoretical construct were examined. The first model was a three-factor model composed of autonomous motivation to transfer, controlled motivation to transfer, and intention to transfer. The second model was a two-factor model in which autonomous and controlled motivation were merged as if representing one factor. Finally, the third model was a one-factor model that forced autonomous motivation to transfer, controlled motivation to transfer, and intention to transfer into one factor (which is the current research practice). Data were screened to test for multivariate outliers, normality and multi-collinearity (Kline, 2005). The direct maximum likelihood approach was used as a missing data specification procedure and robust methods as normality estimator corrections. Assessment of the model fit was based on four criteria reflecting statistical and theoretical considerations. The criteria were as follows: (1) the Yuan-Bentler scaled $\chi^2$ test statistic, (2) the comparative fit index (CFI), (3) the standardized root-mean square residual (SRMR), and (4) the root-mean square error of approximation (RMSEA), with its 90% confidence interval (CI). This rationale was based upon literature recommendations (Bentler, 2005; Kline, 2005). For cut-off criteria, guidelines were followed for CFI>0.95, SRMR<0.09, and the RMSEA<0.06 (Hu & Bentler, 1999) to indicate appropriate goodness-of-fit. Validation of the three-dimensional construct seemed important to test the extent to which the measured variables actually represent the theoretical dimensions.

Once the factorial validity of motivation to transfer was established, its mediating position was assessed in our hypothesized model. This was done using path analysis following a partial least squares (PLS) approach. Contrary to other estimation techniques like multiple regression or structural equation modeling, PLS can be applied to a non-normally distributed data set collected with a small sample (Chin & Newstead, 1999). Based on the SmartPLS 2.0 (Ringle, Wende, & Will, 2005) software, the relationships among the variables were assessed using the path weighting scheme algorithm. Importantly, PLS is an approach for predicting relationships in a model, not for assessing overall model fit. However, Table 1 reports three reliability indices to indicate appropriate psychometrics properties of the measurement models. For cutoff-criteria, guidelines were followed for Cronbach's alpha>0.70, the average variance extracted (AVE)>0.50, and the composite scale reliability (CSR)>0.60 (Hair, Black, Babin, Anderson, & Tatham, 2006). Mediation was analyzed following the recommendations by MacKinnon, Fairchild, and Fritz (2007).

## Results

Screening of the data revealed no multicollinearity but multivariate nonnormality (Yuan, Lambert, and Fouladi's normalized estimate=45.88). Three multivariate outlying cases with a substantial different contribution to normalized multivariate kurtosis were subsequently deleted from all analyses. Table 1 presents psychometric properties and correlation coefficients of the measures. The next two sections describe test results for multidimensionality of motivation to transfer and for the hypothesized path model.

Table 1: Psychometric Properties and Correlation Coefficients of All Measures

| | M | SD | α | AVE | CSR | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 |

*Note.* Values below the diagonal are correlation estimates. Values above the diagonal are squared correlation estimates. OT=organizational tenure, OS=organization size, RE=relatedness, SU=supervisory support, PBC=perceived behavioral control, NO=social norms, AT=attitudes toward training content, UT=utility reactions, AM=autonomous motivation to transfer, CM=controlled motivation to transfer, IN=intention to transfer, TR=transfer of training $p<.05$ for $r>14$.

### Testing for Multidimensionality

The model to be tested a priori postulates that motivation to transfer three months after training is a three-factorial structure composed of autonomous motivation to transfer, controlled motivation to transfer, and intention to transfer. The three-factor model was tested first; then it was compared to the two-factor model and the one-factor model. Fit statistics relative to these models are presented in Table 2. In reviewing the CFI, SRMR, RMSEA, and $\chi 2$ test statistic values in Table 2, it is evident that the hypothesized three-factor model represented the best fit to the data.

Table 2: Confirmatory Factor Analytic Model Fit Statistics.

| Model | $\chi^2$ | *df* | CFI | SRMR | RMSEA (with 95% confidence interval) |
|---|---|---|---|---|---|
| Three-factor model | 112.24 | 62 | .97 | .08 | .05 (.04 - .08) |
| Two-factor model | 148.45 | 64 | .85 | .10 | .09 (.07 - .12) |
| One-factor model | 176.59 | 65 | .76 | .10 | .11 (.09 - .13) |

After CFA, construct validity of the three-factor solution was tested by assessing convergent, discriminant, nomological, and face validity. We followed the guidelines from Hair et al. (2006). First, concerning convergent validity, the variance-extracted measures (AVE) of AM, CM, and IN exceeded the 50% level, and the reliability estimates were larger than .70. Although two factor loadings were below .50, they did not appear to significantly harm the model fit or internal consistency; hence, convergent validity was established. Second, a construct is divergently valid if the variance-extracted estimates for each factor are larger than the squared interconstruct correlations associated with this factor (Hair et al., 2006). Table 1 reports AVE and squared intercorrelations. All variance-extracted estimates are larger than the corresponding squared intercorrelation estimates; hence, divergent validity of AM, CM, and IN was established. Third, concerning nomological validity, Hair and colleagues (2006) recommend comparing the constructs to other variables not included in the model, which, in this study, were demographic and organizational membership characteristics. The three factors were not significantly affected by trainee age, organizational tenure, or organization size; hence, nomological validity was established. Finally, face validity of the three dimensions was established based on discussions among the authors AG and DF about the content of the corresponding items. In summary, both the established construct validity and the acceptable model fit indicated good conditions to further test the hypothesized relationships of the three-factor solution in the PLS path model.

### Testing the Hypothesized Path Model

Table 3 presents the parameter estimates of the hypothesized path model. Mediation analysis (MacKinnon et al., 2007) indicates that intention to transfer mediated the effect of autonomous motivation on training transfer; autonomous motivation had a stronger effect on intentions than controlled motivation. Supervisory support, social norms, and utility reactions significantly affected controlled motivation while attitudes toward training content and utility reactions affected autonomous motivation. It is interesting to note that supervisory support seems to be effective for controlled motivation, but not for autonomous motivation. Despite the hypotheses, the paths from relatedness, support, and perceived behavioral control to autonomous motivation were non-significant, as was the path from controlled motivation to transfer to intention to transfer. This indicates that autonomous motives lead to more activated intentions than controlled motives three months after training.

Table 3: Confirmatory Factor Analytic Model Fit Statistics.

| Effect of | On | Path coefficient | *t*-value |
|---|---|---|---|
| Relatedness | Autonomous motivation | -.04 | 0.06 |
| Supervisory support | Autonomous motivation | .12 | 1.31 |
| Supervisory support | Controlled motivation | .29 | 3.04* |
| Perceived behavioral control | Autonomous motivation | .01 | 0.02 |
| Social norms | Controlled motivation | .24 | 2.11* |
| Attitudes toward training content | Autonomous motivation | .22 | 2.64* |
| Attitudes toward training content | Controlled motivation | .04 | 0.35 |
| Utility reactions | Autonomous motivation | .55 | 7.07* |
| Utility reactions | Controlled motivation | .21 | 2.27* |
| Autonomous motivation | Intention to transfer | .54 | 6.08* |
| Controlled motivation | Intention to transfer | .12 | 1.39 |
| Intention to transfer | Transfer of training | .48 | 6.39* |

*Note*. * $t > 1.96 = p < .05$

## Discussion and Conclusion

The theme of ICLS2010 invited an exploration of disciplinary perspectives and how multidisciplinary approaches can advance the learning sciences. This study explored research practices in the HRD and management disciplines with respect to motivation and transfer Revisiting the Noe model, it was argued that the construct ‘motivation to transfer’ needs to be reconceptualized in several significant respects before learning researchers should follow Pugh’s and Bergin’s (2006) recommendation to adopt motivation to transfer in contexts beyond HRD. This study used a multidisciplinary account in that it lied on the confluence of several literatures. The first is composed of managerial studies on the application of training to the workplace, including motivational processes as their central mediator. The second is composed of theoretical accounts on task and achievement motivation prominent in educational and social psychology. This confluence creates an interesting tension. It is obvious in reading the present study that ‘transfer’ is used in line with what Bransford and Schwartz (1999) have called the Direct Application theory of transfer. Certainly, there are other perspectives on transfer prevalent in other disciplines such as vocational education (Tuomi-Gröhn & Engeström, 2003), mathematics education (Lehtinen & Hannula, 2006), or computer-supported collaborative learning (Kapur & Kinzer, 2009). Many more could be named. The emphasis of the immediate use of what was learned in workplace applications is likely to be a result of the focus on the short-term benefits of training that can be found in many management and HRD contexts. In line with this view, motivation was seen as a single factor that can facilitate quick training application. We have criticized this view in the present study as being too coarse to account for the full complexity of intentional transfer processes It seemed to us that a way to overcome this problem was to use the best of both disciplines—HRD and learning sciences—to create a new account on motivation to transfer. Future research will have to show whether the proposed three-dimensional model is more successful in predicting transfer than a one-dimensional model.

This study revisited Noe's (1986) construct motivation to transfer. In a series of CFA analyses, it was shown that motivation to transfer has a three-factor structure consisting of autonomous motivation to transfer, controlled motivation to transfer, and intentions to transfer. This factor structure was built on a combined motivation theory approach unifying self-determination theory (educational psychology), expectancy theory (management), and the theory of planned behavior (social psychology). In a PLS-modeled path analysis, the study showed that social cues influenced controlled motivation, but not autonomous motivation; affective cues had an impact on both autonomous and controlled motivation. Intentions to transfer mediated the effect of autonomous motivation on training transfer. Compared to past transfer motivation research, this study tested several new directions that have theoretical implications. First, the motivational sequence explored indicates that intentional transfer processes cannot be captured with a single scale; rather motivational states and traits associated with social and affective cues can form an interdependent account of learner and environment (Hickey et al., 2001; Järvelä et al., 2009) This interdependency regulates motivation and has a differentiated effect on motivation and intention (Vauras et al., 2008). Second, the measurement time three months after training can be seen as a significant step toward developing an understanding of how motivation to transfer is affected when the learner interacts within her/his routine work environment, not affected by the training condition. More research in the temporal dimension of transfer motivation is needed, however, to overcome what was termed the dynamic problem of motivation to transfer (Gegenfurtner et al., 2009b). There are three limitations. First, the data consisted of self-report measures only. This was deemed appropriate for this study because the interest was in the trainees' subjective attitudinal, motivational, and intentional perceptions. However, we are aware of problems associated with leniency and self-serving bias that can likely occur in self-reported material. Second, study implications are constrained by characteristics of the population of trainees in occupational health education from which the sample was drawn. Third, generalization of the findings is limited to the time period three months after training. Since motivation to transfer is assumed to be a dynamic construct, all relationships explored must be considered with caution when generalizing to a different time frame.

# Known Knowns and Unknown Knowns: Multiple Memory Routes to Improved Numerical Estimation

Dav Clark, Psychology Department, University of California, Berkeley, davclark@berkeley.edu
Michael Andrew Ranney, Graduate School of Education, University of California, Berkeley, ranney@berkeley.edu

**Abstract:** Conceptual change represents a crucial, challenging, learning component. This study hypothesized and observed evidence for two parallel forms of learning within the Numerically-Driven Inferencing (NDI) paradigm's rather minimalist intervention of providing direct feedback regarding a numerical estimate—feedback that yields remarkably robust cognitive alterations. The present experiment probed the nature of learning apropos recall or estimation improvements observed after participants (a) provided estimates, (b) received feedback, and (c) re-estimated after waiting for one day. The results show that improved estimation/recall was predicted by two independent elements—surprise at feedback and an explicit sense of episodic recall upon testing. This suggests at least two learning processes: (1) an explicit (though perhaps approximate) recollection of a quantity's magnitude and (2) a non-episodic semantic restructuring that correlates with surprise. Thus, even for concise, factual information, we educators might consider students' "unknown knowns"— knowledge that learners gain without any explicit understanding that they have done so.

## Introduction

Various streams of cognitive research suggest that significant conceptual change is difficult to effect (Chi, 2005; diSessa & Sherin, 1998; Lord, Ross, & Lepper, 1979). Numerically-Driven Inferencing (NDI) procedures, however, have yielded notable and encouragingly long-lasting levels of conceptual change with quite minimalist interventions (e.g., by providing estimators with a single, critical, highly germane, feedback statistic; cf. Rinne, Ranney & Lurie, 2006). The EPIC procedure represents one such intervention that is relatively compact and well specified (EPIC and NDI were introduced by Ranney, Cheng, Garcia de Osuna, & Nelson, 2001). Notably, EPIC has been shown to induce long-lasting conceptual change (e.g., Ranney et al., 2008), as evidenced by increased accuracy on estimations up to 12 weeks after the procedure (Munnich, Ranney & Bachman, 2005). If one can determine the cognitive factors that drive the efficacy of this particular curricular intervention, one might then be able to target these factors in developing and refining other pedagogical strategies.

In the EPIC procedure, participants engage with real-world numerical facts that bear on a societal issue, such as abortion, criminal justice, the environment, etc. (e.g., Garcia de Osuna, Ranney, & Nelson, 2004; Munnich, Ranney, Nelson, Garcia de Osuna, & Brazil, 2003). An example item/quantity is "the ratio of murders committed to prisoners executed in the U.S." People often poorly estimate these quantities, and thus the true values are surprising to many individuals. For the example above, individuals estimated anywhere from *two* to *a million* murders per execution (Munnich et al., 2003). (This broad range of innumeracy might be compared to order-of-magnitude errors made in reasoning about physics problems, although crime and physics likely diverge in terms of the complexity of, and one's familiarity with, their respective causalities.) Such starkly diverging estimators might have quite different beliefs regarding the effectiveness of capital punishment as a deterrent to murder (given that deterrence is commonly used in reasoning by both pro- and anti-execution participants).

Successful classroom curricula have been developed for improving students' estimation abilities as part of our laboratory's research on NDI—both in the contexts of high school mathematics and elite graduate journalism classrooms (Munnich, Ranney, & Appel, 2004; Ranney et al., 2008). The EPIC procedure is one component of these curricula in which participants (1) provide an **Estimate** for each policy-relevant item, (2) state what they would **Prefer** each quantity to be, (3) receive actual quantities as feedback to **Incorporate** (as new "**Information")**, and (4) indicate whether their preferences have **Changed** upon receiving feedback. Regarding change, our laboratory found that, after learning that about 250 murders occur per executed U.S. prisoner, participants significantly changed their preferences about the ratio (Munnich et al., 2003).

A fundamental question in cognition concerns the nature of what is learned. Some well-established psychological learning and memory models (Nadel & Moscovitch, 1997) would predict that changes in estimation accuracy must ultimately be mediated by episodic memory (which could give rise to abstracted semantic memories via a process of consolidation). In this case, we would expect participants' explicit memory for feedback (the "I" in EPIC) to correlate well with improvements in estimation accuracy at subsequent testing. Recent evidence suggests, however, that the re-modeling of existing conceptual structures may not depend on episodic memory formation (Tse et al., 2007). Indeed, there is broad evidence that learning may often be subserved by multiple memory systems, perhaps acting in parallel (Clark & Ivry, in press). In this case, we might expect increases in estimation accuracy even when participants report no memory whatsoever for the quantity provided as feedback—particularly if participants had pre-existing knowledge to support such learning.

Surprise upon receiving feedback provides evidence for pre-existing knowledge—specifically an incorrect prior expectation regarding the true value. Thus, surprise may correlate with the kind of non-episodic re-modeling described above. However, surprise may also reflect the emotional impact of the information (Munnich, Ranney & Song, 2007; Thagard, 2006). Therefore, it is important to assess not only surprise, but also whether the surprise had an emotional or intense character. In other words, surprise may mediate improved episodic memory, or it may indicate the existence of prior knowledge that may facilitate changes in semantic memory. Of course, these routes to improved estimation may operate partly or wholly in parallel.

While the hypotheses that follow are certainly not exhaustive, they constitute a set of potential reasons for the efficacy of the EPIC procedure. Most generally, engaging in estimation with feedback may result in a general increase in one's estimation ability (as Ranney et al., 2008, observed following a one-week, EPIC-related/inspired curriculum); such an effect would be seen even for items that received no feedback. We additionally considered that learning would be driven by surprise (e.g., Munnich et al., 2005). Moreover, improvements in estimation could be driven by a direct (potentially approximate) episodic memory of feedback. If *all* improvement were driven by episodic memory, though, we would expect little extra power in a model that included both surprise and episodic memory ratings beyond the power of a model that only included one of these. If, however, a model including both surprise and memory provides a significantly better fit, this offers some indirect evidence that at least a portion of improvement is occurring through a non-episodic route.

We additionally considered the optimal timing for feedback: Immediate engagement with feedback following the generation of an incorrect estimation may (a) interfere with the successful learning of the new, correct, immediately provided information. However, another possibility regarding immediate feedback is that it may (b) help encourage an individual to both engage with and correct her beliefs. Thus, if we were to find that participants improve more with *delayed* feedback than immediate feedback, hypothesis (a) would be supported. Alternatively, if performance were superior with immediate feedback, (b) would seem more plausible.

## Experimental Methods

The following experiment was designed to assess whether estimative improvement occurs even with respect to items for which no feedback was received—as was found in curricular NDI studies (e.g., Munnich et al., 2004; Ranney et al., 2008). The experiment addresses (1) the effects of the timing of feedback on subsequent improvements in numerical estimation—as well as (2) whether these improvements are necessarily mediated by episodic memory. A subset of the EPIC procedure was used to explore these issues; participants engaged only in estimation ("E") and feedback ("I"), leaving aside personal preference (“P” and “C”).

### Participants

Twelve people (seven female) participated (and 19 participated in a later experiment that replicated our main findings), including University of California, Berkeley, undergraduates and members of the general public recruited via online recruitment systems (RPP and RSVP). They received either course credit or $20 for their participation in two one-hour sessions over two consecutive days. Ages ranged from 18-56 years.

### Materials

Numerical facts (106 of them) were selected from Ranney et al.'s (2008) collection (See the introduction for an example). Three statistical facts were set aside for the basis of example items (namely US population, world population, and US Gross National Income). Items ranged over a number of topics, and included politics, population dynamics, economics, the environment, education, crime etc. Most items were expressed in percentage form, with the rest being counts of dollars, people, events, or things. For numbers above 999, a comma was used, as in "13,600." For numbers in the millions, billions, or trillions, the appropriate word was used to indicate the order of magnitude (e.g., "300 million"). This was intended to minimize possible confusions about the exact value of the number.

### Procedure

Custom software utilizing Vision Egg (Straw, 2008) presented all materials and collected responses (source code available upon request). Descriptions of numerical facts were presented in four or fewer lines of text (with fewer than 55 characters per line). A prompt for numeric entry was located below the description. Feedback concerning the veridical value was provided in a third location, between the description and the text-entry area.

#### Blocks of Items

Items were randomly distributed into the following four kinds of blocks. Each of these blocks was involved in two or more phases over the course of the experiment. **E**: Participants *only* provided **Estimates** in a single phase. **EI**: Participants provided **Estimates,** followed *immediately* by correct numerical **Information** as feedback (i.e., feedback was provided in the same phase as the initial estimation). **E_I**: Participants provided **Estimates**, and then received correct numerical **Information** in a phase that was *well-separated* (but by less than 45 minutes) from the phase in which they provided their Estimate (i.e., "_" signifies a temporal delay). **New**: A block of items was reserved to provide a gauge of false recognition or false recollection.

## Experimental Phases

Participants engaged in a number of self-paced phases on each of the two consecutive days, as Figure 1 depicts. The structure of stimulus presentation and response collection was uniform across a given phase. During the first day, analogous to a "study" period, participants completed three partially similar phases of numerical estimation and/or informative feedback. (See Phases 1-3 in Figure 1.) The second day was analogous to a "test" period, in which participants' learning was assessed (Phases 4-7 in Figure 1).

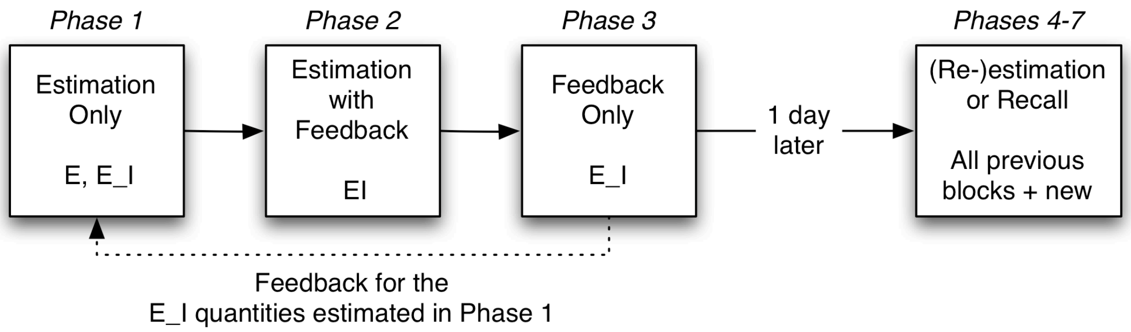

Figure 1. A schematic of the experiment's seven phases. *Phase 1*: Estimates were obtained for the E and E_I blocks of items (23 each), randomly intermixed in one phase. *Phase 2*: Participants provided 23 Estimates that were immediately followed by Informing the participant of the correct value. *Phase 3*: Feedback (I) was provided for the 23 items from the E_I block that had been Estimated in Phase 1. *Phases 4-7*: Subjects estimated (or recalled) quantities and provided explicit memory ratings for all previous items as well as 34 new items.

During estimation (Phases 1 and 2, with 23 items each), subjects were given a textual description of an item's quantity, followed by a prompt to provide an estimate. For Phase 2, feedback was provided 500 milliseconds after each estimate was entered. For Phase 3 (with 23 items), the correct numerical value was provided *prior* to the textual description in order to minimize covert estimation.

In Phases 2 and 3 (thus, for blocks including "I"), participants provided a self-report on their subjective sense of surprise. Their responses were restricted to the following three choices: (1) Little or no surprise, (2) Genuine surprise, or (3)"Visceral" or intense surprise. The presence of any form of surprise is an indication of pre-existing memory structures, while the distinction between levels (2) and (3) may indicate a difference in the emotional impact of the feedback for that item. (Note that Munnich, Ranney, & Song, 2007, found that a prospective measure of surprise reliably predicted the sort of retrospective surprise ratings solicited here.)

On Day 2, trials were similar to the estimation-only trials in Phase 1 described above in that no additional feedback was provided. An additional 34 items from the "new" block were randomly intermixed with the items presented during study. Furthermore, participants rated their memory for the item according to the following four levels: (1) "The item is new to me," (2) "The item was presented yesterday, but I have no sense of the value provided as feedback," (3) "The item was presented yesterday, and I have some sense of the correct value," or (4) "The item was presented yesterday, and I have a fairly accurate recollection of the value."

Choice 1 indicates no recognition or recollection. This is equivalent to labeling the item as "new," and it is the correct response for items from the new block. As a group, choices 2-4 indicate that the item is "old," but with varying levels of familiarity and/or recall. These are correct responses for the E, EI and E_I blocks (although choices 3 and 4 entail a belief that the participant actually received feedback at study, and so might also be considered incorrect for the E block). Choices 2 and 3 indicate perceived recognition, but at least a partial failure in explicit recall. Choice 4 indicates a subjective sense of fairly complete recall.

Explicit recall is used herein in a somewhat different way than in most learning and memory studies. Indeed, these memory ratings can be viewed as a form of metacognition regarding the estimation process.

## Analysis

We modeled improvement as a binomial outcome (as did Munnich et al., 2005). This allows for the treatment of items that have differing distributions within a unified framework. (It would be difficult modeling both percentages and values in, say, the billions, particularly given our sample size.) Items were labeled as to whether estimates improved or not. These labels were fit with a binomial generalized linear model, using the lme4 package in R. This treatment allows for a full multi-factorial mixed-effects analysis. Below, participants are always included as a random effect, and other factors are treated as fixed effects. Contrasts were evaluated using the multcomp package, which controls for family-wise error rate (Hothorn, Bretz, & Westfall, 2008).

Unless otherwise noted, data were pre-processed to remove ties. This was done to allow for a null hypothesis that 50% of the remaining items randomly improved and 50% randomly worsened. If we counted ties as failures to improve, then random drift would end up spuriously suggesting the lack of an effect. Removing ties allowed for tests of whether estimates, on average, improved more than they worsened—both formally and when examining graphs. Otherwise, the removal had little effect on the results.

## Results

### Improvements in Participants' Estimation Accuracy and/or Numerical Recall

Figure 2 shows the proportions for the number of items showing improvement (to any degree), by condition. We can easily reject a null model (i.e., with all conditions modeled by the same mean) in favor of a model including the three feedback conditions ($\chi^2(2) = 25.9$, $p < 10^{-6}$). Post-hoc comparisons between each condition and chance levels, as well as between condition comparisons (as in a Tukey HSD test) were performed simultaneously. In the no-feedback condition (E), estimation improvement did not differ significantly from chance ($p = .39$), although improvement with Immediate (EI) and Delayed (E_I) feedback were clearly above chance ($p < 10^{-4}$). This may seem quite expected, but it *might* have been the case that improvements were at least partially driven by general improvements in estimation skill, and this would have led to at least some modest improvements even without feedback on test items. Indeed, this kind of estimation skill development was the successfully accomplished goal of various EPIC-based curricula (e.g., Munnich et al., 2004; Ranney et al., 2008). In the present, less extensive, experimental manipulation, though, we understandably elicit no such skill improvements. Thus, we assume that these improvements are driven almost entirely by item-specific learning.

Figure 2. Proportion of items from each block for which estimates improved on Day 2 (as compared to estimates on Day 1). Items with identical estimates on Day 1 and Day 2 have been removed; thus chance is .5. Asterisks note significant differences.

Contrary to part of our hypotheses, participants exhibited essentially equal proportions of estimation improvements for the EI and E_I blocks. While these treatments yielded significantly more improvement than for the no-feedback case (both $p$'s $< 10^{-4}$), they did not differ significantly from each other ($p = .79$).

### Recollection and Surprise

As is often the case, the participants' forced familiarity judgments appeared to be superior to their own assessments of their memory (Merikle, 2007). In participant debriefings, several individuals claimed to be uncertain as to whether items were old even from Phase 1 to Phase 3 for items in the E_I block—over an interval of less than 45 minutes! However, participants performed well at discriminating between old and new items a day later when given a forced choice; 76% of new items were identified as new on Day 2, compared to an average of less than 9% regarding previously seen items. This level of recognition accuracy is not surprising, given the considerable depth of processing involved—and the rich, pre-existing, memory structures available for scaffolding these episodes. (This may be another point of departure regarding items such as the likelihood of a murder ending in an execution, in contrast to the pre-existing memory structures K-16 students might hold regarding the physics of mechanics or electromagnetism. In both cases, though, it seems probable that multiple conceptual changes may result—e.g., "Wow, the high murders-per-execution ratio makes me think [a] that gangsters would rarely fear the death penalty, given [b] how rarely their fellow gang members are executed and [c] that death rows are basically blossoming geriatric wards, meaning [d] that gangsters would be more likely to bring guns." Such conceptual changes do not seem wildly different, in many important respects, than those required to understand that ballistic trajectories are curvilinear, rather than diagonally rectilinear.)

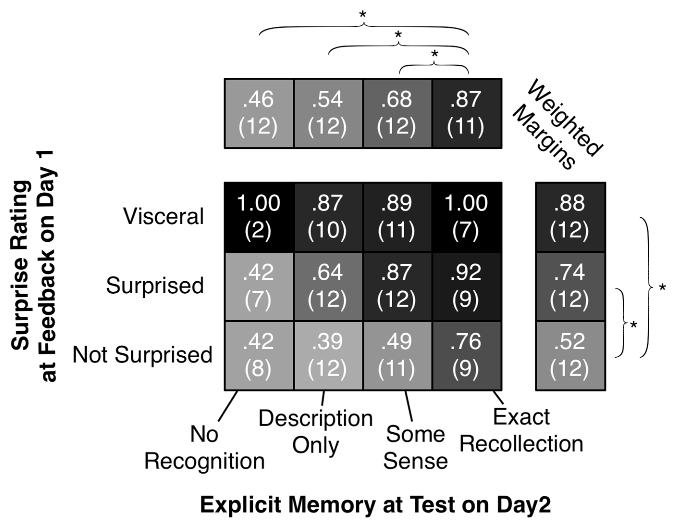

Figure 3. Proportions of items with improved estimation accuracy (or recall) on Day 2. The effects of surprise (Day 1) and explicit memory rating (Day 2) are shown independently via weighted margins, and (the lack of) an interaction via the central table. Asterisks note individual factors' significant differences; significant interactions were not observed. Only items with specific feedback are included (i.e., EI and E_I conditions). Proportions represent between-subject means, and the number of subjects contributing to each cell is shown in parentheses.

As the no-feedback condition (E) yielded non-significant changes in estimation accuracy, we hereafter consider only items from conditions including feedback ("I"; i.e., EI and E_I). These effects are depicted in Figure 3. We find that a model with both surprise and declarative memory responses cannot be rejected in favor of a reduced model excluding memory ($\chi^2(3) = 34.8$, $p < 10^{-7}$), and the comparison involving the removal of surprise is even more striking ($\chi^2(2) = 295.22$, $p < 10^{-16}$). An inclusion of an interaction term does not yield a significantly superior model ($\chi^2(6) = 2.85$, $p = .8$), nor does the inclusion of the feedback condition (EI vs. E_I; $\chi^2(1) = .8$, $p = .36$). There was a small but non-significant difference between surprise ratings for EI and E_I blocks: subjects rated 65% of EI block items as surprising ("2" or "3") vs. 59% for E_I. No straightforward trend was observed with explicit recollection. The timing of feedback may have some effect on estimation improvement that is mediated by surprise, but such issues seem best addressed in subsequent research. Below, we only consider comparisons within surprise level and memory ratings independent from one another.

"Exact recall" for the value of a given item (i.e., memory response "4")—as compared to other memorial impressions—was a highly significant predictor of improved estimation ($p$'s < .001 for ratings "1" and "2;" $p = .01$ when compared with response "3"). No other comparisons between memory levels were significant. For surprise, items with moderate and visceral ratings were significantly more likely to exhibit improvement than those with a no-surprise rating ($p < .002$ in both cases), but did not differ significantly from one another. According to our earlier logic, this suggests more of an effect of prior knowledge than emotional impact, although emotional impacts may still play nontrivial roles. Note that participants provided the exact numerical figure given as feedback only 35% of the time when selecting choice 4. Even if we broaden this accuracy criterion liberally to items for which participants are within 15% of the true value, they were only correct about 74% of the time.

Finally, if we consider the link between surprise and explicit recall, there seemed to have been little relationship in the present study (as opposed to some other studies). The correlation of fixed effects between memory and surprise terms in our model was consistently smaller in magnitude than .1. This, combined with the lack of a significant interaction term, provides some evidence for independent learning processes.

## Exclusions

As many as three items lacked estimates from some subjects or exhibited a clear lack of understanding in a response (e.g., a "10 million" response for a question soliciting a percentage) and these items were excluded from the analyses above. Due to a technical issue, one participant did not receive the standard E manipulation, but was included in memory and surprise-related analyses, as these analyses did not include E trials.

## Discussion

Given the overall improvements in estimation ability evidenced in curricular studies by Munnich et al. (2004) and Ranney et al. (2008), it is of interest that we see no statistically significant improvement in items that didn't receive feedback (the "E" block). Nonetheless, it seems that learning in this considerably shorter present experiment was largely item-specific and related to the integration of feedback. This lack of improvement in the present experiment may be due to a lack of time for reflection or the development of strategies—which were highlighted, taught, and fostered in the curricular studies. (Munnich et al., 2004, and Ranney et al., 2008, also focused, to a fair degree, on preferences and personalized policies.)

In addition, we had originally hypothesized that the EI block would yield the greatest overall improvement in estimation. We assumed that immediate feedback would be more memorable because participants would have the opportunity to directly compare their estimate with the actual value and consider its validity. This would have arguably led to a more tangible interaction with the true value than in the E_I condition. However, our data show that the E_I block, if anything yielded larger improvements. (Although EI and E_I conditions did not significantly differ, this pattern has held up in subsequent experiments as well.) This may be due to a number of reasons, warranting further experimental inquiry.

One possibility is that we are observing something akin to a distributed learning effect—because even though the feedback is provided only once, the size of the effect is reminiscent of the effects of well-spaced study periods reported by Pashler et al. (2007). Note that this is a major departure from standard spacing effects, as the correct information is presented *only once.* However, while EI items were only shown once before testing, item descriptions in the E_I condition were shown twice—initially in Phase 1 (when participants provided their initial estimates) and again in Phase 3 (when participants were given feedback). This may have enhanced those items' representations (e.g., with a bit more time-on-task), providing a richer or more stable context for incorporating feedback (as with Tse et al., 2007). On the other hand, these data might also suggest that we have not explored the most relevant timescales. For example, the optimal estimate-feedback delay may be much shorter, as with the work of Johnson and Siefert (1994). A final possibility is that the participants' assessments of surprise at receiving feedback may inappropriately draw their attention back to their incorrect prior knowledge. Thus, we might find generally enhanced learning and larger effects of feedback spacing, were we to encourage participants to engage more fully with the new information—perhaps as is done in the usual EPIC procedure, in which participants revise their preferences/policies based on the new information and the inferencing that such feedback triggers (as in Munnich et al., 2004, and Ranney et al., 2008).

## Learning Without Recall

From the point of view of a memory theory, the most interesting result is perhaps the existence of learning even when participants claimed "no sense" of the numerical value provided at feedback—rather like a memorial analog to blindsight (Merikle, 2007). This argues against the notion that improvements in estimation are simply the result of explicit episodic memory. The result is reminiscent of extant *dual-process* memory models. For example, Davachi et al. (2003) suggest that successful recognition could occur through a process of recollection and/or a sense of familiarity. These processes moreover appear to be subserved by distinct sub-regions in the medial temporal lobe. In the present study, we see improvement in numerical estimation—which is perhaps most akin to a cued recall task for EI and E_I items—without full recall of the number presented on the previous day. Thus, the task here is perhaps more naturally expressed in the language of the *remember/know* distinction (Knowlton, 1998). That is, while participants appear not to *remember* a number from the previous day, there is still a sense in which they *know* the number better than they knew it the day before.

Based on the significance of the existing results, however, it seems reasonable to posit that a non-episodic form of learning undergirds some of the improvement in participants' abilities to estimate accurately. Further, the learning for improved estimation (or memory) seems to occur even without an explicit recollection of the feedback from the prior day. This argues for some implicit and/or rapidly semanticized learning in support of these improvements.

## Educational Implications

We have provided support for the effectiveness of instruction that engages with a person's pre-existing knowledge. A finding of central importance to educators is the lack of improvement on E items. It seems that if the pedagogical goal is to improve numeracy, then simple engagement with a given set of quantities is not enough to enhance estimation abilities for other quantities. Item specific training could be augmented with more generalizable strategies, though, as has been demonstrated with other interventions (e.g., Munnich et al., 2004). Students' abilities to estimate quantities for which they *have* received feedback can be quite good, and it seems that there is at best a small effect of whether students think about their own beliefs immediately preceding or a day prior to receiving correct instruction. This effect is in line with results from elements of the distributed learning literature (Pashler et al., 2007)—perhaps with some form of priming for subsequent encoding occurring during one's initial estimation. Future studies will examine differing intervals for both feedback and retention. Given our results, though, it is clear that effective learning can occur over a panoply of semantic, statistical, items in a framework that includes engaging students' pre-existing understandings of the material. It is worth noting further that, unlike some other forms of conceptual change cited above, the nature of what was learned here may be of a more continuous nature than, say, "what determines the phases of the moon."

Such information may be more amenable to "implicit" forms of learning than concepts that have a more categorical, intricate, or non-linear structure. It bears considering, though, whether one can introduce more graded forms of learning into the logical structures of science and related fields.

In general, participants displayed fairly good recognition of items they had seen previously, distinguishing new items from ones presented the previous day. However, improvements occurred frequently even when participants claimed "no sense" of the feedback, particularly when they found the item surprising—in other words, when estimation improvement was predicted more by surprise than by explicit recall. In such cases, learners seem to have poor metacognitive inclinations—they do not "know what they know."

Combined with strategies for evaluating one's own estimates (e.g., those provided in curricula by Munnich et al., 2004, and Ranney et al., 2008), a learner could be encouraged to generate what they believe to be a "guess," but which might turn out to be well informed by what they have in fact learned. If encouraged to make such guesses, students should still spend time reasoning about their guess; prior work from our group (Ganpule, 2005) has indicated that good estimators spend more time representing a quantity before estimating it, consistent with work from the problem solving literature. Guessing too quickly is more often counterproductive. Indeed, this result encouraged the curricula of Munnich et al. (2004) and Ranney et al. (2008) to highlight the importance of self-critique and disconfirmation. (However, one of us anecdotally finds people, at times, to be markedly underconfident estimators. For instance, people frequently claim to have "no idea" of the population of California, yet often laugh out loud when asked if it could be "1,000.") Another idea is that students might infer something about the quality of their estimate by introspecting on whether they remember being surprised at a number during instruction. Such surprise could indicate an improvement of one's sense of magnitude.

More generally, participants were able to learn something in this experiment without being aware of their learning. This strongly suggests that non-episodic (i.e., implicit or rapidly semanticized) learning processes could be involved even in the development of "declarative" factual information. Thus, depending upon an instructor's particular pedagogical goals, one might proceed with instruction without concern for students' initial awareness of their improved sense of certain facts (perhaps as in "immersion" language-learning experiences). Over the course of an intervention, one would hope that students would eventually come to know and trust their new knowledge on the topic, but such metacognitive awareness needn't come lock-step with improvements in the more basic knowledge. This line of reasoning is reminiscent of studies of children applying abstract mathematical rules before they are aware of doing so (Siegler, 2000).

Of course there is also a clear role for explicit episodic recall in learning numerical information. In particular, when participants displayed zero or moderate amounts of surprise, improvements in estimation/recollection were likely only if they believed they could recall the number. Thus, when students lack sufficient schemas for incorporating the numerical knowledge and the information imparted is unsurprising, rote memorization may be virtually the only remaining route. Of course, a complete pedagogy could include the construction of knowledge structures that would then allow for the parallel recruitment of non-episodic learning.

Instructional materials that elicit surprise in students may allow such students to learn without conscious awareness that they have learned anything—at least in domains that are scaffolded by nontrivial preexisting knowledge. If the material is unsurprising, it appears that episodic encoding may be a critical step in successful improvement. It should be noted that "surprise" might be often used as too specific a notion. It may be that the relevant feature has more to do with general emotional, motivational, or inspirational, salience—or how interesting the material is to students. (See Kang et al., 2009, on connections between surprise, motivation, and curiosity, the latter two of which are likely enhanced by soliciting estimates—and even preferences—as in the EPIC procedure). Certainly, however, it seems that there are multiple routes to learning even relatively concise facts, and a successful pedagogy might usefully engage factors such as surprise and engagement with pre-existing knowledge to bolster more rote forms of learning.

## Acknowledgments

We thank Tawny Tsang above all others for myriad forms of assistance, Ed Munnich for extensive comments, as well as Andrew Galpern and other members of the Reasoning Group at UC Berkeley. Thanks also to Tom Wickens for statistical advice, Rich Ivry for his overall wisdom and support, and Mick Rugg and Lila Davachi for their input on experimental design issues. Finally, we thank UC-Berkeley's Committee on Research.

# The Role of Concretization in Acquiring Design Knowledge

Tamar Ronen Fuhrmann, tamarrf@gmail.com
Yael Kali, yaelk@technion.ac.il

**Abstract:** This research explored the nature of design knowledge by examining the processes in which graduate students in education learned to design educational technologies. We developed two rubrics to assess: (a) the degree to which students were able to translate their design ideas into concrete design artifacts (concretization rubric), and (b) the degree to which they designed artifacts that followed a socio-constructivist pedagogical approach versus a teacher-centered transmissionst model (epistemology rubric). Outcomes indicated that as students developed their concretization skills, they were able to become aware to and reduce gaps between their "theoretical" and "applied" epistemologies. By making their design ideas more concrete, students were able to carry out productive negotiations about these ideas with instructors and peers, and to explore them in relation to theory and to expert design knowledge.

## Rationale

Research in the learning sciences has shown that many opportunities to learn arise in the course of designing an artifact in general, and in designing an artifact intended for others to learn with, in particular (Papert, 1991). The potential of designing as a process that supports learning has been documented for a wide range of ages and levels of expertise. For instance, Harel (1991) explored the learning that takes place when fourth grade children develop mathematical software products for other students in their school. She showed that the young designers learned not only about mathematics (fractions) and programming (Logo), but also about design and user interface. Kafai (2006) showed similar outcomes with fifth grade children who designed and developed computer games for their peers. She argues that: "The greatest learning benefit remains reserved for those engaged in the design process, the game designers, and not those at the receiving end, the game players" (p. 39). The impact of engaging students in design processes on their learning was also found with middle school students; for instance, Kolodner et al. (2003) indicated that the Learning By Design approach significantly enhanced middle school students' motivation, their collaboration and metacognitive skills, and their scientific understanding in topics included in the products they developed (earth and life sciences).

In this research we explore the learning that occurs in a design process with a target audience that received only little attention in the learning by design literature, namely, graduate students in education. Researchers in various disciplines, such as the sciences of *learning*, *instruction* and *design* have recently begun to synthesize practical and theoretical knowledge regarding how to guide and inspire creators of innovative educational tools (DiGiano, Goldman, & Chorost, 2009). However, more research is required to better understand the ways in which graduate students in education—who are potential educators, curriculum-designers, learning-scientists, or policy makers—develop skills in designing technology-based curriculum modules, and how they can be supported in this process.

In an earlier study, Ronen-Fuhrmann, Kali, and Hoadley (2008), showed that there is an important added value in engaging graduate students in designing their own technology-based curriculum modules; while working on their design projects, students became more aware of gaps between what was defined as their "theoretical epistemologies about learning" (ideas expressed during general discussions about design, usually representing a socio-constructivist approach) and their "applied epistemologies about learning" (ideas reflected in artifacts they created, which tended to apply more transmissionist approaches), and were able to reduce these gaps. In this manner, students' epistemologies about learning became more coherent – an important outcome for students in education, whether or not they intend to design curriculum materials. In the current study we focus on the nature of knowledge and skills that students gain in educational technology design courses – a type of knowledge which the literature generally refers to as design knowledge. We focus on a specific aspect of design knowledge found in this research – the ability to concretize abstract design ideas, and explore the relationship between students' development of concretization skills and their ability to reduce their epistemological gaps.

## Research Settings

This research investigated the learning that took place in a semester-long course named "*Designing Educational Technologies*" designated for graduate students in science education, which was designed, developed and instructed by the authors of this paper. Students in the course were introduced with theoretical and practical aspects of educational technology design; they worked in groups of two or three to design a mockup of an educational technology module, but were not required to develop or implement these modules. The rationale was to focus on exploring students' learning while designing, without the constraints caused by any development tool, and without requiring a time-consuming development process.

The course was based on an instructional model, which evolved in an iterative design process in a previous study (Ronen-Fuhrmann et al., 2008). The final version of the model includes three main elements, which reflect a unique application and integration of three frameworks: (a) the ADDIE structure (Analyze, Design Develop, Implement, Evaluate) (Dick, Carey, & Carey, 2001). (b) the studio approach to instruction (Hoadley & Kim, 2003; Schon, 1983), and (c) the use of the Design Principles Database (DPD) (http://edu-design-principles.org), a web-based resource of socio-constructivist pedagogical design-principles, which were written by design experts (Kali, 2006; Kali & Linn, 2007; Kali, Linn, & Roseman, 2008).

## Methodology

We used a case-study methodology to examine students' learning processes and their development of design knowledge throughout the course. A collective case-study approach–often referred to as "multiple case study" (Stake, 1994)—was implemented. This approach is aimed at providing insights into an issue or problem or to refine a theory by exploring similarities and patterns between several case-studies. In this research, each group of 2-3 students, who worked on one design project during the course, was defined as a case-study.

The study was conducted with 14 groups (33 graduate students) who participated in three enactments of the *Designing Educational Technologies* course between the years 2005-2007. Most students had some experience in teaching or were active science teachers. They had some experience in designing curricula but most of them had no experience in designing technology-based learning modules. In order to characterize student learning in each of the iterations the following data sources were used (Table 1).

Table 1: Data sources.

| Data source | Description |
|---|---|
| Likert type surveys | At the end of each enactment students were asked to evaluate various elements of the course (such as the structuring of the design process, working with peers, using the DPD etc.) on a 1 to 5 scale. |
| Reflective essay | At the end of each enactment students were required to write a reflective assay about their design process. |
| Semi-structured interviews | At the end of each enactment we conducted interviews with two students who were asked to reflect about their design process. |
| Records of online discussions | Whole class online discussions about the literature and group online discussions regarding the design of the group's module were automatically recorded at the courses' website. |
| Student artifacts | During the semester we collected documents produced at various stages of the course. These documents included formal design artifacts students were required to write, as well as informal notes and sketches students created to discuss their ideas with peers and with us. |
| Reflective journal | Following each class-meeting we documented events related to each of the groups' progress, the discussions we had with students, or other events that seemed relevant for analyzing each group's learning processes. |

These data were analyzed using two rubrics; the first, entitled "concretization rubric" was used to evaluate the degree to which students were able to translate their design ideas into design artifacts; the second, entitled "epistemology rubric" was used to examine the epistemological changes that students went through during the course. We explain our rationale for developing these rubrics, and the way we used them in the sections below.

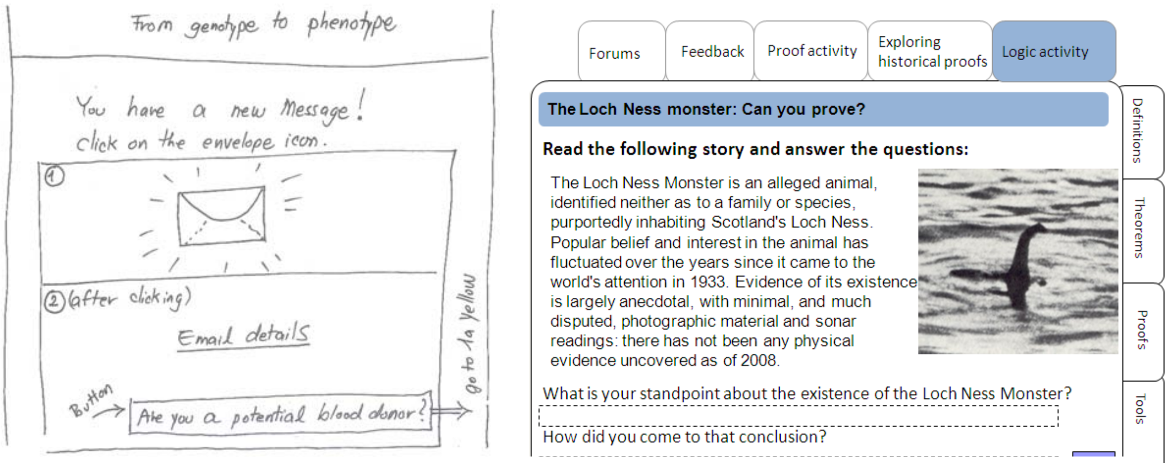
### Concretization Rubric

From early stages of the research we noticed that some students were able to easily translate their design ideas into concrete artifacts, while other students found this process very difficult. Following our preliminary observations, we decided to focus our assessment of design artifacts created by students using this lens. We developed a rubric (Table 2) which describes six levels of concretization of design ideas. Each level is associated with a stage in the design process in which a higher level of concretization is required. Thus, level 0 represents a stage in which students are required to discuss their module only in a theoretical manner. Level 5 represents the highest level of concretization; an artifact at this level should depict a full learning environment with a clear navigation system illustrating sequences of activities with clear instructions for learners.

It is important to note that although each stage in the instructional model was designed to provide students with the design skills required at that stage, including guidelines for concretization, we did not anticipate a one-to-one relationship between the knowledge taught and the knowledge gained by students at each stage. We also want to stress that we do not view concretization as a goal of the design process. Rather, we refer to concretization as important means to reach pedagogically sound artifacts.

Table 2: Rubric for assessing concretization of design ideas.

| *Level of concretization* | *Design Artifact Characteristics* | *Example Student Expressions and Artifacts* | *Required in Stage* |
|---|---|---|---|
| 0 – Theoretical knowledge | No design artifact. Only theoretical sayings regarding a planned module. | "It's very important to build activities that would be relevant and interesting to the learner" | Analysis |
| 1 – Collection of design ideas | A collection of design ideas for the module. The ideas only generally refer to the way a learner might act in the module. | "Learning throughout the whole module should follow a specific inquiry question". (Excerpt from a discussion of one of the groups regarding their design of a biology module. They planned to design the activities around an inquiry question but were not concerned at this stage about the nature of this question). | Brainstorm Activities |
| 2 – Initial activity sequence | Graphical or verbal description of a set of activities, with an indication of which activity should take place before or after another. | "First we should show them [the learners] the story about the family tree, then have them review the algorithm for scanning the tree, and then use the simulation" (Excerpt from a discussion regarding the design of a technology for high-school computer-science learners) | Build Flow |
| 3 – Initial translation into features | Ideas are translated to actual features and presented in a way that shows how a learner might act in the module. | Figure 1a shows a sketch of the way students envisioned an activity they planned for a module in genetics. Learners in this activity were required to decide whether they can donate blood to a kid with cystic fibrosis. At this stage this was the only activity they developed in their module. | Design Features |
| 4 – Initial learning environment | Mockup of the module showing some of the activities, with instructions for learners. An initial navigation system is present. | (See Figure 1b showing design knowledge level 5 – full learning environment as reference). | Mockup: Iteration 1 |
| 5 – Full learning environment | Mockup of the module showing most of the activities with clear instructions for learners. A clear navigating system is represented. | Figure 1b shows one screen from a mockup of a module designed for teaching logical thinking for middle school math students. The buttons at the top and side of the screen indicate that this screen is part of the whole learning environment. Each of these buttons was linked to a screen in the mockup, which was developed in a similar level of detail. | Mockup: Iteration 2 |



(a) Design artifact showing level 3 of concretization (b) Design artifact showing level 5 of concretization

Figure 1. Examples of artifacts showing levels 3 and 5 of concretization.

## Epistemology Rubric

The term "epistemology" in the learning sciences has traditionally referred to several entities in the nature of knowing, such as beliefs, conceptual understanding, perceptions, feelings and emotions. Since our analysis did not enable us to fully distinguish between these entities, we decided to use the general term "epistemology" in order to refer to any idea regarding how people learn expressed by the students, in their sayings and doings.

As mentioned above, a gap between students' "theoretical" and "applied" epistemologies was revealed in an earlier stage of this study (Ronen-Fuhrmann et al., 2008); at the beginning of the semester, when engaged in theoretical discourse, students tended to advocate socio-constructivists paradigms, whereas when engaged in designing their technology-based modules, more than half of the students tended to neglect these ideas and apply more traditional approaches.

In order to quantitatively assess "low" and "high" levels of epistemology, we relied on studies that describe an instructionist view of learning as equivalent to naïve epistemology, and a socio-constructivist view, as analogous to sophisticated epistemology (Maor & Taylor, 1995; Schommer, 1990). Inductive analysis of our data indicated that there are three main dimensions in students' sayings and artifacts in the design process, which express their epistemologies: (a) learner activity, (b) collaboration, and (c) content accessibility. We used these dimensions to develop the epistemology rubric (Table 3)

Table 3: Epistemology rubric.

| Dimension | Low | Medium | High |
|---|---|---|---|
| **Learner activity**<br>The degree to which students expressed ideas that support active engagement of learners within a technology-based learning environment. | Passive: e.g. learner reads or views information. | E.g. learner clicks on links. | Active: e.g. learner manipulates variables |
| **Collaboration**<br>The degree to which the students supported using technology in ways that enable learners to learn from each other | Individual learning | Group work is not supported by technology | Collaboration is intrinsic to the activity |
| **Content accessibility**<br>The degree to which students expressed views that support making the contents of a learning environment accessible to learners. | No effort to connect contents to student world | Motivational aspects are extrinsic to activities | Motivational aspects are intrinsic to activities |

We would like to note that we used the epistemology rubric to assess the level of epistemology expressed in the artifacts created by *groups* of students rather than by individuals. Although in many studies epistemology is attributed to the individual, our rationale for studying group epistemology is based on the work of researchers such as Fuller (1987) and Goldman (2008), who claimed that there is a strong social aspect to epistemology, which cannot be overlooked; the individual's way of thinking is considerably influenced by the ideas expressed by the group of people he or she is interacting with.

## Data Analysis Procedure

To assess the design artifacts of the 14 case-study groups using the two rubrics, we first created digital portfolios for each group, which included all in-progress and final documents created by the group, all of the individual students' posts in the course's discussion forums, transcriptions of interviews (if there were any for students in the group), and their reflective essays. Each portfolio was organized by the stage of the design process (Analysis, Brainstorm, Build flow etc.). To refine initial versions of both rubrics, we took one example case-study, and had four researchers—two external researchers and the two authors of this paper—assess the degree of concretization and epistemology of the group at each stage of the design process. Initially, about 60% agreement was reached. Following several cycles of refinement of the rubric, in which more case studies were assesses, we reached a degree of about 90% agreement between researchers using the current version of the rubrics. In this manner seven of the portfolios (50% of the cases) were assessed. The rest of the case-studies were then assessed by the authors of this paper together (without comparison of individual assessments).

## Combining the Two Rubrics to Map Findings

Initial analysis of the findings showed that using each of the rubrics described above, we can distinguish between two patterns of learning. Using the concretization rubric, we found that one pattern was represented by groups who had difficulties in concretizing their design ideas. The concretization level of their artifacts at various stages of the design process was lower than the level required at that stage (see Table 2). On the other hand there were groups whose pattern did not show any difficulty with the concretization and were sometimes even ahead of the required level in the design process. This enabled us to refer to the dichotomy: *Low versus High* pace of concretization skills acquisition. Using the epistemology rubric, we were able to clearly distinguish between one pattern, in which groups of students showed a gap at beginning stages of the semester, as described above, versus another pattern of those who showed a coherent epistemology throughout the semester. This enabled us to refer to the dichotomy: *Coherent versus Non-coherent* pattern of group epistemology. Using these two dichotomies, we developed a four-quadrant matrix (Figure 2) to map our findings regarding the relations between concretization and epistemology.

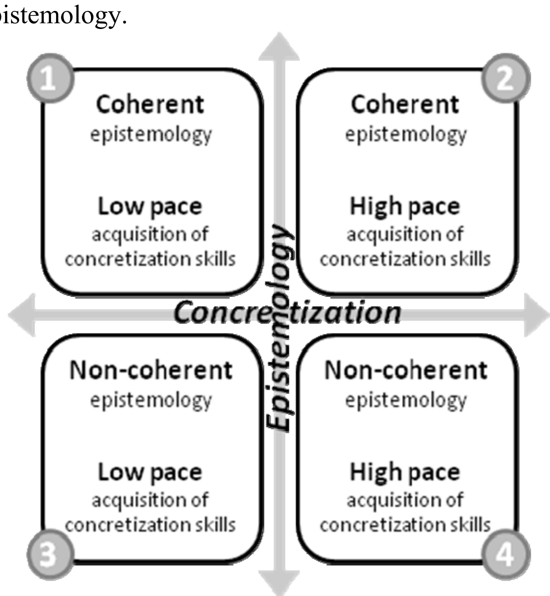


Figure 2. The four-quadrant concretization/epistemology matrix.

## Outcomes

Following an in-depth analysis of each of the 14 case-studies, in which we used both the concretization and the epistemology rubrics using all the data sources, we were able to map the cases into the four-quadrant matrix. The results of this mappying are represented in table 4. As can be seen from the the table, two of the cases were mapped in quadrant 1, another two in quadrant 2, three more in quadrant 3, and 7 cases—more than half of the students—were mapped in quadrant 4. Additionally, the anaysis of each of the cases' patterns of learning revealled that groups that were classified as belonging to quadrant 4 significantly reduced their episteomogical gaps throughout the semester, whereas groups that belonged to quadrant 3 only did so to a small extent. We argue that the high pace of their acquisition of concretization skills was an important factor in enabling groups in quadrant 4 to reduce their epistemological gaps. To support this claim, which we further discuss in the final section of this paper, we first describe in detail one case-study representing and illustrating the learning processes of groups that were classified as belonging to quadrant 4.

Table 4: Mapping of the 14 case-studies using the concretization/epistemology matrix.

| ***Quadrant*** | ***# of Groups*** | ***# of Students*** | ***Pattern*** |
|---|---|---|---|
| **1** | 2 | 5 | Coherent epistemology throughout the semester<br>Low pace of acquiring concretization skills |
| **2** | 2 | 4 | Coherent epistemology throughout the semester and<br>High pace of acquiring concretization skills |
| **3** | 3 | 6 | Non-coherent epistemology at beginning of semester<br>***Minor reducing of epistemological gap***<br>Low pace of acquiring concretization skills |
| **4** | 7 | 18 | Non-coherent epistemology throughout the semester and<br>***Major reducing of epistemological gap***<br>High pace of acquiring concretization skills |
| **Total** | 14 | 33 | |

## Illustrating Learning Processes in Quadrant 4: The case of I,S&E

I,S&E designed a technology-based module designated for high-school computer-science learners. Their module focused on recursive algorithms for scanning data-structure trees. One of the features they designed, from very early stages of the design process was an animation that demonstrates a certain algorithm for scanning a tree. Their (potential) learners were required to solve problems that utilize the demonstrated algorithm.

Analysis of the design artifacts they produced at various stages of the design process using the concretization rubric (left graph in Figure 3) indicates that this group's acquisition of concretization skills was of a high pace (high pace was defined as a slope that is higher or equals to 0.75, where each stage of the design course was numbered consecutively starting with "*Analysis=1*"). I,S&E had come up with the idea of the animation as early as the *Analysis* stage (in which they were still not required to suggest ideas for activities). They continued at a "normal", or "required" pace (see dotted line in Figure 3 - left graph) in the *Brainstorm Activities* and *Build Flow* stages. When required to design features, they were still struggling with their flow of activities, but they gradually progressed until they reached level four of concretization in their final mockup.

The analysis of IS&Es' learning process using the epistemology rubric (Figure 3, right side) revealed that at the beginning of the semester, in general discussions about educational technologies, each of these students expressed ideas that we classified as high level of sophistication with regards to epistemology (level 3 in each of the dimensions of the epistemology rubric). However, as can be seen in figure 3, there was a large drop at the *Analysis* stage, with respect to the *Learning Activity* and *Content Accessibly* dimensions, which continued with a drop of the *Collaboration* dimension at the *Build Flow* stage. These drops represent the gap described earlier, between "theoretical" and "applied" epistemologies. Specifically, when IS&E began to design their animation, it required learners only to passively watch the animation, and there was no attempt to make the contents more accessible. Collaborative aspects were minimal (a forum was designed for Q&A). Gradually, as this feature was revised following discussions with peers and instructors, and following the use of the Design Principles Database, this feature became a manipulable tool, which enabled learners to solve problems by exploring various ways to scan given trees, as well as their own trees. Our analysis of their final mockup, using the epistemology rubric was as follows: Learning Activity = 3 (learner manipulates variables); Content Accessibility = 2 (motivational aspects were eventually at an intermediate level); Collaboration = 3 (activities that required learners to solve problems in tasks created by their peers were designed). Thus - we interpreted their learning process as representing a major reduction of their groups' epistemological gap. The dotted line in left graph of Figure 3, which represents the average between the three dimensions, illustrates this reduction of the epistemological gap.

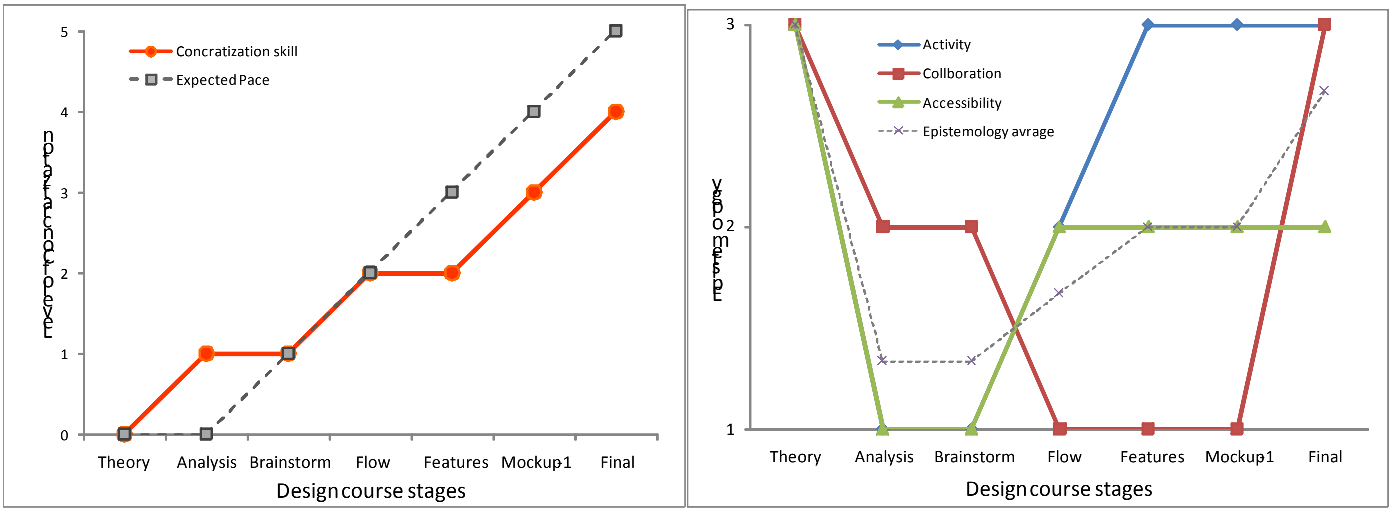

Figure 3: Analysis of the learning processes of I,S&E: Acquisition of concretization skills (left), and changes in group epistemology (right)

## Discussion

The mapping of the 14 case-studies using the four-quadrant concretization/epistemology matrix, revealed the important role of concretization in helping students to reduce epistemological gaps. The cases mapped in quadrants 1 and 3 illustrate that moving from general design ideas to actual activities was a difficult task for many of the students. Concretization of a high level, in the context of educational technology design, requires not only to design the details of certain features, but also to be able to describe how these features fit together in a coherent learning environment, and design different paths learners will be able to use in the environment. This requires a designer to deal with very high level of detail of the activities, and at the same time envision a flow of activities or scenarios that would enable a potential learner to acquire knowledge using the designed module.

Our findings illustrate that as students concretized their design ideas and represented them in sequences of activities, they exposed their pedagogical way of thinking to others. This enabled them to negotiate and reexamine their thinking with peers and instructors and to compare the design solutions they came up with, with those of experts. The exposure of ideas, induced by the concretization, brought to identification of gaps between students' views about how people learn, and pedagogical notions expressed in artifacts they designed at initial stages of the course (Ronen-Fuhrmann et al., 2007). Their views of learning, as stated in discussions, usually represented socio-constructivist approaches, while many of their initial design artifacts represented more naïve, transmissionist views of learning. As students' artifacts became more concrete, they also represented more advanced pedagogical views of learning. The gaps were reduced as a result of refinements students made throughout the design process. Following Wilensky's (1991) notion of concretization as representing the richness and connectedness of abstract concepts, we argue that a person who can verbally explain abstract pedagogical ideas, but has a difficulty to concretize them as features in a learning environment, lacks a deep and connected understanding of these ideas, and of the theoretical underpinnings behind them. To design concrete features that convey their ideas about learning, students in the current research were engaged in a process of connecting their ideas with design knowledge of peers, instructors, and experts. This process enabled them to develop a richer set of connections in their knowledge about learning theory, and thus develop a deeper understanding about learning.

Thus, in the context of educational technology design, we view concretization as: (a) an essential skill in the process of gaining design knowledge, and (b) a way to assist students to reflect and reduce gaps in their understanding about learning theory. This twofold notion of concretization is in agreement with the Learning By Design literature (e.g., Harel, 1991; Kafai, 2006; Kolodner et al., 2003; Papert, 1991), which shows that when learners design an artifact that explains a certain topic in a certain subject matter, they learn many things about design, but they also learn a whole lot about the topic they are designing for. In this study, the topic was not only the science or math embedded in the students' modules, but also the learning theory behind the instruction that they designed.

Finally, we thank all those who contributed from their design knowledge and experience to the Design Principles Database.

# Representational Scripting to Support Students' Online Problem-solving Performance

**Abstract:** This study investigated the effects of representational scripting on student learning while online collaboratively solving a complex problem. The premise here is that effective student interaction would be evoked when the problem-solving task is structured into part-tasks that are supported by providing part-task congruent representations (i.e., representational scripting). It was hypothesized that such an approach would lead to a more appropriate student interaction and as a consequence better problem-solving performance. In triads secondary education students worked on a case-based business-economics problem in four experimental conditions, namely one condition in which the groups received representations that were congruent for all three part-tasks and three conditions in which the groups received one of these representations for all three part-tasks. The results show that using representational scripting indeed leads to a more elaborated discussion about the content of the knowledge domain (i.e., concepts, solutions and relations) and to better problem-solving performance.

## Introduction

Collaboratively solving complex problems is often regarded as an effective pedagogical method that is beneficial for both group and individual learning. The premise underlying this approach is that through a dynamic process of eliciting one's own understanding of the content of the knowledge domain (i.e., concepts, principles and procedures) and discussing this with peers, students acquire new knowledge and skills and process them more deeply (e.g., Hmelo-Silver, Duncan, & Chinn, 2007). Unfortunately, putting students in groups and having them work together on a problem is not always beneficial for learning (e.g., Barron, 2003). Research on Computer Supported Collaborative Learning (CSCL) has shown that proper use of representational tools can beneficially affect externalizing, sharing and negotiating about the concepts, principles and procedures of the domain (e.g., Fisher, Bruhn, Gräsel, & Mandl, 2002). However, whereas these studies show promising results, other research questions how representational tools can best guide student interaction that is beneficial for learning (e.g., Suthers, 2006). Important here is that problem-solving tasks are usually composed of fundamentally different part-tasks, that each require the support of a different representational tool. Important here is that the guidance the tools are intended to provide is matched to the demands of the different part-tasks. Otherwise this will hinder learning (e.g., Van Bruggen, Boshuizen, & Kirschner, 2003). Recently, *scripting* has been advanced as a way to ensure the alignment between tool, tool use and learning goals in collaborative learning (e.g., Weinberger, Ertl, Fischer, & Mandl, 2005). Scripting the problem-solving process with representation tools sequences the problem-solving process and makes the different part-task demands explicit so that they can be foreseen with task-congruent content-related guidance by the representational tools. By doing so, part-task related activities beneficial for collaborative problem-solving can be evoked.

## Collaboratively Solving a Complex Problem

Collaboratively solving a complex problem is regarded to be a sequenced, phased process (i.e., problem orientation, problem solution, solution evaluation) where students actively engage in a process of sense-making in a knowledge domain, articulating and discussing multiple problem perspectives and problem-solving strategies (Ploetzner, Fehse, Kneser, & Spada, 1999; Van Bruggen, et al., 2003). Coping with the task demands of the different problem phases (i.e., part-tasks), requires students to interact in the *content space*; carry out part-task related activities such as discussing the concepts, principles, and procedures of the domain (Barron, 2003; Jonassen & Ionas, 2008). However, where expert problem-solvers experience no difficulties in carrying out these kinds of activities, students (i.e., non-experts) do. When solving problems, students rely primarily on surface features such as using objects referred to in the problem instead of the underlying principles of the knowledge domain, and employ weak problem-solving strategies such as working via a means-ends strategy towards a solution (Chi, 1997). Important here is that students lack a well developed understanding of the knowledge domain and as a consequence have problems creating and combining meaningful problem representations. This hinders students in effectively and efficiently carrying out their problem-solving task because the ease with which a problem can be solved often depends on the quality of the available problem representations (Chi; Jonassen & Ionas). To this end, it would be beneficial if suitable representations were provided and combined in a part-task appropriate manner.

## Representational Scripting

Integrating scripting with the availability of representational tools (i.e., representational scripting) structures the problem-solving process making it more efficient and effective. Scripting shapes the use of the representational tools and therefore also the epistemic and social processes of collaboration (Weinberger, et al., 2005) by sequencing and making the different part-task demands explicit so that they can be foreseen with task-congruent content-related guidance by the representational tools. Different representation tools provide different domain-specific content schemes (i.e., problem representation) representing different problem perspectives. Visualizing the knowledge domain through multiple external representations (ERs) influences student interaction by providing representational guidance (Suthers, 2006). The specific ontology (i.e., objects, relations, rules for combining them) of each ER offers a restricted view of the knowledge domain, guiding student interaction in a specific manner. Matching this representational guidance with the student interaction required to carry out a part-task evokes appropriate student interaction, leading to better problem-solving performance (see Table 1). To effectively do this, one must avoid or neutralize the difficulties encountered when combining multiple ERs, namely: translating from and coordinating between different ERs (Ainsworth, 2006), and incongruence between an ER and required part-task related activities (Van Bruggen, et al., 2003). This means that the representational guidance of the ER must be congruent (i.e., ontologically matched) to the part-task demands and activities of a specific problem phase. In this paper, the focus will be on guiding student interaction' when collaboratively solving a complex business economics problem.

Table 1: Congruence between external representation and part-task demands

| Problem phase | Part-task demands | ER | Representational guidance |
|---|---|---|---|
| Problem orientation | Determining core concepts and relating them to the problem | Conceptual (static) | Showing concepts and their interrelationship |
| Problem solution | Proposing multiple solutions to the problem | Causal (static) | Showing causal relation between the concepts and possible solutions |
| Solution evaluation | Determining suitability of the solutions and coming to a final solution to the problem | Simulation (dynamic) | Showing mathematical relation between the concepts and enabling manipulation of their value |

This study focuses on how the use of representational scripting affects both student part-task related interaction and problem-solving performance in a CSCL-environment. In four experimental conditions, student triads had to collaboratively solve a case-based problem in business-economics that was divided into three problem phases each coupled with a different ER. To study the effects of representational scripting, ERs were either matched or mismatched to the different problem phases; in other words they were either ontologically congruent or incongruent to the required part-task activities. In three mismatch conditions, groups received either a static ER (i.e., conceptual or causal ER) or a dynamic ER (i.e., simulation) that matched only one of the part-tasks. The scripting structured the problem-solving process in three phases, but only one of the ERs is available to the students for solving the problem, yielding a phase-match when the ER ontologically matched one of the three phases and a mismatch for the other two phases. In the fourth condition, groups received all three ERs in a phased order receiving the ER most suited to each problem phase. Here, thus, there was an ontological match between all three ERs and all three part-tasks. Due to the presumed match between ERs and part-tasks, student understanding and part-task related activities were expected to increase, allowing the students to reach better problem solutions. It was, therefore, hypothesized that students in the match condition *(H1)* carry out more part-task related activities and *(H2)* have better problem-solving performance.

## Method

### Participants

Participants were students from a business-economics class in a secondary education school in the Netherlands. The total sample consisted of 39 students (24 male, 15 female). The mean age of the students was 16.74 years (*SD* = .83, Min = 15, Max = 18). The students were randomly assigned to 13 triads divided between the four conditions; four triads in the conceptual and three triads in each of the other conditions (i.e., causal, simulation and match).

### Problem-solving task and materials

CSCL-environment: Virtual Collaborative Research Institute

Students worked in a CSCL-environment called Virtual Collaborative Research Institute (VCRI, see Figure 1), a groupware application for supporting the collaborative performance of problem-solving tasks and research projects (Broeken, Jaspers, & Erkens, 2006). For this study, five tools that are part of the VCRI were augmented with representational scripting. All tools, except the Notes tool, were shared among group members.

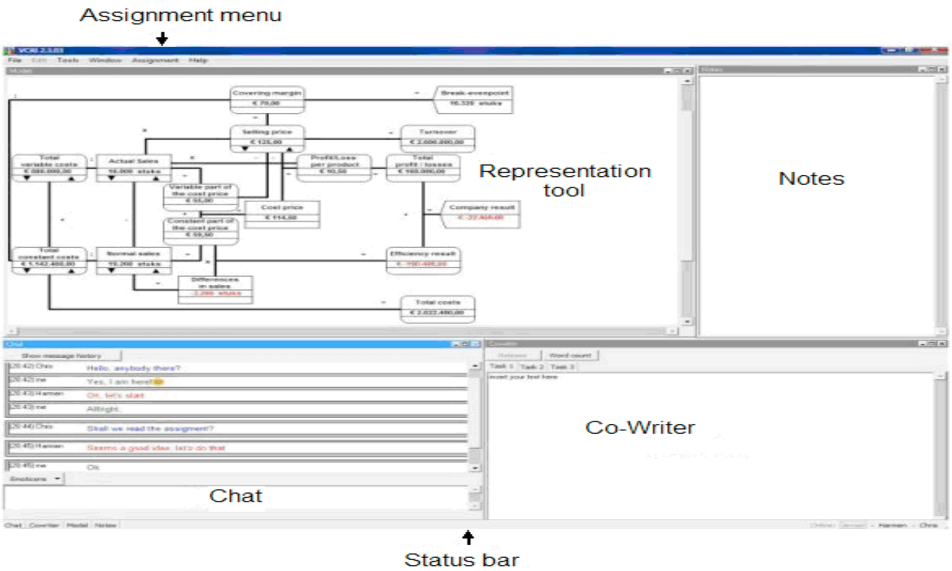

Figure 1. Screenshot of the VCRI-program.

The *chat tool* enables synchronous communication and supports students in externalizing and discussing their knowledge and ideas. The chat history is automatically stored and can be re-read by the students. In the *Assignment menu*, students can find the description of the problem-solving task / part-tasks. Besides this, additional information sources such as a definition list, formula list, and clues for solving the problem were also available here. The *Co-writer* is a shared text-processor where students can collaboratively formulate and revise their answers to the part-tasks. The *Notes tool* is an individual notepad that allows students to store information and structure their own knowledge and ideas before making them explicit. The *Status bar* is an awareness tool that displays which group members are logged into the system and which tool a group member is currently using. All students in all conditions had access to these tools and information sources. In other words, the different conditions were information equivalent and only differed in the way that the ERs are intended to guide the interaction.

## Problem-solving task and design representational scripting

All groups worked on a case-based problem in business-economics in which they had to advise an entrepreneur about changing the business strategy to increase profits (i.e., company result). To come up with an advice, students had to carry out three different part-tasks, namely (1) determine the main factors affecting the company's result and relate them to the problem, (2) determine how certain interventions affect company result, and (3) compare the effects of these interventions and formulate a final advice based on this comparison. Through scripting, the problem-solving process was structured into a problem orientation phase, problem solution phase, solution evaluation phase each focusing on one of the part-tasks. All groups were 'forced' to carry out all the part-tasks in a predefined order; they could only start with a new part-task after finishing an earlier part-task. When group members agreed that a part-task was completed, they had to 'close' that phase in the assignment menu. This 'opened' a new phase, which had two consequences for all groups, namely they (1) received a new part-task, and (2) had to enter their new answers in a different window of the Co-writer. All conditions received the part-tasks in the same order, but only groups in the match condition received a new ER.

The *problem orientation phase* focused on creating a global qualitative problem-representation by asking students to explain what they thought the problem was and to describe what the most important factors were that influenced the problem. During this phase, students received the conceptual ER (i.e., a static content scheme; see Figure 2) that made two aspects salient, namely the core concepts needed to carry out this part-task and how the core concepts are qualitatively interrelated. Students could see that 'company result' is affected by the 'total profit' and the 'efficiency result'. Such information should make it easier for them to create an overview of all relevant concepts, supporting them in finding multiple solutions to the problem in the following phase.

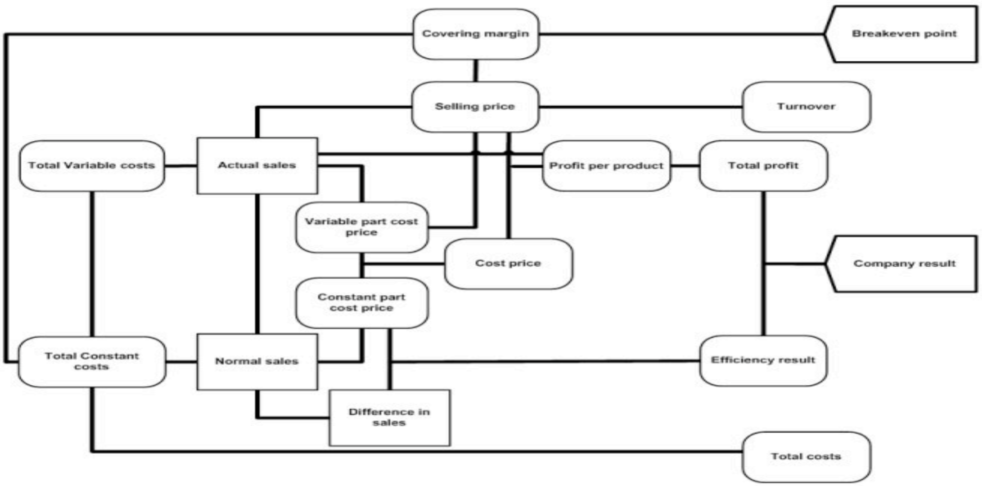

Figure 2. Conceptual ER.

The *problem solution* phase focused on creating a causal problem representation (i.e., explicating the underlying business-economics principles) by asking students to formulate several solutions to the problem. During this phase, students received the causal ER (i.e., a static content scheme; see Figure 3), in which the causal relationships - visible through the arrows showing direction of the relationship between the concepts - were specified. The causal ER also contributed to increasing students' qualitative understanding by providing the students with possible interventions (i.e., changes in the business strategy), each of which had a different effect on the company results. This should make it easier to effectively explore the solution space and should, in turn, support students in finding multiple solutions to the problem. Students could, for example, see that a PR-campaign affects 'actual sales that in turn affects 'total profit'.

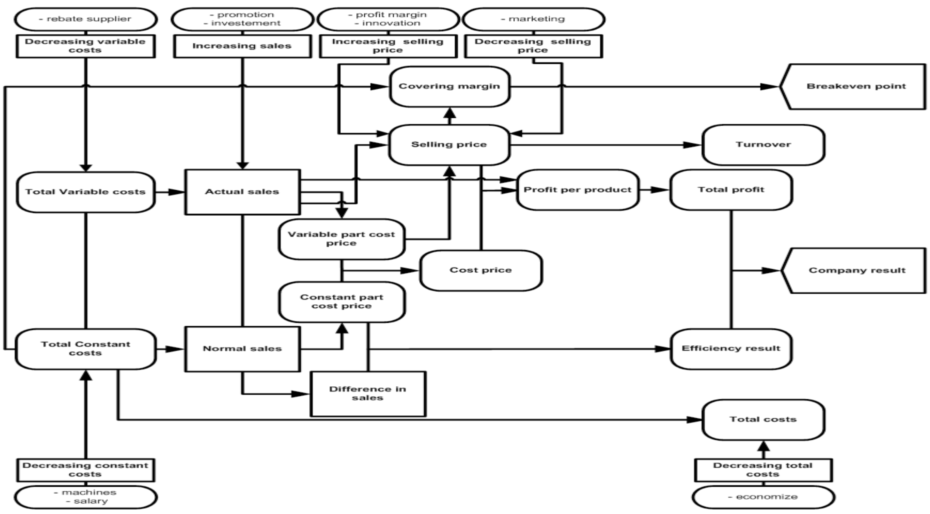

Figure 3. Causal ER.

Finally, the *solution evaluation phase* focused on increasing the students' understanding of the knowledge domain with the aid of a quantitative problem representation. Students were asked to determine the financial consequences of their proposed solutions and to formulate a final advice for the entrepreneur by negotiating the suitability of the different solutions with each other. During this phase, students received a simulation ER (i.e., a dynamic content scheme; see Figure 4) that enabled them to manipulate the values of the concepts by clicking on the arrows in the boxes. When the value of a certain concept was changed (i.e., increased or decreased), the simulation model automatically computed the values of all other concepts. This is meant to facilitate the determination and negotiation of the suitability of the different proposed solutions and reaching a final advice. Students could, for example, test how the PR-campaign affects the 'actual sales' and whether this in turn affects the 'total profit'. Only the simulation ER is capable of providing this kind of support, because the relationships between the concepts in this ER were specified as equations.

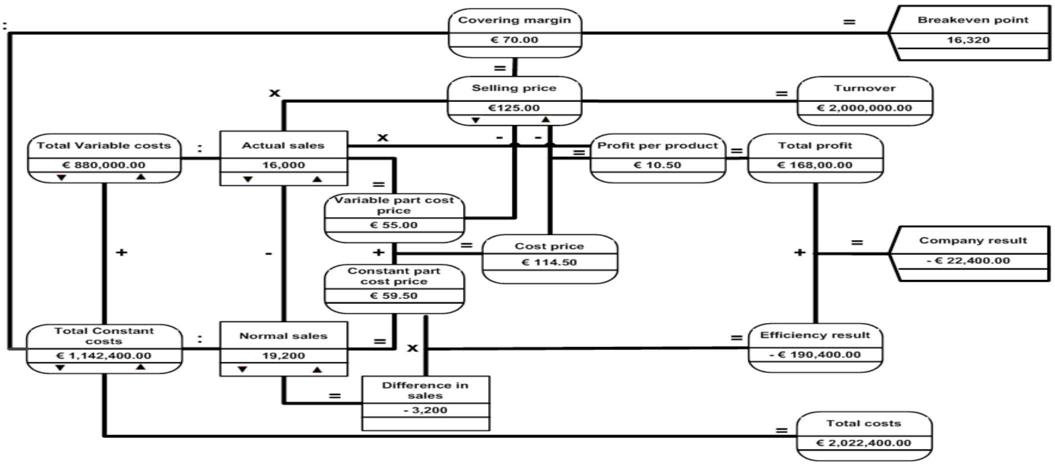

Figure 4. Simulation ER

## Procedure

All groups spent three, 70-minute lessons solving the problem during which each student worked on a separate computer in a computer classroom. Before the first lesson, students received an instruction about the CSCL-environment, the group composition, and the problem-solving task. The instruction made it clear that their group answer to the problem (i.e., problem-solving performance) would serve as a grade affecting their GPA. Students worked on the problem in the computer classroom, where all actions and answers to the part-tasks were logged.

## Measures

### Content-related student interaction

To examine the effect of condition data concerning student interaction was collected by logging the chat-utterances of the group members. The content of these chat-protocols is assumed to represent what students know and consider important for carrying out their problem-solving task (Chi, 1997). Using so called 'concordancers' software (e.g., MEPA, see Erkens & Jansen, 2008) minimizes the work associated with coding chat-protocols and maximizes coding reliability allowing the content of chat-protocols to be searched for the occurrence of characteristic words (i.e., key words) that led to the identification and coding of the dependent variables. This was done automatically with a MEPA-filter using 'if-then' decision rules containing different explicit references to a concept, solution or relation (e.g., name, synonyms) that were coded as representing that concept, solution or relation (see Table 2).

Table 2: Concepts, solutions and relations; coding and reliability MEPA-filter

| Categories | Subcategories | Discussion of | Reliability |
|---|---|---|---|
| Concepts | Sales | how many products are sold / have to produced | 90% |
| | Selling price | what the customer has to pay for the product | |
| | Costs | what the overall costs of the company are | |
| | Turnover | what the total income of the company is | |
| | Company result | whether it is profitable to run the company | |
| Solutions | Changing costs | how the overall costs can be decreased | 84% |
| | Changing turnover | how the turnover can be increased | |
| | Changing both | the combining of the other two solutions | |
| Relations | Conceptual | the definition / meaning of a concept / solution | 80% |
| | Causal | the causal relationship within / between concepts / solutions | |
| | Mathematical | the quantitative relationships within / between concepts | |

### Problem-solving performance

To measure the effect of condition on problem-solving performance an assessment form for all criteria of the problem-solving task was developed (see Table 3). The 41 items were coded as; 0, 1 or 2, whereby a '2' was coded when the answer given was of high quality. All groups could, thus, achieve a maximum score of 82 points (41 * 2 points).

Table 3: Problem solving performance; items and reliability

| Criteria | Description | Items | α |
|---|---|---|---|
| Suitability | Whether the groups' answers were suited to the different part-tasks | 9 | .81 |
| Elaboration | Number of different business-economics concepts or financial consequences incorporated in the answers to the different part-tasks | 9 | .56 |
| Justification | Whether the groups justified their answers to the different part-tasks | 9 | .71 |
| Correctness | Whether the groups used the business-economics concepts and their interrelationships correctly in their answers to the different part-tasks | 9 | .68 |
| Continuity | Whether the groups made proper use of the answers from a prior problem phase | 2 | .67 |
| Quality advice | Whether the groups gave a proper final advice<br>- Number of business-economics concepts incorporated in the advice<br>- Number of financial consequences incorporated in the advice<br>- Whether the final answer conformed to the guidelines provided | 3 | .76 |
| Total score | Overall score on the problem-solving performance | 41 | .92 |

### Data analyses

When conducting studies on CSCL, group members mutually influence each other (i.e., behave more or less in the same way) leading to non-independence of measurement (Kenny, Kashy, & Cook, 2006). This is problematic because many statistical techniques (e.g., *t*-test) assume score independence and such a violation compromises the interpretation of the analyses (e.g., *t*-value, standard error, see Kenny, et al.). The non-independence was determined here by computing the intraclass correlation coefficient and its significance (Kenny, et al.), for all dependent variables concerning student interaction. This resulted in non-independence ($\alpha < .05$) for all tests, justifying *Multilevel analysis* (MLA) for analyzing these data. MLA entails comparing the deviance of an empty model and a model with one or more predictor variables to compute a possible decrease in deviance. The latter model is considered a better model when there is a significant decrease in deviance in comparison to the empty model (tested with a $\chi^2$-test). All reported $\chi^2$-values were significant ($\alpha < .05$) and, therefore, the estimated parameter of the predictor variables (i.e., effects of condition) were tested for significance. Due to the detection of outliers, the utterances of some students were deleted from the MLAs. One-way MANOVA was used for answering the second research question. Since there were specific directions of the results expected (see hypotheses) all analyses are one-sided.

## Results

### Concepts, solutions and relations

MLAs revealed that experimental condition was a significant predictor for the number and kinds of concepts, solutions and relations that students discussed (see Table 4). The results show a main effect for *concepts*, students in the match condition discussed significantly more concepts in comparison to students in three non-matched conditions ($\beta = 9.08$, $p = .00$). When comparing the match condition to the other conditions separately, it appeared that students in the conceptual condition discussed concepts as 'sales' ($\beta = 2.03$, $p = .03$), 'turnover' ($\beta = 1.80$, $p = .00$) and 'company result' ($\beta = 2.55$, $p = .02$) less frequently than students in the match condition. The same kind of results were obtained when comparing students in the match condition to students in the simulation condition; 'sales' ($\beta = 2.00$, $p = .03$), 'turnover' ($\beta = 2.28$, $p = .00$) and 'company result' ($\beta = 3.19$, $p = .02$). Second, a main effect for *solutions* was found. Students in the match condition discussed significantly more solutions in comparison to students in the non-matched conditions ($\beta = 6.33$, $p = .00$). When comparing the match condition to the other conditions for the different kinds of solutions, students in the match condition discussed the solution aimed at increasing the company's turnover more often than students in the non-matched conditions ($\beta = 3.42$, $p = .03$). This effect was also significant between all conditions. Finally, Table 4 shows a main effect for *relationships*, students in the match condition discussed significantly more and different kinds of relationships than students in the non-matched conditions ($\beta = 11.68$, $p = .00$). When comparing the match condition to the other conditions separately, it appeared that (1) students in the conceptual ($\beta = 2.85$, $p = .03$) and the simulation condition ($\beta = 3.67$, $p = .02$) discussed significantly fewer conceptual relationships, (2) students in the conceptual condition discussed significantly fewer causal relationships (β = 6.41, *p* = .01), and (3), students in the conceptual (β = 2.50, *p* = .01) and the simulation (β = 2.68, *p* = .00) condition discussed fewer mathematical relationships.

Table 4: Multilevel Analyses for Effects concerning Students' Discussion of Concepts, Solutions and Relations

| | Conceptual condition (*n* = 10) | Causal condition (*n* = 10) | Simulation condition (*n* = 10) | Match condition (*n* = 6) | Effects match condition (*N* = 36) | | |
|---|---|---|---|---|---|---|---|
| | *M (SD)* | *M (SD)* | *M (SD)* | *M (SD)* | $\chi^2(3)$ | β | *SE* |
| *Concepts* | 8.36 (5.20) | 10.88 (8.64) | 4.50 (4.70) | 26.50 (14.57) | 25.37 | 9.08** | 2.00 |
| Sales | 1.09 (1.30) - | 2.00 (2.14) | 1.20 (1.14) - | 5.17 (6.40) + | 11.53 | 2.03** | 0.72 |
| Selling price | 0.27 (0.65) | 1.00 (1.85) | 0.20 (0.63) | 2.33 (2.50) | 5.67 | 1.03 | 0.54 |
| Costs | 3.18 (3.09) | 3.50 (2.88) | 1.50 (2.17) | 6.50 (3.27) | 13.18 | 1.67 | 0.70 |
| Turnover | 1.09 (1.45) - | 1.25 (1.39) | 0.10 (0.36) - | 4.67 (3.08) + | 16.51 | 1.79* | 0.40 |
| Company result | 2.73 (2.15) - | 3.12 (3.14) | 1.50 (1.78) - | 7.83 (3.66) + | 14.06 | 2.55* | 0.81 |
| *Solutions* | 6.00 (4.65) | 7.12 (5.69) | 2.80 (3.19) | 18.67 (7.74) | 23.29 | 6.33** | 1.45 |
| Changing costs | 3.09 (3.53) | 3.75 (3.50) | 1.50 (2.12) | 6.33 (3.56) | 10.87 | 1.62* | 0.81 |
| Changing turnover | 2.18 (1.94) - | 2.88 (2.75) - | 0.90 (1.11) - | 10.33 (4.89) + | 23.22 | 4.08** | 0.70 |
| Changing both | 0.73 (1.27) | 0.50 (0.75) | 0.40 (0.52) | 2.00 (1.79) | 3.88 | 0.64* | 0.32 |
| *Relations* | 11.73 (5.31) | 18.37 (12.36) | 8.10 (3.81) | 35.17 (15.38) | 39.48 | 11.68** | 2.98 |
| Conceptual | 4.00 (2.97) - | 4.00 (5.16) | 2.30 (2.50) - | 9.67 (5.24) + | 13.71 | 2.86* | 1.25 |

| Mathematical | 0.82 (1.33) - | 2.00 (3.07) | 0.50 (0.85) - | 5.83 (5.42) + | 15.39 | 2.51* | 0.68 |

Notes. * $p < .05$; ** $p < .01$; if match condition significantly > a mismatch condition than the match condition is indicated with a + and the mismatch condition with a -

## Problem-solving performance

One-way MANOVA on the total score of the problem-solving performance showed a significant difference for condition ($F(3, 9) = 1.99$, $p = .04$; Pillai's Trace = 2.00; partial *eta* squared = .67). Bonferroni post hoc analyses showed that groups in the match condition indeed scored significantly higher than groups in both the conceptual ($p = .02$; $d = 2.28$) and the simulation condition ($p = .05$; $d = 1.90$). Table 5 shows the mean scores and standard deviations of the scores on the problem-solving performance. When the results for the dependent variables were considered separately, using one-way ANOVAs with Bonferroni post hoc analyses, condition effects were found for 'suitability' ($F(3, 9) = 4.49$, $p = .02$), 'elaboration' ($F(3, 9) = 3.13$, $p = .04$) and 'correctness' ($F(3, 9) = 4.25$, $p = .02$). The mean scores indicate that there were several significant differences between conditions. First, groups in the match condition scored significantly higher on 'suitability' than groups in both the conceptual condition ($p = .03$; $d = 3.61$) and the simulation condition ($p = .05$; $d = 3.28$). Second, groups in the match condition scored significantly higher on 'elaboration' than groups in the conceptual condition ($p = .04$; $d = 1.57$).

Table 5: One-way Multivariate Analysis concerning Group Problem-solving Performance

| Criteria | Condition | | | |
|---|---|---|---|---|
| | Conceptual condition (*n* = 4) | Causal condition (*n* = 3) | Simulation condition (*n* = 3) | Match condition (n = 3) |
| | *M (SD)* | *M (SD)* | *M (SD)* | *M (SD)* |
| Suitability* | 10.75 (1.50) - | 13.67 (1.52) | 11.33 (4.16) - | 17.00 (1.73) + |
| Elaboration* | 3.75 (2.06) - | 6.67 (2.08) | 6.00 (2.00) | 9.67 (3.78) + |
| Justification | 3.25 (2.06) | 4.67 (3.06) | 3.00 (3.00) | 8.00 (4.00) |
| Correctness* | 4.50 (1.29) - | 6.33 (3.77) | 5.33 (0.58) - | 10.67 (2.89) + |
| Continuity | 2.00 (1.41) | 2.00 (1.00) | 2.00 (1.73) | 3.67 (0.58) |
| Quality advice | 2.50 (0.58) | 3.67 (0.58) | 3.33 (2.52) | 3.33 (1.53) |
| Total score* | 26.75 (4.17) - | 37.00 (7.00) | 31.00 (12.00) - | 52.33 (11.24) + |

# Discussion

As is the case with many other researchers, the present study stresses the importance of using representational tools (Fischer, et al., 2002) and of employing scripting (Weinberger, et al., 2005) to guide student interaction and problem-solving performance. However, instead of using them separately, this study combined the advantages of using multiple representations and scripting (i.e., representational scripting). The representational scripting structured the problem-solving process by sequencing and making the part-tasks explicit so that they could be foreseen with ontologically congruent content-related guidance in the representational tools. It was hypothesized that this would evoke more suited part-task related student interaction and, as a consequence, better problem-solving performance than not receiving it. Although based on 13 triads, the results of our study confirmed that the problem-solving process for these groups was more efficient and effective. Specifically, groups in the match condition had more elaborated discussions of the content of the knowledge domain, gave better answers to the part-tasks and a came up with better final solutions to the problem than groups in the non-matched conditions. Although the results seem very promising student interaction and problem-solving performance of students in the causal condition was very similar to what was found in the match condition. Students in both conditions received the causal ER, that showed all relevant concepts, solutions and their causal interrelationships, providing the students multiple qualitative perspectives on the knowledge domain. Providing ERs that foster causal reasoning seems, therefore, beneficial for collaborative problem-solving (Jonassen & Ionas, 2008). Combining the causal ER with both other ERs might also hinder problem-solving when students experience difficulties integrating the different ERs. When students do not know how to combine multiple ERs, they might choose to stick with the familiar one and make no attempt to integrate the different ERs (Ainsworth, 2006). Future research should be aimed at determining whether the results can be generalized to the same and other kinds of problem-solving tasks. Its seems also interesting to study the effects of the collaborative construction of external representations. Such an approach might lead to more insight into how students use and combine the concepts, solutions and relations within and between different ERs.

**Abstract:** Learning is interweaved into and across students' everyday life activities. Technology that is used to support learning should be integrated with everyday life in the same way that learning occurs in everyday life: seamlessly. Mobile technologies, with their reduced size and ease of use, provide the potential to extend students' learning spaces and enrich the learning experiences in their daily lives where they move between locations, switch from one topic or context to another, and interact with different social groups. This paper proposes mobile technology-supported seamless learning and presents learning scenarios from our research to illustrate how learning occurs seamlessly across time and places mediated by mobile devices.

## Introduction

Learning is interweaved into and across students' everyday life activities such as watching videos, browsing Internet, reading book, playing sports, talking to people, and shopping. These activities can be resources and contexts for learning which should be seen not as a shell that surrounds the learner at a given time and location, but as a dynamic entity, constructed by the interactions between learners and their environment (Sharples, Taylor, & Vavoula, 2007). Looi, Seow, Zhang, So, et al (2009) state that the learning space is no longer defined by the 'class' constrained by scheduled class hours or specific locations, but by 'learning' across spaces as they harness ideas and learning resources gained in one location or context, and apply or develop them in another. They learn across time, by revisiting knowledge that was gained earlier in a different context. They learn by moving from topic to topic, managing a range of personal learning projects, rather than following a single curriculum (Sharples, Taylor, & Vavoula, 2007). They learn across social groups, by co-constructing knowledge with another student, a small group, or a large online community, with the possible involvement of teachers, friends, relatives, experts and members of other supportive communities.

Technology that is used to support learning should be integrated with everyday life in the same way that learning occurs in everyday life: seamlessly. Mobile technologies offer the potential for a new phase in the evolution of technology-enhanced learning, marked by a continuity of the learning experiences across different contexts. Chan, Rochelle, Kinshuk and Sharples et al. (2006) use the term "seamless learning" to describe the situations where students can learn whenever they want to in a variety of scenarios and that they can switch from one scenario to another easily and quickly using their personal mobile device as a mediator.

While there is growing recognition that learning can take place anywhere and anytime beyond the walls of classrooms, until recently learning across spatial and temporal spaces has remained an under-researched area. We are conducting a 3-year project designing and investigating a seamless learning environment to bridge Primary (Elementary) students' different learning spaces by equipping them with personal mobile devices. In this paper, we explore how to use mobile technology to support seamless learning and present learning scenarios from our research to illustrate how students use mobile technologies to extend their learning spaces.

## Seamless Learning Supported by Mobile Technology

The basic premise of seamless learning is that it is not feasible to equip students with all the knowledge and skills they need to have for lifelong learning based on snapshots of episodic time frame, location or scenario. Therefore, students will need to continually enhance their knowledge and skills, in order to address immediate problems and to participate in a process of continuous learning. We consider student learning as moving beyond the acquisition of content knowledge to developing the capacity to learn seamlessly.

As the use of mobile technology such as the Smartphone is becoming more pervasive in our lives, we envision learning to occur when a learner interacts with others and the environment across time and location seamlessly through the use of the technology as a mediating tool. Moving away from the Cartesian perspective where the learner is separated from the world, we view the learner as an active participant in the world. Learning occurs through the rich social interactions with others and interactions with environment as shown in Figure 1. Learning is developmental and occurs through the interactions a learner may experience at different points of time. Technology is a nexus connecting the learning experiences of the learner.

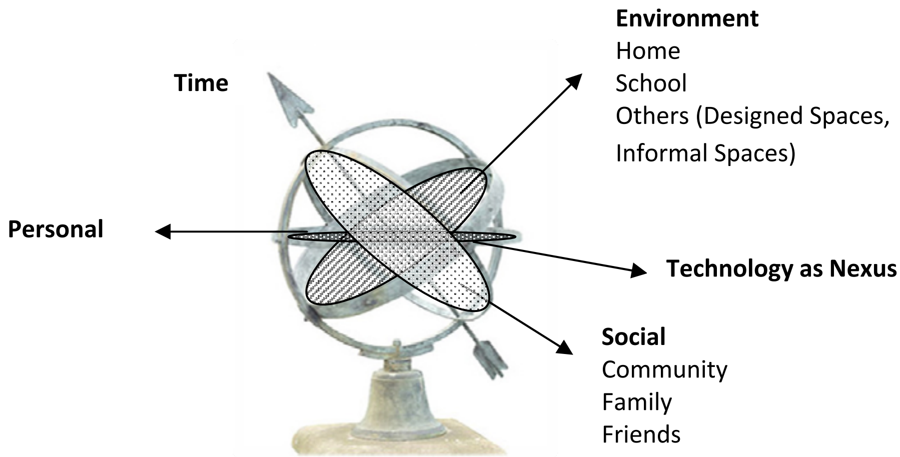

Figure 1. Technology supported seamless learning

Stroup and Petrosino (2003) categorize educational technology into two types: vertical technology and horizontal technology - vertical technology is mainly for teachers' needs in a confined setting whereas horizontal technology is used to meet students' personal needs across multiple physical contexts. Many of today's educational technologies are used as vertical technologies in the classroom. Seamless learning requires horizontal technologies that can meet students' personal needs. Mobile technology is exactly a horizontal technology because of its affordances. The characteristics of mobile technologies are well suited to support seamless learning (Chen, Seow, So, Toh, & Looi, in press). The small size and light weight of mobile devices mean that they can be taken to different sites or moved around within a site, so that they can be available wherever the student needs to learn. The use of the mobile device becomes a routine practice and is assimilated into everyday life experiences. Equipping with mobile technologies, students can learn across time and location. The learning experience supported by mobile technology is unobstrusive -it enables students' data exchange, communication and collaboration with teachers, experts, friends and family members etc. As the mobile device can be turned on and off instantaneously, students can use it whenever they need to, enabling them to make rapid connections between ideas and observations. The mobile device can both gather and respond to information specific to the current location, environment and time. This help student learn in real context.

Besides, mobile technology accommodates versatile learning activities. Students can type, draw, take photos, do audio or video recording, supporting their multi-modal expressions. The artifacts created by students can be saved. The student's personal accumulation of resources and knowledge is persistent and can be made immediately accessible by others. The use of the device is adapted to the learner's evolving abilities, skills, knowledge and learning styles and designed to support individualized learning, rather than general office work.

Some of the requirements of technology to support seamless learning can be satisfied by traditional tools such as notebooks, pencils, textbooks, timetables, and diaries etc. However, mobile technologies can supplement these by offering learners the opportunity to manage their learning over time, to engage in collaboration, and to relate information to situated problems. In sum, it is a *learning hub* for the students to engage in several learning activities across time and location by using the same devices.

In our research, each student is equipped with a HTC Tytn II Windows Mobile Smartphone that came with photo-taking function, stylus pen, keyboard, 3G-enabled Internet surfing data plan and educational applications. The students used the Smartphones in class and were allowed to bring home the devices. With the 3G-enabled Smartphone, they have instant access to the Internet inside and outside school at anytime. The students were trained in the basic use of the Smartphone such as the camera, internet connectivity, web browsing and GoKnow Mobile Learning Environment (MLE). GoKnow's MLE is a suite of educational mobile applications comprising Sketchy for creating animated drawings, PicoMap for creating concept maps, iKWL for creating KWL, and MyProjects for students to carry out their learning activities.

## Research Design

Our research is guided by the following research questions: 1) How does the appropriate use of mobile technologies mediate planned and emergent learning inside and outside school? 2) How do students learn seamlessly across the boundaries of learning spaces? and 3) How do we design for learning to occur seamlessly across the boundaries? To answer our questions, we studied an experimental Primary (Elementary) Grade 3 (P3, with nine-year old students) class comprising 39 students and worked closely with the class form and science teacher. The students have been using the HTC Smartphones since March 2009.

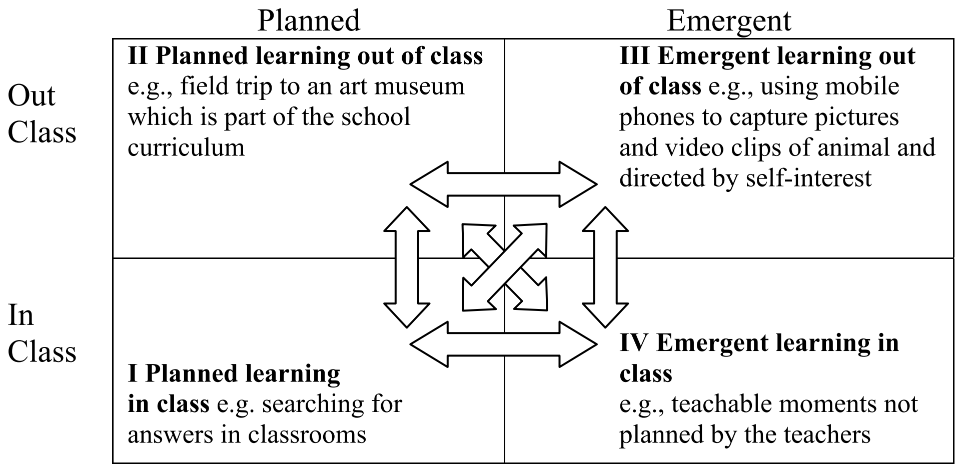

Figure 2: Matrix of students learning spaces (adapted from So, Kim, & Looi, 2008)

Our research attempts to design and investigate a seamless learning environment that allows students to learn at any time and at any location, and provides children with multiple ways of learning throughout the day. This is consistent with what Pea (2009) argues: "we need to treat the activities and life experiences of the learners throughout the day as our units of learning design, description and explanation". The matrix above (Figure 2) shows the students' learning spaces from two dimensions – 1) in class vs. out of class and 2) planned learning (planned by teachers) vs. emergent learning (not planned by teachers, but occurring unexpectedly driven by student self-interest/motivation).

### "Mobilized" Lesson Design

For the planned learning activities, we designed a series of "mobilized" lessons in class (Zhang, Wong, Seow, Chen, & Looi, 2009) to help students learn curriculum subjects better. Instead of relying on the textbooks for instruction, we created instructional tasks for the students to search for information related to the curriculum and scaffold their learning. The instructional tasks took advantage of the affordances of the Internet-enabled Smartphones and the GoKnow's MLE. For example, we used iKWL to draw out students' prior understanding and encourage inquiry about the topic. Students use the Internet-enabled Smartphones to search for resources to answer their queries. Many "mobilized lessons" have an "out-of-classroom" element where the students interact with the environment outside the classroom and engage in activities in their everyday lives. For example, we designed an English mobilized lesson on prepositions (Looi, Wong, So, Seow, et al, 2009) to support students' multiple learning paths. In this lesson, students used the Sketchy application on their mobile devices to represent their understanding of the prepositions, and took pictures outside the classroom to demonstrate their usage in an authentic context.

### Data Collection

A design ethnography approach (Goldman, 2004) is integrated into our research to observe how students are engaged in seamless learning when they interact with their handheld devices, peers, teachers and other people in their learning community (e.g., Barron, 2006; Squire & Klopfer, 2007). Over the past 6 months, we have followed this P3 class closely to study how they use the Smartphone in and outside of the classroom. Data was obtained through extensive observations in the school. The sources of data included classroom observations, informal conversation with students during their recess breaks, conversations with the teachers, and professional development sessions with teachers as we designed and reviewed the lessons. Our researchers spent time observing and interacting with the class every week for about 6 months. They observed how the students used the Smartphones to mediate learning in class, how the Smartphones facilitate interactions and learning with others, and the emergent use of the Smartphone.

We surveyed the students before the introduction of the Smartphone and again six months after they have used the device. In the survey, the students reported on their usage, experience and attitudes towards the use of the Smartphone for learning in and out of school. We conducted structured interviews with the students prior to their use of the devices.

In a seamless learning environment, students are 'on the move' across different modes of space and time. In this project, students have 24-7 access of the mobile device so that they can use the tool to engage in a wide range of activities in and out of the classroom. We have developed and installed a log software program to capture all the data stored in students' HTC phone. To understand more about the nature of students' learning outside school, we selected six students from a diverse set of criteria (academic performance, technology competency, socio-economic status, social skills and richness of informal learning spaces) for in-depth study. For these students, we conducted monthly visits to their home where we interviewed them and their family members. Through the visits, we hope to understand the informal learning environment of the student at home and outside school. Each family was given a digital camera to capture moments that reflect the student's use of the Smartphones during family activities.

## Findings

In this section, we describe a myriad of seamless learning scenarios based on our preliminary findings of the data collected from the research. The scenarios describe how technology facilitates learning in and across the boundaries presented in our framework in Figure 3. We present survey results on the 39 students' experiences with and attitudes towards the Smartphone and its role in learning 6 months after the introduction of HTC phones (September 2009) and "mobilized lesson. We also compare students' attitudes toward using Smartphone for their learning in and out of classroom before (February 2009) and half year after the introduction of HTC phones and "mobilized lesson".

### Seamless learning Scenarios

#### Planned Learning in the classroom – Planned learning outside class

In a lesson on digestive systems, the students learnt about how a digestive system functions as a system. They had to understand how different parts of the human digestive system worked together to digest food in the body. Planned classroom activities included viewing of videos on students' Smartphones and creating animation on the synergistic processes of the digestive parts. The process of creating the animation enabled students to grasp why and how the seemingly disparate parts actually work in tandem as a system. For the planned home activity, the teacher wrote a letter to the parents of the students to invite them to participate in the activity. Students were required to teach their parents on what they know about the digestive system. After the parents had learnt about the digestive system from the child, they were asked to share and recount the parts and functions of the digestive system. The students then used the Smartphone to video or audio record what the parents have shared about the digestive system.

In class, the teacher paired the students and instructed them to listen or view their partner's recording (Figure 4). As they listened or watched the presentation, each student would have to evaluate the parent's knowledge of the digestive system by using checklist provided to them. For example, students need to validate if the parents have indeed described the flow of food in the digestive system or demonstrated understanding of where digestion stops in the system. Learning inside and outside the classroom became a participatory activity between students, teachers and parents. Students took on the role of teaching their parents what they learnt and students learnt from their friends through their feedback on the recording. We noticed that students did exhibit accountability for what their parents had shared and they critically reflected on what they had taught or omitted during the child-parent sharing. One student in the class was concerned that he had omitted "teaching" his father a function of the digestive system. This happened after his partner said that he did not hear any mention of it from the video recording of the student's father.

#### Planned learning in class – Emergent learning out of class

In our planned lesson, we encouraged the students to inquire what they would like to know pertaining to their selected topic. For example, after students listed all that they know about animals, we asked them to list the questions they would like to know about animals. There are no restrictions on the type of questions they can pose. Using the Smartphones, they were encouraged to use the Internet to search for the answers to the questions. As young learners of inquiry, they had initial difficulties in framing the questions. They also needed support from the teacher and researchers in helping them to make sense and filter the influx of information that emerged from their search results.

In class, we promoted inquiry by asking students to list questions they have about a topic and look for evidences that would help them answer the questions. They would use the 3G-enabled phones to search for answers and share their answers in class discussions facilitated by the teacher. The planned lesson on the inculcation of inquiry skills actually spills over to learning practices at home. In one of the interviews with Roy (one of our six targeted participants for ethnographic study) and his family, his father commented that Roy developed an interest in asking questions about things around him. His mother recounted that Roy taught her that guppies give birth to young instead of laying eggs. In one of the lessons, students used the Smartphone to inquire "which fish give birth to young live?" and "which mammal lays eggs?" In class, we encouraged the development of cognitive processing skills which includes observation, recording observation on the Smartphone with the camera, and sharing with others. At home, Roy observed that the fishes in his home aquarium had laid eggs (Figure 3). He used his Smartphone camera to take pictures of the eggs. His interest and habits of inquiry was supported by his parents. On a holiday trip, Roy recorded videos of the fishes and marine life from the transparent base of the boat he was in (Figure 4). The Smartphone is a tool to support Roy's emergent learning arising from his interest in marine animals. He used the Smartphone to record his observations outside the class and search for more information. He has learnt to be observant about the world around him and started to find out answers to his questions independently. Roy told us that he shared his pictures and videos with classmates who shared similar interests in marine animals.

Figure 3. Roy taking pictures of eggs laid by the fish in his home aquarium

Figure 4. Roy taking pictures of marine life he observed from the transparent bottom of a boat

## Emergent learning in classroom - Planned learning out of classes - Planned learning in classroom

Jeremy was one of the participants in our study who showed a keen interest in exploring the use of the mobile devices when it was first introduced in the classroom. During class, he was observed to explore both the hardware and software features of the Smartphone (Figure 5). In one lesson, he used Google Maps to find the location of the school and his home on the map. His exploration was unrelated to what was taught in the class at the time. He was zooming and panning the map to locate, and making spatial comparison to the location-in-question with respect to his neighbourhood. He used Google Maps to find directions from the school to his home by entering the start point and end point of his journey. In a home interview, he shared with the researchers his motivation of using Google Maps - his grandmother had problems travelling from one place to another as she does not know the directions. He planned to use Google Maps to help her get around. Jeremy's exploration extended to the social realm as he shared with his classmates about the use of Google Maps. During class, Jeremy and another classmate used Google Maps to compare the distances of their homes from school.

Some of our ideas for learning design are inspired by the students' innovative use of mobile devices in the emergent learning spaces. For example, when the mobile devices were first introduced to the class, some students used Google Maps to find the location of their homes on the map (Figure 5) and compared the distances of their homes from school. To connect the students' emergent use of the Google Maps on the Smartphone to in-school instruction, the teacher designed a math learning activity for the students to learn distances and length in an authentic context.: Each student was asked to find the distances and directions from one point to another point (e.g. from the school to the swimming complex) by using Google Maps. They then added up the length of the journey and converted the distance from Kilometers to meters. The use of Google Maps enabled the students to have a better sense of distance as the interface displays the directions to places they are familiar with such as the swimming complex or the nearby shopping mall from the school. It enabled them to relate distance and time by viewing the estimated time needed to reach a destination using different modes of travel such as walking or driving using Google Map.

Figure 5. Jeremy exploring Google Map in class

Figure 6. Aaron viewingcollection of fishing rods

## Emergent learning outside class - Emergent learning in class - Planned learning in class

Aaron had a strong interest in fishing. His interest was fuelled by his family activities which include weekend overseas trips for fishing trips on a boat. His house was filled with equipments and artifacts which reflected the family's interest in fishing (Figure 6). During interviews, Aaron showed his fishing equipment to the researchers. At home, he used the Smartphone to view YouTube videos of the marine life. Using search terms on YouTube, he found videos that meet his interest on demand. In the classroom, Aaron shared his videos and knowledge with classmates. One of the students with whom he shared his interest is Roy. In our interview, Roy told us about Aaron telling him how fast a swordfish could swim in the deep sea. This sparked off an interest for Roy to watch "Blue Planet" and borrow books from the public library on the deep sea creatures.

Aaron's interest in the marine life extended to his knowledge about animals. In a lesson where the teacher asked students to animate the characteristics of the mammals, Aaron drew an Elephant Shrew. He correctly identified the characteristics of a mammal. His choice of drawing an Elephant Shrew showed his knowledge of animals. He asked questions about fishes such as "Where do Red Groupers live?", "Where do Water Hares live?" and "How do fish lay eggs?" in his KWL chart (What do I know, what do I want to know, what have I learned) in the Smartphone. His knowledge about fishes is impressive for an 8 year old as he stated that "Rabbit fish live in holes in the water", "fish have gills to breathe in water", and "fish use their fins to swim." In class, he continued to increase his understanding and interest using the Smartphone to look for information and view videos.

## Students' Attitudes towards Smartphones for Learning

The scenarios described above provided us an understanding of how individual student learn in different contexts, in and out of the classroom, and across different social contexts over time. This project seeks to examine changes in the 39 students' attitudes towards learning with the Smartphone in and out of classroom after introduction of the devices and designed lessons. In the survey, the students provided feedback on the affordances of the Smartphone and its role to helping them to learn after six months of usage. The survey results are presented next.

Among the 39 students, around 80% of the students feel Smartphone helps their learning. 85% agree that the Smartphone help them learn class subjects and 79% agree that Smartphone help them learn things outside of school. 62% students agree that they understand better the science concepts learned in class and how things they learn in class are connected to their daily lives.

Table 2. Students' attitudes towards HTC phone & its role for learning (N=39)

| | Agree (%) | Neutral/ Not sure (%) | Disagree (%) |
|---|---|---|---|
| It is easy to use. | 71.8 | 20.5 | 7.7 |
| It is light enough for me to carry. | 74.4 | 17.9 | 7.7 |
| The size of the screen on the HTC Smartphone is too small to do my school work. | 25.6 | 10.3 | 64.1 |
| The size of the keyboard on the HTC Smartphone is too small to do my school work. | 17.9 | 15.4 | 66.7 |

| | | | |
|---|---|---|---|
| I do not think that using the Smartphone helps my learning | 2.6 | 17.9 | 79.5 |
| It helps me learn my class subjects. | 84.6 | 12.8 | 2.6 |
| It helps me learn things outside of school. | 78.9 | 18.4 | 2.6 |
| It distracts me from doing my school work. | 7.7 | 25.6 | 66.7 |
| I understand the science concepts learned in class better | 61.5 | 35.9 | 2.6 |
| I understand better how things I learn in class are connected to my daily life. | 61.5 | 33.3 | 5.1 |

When comparing students' attitudes toward the role of Smartphone in their learning in September survey with their attitudes in the February survey, we found that from the paired-sample *t* test, students' attitudes have a positive change towards the use of mobile devices for learning in class ($t(38)=-2.765$, $p<.01$) and out of class ($t(38)=-2.321$, $p<.05$) after the introduction of the smartphone and a series of "mobilized" lessons (Table 3). Students like the learning activities using computers and gadgets more than before ($t(38)=-2.016$, $p<.05$).

Table 3. Results of paired-sample t test on students attitude (N=39)

| | | Mean | Std. Deviation | *t* |
|---|---|---|---|---|
| Mobile device helps me learn my class subjects. | Feb Survey<br>Sep Survey | 1.46<br>1.82 | .643<br>.451 | -2.765** |
| Mobile device helps me learn things outside of school. | Feb Survey<br>Sep Survey | 1.42<br>1.76 | .683<br>.490 | -2.321* |
| I like the learning activities using computers and gadgets. | Feb Survey<br>Sep Survey | 1.05<br>1.23 | .223<br>.536 | -2.016* |
| I learn more when I work in a group than alone. | Feb Survey<br>Sep Survey | 1.37<br>1.68 | .633<br>.662 | -2.634* |

*$p<.05$, **$p<.01$.

Both survey questions asked students if they think they can learn by "playing video and computer games", "watching videos on the computer or the web", and "browsing the Internet". Before the HTC phone introduction, only 26% students feel they can learn by "playing video and computer games", 38% of them think they can learn by "watching videos on the computer or the web", and 65% think they can learn by "browsing the Internet". Half a year later after the introduction of HTC phone, the percentage increase to 56%, 87% and 92% respectively. After 6 months of using the Smartphone, a student gave the following feedback in the survey:

> I like to have more projects on My Projects and have more Sketchy activities. Sketchy helps me learn to raw (draw) nicer, write nicer, it helps me to search for more information from the Internet….The Internet helps me to search for pictures I like and searching for more information.

The use of the Smartphone facilitates the students learning and fulfills their own personal interest. Another student commented: "I like using because it has games, worksheets and teaches us more about animals, fungi, materials, length and many other more." A student indicated her interest in using the Smartphone outside of school when she said "I prefer to use the phone outdoors like in the zoo or park."

## Conclusion

This paper discusses how the affordances of mobile technology match the premises of seamless learning, and present seamless learning scenarios from our research. Till recently, not many studies in the literature make full use of the vast potential for learning spaces out of classroom to enrich school education. Studying in and out of class learning will enable us to gain insights and build theory on the notion of seamless learning. As discussed in this paper, students' learning spaces can be enhanced or extended by mobile technologies which support learning across multiple contexts and time scales. Mobile technology can support seamless learning in a variety of contexts over long periods of time. By enabling learners to learn 'anytime, anywhere', mobile technology augments the propensity for students to engage in self-directed learning on the fly. Student could adapt the use of mobile technology in different contexts for different purposes that could be related to their interests or learning goals. The mobile technology enables students to learn, through ways of organizing ideas, memories and personal resources, to support seamless learning. It enables students to describe and preserve their observations and reflections, by means of diaries, planners, timelines, picture taking and audio/video recording etc.

From our initial findings, we observed how learning occurs and is connected seamlessly across the boundaries through social interactions and the environment mediated by the use of the technology. Students view the Smartphones as learning tools as they use it over time inside and outside the classroom. Understanding technology-supported seamless learning is important for researchers and practitioners who are interested in connecting classroom learning and out of classroom learning spaces in order to create rich and holistic learning experiences for the students. We hope this paper will stimulate further discussions on how to design and study seamless learning environments that can foster 21st century knowledge and skills among the young generation of learners.

# A Tempest in a Teapot Is but a Drop in the Ocean: Action–Objects in Analogical Mathematical Reasoning

Dor Abrahamson
University of California—Berkeley, Berkeley, CA 94720–1670
dor@berkeley.edu

**Abstract:** We discuss a brief transcribed excerpt from a task-based interview with Li, an 11.5-year-old participant in a design-based research study of probabilistic cognition pertaining to the binomial. We investigate whether and how Li made sense of the behavior of an unfamiliar computer-based artifact—the diminishing proportional impact of successive random samples on the overall shape of a dynamically accumulating outcome distribution. Li constructed two informal analogical situations as multimodal discursive means of concretizing, elaborating, and communicating his emerging understanding of the artifact's behavior. These non-routine utterances shifted the discourse to an explicitly embodied, imagistic space bearing unique affordances for negotiated epistemic syntheses of phenomenological and technological constructions of quantitative relations. Microgenetic analysis suggests that Li's presymbolic notion was not a static magnitude but an intensive-quantity "action–object"; he subsequently unpacked this dynamical "*a*/*b*" qualia into its constitutive "*a*" and "*b*" elements. We reflect on implications of this counter-curricular sequence for educational design.

## Background: Student Analogy as Researcher Opportunity

We are interested in the phenomenon of mathematics learning. We conceptualize mathematics learning as the process in which an individual builds meaning for mathematical artifacts, such as notions, semiotic devices, and procedures. We research this learning process in an attempt to understand what it is that students do when they build meaning for mathematical artifacts, what teachers do to support this process, and what instructional materials may best serve this process. In the current study, we examine one student's metaphorical reasoning as he attempts to construct meaning for the behavior of an unfamiliar mathematical artifact. In particular, we seek to determine the student's initial ontology of the artifact as indicating his pre-articulated phenomenological resources that could plausibly serve as proto-mathematical. So doing, we question the warrant of some epistemological assumptions underlying traditional mathematics curriculum.

Our comments in this essentially theoretical paper should be taken as no more than conjectural. Nevertheless, an appeal of the paper would be the potentially effective theoretical fit, and hence methodological fit, between the dynamical nature of the particular artifact at the center of the student's inquiry and our interest in the dynamics of multimodal mathematical reasoning. This fit enables us to elaborate on Phenomenology tenets and Learning-Sciences conjectures regarding the precedence of unreflective perception of action over analytic construction of concepts, as we investigate the purchase of these conjectures on our empirical data. Ultimately, we hope to draw tentative conclusions aligned with parallel research efforts so as to offer an intellectual space for conversation informing future studies.

Probability—the mathematical content selected for this study—is amenable for our investigation of tension between phenomenological and cultural constructions of situations and artifacts. That is, the unique epistemological "mode" created by situations involving uncertainty, and in particular the challenges of articulating such uncertainty symbolically, appears to impel students to seek non-symbolical discursive genres as means of expressing their intuitive quantitative reasoning (e.g., Rubin & Hammerman, 2007). The consequent protracted discursive interim from the embodied to the symbolical is conducive for examining the microgenesis of meaning. Namely, we conjecture that the metaphors generated by this study's focal student served him as more than vehicles for communicating "ready-made" coherent notions. Rather, we believe that the cognitive–discursive actions of evoking and "grammarizing" these metaphors were instrumental for the student's *initial* articulation of his reasoning. If this conjecture bears out through further research, it would present a number of implications for mathematics-education theory and practice. In terms of theory, we would suggest that idiosyncratic metaphors could enable diverse individual students to ground challenging mathematical constructs in their prior quantitative experiences, both formal and informal. In terms of practice, we would encourage teachers to cultivate socio-mathematical classroom norms of discourse in which such metaphorical constructions are approved and possibly even solicited.

## Metaphor as a Unique Semiotic Means of Objectification

When students encounter a new situation and attempt to determine what it is, they are tacitly attempting to determine what it is *like*. This reasoning process is usually opaque to others as well as, perhaps, to the students. Usually, it is only when the students subsequently respond in non-normative ways to problem situations that we assume that their underlying conceptualizations of the situation are non-normative. By stating their metaphors explicitly, though, students create opportunities to reflect more concretely on their emerging conceptual system for a given mathematical subject matter content as well as to receive targeted formative assessment and guidance in learning this content. We conjecture that instructional discourse around metaphor plays a unique role in students' bridging between tacit and cultural constructions of quantitative situations. Through analyzing a student's metaphorical constructions, we hope to promote research into this conjecture. Our proposal to endorse metaphorical reasoning as central to the practice of mathematicians and, hence, of mathematics-education researchers, agrees with recent emerging interest in "embodied" or "multimodal" forms of quantitative reasoning (Abrahamson, 2009b; Edwards, Radford, & Arzarello, 2009; Lemke, 1998; Presmeg, 2006) as well as with converging testimonies and theory pertaining to the explorative and desultory process of mathematical learning and discovery (Lakatos, 1976; Schoenfeld, 1991; Thompson, 1993). Furthermore, demonstrating pivotal roles of multimodal mathematical reasoning would add to the ongoing conversation among cognitive scientists regarding a looming paradigm shift from amodal to modal conceptualization of human reasoning (see Barsalou, 2008; but cf. Dove, 2009).

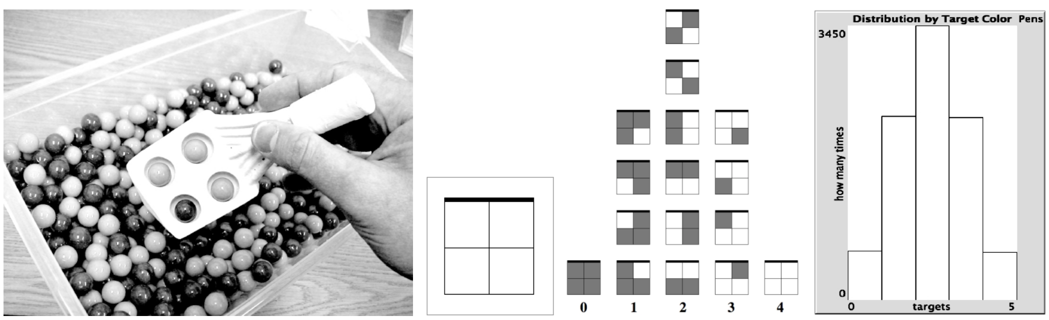
We view mathematical learning as a dialogic, distributed, reflexive, and emergent process. Students learn by building personal meanings for mathematical artifacts. They do so by appropriating these artifacts as significant means for multimodal semiotic objectification of their presymbolic notions. It is thus that designed and guided participation in artifact-based social activities mediates disciplinary knowledge as internalized discursive praxis (Mariotti, 2009; Radford, 2008; Sfard, 2002). And yet, students' naïve presymbolic notions, judgments, implicit heuristics, and inferences for quantitative situations are sometimes more sophisticated than they can initially express (e.g., Gelman & Williams, 1998), particularly when students who are not yet fluent in proportional constructs attempt to express notions of perceptually privileged intensive quantities (Piaget, 1952; Stroup, 2002). Thus, it is important that educators create opportunities for students to avail of their capacity for pre-articulated quantitative reasoning, such as by making available in the learning environment mathematical artifacts that accord with structure information students tacitly seek (Abrahamson, 2009b). In this negotiation of meanings for mathematical artifacts (Cobb & Bauersfeld, 1995), metaphor serves as a powerful discursive engagement, because it explicitizes—for the student, teacher, classroom, *and researcher*—the student's (idiosyncratic) reasoning.

That said, for this study we do not take a philosophical or cognitive position as to how students first develop these metaphors or how they evoke them in situ as inferential discursive mechanisms (cf. diSessa, 1983; Halliday, 1993; Lakoff & Núñez, 2000; see in Ortony, 1993). Instead, we treat the evocation of metaphor at a larger analytic granularity, as a species of abductive inference amid encounter with a novel problem (e.g., Prawat, 1999). Moreover, we are committed to framing students' reasoning as situated not in a solipsistic void but as an integral aspect of discourse (Sfard, 2002). Particularly, we are inspired by Radford's (e.g., 2008) view of mathematics learning as guided discursive processes in which students appropriate semiotic artifacts as means for objectifying their presymbolic notions. From this semiotic–cultural perspective, we wish to examine the hypothesis that metaphor, too, is a means of objectification and to explore its unique properties, roles, and prospects within institutionalized practices of mathematical learning. We propose that students recall personal experiential gestalts as a means of reifying the emerging coherence they sense in mathematical artifacts yet initially lack formal constructs or vocabulary to express.

## Source Data and Research Questions

The transcribed excerpt that constitutes the source data for our study is from an interview with Li, an 11.5 year-old male student ranked by his mathematics teachers as high-achieving. Li was one of 28 Grades 4–6 study participants from a private suburban K–8 school in the greater San Francisco East Bay area. The context of these 1-hr. interviews was a design-based research study of late-elementary and middle-school students' intuitive notions pertaining to the mathematical study of probability as well as the potential roles that a set of mixed-media technologies of our design could play in enabling these students to leverage any such naïve notions toward understanding mathematical formulations of random phenomena, specifically the binomial. Using a flexible protocol, we conducted semi-structured clinical interviews (Ginsburg, 1997). The sessions were videotaped for subsequent analysis, and selected episodes were transcribed. The research team employed collaborative qualitative microgenetic analysis techniques (Siegler & Crowley, 1991) as well as grounded theory (Glaser & Strauss, 1967), through which emergent insights were articulated and iteratively crosschecked against the entire data corpus as a means of consolidating, investigating, and developing new constructs (diSessa & Cobb, 2004). Instances of student elaborate metaphorical reasoning were extremely rare (only four identified within a total of 26 hours of data) yet appear to be uniquely informative. In particular, students' gestures therein enable us to speculate on their conceptualizations of proportionality and probability (e.g., Alibali, Bassok, Olseth, Syc, & Goldin-Meadow, 1999).

Figure 1 overviews four central objects and target artifacts that were used, constructed, and/or automatically generated during the interview. The marbles scooper is used to draw a sample of exactly four ordered marbles from an "urn" of mixed green and blue marbles (see Figure 1a). This hypergeometric experiment—*during* each 4-marbles sample draw, marbles are not replaced—approximates the binomial due to the ratio of *n* (4 marbles) to the content of the urn (hundreds of marbles). In the interview, we first ask the participant to guess what would be the experimental results of scooping. Next, the participant is guided to use crayons and a pile of stock-paper cards each bearing a blank 2-by-2 matrix (Figure 1b), so as to create the sample space of the experiment and assemble it in the form of the *combinations tower* (see Figure 1c). Later, the dyad engages computer-based simulations of the same experiment (e.g., see interface fragment—a histogram—in Figure 1d). Here, we examine one student's reaction to one feature of one artifact—Li's reaction to the diminishing proportional impact of samples in the "4-Blocks" simulation.(1)



*a.* *b.* *c.* *d.*

Figure 1. Materials used in the study—theoretical and empirical embodiments of the 2-by-2 mathematical object: (a) The marbles scooper; (b) a template for performing combinatorial analysis; (c) the combinations tower—a distributed sample space of the marbles-scooping experiment; and (d) an actual experimental outcome distribution produced by "4-Blocks," a computer-based simulation of this probability experiment.

The computer-based model "4-Blocks," built in NetLogo (Wilensky, 1999), simulates the marbles-box probability experiment. 4-Blocks includes a virtual 2-by-2 array (see Figure 2, next page). When a virtual sample is taken, each of the four cells in this array is randomly assigned either green or blue coloration. For example, the sample may be three green and one blue cells in any of the four possible orders (hence, "3g1b"). The model computes the number of green cells in the array, such as 3, and this value is supplemented to a list (that by default is not seen by the user). Immediately, the interface reflects this new result by "bumping up" the appropriate histogram column, such as the second-from-right column, by a vertical extent commensurate with one unit. A feature of 4-Blocks is that its histogram updates dynamically even as the experiment is running. (To interact with the 4-Blocks model as well as to view the video clip discussed herein, visit http://edrl.berkeley.edu/publications/conferences/ICLS/Abrahamson-ICLS2010/.)

The vertical extent of a unit is dynamically calibrated to the histogram's maximum *y*-axis value (e.g., this *y*-value is 43, in Figure 2). That is, the histogram has an "autoplot" feature: when a category column "grows" such that it is about to exceed the maximum *y*-value, this value increases by one unit so as to accommodate the impending growth. The column thus remains as tall as it was, "glued" to the top of the histogram frame, while other columns appear to sag down a unit. Consequently, as the simulation is running, the vertical extent of a single unit keeps diminishing. Thus, when the maximum *y*-value is 10 (the default initial value), a unit is 1/10 of the height of the frame, resulting in the perception of a major upward jolt on the screen when a sample is taken. In Figure 2, a unit would be smaller, at 1/43 of the height. When the maximum *y*-value is relatively large, such as 1,000, a unit is only 1/1,000 of the histogram, resulting in a minute perceptual change. Moreover, at 10,000, an upward motion may demand finer calibration than the pixels could accommodate, so that very often the columns would not register any perceivable change at all.

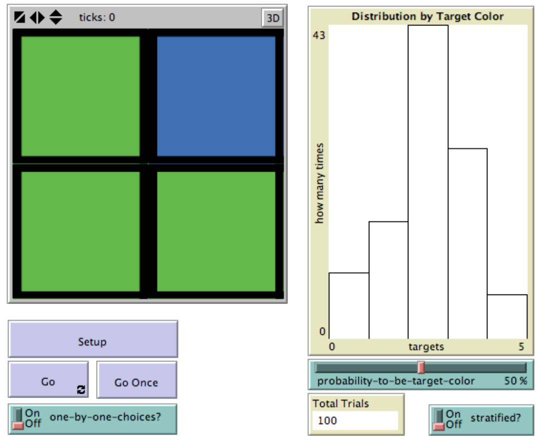


Figure 2. The 4-Blocks NetLogo simulation of the marbles-box probability experiment after 100 samples.

This phenomenon—the diminishing perceptual impact of samples as the experiment runs—is a potentially useful feature of the NetLogo modeling-and-simulation environment, because of its inherent capacity to gradually shift the user's attention away from the impact of each haphazard sample and toward the distribution gestalt, which the user might thus objectify as an aggregate property of the simulated phenomenon (Wilensky, 1997). Moreover, the absence of numerals along the histogram's *x*- and *y*-axes appears to impact the user's primary construction of relations among the histogram columns: rather than constructing these relations as mediated through symbolically notated absolute values and calculated differences among them, the user can construct them proportionately based on immediate perceptions of relative heights and/or areas. Thus, in each and every long-term run of the simulation, the user may experience opportunities to witness and reflect on the gradual yet ineluctable emergence of the distribution shape, such as the 1-4-6-4-1 shape of the marbles-scooping binomial experiment set at $p = .5$ (Figure 1d); with guidance, users may be able to construe this shape as objectifying their presymbolic sense of the phenomenon's aggregate characteristics (e.g., the expected plurality of 2g2b, see Abrahamson, 2009b).

By and large, such was the case with all our 28 participants, including Li. Yet how would Li make sense of the histogram? In particular, would Li perceive the impact of each sample upon the distribution as proportional to the quantity of aggregated outcomes? If so, what resources might this student, who has not studied ratio-and-proportion formally, bring to bear in making sense of this phenomenon of diminishing perceptual impact, and how might he articulate his inferences? From an instructional-design perspective, is the technologically sophisticated semiotic system built into the autoplotting histogram helping or hindering Li's learning?; is this histogram "cognitively ergonomic" (see in Abrahamson, 2009b), and if so, which phenomenological resources could it tacitly cue and how might Li articulate these notions mathematically?

## Analysis: Analogy-Based Unpacking of Intensive-Quantity Action–Objects

In this section we present and discuss a 41-second videographed excerpt and annotated transcription of a conversation fragment between Li and the interviewer, in which Li reasons analogically about the samples' diminishing perceptual impact on the histogram shape. The excerpt begins when Li and Dor have already negotiated the construction of the sample space, have assembled it in the form of the combinations tower, have discussed relations between the marbles-box experiment and the combinations tower, and have been working on 4-Blocks. Doing so, Li draws on non-mathematical phenomena as contexts for his quantitative reasoning. Li's rhetorical strategy is to build an argument by comparing two extreme cases of sampling: (a) at the beginning of the experiment, when a relatively small number of outcomes has accumulated so that each supplementary sample causes quite a "splash"; and (b) well into the experiment, when a considerable number of outcomes has accumulated, so that any additional sample causes but a "ripple." His first context—the glass/lake analogy—will present this contrast in full, and then the second context—batting averages—elides the first of the two cases in pragmatic enthymeme and states only the second case. Just prior to these analogies, though, Li anticipates that the emergent experimental frequency distribution will resemble the combinations tower in shape; he will then monitor this emergence to evaluate his prediction.

Dor: So what do you think might be the shape of the **columns**, as **it** goes up?
Li: [Gesturing to the combinations tower] Something like this.
Dor: Well let's see. [activates experiment, explains autoplotting] So what's happening?

Li: [Gesturing to the distribution] **It's hovering at around this** [gestures to combinations tower]…. [20 seconds later, when 5,000 samples have been drawn] **Look, it's** [the frequency distribution] **almost exactly like this** [the combinations tower]…. [30 seconds later] **Now they're** [columns] **moving less** [inaudible].

Dor: Why is **it** moving less?

Embedded in the interviewer's questions is an implicit linguistic passage from "the columns" to "it." Li picks up this cue and accordingly refers to the columnar frequency distribution with the pronoun "it." Irrespective of the fullness of his understanding at this point, Li's appropriation of the interviewer's singular pronoun as reference to the column collective suggests he is construing the distribution as an intact, if amorphous, object. Soon after, Li again frames the aggregate motion as "plural" behavior. Below, this *motion* is about to become the *object* of discussion. Namely, the histogram's figural change is first described with a verb ("moving") but will soon become a noun ("splash" vs. "ripple") (cf. Bakker, 2007, for a similar case of Peircean 'hypostatic abstraction' in statistical analysis). What is unique about these nouns is that they are inherently about change. That is, the object at the core of Li's proto-mathematical reasoning is not a static magnitude, such as the measured vertical displacement of the histogram bars (an '*a*' element) or the cumulative number of samples (a '*b*' element)—Li's tacit phenomenological primitive in this dynamical experience is a synthetic a priori—an intact action-based *a*/*b* change-over-time intensive-quantity unit (cf. Stroup, 2002). Thus, technological affordances of visualization media—the dynamical autoplotting histogram—may reverse mathematics learning sequences from the traditional magnitudes-before-relation to relation-before-magnitudes. Li's ensuing metaphorical outburst, in which he deftly unpacks the intact *a*/*b* change–object into its *a* and *b* constituents, we submit, implies that we should take pause, as mathematics educators, to consider the possibility that students learning intensive quantities, such as in the mathematics of change, may avail of trajectories that go counter to traditional curricular sequencing. It is thus that computers may "restructurate" mathematical content (Wilensky & Papert, 2009).

Yet what phenomenological resources will Li bring to bear in explicating the change–object? Whereas the NetLogo histogram, when the model is run, foregrounds change as the salient object of attention and may thus render the mathematics of change more accessible to learners, the autoplotting feature may conceivably challenge students due to its ostensible phenomenological aberration. That is, in "real life," we may muse, growing aggregates actually occupy greater space. Intriguingly, however, natural visual perception is a perspectival experience, in which retinal prints of objects depend on their distance:

Li: /2 sec/ **Because**…/3 sec/ [gazes up to the wall] **the larger number**…/3 sec/ uhh… ["checks in" with the interviewer] /2 sec/ [rapidly] **Like if you have a little glass** [iconic gesture: LH cups a glass in natural position near body; gazes at glass] **of water and you drop a marble in** [iconic: LH uncups, rises, drops marble], **it's gonna be... there's gonna be, like, a splash** [LH, palm up, abrupt vertical rise], **but if you have a big giant lake** [LH, palm up, drawn back and up above head to encircle expansive lake; RH, in jacket pocket, budges to complete circumference], **and you throw a marble in** [LH catapults marble, then scratches nose]**, there's just gonna be a ripple** [joins LH thumb and index, lowers hand to chest height on right-side of embodied space; taps fingers together, possibly marking marble's contact with surface, then inscribes smooth horizontal line across to the left; hand opens]. **It's a, it**… [gestures to histogram, orients gaze and pivots body towards it]

Dor: **Oh, ok. Like each individual additional sample** [LH gyrates swiftly, iterating addenda] **is causing less of a** [LH & RH "contain" combinations-tower outline]**…**

Li: [cuts in mid sentence] **Yeah, it's like a batting average in baseball. If you've already had five hundred at-bats**(2) [LH opens, shifts slightly to the left, palm up, "holding" the 500 at-bats, then relaxes]**, and then you get out one more time, it's not going to make it go down that much—it'll make it go down like two points** [LH pinches thumb and index, as per "ripple," as if to subtract two points]**, or**…

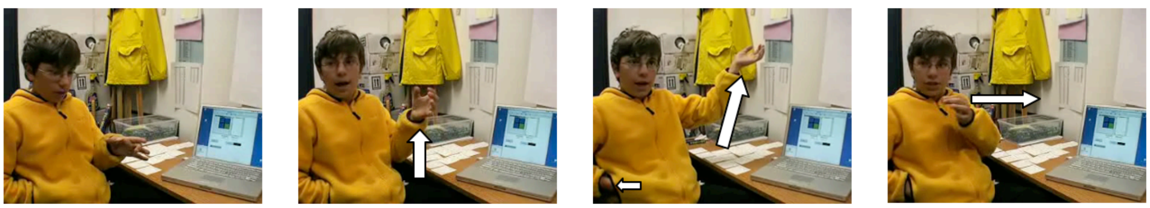
Dor: Ok, so as we go along, each successive sample causes less of a commotion.

Li: **Yeah.** [Gazes back at the computer screen] **Look, they're just barely moving.**

The conversation, above, pertained to variation in the effect of a single sample on the proportional distribution of experimental outcomes: as outcomes aggregate, the proportional impact of each additional sample diminishes. Viewed on the computer screen, the self-compressing histogram converges on the 1-4-

6-4-1 distribution, eventually portraying the dynamic aggregation as perceptually static, albeit the constantly updating maximal *y*-axis value reveals the process as additively active. Li appears to understand this principle. However, this high-achieving $6^{th}$-grader's limited fluency with proportional constructs does not enable him to capture the process with appropriate vocabulary, such as "proportion" and its cognates, or with suitable mathematical constructs and arithmetic operations for conceptualizing and treating rational numbers, as witnessed in his aborted attempt, "Because the larger number…" Consequently, Li evokes a situation analogous to the dynamic artifact yet evaluated as more conducive to objectifying the principle. Li thus unpacks "splash > ripple" as "one-marble-impact : size-of-glass > one-marble-impact : size-of-lake."

The key physical dimension underlying the splash-vs.-ripple articulated comparison is the vertical height of the water displacement in each. And yet, would not a marble thrown into a lake produce a vertical displacement of water that is at least as large if not larger than in a glass? What is at stake here, it appears, is not the absolute physical size of phenomena but their pre-rationalized perturbations to the perceptual field. Thus, ratio is pre-built into perspective as an optical calibration. Moreover, equally sized distal events are normalized by their containers, because these perceptions' phenomenological circumstances are such that events occurring in larger containers are physically farther from the viewer and therefore retinally smaller. Li's spontaneous gestures inscribe the glass and lake *as they would be perceived in the unreflective phenomenology of lived experience*, so that the lake occupies little more optical canvas than the glass does upon Li's "visuo–spatial sketchpad" (see Baddeley & Hitch, 1974).[(3)] Thus, Li can compare two intensive quantities—the splash and the ripple—on the basis of their retinal magnitude alone (see Figure 3, below).[(4)]



Glass Splash Lake Ripple

Figure 3. Dominant gestures in Li's glass-vs.-lake comparison analogy, with arrows as action overlays.

In summary of Li's first analogy, his argumentation responded to the interviewer's request for an explanation regarding the patterned behavior of a dynamical mathematical object—an electronic histogram that is confined in its total interface real-estate yet monitors an ever-aggregating vertically surging outcome distribution. Li's analogical constructions, however, *shifted the dyad into an imagistic discursive space, wherein larger aggregates are in fact embodied in larger objects*. Therein, Li compared two intact experiential events, both a priori intensive quantities; only through engaging in thinking-for-speaking (Slobin, 1996) did Li unpack each of these quantities "cubistically" (Nemirovsky & Ferrara, 2009) such that its respective constituents were "liberated" (Bamberger & Ziporyn, 1991) into *a* and *b* magnitudes so that each event was reconstructed as an *a*/*b* qualitative quotient. This unpacking is anecdotally enhanced by Li's essentially unidextrous sequential gesturing, which radicalizes the discursive caveat of linear utterance.

In selecting a baseball context for his second analogy, Li evokes a situation that is more conducive to mathematizing his argument. First, monitoring quantitative aspects of this popular activity is a familiar, culturally appropriate practice. Second, the baseball example is more ontologically consistent than the water example: in the glass-vs.-lake analogy, the perturbation was caused by a marble dropped into water and thereafter the marble is ignored, whereas in the baseball scenario, the perturbation was caused by the player performing an at-bat, which is thereafter added to the denominator of the "batting average" (and to the numerator, contingent on how the at-bat played out). Third, the baseball analogy offers a pre-enumerated set of discrete units, 500 at bats, whereas the water analogy would demand measurement of the continuous body before further calculation could be performed. Finally, a batting average is an a priori proportional construct, so that this analogy is much nearer to the probability context—culturally, semantically, semiotically, and arithmetically—than the water-surface analogy. Thus, in selecting the baseball analogy, Li also steers the dialogue from the rich imagistic detour, which the interviewer had countenanced, back to the institutionally normative genre of discussing quantitative reasoning numerically. Using numbers as precise signifiers of quantity, in the baseball analogy, Li need not communicate magnitudes gesturally—indeed, comparison of the vast "big giant lake" gesture to the modest "500 at-bats" cupping as well as, analogically, comparison of the lake-impact gesture to the "-2" (read: "-.002") gesture demonstrate pragmatic contraction in iconicity from the first to the second context (see Radford, 2008).

Having completed his two-analogy argumentation sequence (see Figure 4, below), Li looped the dyad back to the phenomenon under inquiry. Presumably, the interlocutors, who renew their co-attention to the histogram, do so with newly shared professional vision established in analogical discursive space.[5]

Figure 4. Analogizing the proportional impact of an addend as a function of the size of the aggregate.

Li's imagistic analogical detour suggests that he needed to step back from the sophisticated semiotic device and reconstruct a phenomenological scaffold by which to perform epistemic adjustment that then enabled him numerical objectification of his presymbolic image of proportional convergence. Implicit to this process of mathematization was re-describing multimodal phenomenology in conventional techno–scientific form. This bridging task, an aspect of meta-representational capacity (diSessa & Sherin, 2000), is cognitively non-trivial. We implicate the technologically sophisticated self-adjusting histogram as complicit to the tension between Li's tacit and cultural presentation of quantitative information: by perceptually foregrounding proportional change over additive change, the autoplotting histogram offers a cognitively ergonomic engagement of the mathematics of change, yet to avail of this restructurated entry to the disciplinary practice, students require guided opportunities to negotiate embodied and inscribed constructions of focal phenomena. Metaphorical reasoning is one means of accomplishing this negotiation.

## Conclusions

Whereas there is a certain logical appeal to thinking of an object as somehow cognitively simpler than an action (object + motion), the phenomenological perspective perceives actions as prior to objects—objects need to be deliberately pulled out of experience as transcendental to unreflective action. Analysis of Li's imagistic construction revealed that he was drawing on phenomenological gestalts that are experientially a priori to mathematically articulated notions of ratio. Understanding such processes could inform the work of mathematics educators. In particular, educators who reason about mathematics logically but not phenomenologically are liable to introduce $a/b$ constructs by initially presenting $a$ and $b$ as separate elements and only then calculating their quotient and suggesting meanings for this number. Yet such would-be scaffolding may sometimes hamper rather than optimize students' opportunities to draw on their informal reasoning, particularly their tacit intensive-quantity gestalts, in constructing mathematical notions. Instructional design solutions, we believe, lie in between, in creating opportunities for students to negotiate phenomenological qualia and their mathematical reconstructions (Abrahamson, 2009a, 2009b, 2009c).[6]

## Endnotes

(1) Elsewhere, we furnish detailed explanation of the design motivation and rationale and report on findings and design modifications throughout the iterated study cycles (Abrahamson, 2009c). Therein, we also report on the earlier part of Li's interview, focusing on his "semiotic leap" from presymbolic to articulated notions.
(2) A "batting average" is the cumulative ratio of hits (successful batting) to at-bats (opportunities to do so).
(3) It could have been fascinating to witness how Li would then inscribe these images using pencil and paper.
(4) The elongated horizontal extent of the ripple gesture does not map onto any *mathematical* analog—it is not the $a$, the $b$, or the $a/b$—yet it is what one would see/feel, so it is gestured. Paradoxically, this mathematically excessive magnitude could constitute a disservice to the comparison, because it inflates the $a$. Yet this "soothing" gesture may be contributing a *holistic* diminutive affect that thus in fact mitigates the ripple in comparison with the splash.
(5) The interviewer never appeared perturbed by dimensions of embodiment, discourse, and inscription implicit to Li's utterance, because he shares with Li tacit cognitive mechanisms for engaging multimodal reasoning.

(6) The data analyzed herein were collected in a study supported by an NAE/Spencer Postdoctoral Fellowship 2005-6. The ideas we present herein are the result of the Seeing Chance group's collaborative work, foremost Mike Bryant

# Quiet Captures: A Tool for Capturing the Evidence of Seamless Learning with Mobile Devices

Ivica Boticki, Hyo-Jeong So
Learning Sciences Lab, National institute of Education, Nanyang Technological University, Singapore 637616
ivica.boticki@nie.edu.sg, hyojeong.so@nie.edu.sg

**Abstract:** Seamless learning environments help students in extending their learning experiences across social, personal and environmental dimensions, and are supported by different tools, information and communication technology. In order to capture the evidence of the ways students utilize mobile devices in their formal and informal learning pursuits, a quiet data capture program was designed and pilot-tested. It is used to capture both quantitative and qualitative data about device use, to track user generated data and artefacts persistent across time and to generate and render aggregated reports identifying usage patterns. It is supposed to serve as a mechanism of identifying affordances of mobile devices within the landscape of seamless learning. Some preliminary findings raising multiple questions and inevitably sharpening our research lenses are presented towards the end of the paper.

## Introduction

Mobile devices are nowadays used by younger generations on a daily basis to access web content, to capture different artefacts (e.g. photos, voice recordings, notes etc) documenting daily activities, and to communicate with peers via synchronous (e.g. Skype for mobile devices) and asynchronous tools (e.g. SMS). However, their popularity is hardly ever extended into classrooms since school policies see mobile devices as a disruptive factor. Moreover, lesson plans and assessment strategies employed in many educational institutions usually do not allow these innovative technologies to be used as pervasive learning tools.

On the other hand, mobile devices are, according to some researchers, an enabling force to transform education (Roschelle & Pea, 2002; Sharples, Taylor, & Vavoula, 2005; Waycott, 2004; Zurita & Nussbaum, 2004). At this point, there exist numerous case studies illustrating innovative ways of incorporating mobile devices into various classroom activities (Anastopoulou, et al., 2008; Ardito, Buono, Costabile, Lanzilotti, & Pederson, 2007; Chen, Kao, Yu, & Sheu, 2004; Colella, 2000; Dufresne, Gerace, Leonard, Mestre, & Wenk, 1996; Facer, et al., 2004; Klopfer, Squire, & Jenkins, 2009; Proctor & Burton, 2003; Rogers & al., 2002; Roschelle, 2003; Sharples, Lonsdale, Meek, Rudman, & Vavoula, 2007; Vahey & Crawford, 2002). Moreover, some researchers have produced encouraging results for policy makers willing to participate in this exciting process of educational change (Klopfer, et al., 2009; Sharples, et al., 2005)

Although there is still lack of theories of mobile learning from pedagogical perspectives (Sharples, et al., 2005; Vavoula & Sharples, 2008), it is evident that mobile devices are becoming pervasively integrated into student activities outside schools. While there is no doubt that students utilize them in their daily leisure activities, it remains unclear whether there is an added educational value brought into students' lives with the help of these ubiquitously present tools. Even more intriguing questions start to emerge as we delve into this heavily under-explored area on pedagogical issues: is there a way of establishing a link between classroom and informal daily activities with the mediation of mobile devices? What kind of skills can be better taught with mobile devices? Can they be used for inquiry learning redirecting knowledge from informal into formally structured learning environments or vice versa? All these together with other emergent issues are being examined under the Seamless Learning project conducted in Singapore (see Looi, 2010 for more details). Both formal and informal learning spaces are being explored together with the synergistic effects of linking the two in order to achieve the continuity of learning experiences across different learning scenarios. The project tries to achieve so called "seamlessness" with the combinations of different parameters across multiple dimensions of learning environments.

The aim of this paper is not to answer all the above stated questions, but to focus on designing a tool that can be both used to capture and analyse invaluable information generated from everyday activities with mobile devices that primary school children are involved in. In order to collect the evidence of the ways students utilize mobile devices in their formal and informal learning pursuits, a quiet data capture program was designed and pilot-tested. The program is used to capture both quantitative and qualitative data about device ussage and to track user generated data and artefacts persistent across time and locations. The gathered data is aggregated in a form of reports helping researchers to pinpoint the areas of informal activities relevant to formal learning. Experiences gathered this way can be used in designing lesson plans which incorporate mobile devices and to accordingly design innovative applications for learning with mobile devices. Ideally, these should coincide with students' informal learning interests and broaden possibilities for seamless learning experiences.

The paper is organized as follows: we first present the theoretical background of the Seamless Learning project in relation to mobile learning. Then, we present the design and development of the quiet capture tool, followed by some collected data and preliminary reports used to better understand seamless learning experiences; and we conclude with future research plans and implications.

## From Mobile Learning to Seamless Learning

The *technological strand* of researchers in the area of mobile learning has focused on mobile devices, such as identification of device characteristics important to learning, the development of systems for mobile learning, appropriation of mobile devices for effective learning. An example of device-focused definitions of mobile learning can be described as learning activities using mobile phones, handheld computers, digital portable devices for music reproduction, digital cameras, voice recorders and digital pens (Excellence, 2006; Freitas & Levene, 2003; Wikipedia, 2009; Wood, Keen, Basu, & Robertshaw, 2003) The other strand of mobile learning research still focuses on devices, but explores the role of related technological aspects, including wireless networks, intelligent user interfaces and generally the advancements in the development of both hardware and software computer equipment which makes mobile learning possible (Boticki, Mornar, & Bozic, 2006; Holzinger, Kickmeier-Rust, & Albert, 2007; O'Malley & al., 2004; Wang, 2004). On the other hand, the *pedagogical strand* positions technological solutions coupled with the areas of learning and teaching they can best support (O'Malley & al., 2004). According to this strand, technology should be designed to support learning, rather than being appropriated to reach certain pedagogical goals. Hence, mobile devices are seen as mediating tools for activities supporting constructivist and situative approaches to learning.

Some researchers analyze the *mobility* of the learners as the primary characteristic of mobile learning (Kress & Pachler, 2007). Since learners learn on various locations, knowledge acquired at one location can be applied to others (Freitas & Levene, 2003; Sharples, 2000). Mobility of knowledge can be seen in terms of time scales as well. Previously acquired knowledge is supplemented with new ideas and strategies over time. For instance, Sharples and colleagues (2005) suggest that Some researchers suggest hat by placing the "mobility of learning as the object of analysis we may understand better how knowledge and skills can be transferred across contexts such as home and school, how learning can be managed across life transitions, and how new technologies can be designed to support a society in which people on the move increasingly try to cram learning into the interstices of daily life (p.2)".

The *Seamless Learning* project in Singapore presented in this paper examines synergistic effects of linking formal and informal learning environments in order to achieve the continuity of learning experiences across different learning scenarios. It examines both individual and social approaches to learning and tries to determine the role of one-to-one TEL (technology enhanced learning) in Primary (elementary) School children's learning experiences (Looi, et al., 2010)..

From pedagogical perspective, seamless learning examines an inevitable shift from teacher-centred to learner-centred learning environments and tackles the issues of traditional schooling practices suffering from the excessive amount of decontextualized information, indirect and abstract knowledge, and second hand experiences (Barab, 2002). Many of today's classroom learning still have a strong focus on individual cognition, pure mental activity without tool use and overly context-general learning (Brown, Collins, & Duguid, 1989). Through the notion of seamless learning, we aim to examine learning that takes place through the individual learning in private spaces, collaborative learning in public spaces, together with the cognitive artefacts created across time and physical or virtual spaces mediated by technology within a context. These artefacts facilitate knowledge construction and social discourse, and mediate interaction among a community of learners. To achieve so, we have employed distributed cognition as a theoretical lens and have integrated ethnographic approaches into our research design, especially in examining informal learning experiences (Hollan, Hutchins, & Kirsch, 2001; Looi, et al., 2010).

Our research is twofold: on the one hand, it examines formal learning environments and proactively tries to "mobilize the curriculum" or to achieve systematic changes in terms of how in-class learning can be implemented, sustained, and assessed through the use of mobile technologies. For this purpose, existing curricula have been "unpacked" to designing lesson plans that promote collaborative, inquiry-centred, and self-directed learning experiences (Looi, et al., 2009). Mobile devices and applications play an important role in this. For example, our participants, 39 primary school students, organize and externalize their knowledge with the help of GoKnow mobile learning suite (Figure 1), practice collaborative skills using the Seamless Mobile Forum (Figure 2), and other applications available on their HTC Windows Mobile 6.0 based smartphones.

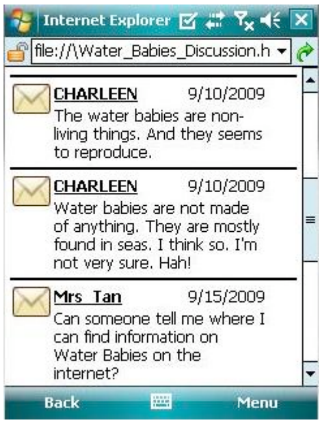

Figure 2. Seamless Mobile Forum Created Within the Seamless Learning Project

## Capturing the Evidence of Seamless Learning on Mobile Devices

### Choosing a Data Collection Approach

In addition to examining seamlessness within formal learning environments, our goal is to examine student-initiated learning that is impromptu and emergent (Sefton-Green, 2004). To achieve that, we have decided to employ a concurrent mixed method as a data collection and interpretation approach (Creswell, 2009). Quantitative data collection helps us in getting the idea of general trends while qualitative methods allow us to extract specifically significant patterns or cases for more in-depth analysis. Qualitative and quantitative data collection mechanisms are exercised concurrently, thus bringing us towards a clearer picture of informal learning spaces, together with the role of mobile devices in facilitating such learning experiences.

In our Seamless Learning project, qualitative data collection methods include sustained classroom observations, interviews with the students and their families, and observational studies (Sefton-Green, 2004). Sustained classroom observations enable us both to gain the holistic picture of the classroom atmosphere and to capture the emergent social processes. Interviews are done in participants' homes and include students and their family members primarily focusing on the informal learning experiences outside classrooms. Observational studies are used in designed spaces (currently in a science museum) to capture both video and sound clips of entire family visits to examine family interaction and discourse in a designed informal learning space.

Quantitative instruments utilized in the project include surveys, experiments and log files. Surveys primarily serve as a mechanism for longitudinal evaluation used to compare formal assessment results and students' attitudes towards the mobile device use at project milestones. Survey instruments therefore both guide us in our future research pursuits and provide us with a means of evaluating long-term effects of our inevitably interventionist approach. Experiments are used to test out novel tools, such as mobile computer supported fractions software, primarily in order to gather usability and learning experience feedback. Unobtrusive methods such as log files provide an authentic, time-efficient means of recording student learning behaviours and can capture a wide range of data that reflect student practices, activities, context, situations and events (Buckley, Gobert, & Horwitz, 2006; Cole, 1995).

### Mixed Method Approach to Quiet Captures

One of the common methods of collecting data from mobile devices is through log files that support an objective data collection method of acquiring quantitative data on device usage. Due to the convergence trend (i.e., mobile and communication devices merging into a single device), mobile devices are becoming powerfully connected computers allowing the development of specialized applications to be installed and used on them. Log files are sometimes referred to as the quiet captures emphasizing the unobtrusiveness of the way they are embedded into user's experiences. They typically capture the data on applications used and the overall time spent.

In addition to their obviously limited coverage and purely quantitative orientation, current log file applications require researchers to periodically gather logs from participants' devices, thus to a certain level interfering their experiences. Furthermore, user generated artefacts are not tracked persistently across time (i.e. students delete self-created videos), and do not capture the context of student-device interaction during the identified patterns of usage. *Therefore we propose a mixed mode quiet capture approach with the following features: (a) the ability to capture both quantitative and qualitative data about device usage, (b) the ability to transfer and track user generated data and artefacts persistently (i.e., created movies, sound clips and pictures) to researchers in real-time 24/7 and (c) the ability to generate and render aggregated reports identifying usage patterns.*

Qualitative approaches to collecting device usage data consist of capturing device screenshots when some specific applications are used and/or when users start interacting with the device. Those screenshots are timely ordered and sent to the central repository through the 3G wireless mobile connection. Captured screens are then available to researchers in form of a web site and can be browsed and filtered according to the attached contextual information. Quantitative approaches to collecting data rely on the classical log file method of collecting the duration of application usage extended with a possibility of transferring content to the central repository in real-time.

Our subjects are equipped with mobile broadband plans with unlimited data transfer package. In this context, 3G connection serves as a means of providing affordable real-time 24/7 data transferring channels to central data repositories. This eliminates two drawbacks of the classical quiet captures approaches: (a) researchers do not have to manually gather the collected data from mobile devices in order to analyze it, and (b) data is available for the analysis whenever the need exists. Moreover, student generated artefacts are stored across time: pictures, files and videos are stored and become inerasable proof of user activities available for future analysis.

Researchers are provided with the web interface through which qualitative and quantitative data can be analyzed (Figure 3 on the next page). Quantitative data can be examined through the various reports while qualitative data is given to researchers for further detailed analysis. Both can serve as a connecting point not only in cross-modality verification of the results, but also in the interpretation of data acquired by employing various collection methods.

## Quiet Capture Tool Architecture

The tool gathers various types of information, such as application usage, student generated artefacts and screenshots to transmit them to the server side web service over the 3G wireless network. The transferred data is kept persistently into the server-side database for later retrieval. The stored data is available to researchers in the forms of predesigned reports 24/7. Students can therefore be monitored real-time, and usage statistics are generated on demand (Figure 4.)

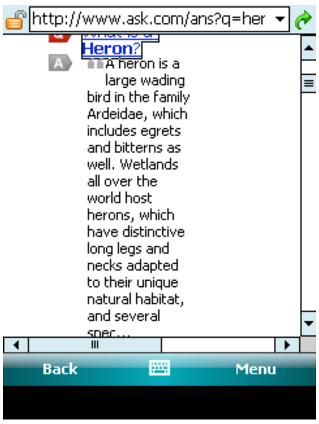

Figure 3. A (quiet) screen capture used to examine emergent inquiry based learning (a student searching for information on Heron birds)

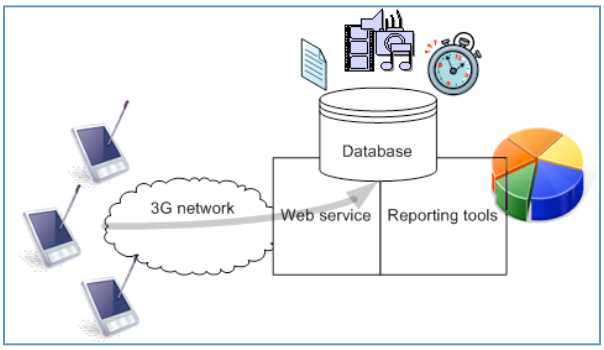

Figure 4. Quit capture tool system architecture

Needless to say, such a design requires mobile devices to be equipped with mobile broadband wireless Internet access plans with adequate bandwidth. In our project, students, in addition to the devices themselves, are given the 24/7 Internet access with unlimited data transfer plans. Instances of the quiet capture tool were installed onto the student devices, and they run as long as the devices are on. As soon as students decide to turn off the device, the tool's activity is suspended, thus saving resources such as battery life and Internet data connection. The client-side component of the quiet capture tool is composed of the following modules: Activity Detection Module, Artefact Gathering Module, Screen Capture Module and Data Transfer Module.

## Reports on the Formal and Informal Device Use

The value of the described quiet capture approach lies in the analysis performed on the collected data generating aggregated reports about device use. At this point, we are able to share rough reports generated from the data of our 39 primary school students tracked both in and out school over one month. Although the amount of data is not significant to draw any final conclusions, we feel that the reports match and supplement the findings from other employed data collection instruments and surely inform us of behaviours exhibited by the students.

To depict the average time students spent on using the devices, we employ the functional framework in informal learning activities on mobile platforms (Clough, Jones, McAndrew, & Scanlon, 2007; Patten, Sánchez,

& Tangney, 2006). Activities are therefore classified into (a) Collaborative, Location-aware, (b) Data collection, (c) Microworld, (d) Administration, (e) Referential, (f) Appropriation and (g) Interactive (Figure 5).

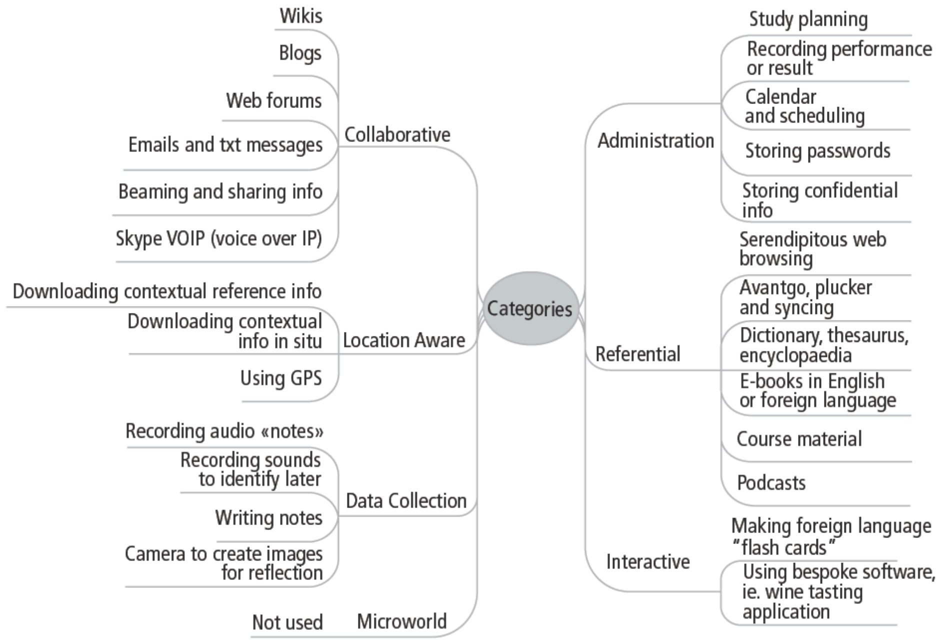

Figure 5. The map of the functional Framework in informal learning activities on mobile platforms (Clough, et al., 2007; Patten, et al., 2006)

Figure 6. shows that our students were mostly involved into the "Referential" activities (46% of the average time a student spent on purposely using the device) which include web browsing, checking dictionaries, accessing course materials, etc. In addition to that, students were often engaged into the Data Collection, Interactive Activities and Games. Since Patten et al's (2006) functional framework does not clearly state which category should mobile computer games assigned to, in our analysis we are considering them as a separate category (Figure 6).

To get a clearer picture on the data presented in the Figure 6, a more detailed report is made available to researchers (Table 1). In addition to the average time students spent on a specific activity type, the report shows minimum, maximum values and the standard derivation extracted from a month data of student activities. This report makes the differences in student interest more evident, particularly when some categories, such as games or interactive applications are concerned.

In order to gain an in-depth picture on the specific application use, researchers can drill-down the report and obtain specific application usage statistics (Figure 7). The figure shows 15 applications students on average spent the most time on (in minutes). The analysis reveals that Web browsing applications such as the Internet Explorer and Skyfire are the most utilized tools on students' devices, closely followed by the applications for watching videos such as YouTube, Player, and Streaming Media.

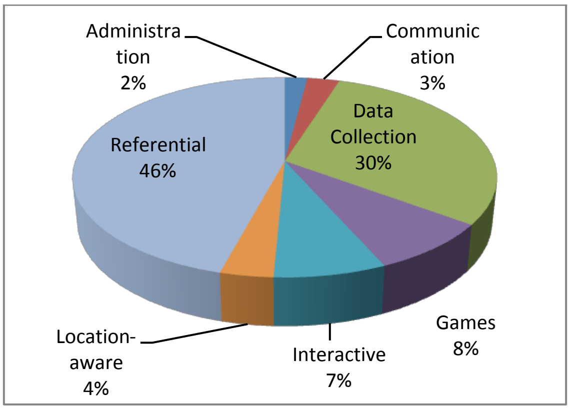

Figure 6. Distribution of student device use time according to the application types

Table 1. Monthly time (in minutes) students spent on an application type

| *Application type* | *MIN* | *MAX* | *AVG* | *STDEV* |
|---|---|---|---|---|
| **Administration** | 0.02 | 47.55 | 4.72 | 8.78 |
| **Communication** | 0.03 | 40.95 | 6.77 | 10.74 |
| **Data Collection** | 24.95 | 150.58 | 70.93 | 0.28 |
| **Games** | 0.12 | 169.13 | 19.43 | 3.55 |
| **Interactive** | 5.50 | 65.68 | 17.27 | 13.56 |
| **Location-aware** | 0.05 | 29.95 | 8.18 | 10.13 |
| **Referential** | 2.67 | 705.42 | 107.58 | 12.58 |

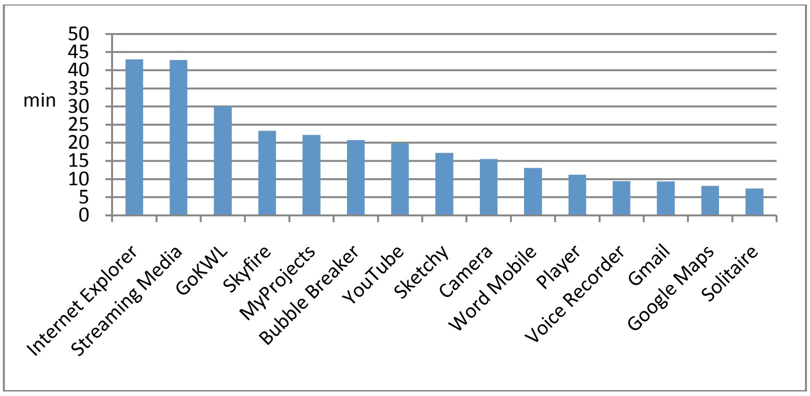

Figure 7. Average monthly time (in minutes) a student spent on using specific application (given only for the 15 top applications)

One of the main aims of our project is to examine the relationship of the formal and informal learning environments. In order to achieve so, we have analyzed specific application usage according to the time of the day: Table 2 has specific application names and times of the day as its two-dimensional base, while the third dimension contains average student monthly usage. The chart serves as a visual aid in determining the patches of significant user activities enabling researchers to drill down and identify specific sub-categories of interest.

Table 2. A table showing average monthly time (in seconds) a student spent on a specific application according to the time of the day

| Application name/Time of the day | 0 | 1 | 2 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Skyfire | | | | 279 | 1635 | 1699 | 1557 | 33 | 184 | 328 | 359 | 307 | | 1466 | 73 | 474 | 995 | 2 | 2766 | 728 | 391 | 15 | |

Researchers might opt to examine a specific application for a more refined analysis. For example, the contour chart signals high overall usage of the Internet Explorer application throughout the entire day, especially being the extreme in the end of the day.

## Conclusion and Future Plans

The paper presented one of the tools in the mixed mode approach for capturing mobile device use data from both formal and informal learning environments. We presented the quiet capture tool to gather application usage information, student-created artefacts and screenshots. Researchers can use the reports generated from the collected data to examine students' use of mobile devices across different location and time scales.

Preliminary findings presented in this paper show that students tend to spend a significant amount of time on using the device in their personal spaces. They mostly browse the Internet for information and videos, and create interactive digital artefacts. For some students, the informal use of mobile devices produces a shift in cognitive processing skills, while for the others the device has become a social mediating tool facilitating interaction with the classmates.

It should be noted that all data reported in this paper is collected with the participants' consensus for confidentiality and privacy issues. Researchers need to consider that such quiet capture tools may collect private data unwanted by the participants so that it is important to ensure user anonymity and ethical use of collected data.

Future research plans include working with researchers on developing new views on the collected data, developing triangulation methods for merging data gathered from other data collection methods and further expanding the amount of data to be collected. As an example, there are plans to introduce geo-tagging of all collected information in order to enable the creation of location-based reports. In addition to analysing informal learning experiences according to a new spatial dimension, we will employ data mining and aggregation techniques to determine in what extent our students use the devices in and out school, specifically focusing on several spatio-temporal categories: in-school, holiday, during weekends and during the week.

Although at this point we observe that students use mobile devices to learn beyond the walls of classroom and formal institutions, and the usage clearly impacts their formal learning experiences, we are still in the process of designing mechanisms to clearly prove so. We believe the Quiet Captures tool presented in this paper can be used to give us better understanding of the context in which the links emerge and vanish. We have only begun to understand the complex interplay of formal and informal learning spaces constantly having in mind that it is our job to nurture the link between formal and informal learning environments and to utilize this unique opportunity to promote holistic learning experiences.

# The Many Dimensions of Having a Good Eye: A Methodological Reflection of Metaphors in Visual Cognition Analysis

Andreas Gegenfurtner, Anna Siewiorek, Centre for Learning Research, University of Turku, Finland
Email: angege@utu.fi, amsiew@utu.fi

**Abstract:** There seems to be a stable and widely held belief among medical practitioners that good diagnosticians have a good eye that is innate, rather than trained. However, there is no evidence for any identifiable perceptual trait. Nonetheless, the process of developing a good eye in medicine is proposed, indicated, and elaborated by various measures contingent on diverse methodological arenas, all of which attempt to advance our understanding of what constitutes visual cognition in diagnosing medical images. The purpose of this paper is to provide a reflection on this methodological pluralism. We first identify four metaphors used in the analysis of visual cognition: activation, detection, inference, and practice. These metaphors are described with an empirical example and discussed to elicit (partly tacit) assumptions associated with prototypical method decisions. We then link the proposed metaphorical mapping to what it implies for current epistemological, methodological, and curricular discussions in medical education.

## Introduction

There seems to be a stable and widely held belief among medical practitioners that good diagnosticians are born rather than made (Elstein, Shulman, & Sprafka, 1978; Ericsson, 2004; Norman, Coblentz, Brooks, & Babcook, 1992). Indeed, it is a common observation, both in training programs and in clinical practice, that some residents are quicker and more accurate than others in recognizing subtle abnormalities in medical images. Based on everyday observation of these kinds, it has subsequently been concluded that diagnostic accuracy is due to having a "good eye"—one that is innate, rather than trained. However, there is no evidence for any identifiable perceptual trait. To the contrary, recent research has indicated that what has been labeled as a good eye can in fact be developed through training. For example, Dawes, Vowler, Allen, and Dixon (2004) demonstrated that detection performance of clinical students was significantly higher after a 26-week training period than it had been before; materials included graphics used in diverse medical disciplines such as plain X-ray films, ultrasound, computer tomograms, magnetic resonance images, and positron emission tomograms. Similar training effects have also been reported in cardiology (Issenberg, McGaghie, Gordon, Symes, Petrusa, Hart, et al., 2002), radiology (Brazeau-Lamontagne, Charlin, Gagnon, Samson, & Van der Vleuten, 2004), and microscopic pathology (Crowley, Lecowski, Medvedeva, Tseytlin, Roh, & Jukic, 2006). Overall, we can conclude that training can improve visual accuracy; that recognition of abnormities in perceptual tasks can be learned; and that good diagnosticians are made rather than born.

Thus, there is consensus that the development of being a good diagnostician goes in concert with the development of a good eye. What is less clear is what a good eye is. What precisely is it that develops in novice diagnosticians through medical education? What must be appropriated to move toward higher accuracy? Some investigators, particularly Kundel, Nodine, and Carmody (1978), in a now classic study, suggest that the highly perceptual nature of image comprehension requires intensive processing of visual data through oculomotor activity that guides signal detection and decision-making. Others, particularly Lesgold and colleagues (1988), in what is now also a classic study, put less emphasis on the perceptual aspect; rather, they suggest that diagnosing is mainly a cognitive inference that aligns disease schemata from episodic memory consistent with the perceptual features detected. Much medical research done in both traditions has been reviewed elsewhere (Boshuizen & Schmidt, 2008; Ericsson, 2004; Kundel, 2007; Norman et al., 1992; Patel, Arocha, & Zhang, 2005). Recently, alternative approaches have been formulated; these suggest that a good eye is indicated by neurophysiologic events in certain brain areas (Haller & Radue, 2005), and is accomplished through situated social discourse (Koschmann, LeBaron, Goodwin, Zemel, & Dunnington, 2007). In short, the metaphor of having a good eye in medicine is proposed, indicated, and elaborated by various measures contingent on diverse methodological arenas that all attempt to advance our understanding of what constitutes visual cognition.

The main task of the present study is to provide a first step in proposing a reflection on this methodological pluralism. Our goal is to present a framework in which the many dimensions of having a good eye can be considered as mutually constituting the richness we have on ideas, concepts, and theories relating to medical image diagnosis. We have no intent to judge some methodological traditions as being more valuable than others, nor do we intend to unify them in some abstract way. Although the idea of what was termed *interactive complexification* (Alexander, Schallert, & Reynolds, 2009) is considered meaningful for highlighting the confluence of factors that determines "any given aspect" of the product and the process of learning to diagnose medical images, we believe there is, at times, also a place for simple answers. We hope that the framework put forward in this study will provide such a simple answer. The study addresses the questions of how to analyze visual cognition; how to elicit tacit assumptions underlying common research practice; and how to inform curriculum design for medical training in corporate and higher education settings. By discussing four examples drawn from radiology, we identify four metaphors that constitute our framework on visual cognition analysis. Despite its groundwork in medical literature, it could be assumed that the framework also has implications beyond medicine, due to its common interest in learning and comprehension in technology-rich vision-intensive contexts. In the first part of this paper, we introduce four metaphors for visual cognition: activation, detection, inference, and practice. In the second part, we discuss the potential implications of these metaphors in reconsidering standpoints on epistemology, methodology, and curriculum design.

## Four Dimensions of Visual Cognition Analysis: A Metaphorical Mapping

Metaphors are a useful tool for mirroring in simple terms the often complex fundamentality underlying theory and applied research practice. An example of how metaphors are able to elicit complex, different, yet partly tacit, assumptions on a commonly studied phenomenon is the reflection on learning by use of the metaphors acquisition, participation, and knowledge creation (Paavola, Lipponen, & Hakkarainen, 2002; Sfard, 1998). As Sfard (1998, p. 4) notes, "metaphors are the most primitive, most elusive, and yet amazingly informative objects of analysis". We believe that their value and power stems from the fact that metaphors converge and portray, in a snapshot format, what took years of scientific discourse to develop; this allows frank presentation of positions and their entailments in a condensed way and invites a critical (re)consideration of accepted and perhaps unreflected practice. Of course, metaphors are simple and simplistic; there is no claim that they attempt to depict all of the breadth and depth of what often is a complex epistemology.

Below, we identify, exemplify, and discuss four metaphors often used when analyzing visual cognition; these metaphors are seen as four of the many dimensions possessed by one with "a good eye" in medicine. We reflect on these metaphors in terms of what they contribute as an answer for the two questions stated above: The nature of what develops in novice diagnosticians through medical education is not yet clear. The question of what must be appropriated to move toward higher accuracy remains to be answered. It is hoped that the value and significance of this methodological reflection will be that it helps to map a scattered and fragmented field of inquiry. Table 1 serves as the guiding framework for the comparison of the four metaphors, including their methodological entailments: activation, detection, inference, and practice.

Table 1: A comparative metaphorical mapping of visual cognition analysis in medicine.

| | Activation | Detection | Inference | Practice |
|---|---|---|---|---|
| Indicators of visual cognition | Neurophysiologic activity | Eye movements | Verbal reports | Representational practices |
| Unit of analysis | Individual | Individual (social) | Individual and social | Sociotechnical |
| Place of visual cognition | Neural network system | Optic system | (Distributed) memory system | Activity system |
| Analytic time span | Milliseconds | Seconds | Minutes to few hours | Minutes to decades |
| Associated methodology | Cognitive neuroscience | ROC analysis; eye tracking methodology | Protocol analysis | Ethnomethodology |

### Activation Metaphor

Research adhering to the activation metaphor uses measures of neurophysiologic activity as an indication of visual cognition. In the activation metaphor, there is a strong emphasis on the neurological and biological basis of our *humanness* (Alexander et al., 2009; see also Meltzoff, Kuhl, Movellan, & Sejnowski, 2009). This emphasis might originate from the widely held belief that "information is stored in neural networks in the brain, and that human behavior arises from extremely complex communication between neurons in these networks and also between separate networks or assemblies" (Sauseng & Klimesch, 2008, p. 1003). This neural network system is seen as the place where visual cognition occurs. Hence, visual cognition is indicated by neural activity. Specifically, this activity can be measured by an electroencephalograph (EEG) as the electric current in axons; by a magnetoencephalograph (MEG) as the magnetic field induced by those electric currents; by a positron emission tomography (PET) as the blood flow distribution in the cells; or by functional magnetic resonance imaging (fMRI) scanning as cellular oxygen consumption. Whenever information stored in neural networks is used for cognitive processes, neural activation occurs that can be measured with one of those tools. For example, if a radiologist formulates a diagnosis based on a patient's fMRI scan, an fMRI scanner could be used to indicate the processes of this radiologist's visual cognition. These processes are extremely fast; the best conventional apparatus currently available—the EEG scanner—is able to trace this activity with a temporal resolution in the range of milliseconds (Sauseng & Klimesch, 2008). An empirical example prototypical for the activation metaphor can further illustrate epistemological and methodological premises.

Haller and Radue (2005) investigated differences in neuronal activations of radiologists and laypersons in reading radiologic and non-radiologic images. Using functional magnetic resonance (fMRI) imaging, the brain scans showed that radiologic images evoked stronger activations in the brains of radiologists than in those of laypersons, with the bilateral middle and inferior temporal gyrus, bilateral medial and middle frontal gyrus, and left superior and inferior frontal gyrus being particularly affected. These regions are generally assumed to be linked to the encoding and storing of memory of visual objects and events. Hence, this finding seems to imply that what is seen on the presented image is automatically referenced to memorized images, indicating an unconscious, stimulus-driven indexical relation between the pictorial representation and the corresponding mental representation. Being prototypical for research in neuroscience, Haller and Radue (2005) used technological images as stimuli in a series. Stimuli were shown for 2.5 seconds followed by a fixation cross for 8.5 seconds to compensate for blood oxygenation level-dependent signal delay. Subjects gazed at the stimuli series with an immobilized head in darkened and (electrical and auditory) noise-protected rooms. Settings of this kind are highly controlled. These types of controls are necessary because neural measures are highly sensitive: activation should be shown in response to the stimulus only. Strong controls therefore aim to guarantee bias-free recordings.

At this point in time, the activation metaphor for visual cognition has rarely been used in medical diagnosis studies. However, the coming together of the learning sciences and neuroscience is beginning to form an exciting new field (Ansari & Coch, 2006; De Jong, Van Gog, Jenks, Manlove, Van Hell, Jolles et al., 2009). An answer comes into play regarding the question of what develops in novice diagnosticians through medical education; namely, that neuroscience has the potential to trace implicit and experiential learning before it can be observed in behavior. This will allow us to understand when, how, and why learning occurs. In particular, the how and why can be tackled within these highly controlled settings. Certainly, it is not a novel statement that behaviors, such as diagnosing a medical image, that appear similar on the surface may involve very different cognitive/perceptual mechanisms underlying this behavior. Neuroscience, in combination with the learning sciences, now provides a new avenue for tackling these issues, to further understand expertise development in novice diagnosticians. Results derived from the activation metaphor therefore have the potential to inform the design of medical education and training; more on this issue will be offered at a later point in this paper.

## Detection Metaphor

Detection can be defined as "determining whether a simple, featurally defined stimulus is present in, or absent from, the visual field" (Smith & Ratcliff, 2009, p. 283). A central premise of research using the detection metaphor is uncertainty, that is, the degree to which a subject is able to discriminate between signal (the stimulus of interest) and noise (background stimuli distracting visual attention, thus causing decision-making under conditions of uncertainty). In medical image diagnosis, the signal would be a tumor, while noise would be (healthy) organic material surrounding the tumor. Clearly, in pictures as complex as radiographs, with an abundance of structures, forms, and elements displayed in manifold shadings of grey, detection of a tumor is a challenging task. Tasks of this kind are frequently used to quantify the ability of discerning between signal and noise. Two approaches are prevalent: eye-tracking methodology and receiver operating characteristic (ROC) analysis. Below, an empirical example by Kundel, Nodine, Conant, and Weinstein (2007), which combined eye-tracking with ROC analysis, can illuminate prototypical premises of each approach.

Kundel et al. (2007) investigated rapid initial fixations (detections) on abnormalities on mammograms. Briefly, they found that more experienced radiologists showed global perceptual processes that helped them detect the abnormality (malignant breast lesions) in less than a second. In contrast, less experienced radiologists showed search-to-find strategies that took considerably longer to first fixate the abnormality. Visual cognition differences in these two groups were indicated by eye-tracking and by ROC analysis. With respect to eye-tracking, the recording of eye movements is usually used to visualize the scan paths of observers. In Kundel's study, radiologists with more experience had longer saccades and fewer fixations than did less experienced radiologists. This empirical evidence is consistent with many studies that adhere to the detection metaphor in radiology (Mello-Thoms, 2003), cardiology (Augustyniak & Tadeusiewicz, 2006), and microscopic pathology (Krupinski et al., 2006). With respect to ROC analysis, detectability was significantly higher for observers with more experience than for those with less experience. Detectability is a measure that quantifies the sum of true positives and true negatives, divided by the sum of all positives and negatives in a detectability value, $d_a$.

A conclusion can be made that the detection metaphor indicates that novice diagnosticians develop a good eye through medical education in terms of their ability to discriminate a potential signal from background noise. This ability can be quantified and expressed mathematically in a formula that allows comparison of observers at the individual or the group level. Studies in the detection metaphor, which usually employ eye-tracking methodology and/or ROC analysis, indicate that superior visual cognition can be characterized as a high decision-speed accuracy relation: Visual perception changes with a rise in experience, from a relatively slow search-to-find mode to a global holistic mode. This change then increases sensitivity, specificity, and accuracy of the detection performance. Usually, the analytic time span is longer than the time span of cognitive neuroscience studies. The work of Kundel et al. (2007), which can be seen as a prototypical example, reported an average search time of 26.90 seconds, and a median time to first fixate the abnormality (the signal) of 1.13 seconds. Traditionally, eye-tracking studies have focused on individual observers as the unit of analysis; however, recent developments of eye-tracking technology and of new analytic algorithms now allow collaborative gaze studies (e.g., Sangin, Molinari, Nüssli, & Dillenbourg, 2008). It will be fascinating, from an epistemological point of view, to follow the coping of tension between attentional detection as an individual quantifiable performance, notable in mathematical functions (i.e., Smith & Ratcliff, 2009) on one hand, and detection as collaborative achievement and intersubjective meaning-making (much in line with Koschmann & Zemel's, 2009, notion of *discovery as occasioned production*), on the other hand.

## The Inference Metaphor

Lesgold and colleagues (1988, p. 336) speculated that radiological diagnosis "is largely a matter of cognitive inference. That is, given a set of findings (perceptual features), one has to determine which diseases are consistent with those findings. If more than one disease is consistent, then one either looks further, (…) or suggests additional medical tests to discriminate among the possibilities". Two issues are striking in this initial quote. First, Lesgold emphasizes cognition and memory processes in diagnosing medical images. Back in the 1980s, this was not customary in the medical literature. Although there have been pioneering studies on cognitive processes (e.g., Patel & Groen, 1986), most focused on perceptual processes (based on Arnheim, 1969, see also the section on the detection metaphor). What Lesgold indicated and empirically tested was thinking as an essential function in medical diagnosis. Second, in this quote and elsewhere in his chapter, Lesgold emphasized how vision and cognition correlated in the formation and evaluation of diagnostic decisions. Experienced radiologists build mental representations that guide perception. The literature now knows a variety of rhetorical functions built from verbal protocols to describe those mental representations, among them Lesgold's schemata, encapsulated scripts (Boshuizen & Schmidt, 2008), E-MOPs (Kolodner, 1983), SUSTAINs (Love, Medin, & Gureckis, 2004), or PANDEMONIUM processors (Selfridge, 1959). In the next paragraph, we describe a more recent example on the correlation of vision and cognition in medical image diagnosis that nonetheless is still informed by Lesgold's (one might tend to say: seminal) speculation of cognitive inference.

Morita and colleagues (2008) investigated how perceptual and conceptual processing interrelates in the diagnosis of computer tomograms (CT). Shortly, they found that expert compared to novice CT readers verbalized more findings, more hypotheses, and more perceptual activities. Importantly, experts verbalized many perceptual features during conceptual activities, and verbalized conceptual words during perceptual processing. Put differently, this indicates that experts retrieved and used knowledge from memory based on information that they saw on the CT image, which iteratively stimulated looking at the image based on knowledge coded in memory (be it in the form of encapsulated scripts, E-MOPs, or schemata). From a methodological point of view, it would be tempting to criticize the neglect to use eye movement recordings; this would have allowed highly specific, quantifiable measures of perceptual activity. Yet, verbal protocols can also be used as indicators for visual cognition. Usually, as prototypically shown in this example, protocols are collected for a duration of up to few hours and then are analyzed with a focus on cognitive mechanisms. From this perspective, the inference metaphor on visual cognition clearly emphasizes the cognitive parts of the interrelated process. Morita and colleagues (2008) decided on individual CT readers as a unit of analysis. However, protocols can also be used at a group level (Greeno, 2006; see Simpson & Gilhooly, 1997, for an example in cardiology) to indicate collaborative negotiations and intersubjective meaning-making.

The inference metaphor on visual cognition can answer, in two respects, the question regarding what develops in novice diagnosticians that moves them toward higher accuracy. First, knowledge develops; an extensive knowledge base is the foundation for expert performance and for rapid inference of coded memory to detected visible features. Second, the perceptual-conceptual processing linkage develops. Morita and colleagues have demonstrated that protocol measures are a valid tool for eliciting cognitive mechanisms underlying CT diagnoses that guide, and are guided by, perceptual detection. Epistemologically, the inference metaphor appears to account for both signal detection and the alignment of knowledge from memory (inference) that is consistent to what is detected. Nevertheless, methodologically, it lacks the precise and time-sensitive measures such as eye-tracking gaze recordings or cortical oscillation EEGs. This is because researchers rely on explicit, conscious think-aloud utterances from subjects and these cannot account for the underlying implicit, non-conscious processing of these subjects. Hence, the sole use of protocols—be it at an individual or at an agglomerated group level—risks the resemblance of linguistic descriptions that play a rhetorical function in describing and illustrating phenomena; examples of these fancy rhetorical functions, which simply cannot be fully validated by protocol analysis alone, are provided above (SUSTAINs and the like). Due to their intrinsic method constraints, it thus seems reasonable to aim toward combining protocols with other measures, and hence to avoid the risk of using one single metaphor only. More on this issue will be elaborated below.

## The Practice Metaphor

Finally, the last metaphor we identify as being frequently used in visual cognition analysis in medicine is the practice metaphor. Practice generates semantic structures of information that shape and are shaped by sequentially unfolding activity in relevant manners for a domain of scrutiny such as laparoscopy (Koschmann et al., 2007). As a starting point, we present the following quote from Carsetti (2004, p. 307) that we found interesting enough to use to introduce our reflection on the practice metaphor "A percept is something that lives and becomes, it possesses a biological complexity which is not be explained simply in terms of the computations by a neural network classifying on the basis of very simple mechanisms". This quote has two interesting elements. First, it emphasizes the lived nature of visual cognition, or what Livingston (1986) referred to as the lived work of reading. We will present an empirical example in the next paragraph that elaborates on this notion. Livingstone, in a series of ethnographic field descriptions, highlighted the sociability of practices that constitute intersubjective thinking and acting As such, the author provided a look that differed from looks "behind the skull" (Garfinkel, 1967) or from "computations by a neural network" (Carsetti, ibid). The second interesting element in this quote is that it seems to align neuroscientific work with labels such as "simply" and "very simple". We lack authority and motivation to judge such a judgment about the simpleness of neuroscience as being itself simplistic. Nevertheless, it illustrates the position of this author that something that focuses only on neural activation is unable to account for the full complexity of visual cognition (interestingly, compare the quote of Sauseng & Klimesch, 2008, starting the activation metaphor section, where the complexity of neural network communication is emphasized). Certainly, it is a matter of definition what "complex" is or what shall be allowed—based on which methodological and epistemological considerations—to have "complexity". Making such (maybe tacit, maybe deliberate) assumptions explicit is one of the purposes of this contribution.

To further illustrate the methodological entailments of the practice metaphor, we describe a recent example elaborating on the lived work of mammography. Slack, Hartwood, Procter, and Rouncefield (2007) highlight how diagnosing a mammogram is reflexively contingent on artful practices, in which multiple readers interact and intersubjectively constitute breast biographies. Central in their analyses are practices. Goodwin (1994, 2000) indicated that seeing and interpreting what is seen are not exclusively cognitive processes located in the individual brain (cf. activation and detection metaphors); rather, seeing is a socially situated activity accomplished through the deployment of a range of historically matured discursive practices. These practices constitute visual cognition in Goodwin's terms, and they are negotiated around a common object of disciplined perception (Lindwall & Lymer, 2008; Stevens & Hall, 1998), in the study of Slack and colleagues (2007): pictorial representations of the breast produced by an X-ray apparatus. Slack et al. identified practices such as arranging mammograms, manipulating, annotating, gesturing, and pointing that contribute to the lived work of doing a radiologic diagnosis. These representative practices (Greeno, 2006) unfold within an activity system, in many cases temporally over the course of minutes, but their sociogenesis stretches over the course of decades (such as the material resources used, i.e., pictures produced by X-ray technology). Hence, analysis of visual cognition using the practice metaphor adopts a different analytic time span than does, for example, analysis using the activation metaphor; and it adopts a sociotechnical system as the unit of analysis that explicitly accounts for the role of technology in medical image diagnosis (Burri & Dumit, 2008; Gegenfurtner, 2009). It is essentially the focus on embodied talk-in-interaction—talk between people and between humans and non-human objects (Gibson, 1979; Suchman, 2007)—that makes the practice metaphor a useful tool to analyze the fourth perspective; namely, what constitutes visual cognition, what medical students have to appropriate to move toward diagnostic accuracy, and how medical educators act to help develop this higher level of accuracy (see, e.g., Koschmann et al., 2007; Slack et al, 2007).

## Implications and Conclusions

This paper has presented and discussed a mapping of visual cognition analysis in medical education centered on four metaphors: activation, detection, inference, and practice. Reflection on these metaphors can give significant answers in three areas, namely: epistemology, methodology, and curriculum design. First, it provides an epistemological answer on the ongoing debate regarding the vision-cognition divide. Are perceptual and cognitive processes independent of each other? Or is the separation between vision and cognition artificial, a mere analytical distinction? Specifically, many studies in medical research adhering to the detection metaphor include no additional measures that are more prevalent in the inference metaphor, and vice versa. This neglect to combine measures for less fallibly accounting for visual cognition indicates the (maybe tacit) assumption in the medical literature that vision and cognition are independent. An assumption of this kind results from a way of thinking informed by an information processing view of cognition. This view stands in contrast to an ecological view on visual perception and cognition (Gibson, 1979), in which seeing, thinking, and acting are mutually interactive and nondualistic. It is questionable which approach is better: the information processing approach or the ecological approach. We argue here, as we have at the beginning of this paper, that it is not a question of truth or value judgment. Different methods lead to different answers based on different indicators. It is a reflection on these indicators, and more generally on the methodological entailments behind seemingly different metaphors, that can help raise awareness of each metaphor's (epistemological and pragmatic) potentiality and contingency, and that can thus advance our research practice in medical education and the learning sciences.

The second answer that is informed by the reflection on different metaphors on visual cognition concerns the dangers of choosing just one. Sfard (1998) indicated that a combination of learning metaphors yields to more robust findings than does a non-combination. This is in line with research in times that have been labeled the *decade of synergy* (Bransford et al., 2006). Yet, combining methods is neither trivial nor simple. As a first step, we briefly list three initial approaches for method synergy. First, eye-tracking and verbal reports can be combined to trace the interaction of perceptual and conceptual processing of visual information. Second, eye-tracking and EEG/fMRI recording can be combined to assess the first seconds of scanning an image—a period that is crucial, especially for higher levels of expertise. Third, video-recording and eye-tracking can be combined to measure the relationship between (1) mutual gaze patterns and (2) collaboration patterns as indicators of distributed visual cognition (Sangin et al, 2008; Stahl, 2006). In sum, synergies between metaphors need to be explored to avoid the dangers associated with choosing just one metaphor.

Finally, the third answer relates to curriculum design. It is thanks to the variety of metaphors available that we can illuminate ways to remake curricula in medical education. Specifically, the activation metaphor and its related methodologies inform the high speed with which visual information is processed, in the range of milliseconds; this cannot be captured with other methods. It also indicates the automaticity of information processing. Together with eye-tracking research, these findings indicate the role of implicit learning. In addition, the practice metaphor highlights the role of hands-on activities in interaction with the technological tool that is not merely used as a stimulus, but rather as a mediating object in the learning process. Learning to handle the tool is considered as important for medical education as is learning to discriminate features in the image; hence, curricula in medical schools can aim (or maybe have aimed) to also develop epistemic practices and professional identity. In summary medical curricula aimed at fostering implicit learning, identity formation, and participation can combine classroom-based direct instruction on disease etiology, learning in the lab with authentic tools, and work-based learning in real-life clinical workplaces, in ways that best support the development of "a good eye" in medial image diagnosis.

The ICLS 2010 conference theme invited an exploration of the ways disciplinary perspectives can inform the study of learning in educational or workplace settings. This theme—elaborated in the call for proposals—suggests an awareness of the multispectral image of learning caused by different, discipline-specific thinking traditions and their associated research custom. This paper has attempted to take up this theme; it did so by bringing together tradition and custom that have evolved over the years around a common topic: the analysis of visual cognition in medical image diagnosis. It can be argued that this disciplinary view, a medical education view, has implications for the study of learning that go beyond medicine. Specifically, in mathematics education, similar research practices can be identified that have as underlying inspiration the activation metaphor (e.g., when children focus spontaneously on number aspects during encoding of photos; Hannula, Grabner, & Lehtinen, 2009); the detection metaphor (e.g, when elementary students solve addition and subtraction word problems; De Corte, Verschaffel, & Pauwels, 1990); the inference metaphor (when schema-based instruction facilitates algebraic thinking for students with learning disabilities; Xin, 2008); or the practice metaphor (when participating in disciplined mathematical practices around coordinate systems; Stevens & Hall, 1998). These snapshots from mathematics education illustrate that the four metaphors identified in medical education literature might also have traces in other domains; if a more in-depth analysis of mathematics education research corroborates this initial snapshot finding, then this would answer one of the questions posed in the ICLS 2010 call for proposals—that is, what seems to be constant in learning processes (more specifically: in visual learning processes) beyond intrinsic disciplinary variations can be captured by different metaphors that highlight the multispectral image of our field: learning research.

## Acknowledgments

This work was supported by Grant No. 128766 of the Academy of Finland; it is part of an interdisciplinary research project at the confluence of medical sciences and learning sciences investigating “Technologies for seeing and technologies for knowing: Learning and medical imaging (LearnMedImage)”. In this project, research seldom is an individual endeavor, but more often is a collaborative achievement. Thus, we would like to thank Roger Säljö, Erno Lehtinen, Hans Rystedt, Laura Helle, Markus Nivala, and Minna M. Hannula for developing with us a good eye for metaphors with which to analyze visual medical cognition.

# Delinquent or criminal? Fostering conceptual understanding of technical terms in computer-mediated collaborative learning

Elisabeth Paus, University of Muenster, Fliednerstraße 21, 48149 Muenster, e.paus@uni-muenster.de
Gisela M. Gerhards, University of Frankfurt, Senckenberganlage 15, 60054 Frankfurt, giselagerhards@web.de
Regina Jucks, University of Muenster, Fliednerstraße 21, 48149 Muenster, jucks@uni-muenster.de

**Abstract:** To ensure a complex understanding of the topics addressed in collaborative learning scenarios, learners have to develop a conceptual understanding of the relevant specialist vocabulary. To this end, they have to exchange and discuss their individual knowledge, which is usually gained through individual exploration of different learning materials. Based on the psycholinguistic concept of lexical alignment, the following study analyzes whether providing learners with different technical terms in their respective learning materials has a positive impact on information exchange, term understanding, and learning. Results showed that dyads whose materials contained different terminology exchanged more information and performed better in a subsequent knowledge test than did dyads whose materials contained the same terminology. The inclusion of illustrations containing different terminology enhanced these effects. Implications for the selection and design of learning materials as well as perspectives for further research are discussed.

## Introduction

In general, language serves as a main tool by which thoughts, needs, attitudes, etc., are expressed. The main challenge in all verbal and written interactions is to achieve mutual understanding. This holds both for everyday situations, such as referring to a person or a thing when telling a story, and for more formal situations, such as referring to the conceptual knowledge that is usually encoded in specialist vocabulary in peer-to-peer learning situations (Bromme, Rambow, & Nückles, 2001). Focusing on the second scenario, let us imagine a typical situation in the life of university students: Peter writes Linda a message to coordinate the content of a presentation they are preparing for a course dealing with Freudian theory. He writes: "… and suppression is another important defense mechanism we should mention!" Linda answers: "I agree. I'll add suppression to the defense mechanisms." They probably both know the terms "suppression" and "defense mechanism" because they have read various texts to prepare for this exchange and the subsequent presentation. From the perspective of classic communication psychology, this discourse sequence clearly seems to be successful. Peter introduces two central terms and Linda signals understanding by using the terms without asking for clarification of their meaning or showing any other signs of mis- or non-understanding.

Following Clark and colleagues, the process by which interlocutors try to establish that messages have been received and understood is called grounding (Clark & Brennan, 1991). Grounding is an ongoing process during communication that serves to determine, to update, and to expand the so-called common ground (e.g., Clark, 1992; Clark & Marshall, 1981), that is, the assumed shared knowledge that provides the basis for communication. The common ground is inferred on the basis of different types of evidence; Clark and Marshall (1981) described three heuristics that people use to estimate what an interlocutor knows. Because in our example Peter and Linda communicate in written form and thus cannot rely on verbal or visual signs of mutual understanding (Monk, 2003), their assumptions about their shared knowledge are based mainly on word use (*linguistic co-presence heuristic*). In ongoing communication, newly introduced terms are usually repeated; they "become part of a 'discourse record' that is a subset of interlocutors' common ground" (Barr & Keysar, 2006, p. 6). The use of the same vocabulary is called lexical alignment (Pickering & Garrod, 2005) and takes place in both spoken (Barr & Keysar, 2002) and written communication (Bromme, Jucks, & Wagner, 2005). According to Clark and Marshall (1981), it is reasonable and efficient to stick to the lexical decisions made by the interlocutor in order to express one's own intended meaning. Interlocutors thus "minimize their collaborative effort—the work that both do from the initiation of each contribution to its mutual acceptance" (*principle of least collaborative effort*, Clark & Brennan, 1991, p. 135). Lexical alignment has also been demonstrated for technical terms in technical communication (Bromme et al., 2005; Jucks, Becker, & Bromme, 2008) such as that engaged in by Peter and Linda in our example. However, in the context of technical terms – as opposed to everyday terms – the difficulty arises that a term's connotations and complexity have to be transmitted within the choice of words and that an important part of the exchange concerns the underlying concepts. For example, whereas interlocutors in everyday communication may have different concepts of the meaning underlying the term "man," this is not relevant for successful communication ("The man is standing on the street."). In contrast, when interlocutors refer to the meanings underlying technical terms, as in our example, lexical alignment can conceal different meanings of a term that are relevant for discourse. Thus, where the deep understanding of the meaning underlying a term is concerned (and not simply the reference to an object in the world), lexical alignment may obscure the fact that the interlocutors have different conceptualizations of a term.

It has already been demonstrated that interlocutors' comprehension of the meaning of a technical term may be differently elaborated (Bromme et al., 2001). In particular, research on expert – layperson communication has shown that the underlying meaning of a technical term and the interlocutors' mental representation may differ (Jucks & Bromme, 2007). Whereas experts are usually aware of the complex knowledge encapsulated by technical terms (Schmidt & Boshuizen, 1992), laypersons' understanding of their meaning is often rather vague or even erroneous (Gittelman, Mahabee-Gittens, & Gonzalez-del-Ray, 2004). When interlocutors use the same words, differences in their knowledge of the underlying concepts are very difficult to detect. In general, it is difficult for people to distinguish between their own and their partner's knowledge of a particular subject, as has been demonstrated experimentally by Keysar (1994). In the same vein, Nickerson (1999) has shown that people tend to impute their own knowledge to others and only gradually become aware of others' knowledge states. Gauging others' conceptual knowledge about technical terms poses an additional difficulty: Because the underlying meaning is usually rather complex and the context of definition may vary (Paus & Jucks, 2009), it is very difficult for interlocutors to define an explicit criterion for knowing "enough" about a term.

Let us now return to our example: Peter introduces the words "suppression" and "defence mechanism." Linda absorbs these words without showing any signs of mis- or non-understanding – lexical alignment occurs. However, the assumption of shared knowledge, or common ground, may be mistaken, because Peter and Linda do not necessarily share the same knowledge of the underlying conceptual meanings. Consequently, using the same words can lead to particularly ineffective communication: Interlocutors communicate based on an illusion of common ground that prevents them from exchanging their knowledge explicitly and thereby developing a differentiated understanding of the concepts underlying the specialist terms. Lexical alignment of technical terms can thus be expected have certain costs in the area of learning and understanding. Indeed, Paus and Jucks (2008) have shown that the use of the same lexical encoding may—tacitly—be taken as an indicator of common ground in computer-mediated peer-to-peer learning settings. In an experimental study, university students working on a cooperative learning task gained more individual knowledge and showed more elaborated discourse patterns when the two participants in a learner dyad were provided with different terminology describing the same technical concept. These findings can be interpreted as follows: If linguistic co-presence is interrupted because the learning partners lack a joint vocabulary, their attention is explicitly drawn to their own and their partner's understanding of the terms. Not having the same words available allows them to assume less overlap in knowledge (Wu & Keysar, 2008). To increase their shared knowledge, they discuss the meaning of the terms. Individual knowledge about the underlying conceptual meaning is therefore exchanged more explicitly, thus fostering the development of a differentiated understanding of the meaning of technical terms as well as a better understanding of the topic in general. To conclude, learners' attention has to be focused on their understanding of technical terms.

Research has already shown that scientific illustrations in text materials attract readers' attention (Jucks, Bromme, & Runde, 2007) and "… exert a specific impact on the form and content of replies" (pp. 213-214). Providing learners with content-specific visualization tools is also known to have a positive effect on both communication and problem solving (Fischer, Bruhn, Gräsel, & Mandl, 2002). Nevertheless, the use of a term unfamiliar to the learning partner may initially cause confusion (Wu & Keysar, 2008). Although this confusion should prompt the more explicit elaboration of the meaning of specialist terms, interlocutors may not be aware of the resulting knowledge gain and instead feel a higher level of uncertainty.

Based on these considerations, our hypotheses for the present research were as follows: (1) We expected learning partners who were provided with different terms encoding the same underlying concepts to exchange more information and to gain a better understanding of the terms and the learning content than learning partners who were provided with the same terms. (2) Additionally, because learners' attention is attracted to the information provided in illustrations, we expected the predicted effects to be increased by the inclusion of illustrations in which the main concepts were also encoded by different technical terms. (3) Finally, we examined the effect of different terminology on learners' feelings of uncertainty. We expected learning partners provided with different technical terms to feel more uncertainty about their own knowledge than learning partners provided with the same terms.

# Method

## Participants and Design

Participants were 72 undergraduate psychology students (47 female, 25 male) at the University of Frankfurt. Mean age was 24.37 years (*SD* = 4.63). All participants were German native speakers. They were assigned to 36 learning dyads and randomly assigned to three conditions: texts with the same terminology, texts with different terminology, texts with an illustration and different terminology. Participation was voluntary and rewarded with 7 euro. Learning outcomes were assessed for each participant individually (sample size: 72

participants, with 24 in each condition); the communication process was analyzed within dyads (sample size: 36 dyads, with 12 in each condition).

## Procedure

Two students participated in each trial. They were tested individually in separate rooms and were assigned gender-neutral pseudo-email addresses to prevent them from making any assumptions about each other. Note that we decided on email rather than chat as the communication medium due to practical aspects of data collection. Each room was equipped with the necessary technology and an experimenter was present throughout. Access to external Internet sites was blocked to prevent participants from using information sources other than the texts provided. First, it was ensured that the participants' computer skills met the demands of the experiment. The partners in each dyad were then given different texts to read and understand with no time limit. They were then set a collaborative task, to be discussed and completed with their partner at their own pace via e-mail. To ensure that the learning scenario was as realistic as possible, no further instructions were given on the procedure and/or the collaboration process (e.g., length, structure, etc.). After the collaborative task, the learning materials were removed to ensure independent knowledge generation in the knowledge tests. Participants provided with an illustration were asked to rate the perceived importance of the illustration for solving the collaborative task. Moreover, all participants were asked to rate their feeling of uncertainty with regard to their knowledge of the topic covered. Afterwards, they were administered a knowledge posttest comprising a cloze task (Taylor, 1957) and a multiple-choice test. Finally, demographic data including the frequency of computer usage were obtained.

## Materials

### Learning texts

The learning texts were original extracts from two child psychiatry textbooks (Herpertz-Dahlmann, 2005; Schmeck, 2004). Both extracts dealt with the development of a social behavior disorder; each was around 500 words long. Except for some abridgements to ensure that the two texts had the same length and format, no modifications were made. Although both texts addressed the same topic, there were differences in the description of theoretical models and in the detail of the information presented. Both texts covered all information assessed in the knowledge posttest.

### Manipulation of the learning material

We first drew up a list of terminology specific to the topics covered. Fifteen key concepts were identified. Some of the terminology used to designate the same underlying concept in the original texts differed (e.g., prevalence vs. frequency); some of it was the same (e.g., monozygotic). In cases where the terminology was the same in both texts, we looked for synonyms in a dictionary of foreign words (Wermke, Klosa, Kunkel-Razum, & Scholze-Stubenrecht, 2001). Each term was matched with a synonym that had the same meaning in the present context. Two different versions of the text material were then constructed by manipulating the usage of the 15 key concepts. In the different terminology condition, the 15 key concepts were used in one encoding (e.g., prevalence) in one text and in the other encoding (frequency) in the other text. In the control condition, the same terminology (prevalence) was used in both texts. When matching the words, we sought to maintain a balance across the texts in the use of terms stemming from Latin or Greek and terms with German roots. The illustrations were both taken from the respective textbooks. They contained 5 vs. 6 of the 15 manipulated terms as well as further terms relating to the development of a social disorder. The terms in the illustration were adapted to the terminology used in the respective version of the text.

### Collaborative task

We set participants two questions to be worked on collaboratively. The questions were designed to support the integration of factual knowledge on the topic at hand as well as the production of inferences during the learning process. To answer the first question, they had to refer to the case study of a 13-year-old boy with behavioral problems. They were asked to list all factors that might have influenced his behavior. The second question concerned the prevalence of social behavioral disorders in boys and girls. Learning partners had to exchange the information contained in their individual texts in order to succeed in the collaborative task.

## Dependent Measures

Three sets of outcome measures were considered: information exchange, individual knowledge gain, and subjective measures.

### Information exchange

Three measures were used to assess information exchange within the dyads:

*Communication.* To assess information pooling during communication, we determined the number of questions asked and the number of explanations given within each dyad. We restricted the assessment to questions and explanations relating to the relevant terminology. Participants' questions and explanations were transcribed and analyzed (by a second rater) according to predefined criteria. Interrater reliability for the numbers of questions asked ($K = 1.0$, $p < .001$) and the number of explanations given ($K = 1.0$, $p < .001$) was satisfactory.

*Knowledge exchange items.* The multiple-choice test included questions tapping knowledge of contents that were included in only one version of the text (six questions for each text). These items were intended to measure information pooling between the learning partners, regardless of the usage of technical terms. Learning partners could answer these items correctly only if they had exchanged their individual knowledge. Additionally, for the two conditions in which learners were provided with different terms, we counted the number of technical terms from the partner's learning material that were used in a cloze procedure to determine how many of these terms had been absorbed from the partner.

### Individual learning outcomes

Individual knowledge gain was measured by the following indicators:

*Multiple choice test:* General understanding of the contents covered was assessed by a multiple-choice test with 28 tasks, each with four response alternatives. All distractors were chosen such that an uninformed participant perceived them as being correct with the same probability (Bortz & Döring, 1995). One point was given for each correct answer, and one point was subtracted for each incorrect answer. Hence, the maximum number of attainable points was 28.

*Cloze procedure.* We developed a cloze test requiring participants to fill in words that had been removed from a text to determine whether they could reproduce the topic-relevant terminology in a continuous text, thus demonstrating an understanding of the underlying concepts (Taylor, 1957). A rational deletion procedure was used to identify the 10 words that were omitted; only content words (subjects, objects, adjectives, and verbs) were removed (Kobayashi, 2002). Eight of the omitted words were drawn from the list of manipulated terminology. We were thus able to test the participants' understanding of the terms. The remaining two items tested the main topics covered in the two texts. Participants were given one point for each gap filled correctly. Thus, the maximum number of attainable points was 10.

### Subjective ratings

*Relevance of illustration.* Participants were asked to rate the perceived relevance of the illustration on a 5-point scale ranging from *not true* to *true*.

*Feeling of uncertainty*. Likewise, participants were asked to rate their perceived uncertainty on a 5-point scale from *not true* to *true* to determine whether the provision of different terminology influenced their feeling of uncertainty.

## Results

In this section, we report the effects on the three sets of outcome measures. Unless otherwise indicated, analyses were performed using SPSS 17. Participants in the three conditions did not differ in frequency of computer usage, $F(2,69) = 0.92$, $p = .402$, frequency of internet usage, $F(2,69) = 0.14$, $p = .873$, or subjective self-ratings, $F(2,69) = 0.64$, $p. = .53$.

## Information Exchange

*Communication.* The length of communications was $M = 587.36$ words ($SD = 215.37$); there was no effect of condition, $F(2,33) = 3.10$, $p > 0.05$, *ns*. MANOVAs with the number of questions/explanations relating to the manipulated vocabulary as dependent variables revealed a main effect of condition, $F(4,66) = 2.79$, $p < 0.05$, $\eta_p^2 = .15$. However, a univariate analysis revealed no differences in the number of questions across the three conditions, $F(2,33) = .88$, $p > 0.05$, *ns*. In contrast, a univariate analysis of the number of explanations revealed a main effect of condition, $F(2,33) = 6.67$, $p < 0.05$, $\eta_p^2 = .15$, with participants in the different-terminology with illustration condition giving more explanations ($M = 5.92$, $SD = 3.0$) than participants in the different-terminology without illustration condition ($M = 3.92$, $SD = 3.2$) or participants in the same-terminology condition ($M = 1.67$, $SD = 2.27$). Most explanations related to the terms "prevalence," "frequency," "social pressures," "age group," "adolescence," "psycho-social risk factors," and "genetic."

*Knowledge exchange items.* An ANOVA revealed an effect of condition on the number of correctly solved multiple-choice items designed to measure information exchange, $F(2,69) = 11.17$, $p < 0.001$, $\eta_p^2 = .25$. A post hoc test (S-N-K) showed that the same-terminology group differed from the different-terminology group with illustration ($p < 0.05$) and from the different-terminology group without illustration ($p < 0.05$), whereas no difference was found between these two groups ($p > 0.05$, *ns*).

In the cloze task, participants in the different-terminology condition used *M* = 0.75 (*SD* = 0.98) terms from their partner's learning material to fill the gaps and *M* = 3.25 (*SD* = 1.90) terms from their own material. However, the difference between groups in term usage was not significant, $t(46) = -.29$, $p > 0.05$, *ns*.

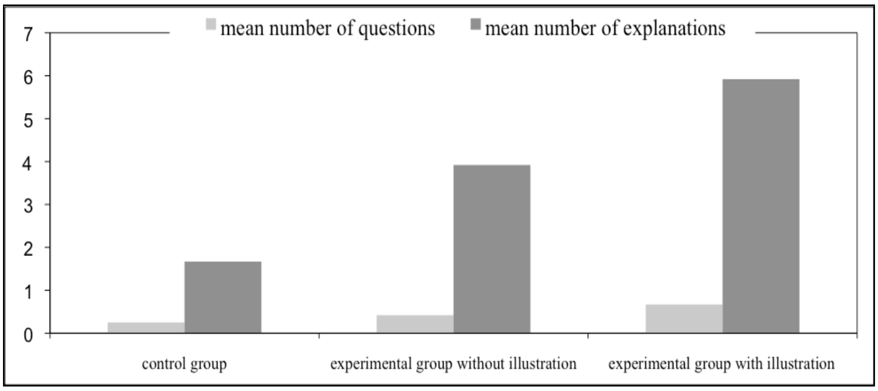

Figure 1. Mean number of questions asked and explanations given in the communication process

## Individual Learning Outcomes

To examine the effects of condition on students' learning performance, we conducted a MANOVA on the number of points attained in the multiple-choice test and in the cloze test. Pillai's trace showed an effect of condition, $F(4,138) = 6.65$, $p < 0.001$, $\eta_p^2 = .16$.

*Multiple-choice test.* On average, participants scored 14.46 (*SD* = 7.61) of the available 28 points. Univariate analysis revealed a main effect of condition on points attained in the multiple-choice test, $F(2,69) = 12.8$, $p < 0.001$, $\eta_p^2 = .27$. A post hoc test (S-N-K) revealed that the same-terminology group differed from both different-terminology groups ($p < 0.05$). Moreover, the two different-terminology groups differed from each other ($p < 0.05$).

*Cloze test.* On average, participants correctly filled in 5.46 (*SD* = 2.53) of the 10 gaps. An ANOVA showed a main effect of condition, $F(2,69) = 10.53$, $p < 0.001$, $\eta_p^2 = .23$. A post hoc test (S-N-K) revealed that the same-terminology group differed from both different-terminology conditions ($p < 0.05$). However, no difference was found between the different-terminology conditions with and without illustration ($p > 0.05$, *ns*).

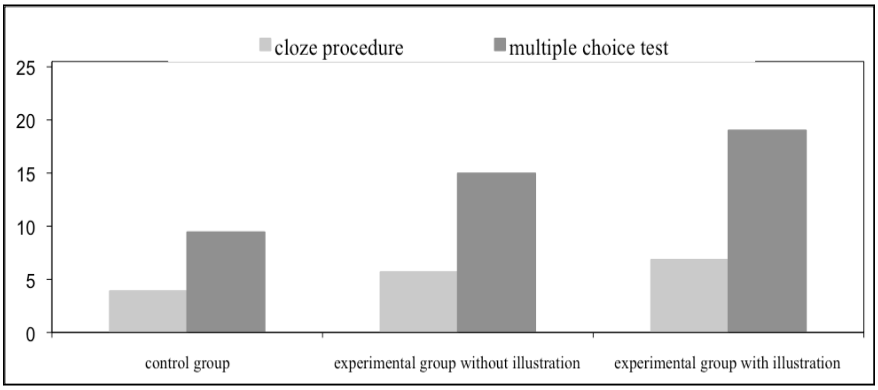

Figure 2. Mean scores in the cloze test and multiple-choice test

## Subjective Ratings

*Relevance of illustration.* On average, the illustration was rated as being rather helpful (*M* = 3.46, *SD* = 1.41). To test how this perception related to objective learning outcomes, we correlated the subjective rating of the illustration's relevance for learning with the objective learning outcome in the multiple-choice test. The correlation was not significant, $K = .251$, $p > 0.05$, *ns*.

*Feeling of uncertainty*. Participants reported little uncertainty about their knowledge (*M* = 1.71, *SD* = 0.86). An ANOVA revealed no difference between the three groups, $F(2, 69) = 0.39$, $p > 0.05$, *ns.*

## Discussion

These results emphasize the pivotal role played by technical terms in the development of a conceptual understanding of learning contents. We hypothesized that presenting learners with materials containing different lexical encodings of the same concept would initiate more reflection on their own and their partner's knowledge. We therefore expected learners to realize that their knowledge differed from that of their partner, which would prompt them to exchange knowledge and to elaborate the meaning of the technical terms in more depth. In the following, we discuss our findings with regard to information exchange, individual learning outcomes, and additional subjective self-ratings.

### Information Exchange

In accordance with our hypothesis, learners in the different-terminology condition with an illustration made more explanatory statements about this terminology than did learners in the same-terminology condition. Taking into account that our experimental manipulation was limited to the lexical encoding of 15 key concepts, we interpret these results as evidence for the role of word choices in learning situations. The findings indicate that exposure to different terminology prompts learners to communicate in a more productive way, exchanging information about the underlying meaning of the terms. We attribute this difference to the use of different terms in their communication on the collaborative task making participants being more aware of potential problems of understanding. In particular, the results highlight the specific role of illustrations for information exchange in the given learning setting. As hypothesized, illustrations strongly focused the learners' attention on their own learning material, making them more aware of differences in the terminology used. To establish a common ground, they provided an explanation for the terms they used. In contrast, the explicit exchange of information did not seem necessary for dyads in the same-terminology condition, who assumed their partners to have similar understanding of the term as themselves (*knowledge effect*; Bromme et al., 2001).

Moreover, learners who exchanged more information were more familiar with the contents of their partner's learning material: Participants in the different-terminology conditions were better able to solve the multiple-choice items designed to measure information exchange. However, the same did not apply to recall of technical terms: In the cloze task, participants clearly reverted to the technical terms used in their own material. Hence, whereas increased information exchange led to more knowledge about non-shared contents, learners stuck to their own material on the lexical level.

### Individual Learning Outcomes

We examined learners' individual learning outcomes in terms of their conceptual understanding of the topic and their understanding of the technical terms used. Performance on the multiple-choice test differed across all three groups, with participants in the different-terminology with illustration condition achieving the highest scores. These findings support our hypothesis that elaboration of learning content can be improved by placing different vocabulary in cooperative learning texts and that this effect can be further enhanced by including an illustration. Besides focusing learners' attention on the technical terms used, illustrations also help them to better understand the relations between the concepts (Larkin & Simon, 1987). In the cloze task, participants in the different-terminology conditions outperformed participants in the same-terminology condition. However, provision of an illustration had no additional influence here. In conclusion, it seems that inclusion of an illustration using different terminology to encode the same concepts has a positive effect on the development of a differentiated understanding of learning contents, but does not particularly affect term understanding.

Participants also reported that the illustration helped them to understand the learning contents. However, this perception was not systematically related to objective learning outcomes.

### Limitations and Future Perspectives

In contrast to our hypothesis, participants' subjective ratings of uncertainty did not differ across conditions: Participants in all conditions reported little uncertainty about their knowledge. It is likely that the meaning of most of the manipulated terms could simply be deduced from the context. This interpretation is supported by the finding that the number of questions asked to clarify the underlying meaning of terms did not differ across conditions either. Participants only explicitly queried the meaning of very specific terms that are not used in everyday language. It seems that communication partners exchanged knowledge not because they were unable to understand each other, but because the different terminology used in the learning materials signaled different knowledge and thus led to perspective taking. Participants realized that their knowledge was not necessarily the same and thus started to explain their individual understanding of the term. It seems likely that this spontaneous provision of explanations directly reduced uncertainty and, in turn, the need to request more details. It remains an open question whether the lack of questions formulated can be attributed to characteristics of the terms or to the fact that the meaning was already clarified. Paus & Jucks (2009) have shown that learners' perceived understanding is affected by the origin of terms (e.g., Greek, Latin, Germanic).

In Germany, terms with Germanic roots are more easily accessible, perceived to be more familiar, and better understood. To address this question, the characteristics of the terms used in collaborative learning situations could be varied more systematically in future research. Individual factors, such as the degree of expertise in the field (see Gittelman et al., 2004; Schmidt & Boshuizen, 1992) or foreign language skills, may also affect perceived understanding of terms. Additionally, the correspondence between subjective assessments of the cooperation process and the perceived difficulty of the learning materials warrants analysis. It is important to find out whether and how learners perceive themselves to learn in collaborative learning environments and to identify how much pressure they face in coming to a mutual understanding. Future research should thus assess the mental processes underlying the learners' behavior; for instance, in retrospective analyses. Last but not least, it remains unclear what role social expectancy plays in admitting a feeling of uncertainty about one's knowledge.

The experimental setting investigated in this study can be considered a typical learning situation at university. However, although learning partners often do not know each other, especially in distance universities, the question arises of how their level of acquaintance affects communication behavior. It can be assumed that learners are acting in social roles predefined by previous interaction situations and that motivational and social-psychological aspects of discourse behavior are strongly influenced by those roles. In the present study, for instance, participants made assumptions about their partner's gender based on his or her way of formulating messages and coordinating the interaction. Future research should clarify whether our findings can be transferred to other learning situations: What is the impact of group size? How does the medium influence communication behavior? Are there any differences in comparison to face-to-face learning scenarios? Characteristics of the learning partners should also be taken into account. Spiro, Coulson, Feltovich, and Anderson (1994) argued that humanities students can be expected to use heuristic procedures to solve problems and to debate different alternatives. These students can thus be able to recognize that two terms may exist to describe the same underlying concept. In addition, learners' age can be expected to impact the development of assumptions about knowledge. Several researchers have concluded that this development proceeds stepwise (King & Kitchener, 1994; Kuhn, 1991; Perry, 1970). The validity of the present results should thus be verified for other learners, such as school students.

In summary, our findings indicate that the terminology used in learning materials impacts learning behavior in discourse. Moreover, the notation of knowledge contents (text vs. illustration) influences the way learners elaborate information. These aspects should therefore be considered in the design and selection of learning materials.

# Leading to Win: The Influence of Leadership Styles on Team Performance during a Computer Game Training

Anna Siewiorek, Andreas Gegenfurtner, Centre for Learning Research, University of Turku, Finland
Email: amsiew@utu.fi, angege@utu.fi

**Abstract:** The purpose of this study is to examine how leadership styles will influence the team performance during a computer game training. In order to get a better understanding what leadership styles are going to be distinguished, researchers observed students' interactions while they played a strategic computer game. In the study, a group of Stanford University graduate students participated in the training with a 'real esate' computer game. The participants' task during the game was to manage an estate company in small teams. Students developed goals, discussed problems and tracked progress in order to win the game. The results showed that the teams had different leadership styles which affected their performance. The leadership styles that participants used and how they affected the teams' performance are described in the paper.

## Introduction

Increasingly, employers are demanding that college graduates have integrative skills (Stephen, Parente, & Brown, 2002) for an interdisciplinary understanding of the organization and business dynamics (Hartenian, Schellenger, & Frederickson, 2001). However, methods and tools commonly used for teaching this business dynamic in collages are insufficient to cope with the complexity of organizations and the unstable conditions of today's market (Baker & O'Neil, 2002; Day, 2001; Lehtinen, 2002). Especially, it is difficult to teach leadership—a central competence for coping with these kinds of conditions—using traditional classroom-based methods of teaching (e.g., lectures). One solution for that problem is to teach about leadership styles through strategic computer games. Thus, more studies need to be conducted about the ways of teaching leadership styles in practice. It would be especially interesting to study how leadership styles influence team performance during computer gaming training. Previous studies have demonstrated significant linkages among leadership behavior, team efficacy, and team performance (Pescosolido, 2001). However, there has been a lack of integration concerning the relationship between specific leader behaviors and team performance outcomes (Burke et al., 2006).

This paper describes serious gaming session that aimed to teach students about business dynamics and about leadership styles i.e., which leadership style should be used in a specific situation to manage similar situations in their future workplace. Past studies have shown that serious games can successfully foster student learning (Kafai, 2006), engagement (Kiili & Lainema, 2008), and motivation (Hense & Mandl, 2009). It is worth noting that there is an evidence to suggest that playing games allows the brain to 'work' more efficiently and thus, to take in more cognitive material than it would in a more traditional setting (Jenkins, 2002; Perry & Ballou, 1997). In addition, games can be considered as powerful learning environments because of the following: (a) they are based upon active-learning techniques, (b) they favor activation of prior knowledge given that players must use previously learned information in order to advance, (c) they provide immediate feedback enabling players to test hypotheses and learn from their actions, (d) they encompass opportunities for self-assessment through the mechanisms of scoring and reaching different levels, and (e) they provide opportunities for critical thinking and problem solving skills (Oblinger, 2004). Furthermore, few examples of using simulation games to develop leadership skills can be found in the military sector (O'Neil & Fisher, 2004). The military sector also uses simulation-based games in flight and combat training (O'Neil & Andrews, 2000). For this study, a strategic computer game, "Build-a-lot" (see Appendix), was used in which players met face-to-face in small teams to manage a virtual real estate company. Participants collaborated in teams in order to win the game, and group work helped them to share and develop alternative viewpoints. Furthermore, the use of teams to promote student learning in education has been proven to be fruitful (Michaelsen, Bauman Knight, & Fink, 2004). For example, in Light's study (2001) of student learning at Harvard, he found student learning teams to be highly effective. On the contrary, small group research has identified a number of factors that negatively affect team performance and member satisfaction. These include over-dependence on a dominant leader (Edmondson, Bohmer, & Pisano, 2001).

The computer game used for the study presented an enormous amount of complex operations in which a team leader needed to address the final decision to lead the team to win the game. This kind of computer game, involving many complex decisions, can connect the players to everyday life experiences. In addition, the time pressure in the game was crucial, and participants had to make decisions quickly in order to advance to the next level. The speed of the game was fast, and only quick decision-making could lead teams to win the game. This gaming environment was interactive, and participants interacted by solving the given tasks in the game.

Therefore, strategy and an appropriate leadership were needed in order to be successful. Furthermore, the training was competition-based and that also required implementation of leadership skills. The research questions were as follows: 1) what leadership styles (if any) could be distinguished during the computer game, and 2) how have leadership styles influenced team performance during the game?

## Leadership styles

Most definitions of leadership claim that it is a process of intentional influence by one person over others "to guide, structure, and facilitate activities and relationships in a group or organization" (Yukl, 1998, p. 3). In other words, leadership is defined in terms of problem-solving activities directed at the generation of solutions that advance team goal attainment (Zaccaro, Rittman, & Marks, 2001). Leadership is typically associated with more mystical, charismatic qualities such as the ability to influence, arouse, inspire, enthuse, and transform (Bass & Avolio, 1994; Goleman, 2000), qualities that exist outside of the ordinary and mundane features of daily life. Additionally, leadership is frequently theorized as the exercise of power, the setting of goals and objectives, the managing of cultures, and the mobilization of others to get work done (Alvesson & Sveningsson, 2003; Gemmill & Oakley, 1992). In addition, leadership has been defined in terms of individual personality traits, leader behaviors, responses to leader behaviors, interpersonal exchange relationships, interaction patterns, role relationships, follower perceptions, task goals, organizational culture, and nature of work processes (Mello, 2003; Rost, 1991; Yukl, 1989). Hence, leadership is an important component in business dynamics. Below, we specify four leadership styles in more details: transactional, transformational, heroic, and post-heroic leadership.

First, transactional leadership is characterized by the clear specification of what followers are expected to do (e.g., Bryman, 1996) and it is based on a rational exchange relationship between leader and subordinate (Bass, 1985; Howell & Costley, 2001). The leader articulates what behaviors are required and what will be rewarded, and provides feedback to the subordinates about their behaviors. The subordinate, in turn, complies with these behavior requirements if rewards are desired (Yun, Cox, Sims, & Salam, 2007). In short, transactional leadership can be defined as a cost-benefit exchange between leaders and their followers and it is comprised of three dimensions: contingent reward, active management by exception, and passive management by exception.

On the other hand, transformational leadership is characterized by concern with people. Transformational leaders lead by inspiring and stimulating followers; by creating highly absorbing and motivating visions; and by utilizing behaviors such as charisma and intellectual stimulation to induce performance of subordinates beyond expectations (Conger, Kanungo, & Menon, 2000; Kark, Shamir, & Chen, 2003; Yun et al., 2007). Bass (2000, p. 21) states that transformational leaders "move followers to go beyond their own self-interests for the good of their group, organization or community, country or society as a whole". Transformational leadership is comprised of the following dimensions: idealized influence, inspirational motivation, charismatic and intellectual stimulation, and individual consideration.

Third, heroic leadership is characterized by the following: feelings that leadership is based on superior knowledge and information (omnipotence); fearing failure (rightness); keeping up appearances at any cost including blaming others (face-saving); and viewing subordinates as inferior creatures in constant need of assistance and rescue (codependency) (Eicher, 2006). Two sub-classes could be distinguished in heroic leadership such as: autocratic and coercive leadership styles which have many similarities. The autocratic leader sequesters a high degree of control and makes decisions without consulting team members. The heroic-autocratic leader determines all policies, techniques, and activity steps, and dictates the particular work tasks and work companions of each member. The autocratic leader tends to be personal in her praise and criticism of the work of each member but remains aloof from active group participation (Choi, 2007). On the other hand, in coercive leadership style leader demands immediate compliance and drive to achieve, initiative, and self-control (Goleman, 2000).

Finally, post-heroic leadership takes place when the leader wants others to take responsibility and gain knowledge (empowerment), encourages innovation and participation even in ambiguous situations (risk-taking), seeks input and aims for consensus in decision-making (participation), and wants others to grow and learn even at the expense of becoming dispensable herself (development). Post-heroic leadership has thus become a concept used to describe a new conceptualization of leadership that refutes the top-down focus on the leader typical of most leadership literature and discourse (Bradford & Cohen, 1998; Eicher, 2006, Fletcher, 2004). This leadership style is well-suited to complex, changing, and inter-dependent environments. There are two sub-classes in post-heroic leadership: democratic and shared leadership. First, democratic leadership style emphasizes high group participation, discussion, and group decisions based on consensus encouraged by the leader. By giving workers a voice in decisions, democratic leaders build organizational flexibility and responsibility and help generate fresh ideas. In addition, because they have a say in setting their goals and the standards for evaluating success, people operating in a democratic system tend to be very realistic about what can and cannot be accomplished (Goleman, 2000). Second, shared leadership occurs when all members of a team are fully engaged in the leadership of the team and are not hesitant to influence and guide their fellow team members in an effort to maximize the potential of the team as a whole (Pearce, 2004). In summary, shared leadership represents teams whose members are empowered to share the tasks and responsibilities of leadership (Ensley, Pearson, & Pearce, 2003; Katzenbach, 1997).

## Methods

In order to get a better understanding of how leadership styles will affect team performance during computer game training, three researchers observed students' interactions when they were playing a strategic computer game called "Build-a-lot" (see Appendix). Researchers were taking detailed notes of all student dialogs and actions; each researcher had one team to observe and take notes of their interactions and dialogs. The goal of this observation was to determine what leadership styles (if any) students are going to use during the game and how this styles will affect team performance. All notes that researched made were transcribed verbatim. For the purpose of data analysis the detailed codes were developed which described each leadership style characteristics. The notes (i.e. each team dialogs and interactions) were coded using those leadership styles characteristics. Nine participants took part in the gaming session. They were divided into three teams, which competed against each other for one hour. Final scores of the game determined which team won. During the game, students made many decisions related to running a real estate company. Due to the game's limited time, the participants became focused during the gaming session and were thoroughly engaged and immersed in the game. The time pressure increased the speed of their decision-making. The gaming session took place at Stanford University, California, USA in the autumn semester of 2007.

### Participants

Nine participants took part in the study (two females and seven males). They were Stanford University graduate students from different academic backgrounds such as engineering and humanities. The participants in the teams did not know each other. There were three teams with three participants in each team. They did not consider themselves experienced users of computer games. The study was the first in which all of them took part in a gaming session. During the experiment, participants worked together in teams because only in teams could leaders be distinguished. Participants were unaware of the purpose of the study.

### Description of the game and setting

Participants played "Build-a-lot" (see Appendix) in teams. Players represented real estate moguls whose task was to take over the housing market as they build, upgrade, sell, and buy houses for huge profits. The purpose of the gaming session was to teach students business dynamics, how to make decisions quickly. Their goal was to win the game; the team with the most profit and the highest achieved level won the game. From time to time, a message from the Mayor (of the city in which they were building houses) appeared on the computer screen with hints or tasks about the game. If a team managed to get every operation correct, they passed the level in the game and advanced to the next level. If a team failed a level in the game, they had to repeat that level from the beginning. Every team had one notebook computer to use along with a computer mouse. The teams played simultaneously for one hour. During the experiment, there were three researchers to observe the teams; each researcher had one team to observe. Researchers introduced the game to participants at the beginning and told them that they could look for help and instructions in the tutorial section in the game, but they could not ask the observing researchers any questions. Team members could ask questions of other teams. The aim of the researchers was to observe students' interactions while playing the game (how they collaborated, how they made decisions, etc.) and to make detailed notes of all their dialogs and students interactions.

### Data Analysis

The main aim of the study was to research how leadership styles which participants applied during the gaming session will influence the teams' performance. The method of data analysis was discourse analysis (Silverman, 2006). After reading through the transcripts of notes from observations and students dialogs, the transcripts were coded in terms of transactional, transformational, heroic and post-heroic leadership styles. These developed categories of leadership styles (each had subcategories referring to the given leadership style characteristics) were used to analyze the data.

## Results

The conclusion drawn from the observations is that the teams had different leadership styles, which affected their performance. The following three sections describe each team's leadership style and how it influenced performance and the game results.

### Team 1.

The leadership style of Team 1 could not be described as one leadership style. The leader of this team applied different leadership styles such as transformational, heroic, as well as post-heroic leadership styles. In this team there was an accountable leader who had superior knowledge; all wisdom was concentrated in him, and he displayed a sense of power and confidence. The leader knew what actions to take during the game, although he has not played that game before. He possessed superior knowledge which helped him to make the right decisions. The dialog below is an example of participant 2 (the leader's) omnipotence:

Participant 1: 'Do we need to train (workers)?'
Participant 2: *'Yes, but it is too expensive.'* (He is upgrading houses)
Participant 1: 'How about (if) we build this one?'
Participant 2: *'Maybe not... we have to make more money.'*

Participant 2 knew what to do in this situation, and he determined his teammates' opinions to be less valuable at this point. In the dialog above, even if participant 1's opinions were turned down by the leader, he agreed with it without insisting on his opinions and without trying to persuade participant 2, which could suggest that participant 2 (the leader) was respected for his knowledge and rightness. This behavior could be described as an idealized influence which is a characteristic of transformational leadership – leaders are admired, respected and trusted. At the same time, the leader of this team applied intellectual stimulation to manage his team. During the competition, participant 2 was the leader who controlled the mouse, read aloud game instructions, and tried to generalize the guidelines for the team. There were several times when two other team members brought up questions, and he answered them very quickly. Although he controlled the mouse during the whole process, he often asked his team members opinions before implementing ideas; hence, team members were included in the process of addressing problems and finding solutions. They participated in making some of the decisions, such as what to do next, but they depended on their leader to make the final decision. Thus, the leadership style was democratic and leader-centered at the same time. Group participation and discussion was encouraged by the leader. Below is an example:

Participant 2: 'Do you want a workshop?, then, he explains, 'the strategy of this level is to build a house and get cash, and you need to build a library.'
Participant 3: 'We need more training.'
Participant 2: 'Oh, mail! That's good.' (He opens the mail, team members look at the screen), then he asks: 'how do you feel about an upgrade?'

From the dialog above, it could be noted that participant 2 asked for his teammates' opinions because probably he wanted to share the responsibility. Thus, the leadership style present in this team could be interpreted as shared leadership also. The leader shared his leadership to some degree with the team members; he asked them what they think should be done next and waited for their agreement to proceed further. However, this kind of leadership does not always have a good influence on team performance. Sometimes leaders cannot make any decision without getting input from their team members. This slows down the process and the organization cannot react quickly enough. In this team, participant 2 was often asking his team members for opinions (although not all of their ideas were adopted and implemented) that helped him to lead the team to win the game. The best leaders favor participation, but also know when they need to be directive or make decisions on their own. According to Lingham (2004), teams with high dependence on a single leader had lower performance, less member satisfaction, and a decreased climate of psychological safety. The dependence on a single leader could be observed in Team 1; however, in the case of this team, team members did not show the aforementioned attributes. Overall, there was no conflict in the team during the playing the game. Everyone seemed to be content with the decisions participant 2 made, and the atmosphere of the team was harmonious. Team members were satisfied with the leadership styles the leader implemented. In summary, leadership techniques used by the leader brought success to the overall team performance; this team won the game competition.

### Team 2.

This team's leadership style could be described as heroic leadership and to some degree as a post-heroic leadership. Disagreements in this team came from the fact that one participant dominated and was pushing other team members to realize his ideas. It could be noted from observations of this team that he was behaving like a heroic-autocratic leader. He issued orders and he expected them to be followed without questions. He wanted to determine all activity tasks and steps. A high degree of control is a main characteristic of the autocratic leadership style. He wanted to win the game and he was concentrated more on the game performance than on his team members' satisfaction and their opinions. The example of participant 4's autocratic leadership style can be noted in the dialog below:

Participant 5: 'What should we do?'
Participant 4: 'We buy houses later, buy one Tudor, we can sell it later.'
Participant 6: 'Colonial first.' (He meant colonial buildings)

Participant 4: ‘No, definitively don’t do it, buy Tudor. Better to build the Tudor. *Listen to me!*’
(Participant 6 was against that)
Participant 4: ‘Sell a Tudor and buy this one of a higher price, *listen to me!’*

In addition, coercive leadership styles could be noted from his behavior as he demanded immediate compliance. This leadership style is the least effective. It is appropriate during an emergency or crisis situation, and when used in the short term, but it is not successful in the long term. In this leadership style, team members do what they are told because they fear being reprimanded. As a result, team members are easy to manage and the leaders have all the control. Unfortunately, team members feel burdened to question ideas and make suggestions, which prevent good ideas from being heard. Another downside involves team members never deviating from their leaders’ orders, even if they do not agree with the orders. When participant 4 was behaving like a demanding leader who gives orders to team members, they disliked it. During the game, they were willing to collaborate with each other more, but not with participant 4. They were not satisfied with participant 4’s attitude towards them and the game competition. However on the contrary, highlights of shared leadership style could be noticed from this team conversations. From time to time there was mutual influence between the team members. In particular, the female participant was asking two other members’ opinions and encouraged them to exchange ideas. She had the mouse in her hand during the game’s competition, and she was trying to discuss with others all decisions she was about to take. The two other participants were expressing their opinions to her, and she was implementing what she had been told to do. In general, all team members tried their best to win the game, and ideas were coming from every team member. They always tried to help each other by expressing opinions and comments. Here is a note from the observations showing highlights of shared leadership style and mutual influence in this team: participants 4 and 5 had an idea of buying a house, and participant 6 commented as follows:

Participant 6: ‘Not buy, let’s build a house.’
(They listened to his comment and constructed the house)
Participant 4: ‘We can sell it later.’
Participant 6: ‘No, let’s sell it now.’
Participant 5: ‘We’ll sell it when we don’t have money...’

Based on the results of the study, the mix of leadership styles implemented in this team cannot lead the team to be successful and to achieve high performance. Team 2 was the second team to finish the game, and perhaps this was due to one participant’s coercive leadership style which was not effectively implemented within the team. In addition, team members were not satisfied with participant 4’s dominant influence.

### Team 3.

In this team, no clear leadership style could be distinguished, however collaboration could be noted from the team’s dialogs but nobody in this team wanted to have a leadership responsibility nor did anyone have a personality with which to influence others. Leadership involves influence; without influence, leadership does not exist. This team’s way of playing the game lacks clearly distinguished leadership style, although highlights of shared leadership could be noted in the team’s conversations. This team’s game score was the lowest, so they lost the game competition. In general, the lack of leadership could be explained by the “official leader” being not present – physically or mentally. Most of the time, team members want to have their leaders to direct, inform, or give them feedback. Thus, when the team has no leader, the team’s potential is hindered. In addition, most team members want to feel a connection to their team; however, without the leader, there is no organization, but rather chaos. See the note from the observations below as an example of Team 3’s lack of organization:

Participant 8: ‘We have to build it. How many do we have to build? 75? We’re out of materials. So what’s next? Do we have additional instructions? Or just make more money?’
Participant 7: ‘We keep making money.’
Participant 8: ‘Our strategy is to make money, right?’ (Silence, nobody answered the question)

From the dialog above, one could notice uncertainty of what they have to do. Later, during the game, when one team member was trying to organize the structure of the team, other team members did not consider that to be necessary. See the dialog below as an example:

Participant 7: ‘We have to buy a house. Raise income.’ (Spoke louder)
(Team members moved forward to read the game instructions)
Participant 8: ‘We don’t have enough money’.
Participant 9: ‘Materials.’
Participant 8: *‘OK, now each of us should be in charge of one job.’*
Participants 7 and 9 laughed and nodded their heads.

(They almost developed the strategy but without a success)
Participant 7: 'Buy a house to raise income. We need to buy or construct.' Then he adds: 'Time is running out…'

In this team, nobody had authority or an answer to the questions other team members were asking. Furthermore, nobody wanted to be responsible and everyone was making suggestions. Nobody demonstrated a tendency to dominate this team and to be a leader. Also, nobody's opinion was respected or considered to be important, they avoided getting involved when important issues aroused. They usually made a decision based on a situation rather than a person. This team did not respond to situations and problems systematically. The team cannot have successful performance without a leader who has the authority to make decisions. A team needs a leader to organize its structure and to successfully lead team members in a complex environment. This team leadership could be described as laissez-faire and team's behavior could be described as passive/avoidant behavior. The "passive leaders" avoid specifying agreements, clarifying expectations, and providing goals and standards to be achieved by followers. This style has a negative effect on desired outcomes and has negative impacts on followers and associates. Therefore, the lack of a leadership role in this team probably caused them to lose the game competition and have the lowest score. These results provide added support for prior research that has shown the use of managing-by-exception (laissez-faire) to be an ineffective leadership style (Avolio, Waldman, & Einstein, 1988).

## Discussion

The main concern of the study was to research how leadership styles will affect the team performance during a computer game training. As a result of the game competition, Team 1 won the game. The leader of this team used different leadership styles such as transformational: shared and democratic leadership styles. The best leaders do not just use one style of leadership – they are skilled at several, and have the flexibility to switch between styles as the circumstances dictate (Goleman, 2000). In the case of Team 1, the transformational leadership and the dependence on a single leader (leader-centered style) resulted in effective team performance. However, the leader-centered leadership style is hardly used alone in today's organizations. One leader alone is not enough in today's complex work environment. It is becoming more difficult for any one person to be an expert in all aspects of the work that needs to be done. In fact, research indicates that poor-performing teams tend to be dominated by the team leader, while high-performing teams display more dispersed leadership patterns, i.e., shared leadership (Pearce, 2004). Shared leadership is a complex process, but it was successfully implemented in Team 1. In this team, the role of the heroic leadership was implemented with shared and democratic leadership styles that made a positive impact on the team performance. On the contrary, in Team 2 shared leadership implemented with autocratic and coercive leadership styles did not bring effectiveness to the team performance. The leader's personality was too strong and his demanding attitude towards other team members had a negative influence on the team members and the team performance. He wanted to direct and control all decisions without any meaningful participation by the team members. With this leadership style, it has been found that most of the decisions made lack in creativity. Although shared leadership was applied in Team 2, it did not help to win the game. In Team 3, there was no clearly distinguished leadership style which probably caused them to lose the game. Team members demonstrated a failure to take responsibility for managing and decision-making. No one in this team provided direction or support; rather, they showed a lack of caring for their team's performance. This 'non-leadership' style could be described as laissez-faire leadership, a principle which emphasizes independence. So, team members are left alone to do their work with little direction or supervision. The conclusion from these results is that leadership is needed for successful team performance.

According to Brousseau, Driver, Hourihan, & Larsson (2006), in order to advance in complex organizations, leaders need to learn and apply more advanced decision styles for using information and evaluating options. It was found that leader decision styles must evolve to include more complex information processing that are capable of managing the challenges of a turbulent environment. Today's organizations are more complex than they used to be, and traditional, heroic leadership styles, when used alone, are not enough to be successful. Therefore, teaching leadership should change as well. One approach to teach leadership is by playing a strategic computer game in teams. Teaching with computer games could prepare students to better cope with business world complexity. Gaming sessions as described in the paper could be implemented in college business education to teach students which leadership styles should be used in a specific situation to manage similar situations in their future workplaces. Classes based on organizing training sessions with strategic computer games to teach leadership styles have two advantages. First, students experience how they behave in pressure situations (competition, time pressure, etc); these situations push them to be more successful and creative or they cause them to drop out without caring about actively participating in the training session. Second, they see which team wins the game, attempt to interpret the game results, and come to the conclusions as to why their team performance was not effective if their team lost. This type of experience teaches students how to behave in certain situations and how the competition affects their behavior. After the gaming session, they will realize from the experience which type of leadership styles work well and how to behave next time when placed in a similar situation. However, not everyone has a predisposition to being a leader; a particular personality type is usually needed. People who have a 'leader personality' could be trained to be better leaders and training such as the type mentioned in this study could help them to develop strategies on how to be more successful. In summary, playing a strategic computer game in teams of three could provide the tool to learn applying different leadership styles in different situations.

The interesting area for future inquiry would be to organize leadership training sessions in which participants play in more than one team. In this way, they will have an opportunity to experience different leadership styles with different team members. It would be fruitful for the game participants to conduct interviews with them after the training and evaluate the leadership styles they have experienced. This kind of debriefing could help participants to articulate what they have learned for the purpose of knowledge building (Jonassen, Peck, & Wilson, 1999).

## Appendix

Build-a-lot – a strategic computer game, where players are real estate moguls whose task is to take over the housing market as they build, upgrade, sell and buy houses for huge profits. The objective of the game is to get Net Value to the highest possible number by building, upgrading and selling properties. The team with the most profit and the highest achieved level wins the game. If the players manage to get every operation correct, they pass the current level in the game and advance to the next level. If a team fails a level in the game, they have to repeat that level from the beginning. During the game, players get the instructions from the mayor of the city in which they are building houses. To construct a property, players must have the blueprint, enough workers and enough materials. The players' task is to move from one town to another to improve them and achieve all the goals in a given period of time. They are asked to build different kinds of houses and buildings, earn a specific rental income, or earn cash. To achieve these goals, players have to choose exactly what they have to build and demolish, which requires certain calculations. Players can build the following kinds of houses: Rambler, Colonial, Tudor, Estate, Mansion, and Castle. They should buy the blueprint of each of these, the materials needed, and a certain number of workers. They can also build a number of buildings like a Post office, Library, Workshop, Bank, Sawmill, etc. The main advantage of this game is the fact that it makes players think and calculate items (for example, taxes that they should pay) in order to win. In this environment, participants played in teams, with three members on each team. Game play with small teams forces team members to express and exchange their ideas and opinions to form a strategy. Furthermore, teams are indispensable for successful performance, and individuals have to be trained to be able to work efficiently and effectively in groups.

# Validation of a Learning Progression: Relating Empirical Data to Theory

**Abstract:** Learning progressions (LPs) are theoretical models of learning trajectories in a domain. Recent policy reports have touted LPs as a promising approach to align standards, curriculum, and assessment. However, the scholarship on LPs is sparse, and the jury is still out on the theoretical and practical value of this approach. To realize any potential of LPs we need to systematically validate and refine these hypothetical models in real-world contexts. Such validation efforts are challenging, as they require the coordination of messy empirical data with, often, under-specified theoretical models. In this paper we report on our efforts to validate a genetics LP through a two-year longitudinal study in middle school. We describe how we used interview data to refine the hypothesized levels of progression in our LP and to identify contingencies between constructs (big ideas) within our LP. We conclude with some tentative heuristics for coordinating data and LP models.

## Introduction

Recently there has been a resurgence of interest in learning progressions (LPs) - a theoretically driven pedagogical approach that emphasizes the learning of big ideas and practices, in a domain, over extended periods of time (Author et al., 2009a; Lehrer & Schauble, 2009). Advocated by policy reports as means to align standards, curriculum, and assessment, LPs have the potential to be a transformative new approach to science education reform (e.g. NRC, 2007). However, the scholarship about LPs is still in its infancy and extensive validation efforts are needed to move this scholarship forward and ascertain the theoretical soundness of LPs and practicality of using them in the science classroom.

LPs are theoretical models of learning in a domain that describe progressively more sophisticated levels of reasoning that a learner exhibits as she develops expertise (NRC, 2007). These progressions describe learning as it unfolds over extended periods of time (grades and grade bands). LPs are not developmentally inevitable but require targeted instruction and curriculum. Most importantly, LPs are hypothetical constructs; and while they are grounded in research in student learning, to the extent possible, they do require validation. Existing examples of progressions vary in the number, and hence grain size, of the levels they postulate (e.g. Author et al., 2008; Schwarz et al., 2009; Songer, Kelsey & Gotwals, 2009). These differences raise the question of what is a useful grain size for LPs? Too many levels and it is difficult to generalize (you loose the forest for all the trees), too few levels and one looses explanatory power (Lehrer & Schauble, 2009). Determining the appropriate number of levels is not merely a theoretical exercise; it also entails empirical tests (often classroom studies) in which LPs can be validated. Such validation is not trivial as students' ideas, or levels of performance, may not fall neatly into the LP's expected levels. The researcher must decide, given the empirical data, when to add new levels, consolidate levels, or remove levels from the hypothetical LP.

LPs also differ in the number of big ideas or constructs they encompass, and in the ways in which progress along one construct is related (or not) to progress along other constructs. Wilson (2009) described different assessment structures of LPs that exemplified distinct types of relationships between constructs. For example, progress along two constructs may occur independently in a parallel structure, or constructs may be linked such that progress along one construct may only begin after the attainment of some level of sophistication on another. Establishing the existence of such links is an important part of the LP validation process. Like the validation of the number of levels in an LP, the validation of links between constructs presents both theoretical and methodological challenges. In this paper we describe out efforts to address the challenge of validating an LP, and coordinating between the hypothetical model and empirical data, in the context of a genetics LP previously described (Author et al., 2009a). We describe how we refined the number of levels (for a construct in our LP) and how we identified contingencies, or links, between levels of two constructs within the LP.

Here we will focus on two constructs within this eight construct LP and describe the progression along these constructs as hypothesized in the LP. We chose to focus on these constructs as they are core ideas molecular genetics that are often underrepresented in middle school curricula, and therefore students had a wide array of understandings about these ideas (providing a fruitful context for our validation efforts). The first construct (construct B of our LP) concerns the nature of the genetic information. Genes are essentially instructions that encode the order and type of building blocks of proteins. While the outcomes of genes have far reaching effects, the information itself mostly specifies the structure of one, very important, biological molecule - the protein (Author et al., 2009a). The second construct (construct C of our LP) focuses on the idea that proteins act as the intermediary between genes and traits and are required for the functioning of all organisms (Author et al., 2009a). These molecules have many biological functions such as catalyzing chemical reactions, building channels, structural support, relaying messages within cells, among other functions. Understanding the link between genes and proteins, and the role of proteins in biological traits is at the core of molecular genetics.

Table 1 illustrates the levels of knowledge to be reached by students at the specified grades. We explain the hypothetical progression for these constructs in more detail in the results and discussion section.

Table 1: Construct B and C from the hypothetical learning progression.

| | Level 1: Grades 5-6 | Level 2: Grades 7-8 | Level 3: Grades 9-10 |
|---|---|---|---|
| Hypothetical Construct B (Author et al., 2009a) | Genes provide instructions that determine how organisms develop. | Genetic instructions encode for proteins which have specific functions within organisms. | Genes encode for amino acids, which make up proteins. |
| Hypothetical Construct C (Author et al., 2009a) | Cells are one level of organization within our bodies. Cells have specific organelles that help the cell perform its function. | Proteins perform specific functions within cells. Genetic mutations can result in changes within the structure and function of proteins. | The amino acid sequence of a protein determines its shape/function. There are different kinds of genetic mutations which can affect the structure and function of proteins. |

## Methods

### Study Context

The data analyzed in this paper was collected as part of a two-year longitudinal study designed to empirically test the genetics learning progression described by Author et al. (2008). Due to logistical concerns, 8th graders were used as a proxy for high school students. In order to validate the progression we instantiated it within two instructional units. These units were project-based, where students investigated three genetic diseases in the first unit and focused on a genetic engineering problem in the second unit. These units were developed by a collaborative design team of educational researchers and teachers. The units were implemented by of one of the teachers on the design team in her mixed grade classroom (6th, 7th, and 8th grade students) in a small urban, public K-8 charter school. The school has a total of 234 students (with 59 6-8th grade students in the study) with a large proportion of minority students and about 35% of the students eligible for free or reduced lunch.

### Data Collected

Four types of data were collected: (a) pre and post written assessments, (b) artifacts of student work (including a performance assessment), (c) individual pre and post clinical interviews, and (d) video tapes of classroom instruction and group work. For this paper we discuss the collection and analysis of the clinical interviews only. We conducted pre and post interviews during the first year of the study (before and after implementation of the first unit); and a second round of post interviews were conducted at the end of the implementation of the second unit. The interviewed students (N=24) were selected by the teacher to offer the most representative sample of students from the study classrooms (Total N=60).

Interviews included three open-ended tasks that all provided opportunities for students to discuss their understanding of how genes bring about their effects and the role of proteins in genetic phenomena. In the first task students were asked to reason about the inheritance of a genetic disorder based on a family pedigree and to speculate about the molecular mechanism underlying this disorder. Part of this task specifically focused on how students used ideas about genes and proteins to formulate explanations of the mechanism of the genetic disorder. The second task, involving a genetic trait in bacteria (chemotaxis), prompted students to provide a hypothetical explanation, at the cellular level, how bacteria can sense substances in their environment. As well as to speculate about cellular mechanisms that could render mutated bacteria unable to sense (Author et al., 2007). In the final task we asked students for specific definitions of genetic terminology such as gene, protein, DNA, and chromosome. In this task we also prompted students to share their ideas about how these entities are related to one another.

### Data Analysis

In this paper, we report our analysis of the second round of post interviews. We chose this set of interviews because it exemplified the largest variation in student ideas and represented multiple levels of understandings in the domain. This variation in student ideas provides a suitable context for examining the different levels of sophistication and any relationships between ideas in distinct constructs in the progression. All interview transcripts were blinded for analysis. As noted earlier, we will discuss students' understandings of constructs B and C in the progression, which pertain to the molecular model.

We conducted a content analysis of all interview tasks and characterized students' ideas regarding the two constructs in the progression. The expected levels of sophistication, as detailed in the progression, informed the initial coding schemes. Through an iterative process these initial coding schemes were refined to capture relevant variation in the data. Within the first construct, several levels of sophistication were identified and they ranged from identifying genes as passive particles associated with traits, to the most sophisticated level of understanding- the cellular mechanism by which genes code for proteins. Similarly, several levels of sophistication were observed for the second construct, ranging from a vitalistic view of proteins (a general notion of proteins as important to vitality and health) to a view of proteins as having specific functions that mediate genetic effects in an organism. We also determined the number of student responses associated with each level of sophistication for both constructs.

Another aspect of analysis was to determine dependencies, or links, between the two constructs; we characterized the ways in which students connected ideas relating to the two constructs. For this analysis we examined the interview as a whole and looked for evidence of connections between ideas in the two constructs. We created individual profiles for each student that described the extent to which the constructs were linked. We were able to triangulate our findings by referring back to two previously coded aspects of the first interview task: how gene mutations affect protein function and how students organized ideas about genes and proteins. Referring to this analysis provided supporting evidence for the contingencies determined between the two constructs. Inter-rater reliability for these two aspects was 91%.

## Results and Discussion

### Refining the Levels of a Learning Progression

One of the major difficulties with validating LPs is mapping the theoretical framework onto empirical findings. In our analyses we found several levels of understanding that had not been captured by the hypothetical progression. This was particularly prominent in our analysis of Construct B, which deals with the nature of the genetic information. At the lower anchor of the progression for construct B are non-information based views of the genetic material, namely, genes as passive particles associated with traits. As a result of instruction students are expected to develop information-based views of genes at various levels of sophistication. According to the progression students move from a view of genes as instructions "for how organisms grow, develop, and function", but without a notion of genes as coding "exclusively" for proteins (level 1 of the progression), to a view of genes as productive instructions for protein molecules that perform tasks within cells (level 2), and finally to a view of genes as instructions that encode for the order and type of amino acids in a protein (level 3) (Author et al., 2009a, p.660). Our data did reflect the existence of these levels. However, we also found evidence for other students' ideas and levels of understandings that were not previously captured in the LP.

Thus the data allowed us to refine the construct map regarding idea B in the following ways. First, while the instructional units mapped onto levels 2 and 3 of the progression, we found that students in our study entered the progression with understandings that were below a level 1. The progression at a level 2 anticipates that students will already have an information-based view of genes (essentially level 1 of the LP is getting to this understanding). What we found is that 23 of the 24 students were at a level 0 (non-information based view of genes) upon entering the study and only 1 student still held this view at the end. Given that students did not receive any genetics instruction prior to the study, this finding is not surprising. However, it does underscore the importance of moving students from a non-information based view of genes to an information-based view of genes as a precursor to any of the more sophisticated understandings regarding gene function.

Second, we found that many students struggled with the transition to an information-based view of genes, and that there seems to be an intermediate level of understanding, not captured by the current progression, that instantiates this transitional understanding (genes as active information). Students who held this view believed that genes could literally "tell" proteins, the cell, or the body how to do a function. This view is information based, but no translation is required between the genetic information and a physical entity, as the gene itself directs the function. For example, in the case of a genetically inherited blood clotting disorder, Barry claimed that "[the genes are] giving instructions for uh, to tell the cell, to tell the cell what to do". When we identified this transitory level of understanding we had to decide whether it was sufficiently distinct from other levels of understanding to merit inclusion, as its own level, in the progression. Given that the transition from the non-information based to an information-based view of genes is a particularly challenging one (Author et al., 2007; Venville & Treagust, 1998) we decided that capturing this understanding as a distinct level was merited for two reasons. First, cognitively this understanding reflects an ontological shift in students' understandings of genes, in essence the beginning of an important conceptual change. Second, and following from the first, it is pertinent that teachers (and curriculum/assessment designers) recognize this understanding as bridging across ontologies and leverage it in their instruction.

We also found that there were variations in the ideas that fell within level 1 of the progression (genes as information for growth and development). At this level of the progression, students tend to assume that genes can code for multiple biological entities (and functions) such as cells, tissues, organ functions, and whole traits. While students may include proteins as one of the many things genes code for, they usually do not view proteins as the predominant product of the genetic instructions. We found that some of the students in our study included only proteins and cells as entities specified by the genetic information. We initially thought of separating this understanding out into its own level, as thinking at the cellular level seemed more sophisticated than thinking at the tissue or organism level. However, we decided against this because our sense was that students tended to map the genetic information onto the lowest level of organization they were familiar with, for some students this was organs, for others cells. Making a distinction between these ideas did not seem like a true representation of students' knowledge of genes, but rather their knowledge of biological organization levels. Moreover, we felt that this understanding tended to be context dependent such that a student may map the genetic information onto cells in one context and onto organs in another.

Table 2 illustrates our data-driven refinements of construct B. Overall, we found that 6 of the students were able to reach level 2 of construct B of the progression. There were 5 students still at level 1 and 9 students were at the new transitory level between levels 1 and 2 of the progression. Very few students were able to reach level 3 of the LP (4 students total), and even for those who did express a level 3 understanding it was not as robust as we had hoped.

Table 2: Data-driven refinements of construct B.

| | Level 1: Grades 5-6 | Level 2: Grades 7-8 | Level 3: Grades 9-10 |
|---|---|---|---|
| Hypothetical Construct B (Author et al., 2009a, p. 660) | Genes provide instructions that determine how organisms develop. | Genetic instructions encode for proteins which have specific functions within organisms. | Genes encode for amino acids, which make up proteins. |

| New LP level | | Original LP level | Level Description |
|---|---|---|---|
| Construct B Revised | Level 1 | Level 0 (lower anchor) | Genes are non-informational in nature. They are passive particles associated with traits. |
| | Level 2 | Was not captured | Genes are non-informational in nature. They are active particles associated with traits. Genes "determine" traits. |
| | Level 3 | Was not captured | Genes are active instructions that "tell" proteins, the cell, or the body to carry out specific functions. |
| | Level 4 | Level 1 | Genes have information about biological entities and function at multiple organization levels. |
| | Level 5 | Level 2 | Genes are instructions for molecules (many of which are proteins) that carry out functions within the organism. All organisms use the same genetic language for their instructions. |
| | Level 6 | Level 3 | The genetic code is translated into a sequence of amino acids that makes up the protein. Almost all organisms use the same genetic code. |

We now turn to our findings regarding construct C of the LP, which involves the understanding that proteins have a central role in organism function and are essentially the link between the genetic information (genotype) and the resulting physical trait (phenotype) (Author et al., 2009a). Again, three levels were defined in the hypothetical LP. The first level involves a non-protein based understanding of biological phenomena whereby proteins are not yet central to biological function (and may not be mentioned by students) however, students are able to reason about biological organization levels and in particular cells as the building blocks of life and as having specific functions within tissues and organs (see Table 3). Level 2 of the progression anticipates a protein-based view of biological function; at this level students should be able to explain biological phenomena by invoking proteins as central players, and be able to propose specific functions for those proteins in cells and tissues. Finally, by the end of the LP (level 3) students are expected to understand that that proteins are made up of amino acids and that the properties of the amino acids determines the proteins' three dimensional structure, which, in turn, determines the protein's function. At this level students should also be able to reason about the ways in which changes to the genetic code (mutations) can affect the structure and thus the function of a protein and ultimately the trait.

For this construct, we analyzed the interviews and identified three distinct levels of sophistication that students exhibited with respect to proteins (see Table 3). In the first level students had vitalistic notions of proteins and considered proteins as solely providing positive health benefits for the body. For example, Alyssa suggested that "proteins, they do like, um, help you grow, with like your bones and stuff", reflecting a vitalistic view of proteins. These students were unable to suggest specific protein functions but did have a sense that proteins are necessary. These students also explained that without proteins negative health affects would ensue, that is, they realized that proteins have an important biological role and that there are consequences to interfering with protein function. This level was not captured by our hypothetical LP, but is considered to be below level 2 of the hypothetical LP in terms of sophistication. In the next level students explicitly described proteins as central to genetic phenomena but were unable to provide any contextual examples, which corresponds to level 2 of the hypothetical progression. These students held a schema which invoked "proteins" as an explanatory element of the genetic phenomena. That is, these students knew that if a phenomenon is genetic, it must involve proteins. However, they struggled to apply this schema in context and provide specific examples of protein involvement. For example, when presented with a reasoning task concerning an inherited genetic disorder, Daniel immediately discussed inheritance of genes from family members. He also agreed that proteins are involved in the genetic disorder, but when prompted to give an explanation of this he responds that "like [genes] gives protein to the person, so the person can be healthy and stuff like that". Daniel believes that proteins are involved in the genetic phenomena but cannot provide examples beyond his acknowledgment of their presence. In the final level students could instantiate their ideas about proteins as related to genetic phenomena by providing specific examples of protein functions and how a genetic mutation might affect protein function (corresponding to level 3 of the LP).

Table 3 illustrates our data-driven refinements for construct C. We did not have any students at a level 1 of the hypothetical progression by the end of the two units. However, we did have evidence from earlier interviews that a non-protein based view of genetic phenomena exists. We found that 12 students remained at level 1.5 of the refined construct C. Several students (8 total) were able to reach a level 2 understanding where some could provide contextual examples, while others could not (suggesting this level could be split further). Very few students (4 total) were able to reach level 3 of the refined construct C and could reason about amino acids as building blocks for proteins. Again, as with construct B, their ideas about proteins were not as robust as we had hoped.

Table 3: Data-driven refinements of construct C.

| | Level 1: Grades 5-6 | Level 2: Grades 7-8 | Level 3: Grades 9-10 |
|---|---|---|---|
| Hypothetical Construct C (Author et al., 2009a) | Cells are one level of organization within our bodies. Cells have specific organelles that help the cell perform its function. | Proteins perform specific functions within cells. Genetic mutations can result in changes within the structure and function of proteins. | The amino acid sequence of a protein determines its shape/function. There are different kinds of genetic mutations which can affect the structure and function of proteins. |

| | New LP level | Original LP level | Level Description |
|---|---|---|---|
| Construct C Revised | Was not captured | Level 1 | Cells are one of the basic levels of organization in the body. They can perform specific functions. |
| | Level 1.5 | Was not captured | Proteins are vitalistic in nature. They are good for you and provide positive health benefits without them, general health declines. |
| | Level 2 | Level 2 | Proteins are required for optimum health. Their function is dependent upon their structure. Students cannot provide contextual examples of protein function. |
| | Level 3 | Level 3 | Proteins are central in the genetic phenomena. Their function is dependent upon their structure. Students provide specific contextual examples of how protein function (or lack of function) contributes to the genetic phenomena. |

## Identifying Connections and Contingencies between the Constructs

The theoretical LP in genetics did not include any hypotheses regarding links or dependencies between constructs, there was simply not enough evidence in the literature to support such assertions. Our second goal for this analysis was to ascertain the ways in which understandings along constructs B and C might be related, or dependent upon each other. From a canonical point of view these constructs must be related as construct B essentially defines what biological entity the genetic information specifies (genes code for proteins), and construct C defines the role of proteins in genetic phenomena (the idea that proteins bring about the phenotype). However, it is not clear whether these understandings develop in parallel, or whether a student needs to attain a certain level of sophistication for construct B in order to reason at particular levels for construct C (or vice versa). Towards this end we tried to map out the connections between these constructs as manifested in students thinking. Overall, we found that students had difficulty drawing a relationship between genes and proteins and thus these constructs seemed to exist (and to some extent develop) in parallel.

We found that for 8 of the students there did not seem to be any connection at all between genes and proteins (see Figure 1 – light shading). There were 11 students that demonstrated understandings that suggested a weak link between these constructs, a sort of touch-and-go connection, in which the extent of linkage varied with the task context (see Figure 1 – medium shading). Only 5 students expressed understandings that suggested fairly stable and robust connections between the constructs. Figure 1 further illustrates the distribution of students in each category of connections between the two constructs as well as students' level of understanding for each of the constructs individually. We found that only students who showed a level 6 understanding for construct B (understands that genes provide instructions to make proteins) and a level 3 understanding for construct C (provides contextual examples of protein's role in genetic phenomena) exhibited stable and robust connections between these constructs. For these students, the constructs seemed intertwined and they were able to easily reason about the relationship between genes and proteins. For example, in reference to a genetically inherited skin elasticity disorder, William immediately suggested that "the gene coded for the wrong amino acid so the protein was like misshaped, and then that means that [the protein] didn't work".

| Role of proteins in genetic phenomena (levels 1 – 3) | Genes and their relationship to proteins (levels 1 – 6) | | | | | |
|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6 |
| 1 | | | | | | |
| 1.5 | 3 | 2 | 3 | 2 | 2 | |
| 2 | | | 2 | 2 | 3 | |
| 3 | | | | | | 5 |

Figure 1. Contingencies between constructs B and C.

Not all cases for intertwined understandings were as robust as William's. In another case for intertwined understandings, Amy also held a level 6 understanding for construct B (genes encode for amino acids which provide structure and function for proteins), and a level 3 understanding for construct C (proteins as central to genetic phenomena with contextual explanations). However her understanding of the connection between genes and proteins was not as straight forward. It is also possible that she held a higher level of understanding but did not provide evidence of this in her interview. For example, in the following exchange, Amy was asked to reason about a genetically inherited blood clotting disorder:

Interviewer: Now do you think proteins have anything to do with this?
Amy: Mmm hmm (agrees)
Interviewer: Okay, what do you think proteins are doing?
Amy: Um, I think the proteins that should be doing its job is, has to um, has to send a message to the cells to like, um, to um, to duplicate their cells and um close the, close the, the cut.
Interviewer: Okay, very good. What about genes? Do genes have anything to do with this?
Amy: Mmm hmm (agrees)
Interviewer: Okay how do genes work?
Amy: The genes have instructions to make a certain protein and if there's something wrong with it or they have a mistake, the protein won't work that how it's supposed to work. Or sometimes it doesn't, it isn't there at all.
Interviewer: Okay, very good. So what's wrong with the genes specifically?
Amy: The genes isn't giving the information to…there's something wrong with the instructions and the protein won't give the message to the cells to repair the, the cut or something.

In this example, Amy provides intertwined understandings of the two constructs. She is able to define the role of the protein (causing the cell to undergo mitosis and close the cut) and the role of the gene (to provide instructions to make the protein). She also demonstrates her knowledge that a mutation ("something wrong") in the gene leads to the protein's loss of function resulting in the genetic phenomena. However since she uses ambiguous phrases like "something wrong" and does not explicitly define the role of the protein other than sending messages, this suggests that intertwining the progressions is a progressive process.

An understanding of the role of protein structure and function in genetic phenomena was critical for students to fully explain how genes and proteins are related to one another. This was also reflected in the other two categories of relationships between the constructs (no link, and weak link). If students were at a level 2 on construct C (proteins as central to genetic phenomena without specific contextual examples), they were limited to providing only specific touch-and-go connections between genes and proteins. For example, Kaitlyn (at a level 2 for construct C and level 3 for construct B) was asked how genes and proteins are involved in an inherited skin elasticity disorder:

| | |
|---|---|
| Kaitlyn: | I think it has to do with that their body is not making that protein. |
| Interviewer: | Okay, why isn't their body making that protein? |
| Kaitlyn: | Maybe because there is a mutation in the code or something. |
| Interviewer: | So why would a mutation in the code prevent them from making a protein? |
| Kaitlyn: | Because it's messing everything up and not letting it do its job. |
| Interviewer: | So the mutation is messing up the protein? |
| Kaitlyn: | Mmm hmm (agrees) |
| Interviewer: | So the protein can't do its job. What do we think the job of the protein might be here? |
| Kaitlyn: | Um, to make [the patient's] skin firm and flexible and not like get bruised easily. |

In this example, Kaitlyn was unable to explain the link between a change to the gene and a resultant change to the protein-- what precisely was being "messed up" and how this ultimately led to a missing protein. This example illustrates the incomplete explanations students generate when they only have weakly connected knowledge of the two constructs.

The strength of the linkage was reflected in the level to which they progressed for each construct. For example students reaching level 3 on construct B and a level 2 on construct C (the lowest score possible for linkage) held weaker associations between genes and proteins than a student reaching a level 5 on construct B and a level 2 on construct C. There were several students (8 total) who did not demonstrate any understandings that genes and proteins are related, and this was symptomatic of their understanding of proteins. These students tended to view proteins as vitalistic or being required to maintain optimal health; these views of proteins were paired with views of genes as non-informational or, at most, as active information (level 3 of refined construct B). Two of these students held a level 5 understanding of genes in construct B (genes as information for proteins), but only a level 1.5 understanding of proteins in construct C (proteins as required for optimum health). In these cases, the students both viewed genes as providing information to make proteins, yet at the same time did not view proteins as central to the genetic phenomena (described proteins as required for health and vitalistic). This is unique, since other students who held a similar level 5 understanding for construct B, had at least a level 2 (or higher) understanding for construct C (proteins as central without contextual examples). This suggests that high levels of sophistication for construct B do not necessarily bootstrap connections between the two constructs.

By analyzing the relationships between two constructs within our LP we were able to determine that students' views of proteins were, to some extent, contingent upon their understandings of genes. In many cases students were able to describe genes in terms of genetic inheritance quite accurately (relate genotype to phenotype), but it was not until they viewed proteins as central to genetic phenomena that linkages between ideas about genes and proteins could be made. Based on our data we can both revise these two constructs within our LP and describe the ways in which development along one construct depends, or is dependent upon, development along another.

## Conclusions and Implications

We, like others, are cautiously optimistic about the potential of LPs to inform instruction, curriculum and assessment (Author et al., 2009b; Lehrer & Schauble, 2009; NRC, 2005; NRC 2007). Their potential can only be realized if we can effectively validate and revise them based on empirical findings. Such validation efforts are challenging given the messy, and context dependent, nature of the data. In this paper we presented our efforts to use our empirical findings to inform revisions for a theoretical LP in genetics. Based on this research we next provide a few heuristics and suggestions for the process of refining LPs in relation to data.

Levels should be added (or split) when the ideas inherent to the new level are directly related to the construct and offer explanatory power (in terms of student cognition) or instructional leverage. In the case of our refinement of construct B (Table 2) we added the transition level because it highlighted the initial step of conceptual change. This new level provides explanatory power in terms of modeling conceptual change and is an instructional leverage in the sense that it can be a bridging understanding from a non-information based view of genes to one that is information-based. We did not, however, include a new level to capture students' ideas that genes have information about cells, despite their existence in the data set. This new idea was not directly relevant to the construct as it reflected an understanding of biological organization levels rather than notions about genetic information per se.

While we did not have to consolidate or remove levels based on our data, our sense is that such a move would be necessary if there are no cases, in the data set, of the specific level of understanding, and the level provided little explanatory power in terms of predicting student performance or modeling student cognition. Given that starting point for the LP included only three levels, it was unlikely that we would need to remove any levels. It was the case that we observed very few data points for level 3 understandings, however, we do see this is reason to remove the upper target of the progression. It does, however, suggest ways in which we would need to revise our instructional materials in order to move more students along the progression.

It is very likely, given the complex nature of learning, that movement along one or more constructs in a progression would depend, in some way, on the students' level of understanding of other constructs (Wilson, 2009). In order to identifying such links or dependencies between levels across multiple constructs it is necessary to map out (as we did in Figure 1) the relationship between the constructs as a function of students' level of understanding in each. Such a representation allowed us to see the constraints and affordances that different levels of understandings have in relation to other constructs. In this paper we conducted the analysis for two constructs. Adding more constructs to the mix will certainly present a challenge, but we believe that a similar approach could be used with larger numbers of constructs at play.

We anticipate that our revisions to the genetics LP will be a first step in a series of refinement and revision cycles. In future studies we also intend to vary the curriculum in order to begin to tease apart aspects of student thinking and learning that seem curriculum dependent. This is another challenge in validating the LP approach and much additional work is needed in order to develop our understanding of the relationship between LPs and the instructional context.

# What Counts as Scientific Practice? A Taxonomy of Scientists' Ways of Thinking and Doing

Lori M. Takeuchi, The Joan Ganz Cooney Center at Sesame Workshop, 1 Lincoln Plaza, New York, NY 10023
lori.takeuchi@sesameworkshop.org

**Abstract:** Education reformers advocating the use of GIS in K-12 science classrooms claim that the tool provides authentic contexts for students to think and act scientifically. However few studies, if any, have empirically investigated the latter. I observed a marine ecology laboratory to determine what counts as scientific practice, and then an 8th grade oceanography classroom to see whether and how these practices played out there, especially around participants' use of GIS software. This paper focuses on the methods I used to draw meaningful comparisons between the novice and expert settings I studied. In particular, it describes the taxonomy of scientific practices derived from my laboratory observations, and then the nature of work in the lab as seen through this framework.

## Introduction

As globalization and rapid advances in technology change life as we know it on a daily basis, the ability to navigate complex information, reframe problems, evaluate evidence, argue persuasively, innovate, and adapt to ever-changing circumstances has come to comprise the standard repertoire of skills required to survive and succeed in the 21st century. Consequently, preparing students to think and act scientifically is an increasingly critical concern. National standards urge teachers to engage students in the practices of professional scientists as a means of developing these habits of mind, and suggest the use of scientists' tools to support their inquiry. A geographic information system is one such tool, and though around since the 1960s, is gaining popularity among a variety of professions. Earth and environmental scientists, fast food franchise developers, epidemiologists, and others use GIS to capture, store, analyze, and display geo-referenced data, which is information tagged by latitude and longitude coordinates. Layering different data sets atop a base map can reveal spatial relationships among the data that are not ordinarily perceptible in nature.

GIS has also been in K-12 classrooms for more than a decade. In addition to fostering students' spatial skills (NRC, 2006), these tools can help science learning better resemble science practice, heightening the much-desired element of *authenticity* in science classrooms—or so education reformers have claimed (e.g., Edelson, 1998; Gordin & Pea, 1995). To empirically test the assumption that GIS promotes authentic science learning, I observed a marine ecology laboratory first to determine what counts as scientific practice, and then an 8th grade oceanography classroom to see whether and how these practices played out there, especially around participants' use of GIS software. When students have access to scientists' tools, do they use them in ways that scientists do? While the primary interest of my larger study was inquiry learning in science classrooms (Takeuchi, 2008), this paper focuses narrowly on the methods I used to draw meaningful comparisons between the novice and expert settings. In particular, it describes the taxonomy of scientific practices derived from my observations in the laboratory, and then the nature of work in the lab as seen through this framework. As far as I am aware, no other such taxonomy exists. Limitations of the catalog and its implications for science education research are also discussed.

## Past Approaches to Studying Authentic Learning

What counts as scientific practice? Would I recognize authenticity in the 8th grade classroom when I saw it? To be sure, the field of science studies (1) has over the past quarter century generated a multitude of models of scientific practice, but none to date have examined scientists who use GIS per se. And while other studies of authenticity in science learning reference models of professional practice, few have directly compared the naturally occurring activities of novice and expert scientists. Rosebery et al (1992) and Krajcik et al (1999), for instance, focused on classroom inquiry but made comparisons with the generic, composite portraits of working scientists advanced by the science studies literature. Other studies have directly compared experts and novices, but on simulated tasks (e.g., Kuhn, 1989; Lowe, 1999), raising issues of ecological validity.

Another approach to studying the practices of novice and expert scientists involves the comparison of archival accounts of scientific work. Since this approach makes use of audio- or videotaped footage of naturally occurring activity, researchers are able to take into account the situational features that simulated tasks cannot. Hall (1999), for example, examined videotaped footage of people "having a theory" in a medical school classroom and around a family dinner table. Similarly, Koschmann and Zemel (2006) compared audio- and videotaped accounts of professional astronomers "doing discovery" at an observatory and two high school students doing the same using a physics simulation on a computer. Since comparisons were based upon other people's recordings, interpretations of recorded events were necessarily mediated through the original researchers' selection, framing, and view of events. Another limitation of this approach is that researchers have limited access to information about the participants or about the broader contextual features of each situation, as the events depicted in Hall (1999) and Koschmann and Zemel's (2006) studies had long passed by the time these authors got around to analyzing them.

My research is more closely modeled after Stevens' (1999) first-hand accounts of activity in the novice and expert settings he set out to compare by intent. He investigated everyday math activities as they emerged in a middle school design project and in the real-world design projects of an architecture firm. In the seven months he spent in the classroom and year observing architects, he witnessed how tools such as CAD software, available to both students and architects, mediated project activity in ways reflecting the culture of each institution. Comparing the forms of mathematical practices across the two settings, Stevens concluded that the organizational environment of the school—e.g., an assessment system that values equality over diversity, and the structure of the school day—makes it difficult for students to engage in meaningful mathematical practices and, consequently, learn very much.

## Methods

I adapted the design of Stevens' (1999; described above) study to investigate how scientific practices emerge around the use of GIS in an 8th grade oceanography classroom and a university marine ecology laboratory. The unit of analysis in each setting was the activity system (Engeström, 1999) of a small team conducting a research investigation. The laboratory case team consisted of a marine ecology doctoral student and his field assistant, who were studying the movement patterns of a particular fish species. The classroom case team comprised two 13-year-old boys investigating the kelp forest ecosystems of Catalina Island. I collected data intermittently over a 9-month period in the laboratory, and over 11 consecutive weeks in the classroom. In both settings I took field notes, conducted interviews, collected artifacts, and videotaped human-human and human-computer interactions.

### Operationalizing "Scientific Practice"

To identify scientific practices in the laboratory, I first had to define "scientific practice." Operationalizing the concept to support meaningful comparisons between laboratory and classroom settings proved challenging: Framing it too closely around the technical aspects of scientists' work, for example, provided too little to compare or even contrast. Crafting a definition around the inquiry processes we want students to develop, on the other hand, rendered the comparison to professional practice extraneous. In the end, I combined aspects of Rouse (1994), Pickering (1992), and Edelson's (1998) ideas into a definition that I thought would best serve the purposes of this study:

> Scientific practices are sustained, dynamic, and communal acts of purposeful inquiry. These "patterns of activity in response to a situation" (Rouse, 1994) manifest the beliefs, values, and experiences accumulated by the scientific community over time, and include ways of thinking and doing, attitudes, and social interactions.

This definition does not include scientists' tools and resources per se, and it intentionally omits formalized investigative procedures like *run experiment* or *analyze data*. I instead use these organized activities as framing contexts for their more spontaneous acts of scientific thinking, doing, feeling, and interacting. Moreover, since I observed all phases of the students' investigation but just the scientists' data collection phase, the case teams' individual sets of procedures would have been incommensurable.

### Coding for Scientific Practices

Several science studies scholars have contributed to theoretical notions of scientific practice (e.g., Latour & Woolgar, 1987; Knorr-Cetina, 1981; Pickering, 1995; Rouse, 1994). However, I was unable to locate previous work that comprehensively indexed a practical list of scientific practices that could serve as the basis for my cross-setting comparisons. I myself would have to empirically determine what counts as scientific practice. So, once data collection was complete, I used the above definition to generate codes for scientific practices seen in the laboratory. Through the process of analytic induction (Znaniecki, 1934) and deduction, each practice was assessed for its generality across the corpus of data and revised or dropped if counterexamples were found. I made several passes through the data to ensure that all practices fit the working definition—itself revised several times—and that none were subsets or duplicates of others. While the present set of codes is by no means comprehensive, it is a starting point for more systematic efforts to concretize the rather abstract notion of scientific practice.

I then used HyperRESEARCH qualitative data analysis software to code instances in the laboratory case's field notes and video content logs for the identified practices. I also chunked these data by *task*, which I've defined as "a clearly delineated piece of work that is of short or limited duration and performed to move the investigation forward." The task served to bound the scientists' work activities into discrete units of analysis so that scientific practices could be tallied within each task. However it is important to note that these tallies may be more indicative of my observational sampling than the quality or complexity of the corresponding tasks.

### The Laboratory Setting and Participants

Kinder Marine Laboratory (all names are pseudonyms) is a large, ocean-side research facility of a prominent West Coast university. Between July 2006 and April 2007, I observed marine ecology doctoral student Fred (age 33) and his field assistant Kyle (age 28) during the fourth of Fred's five-year long dissertation study. Fred's research focused on the movement patterns of individual spotted purplefish in relation to features of the local purplefish population (size, density, reproductive behavior) and environment (bottom types, biological habitat). Findings would have implications for the design of marine protected areas (2), since the effectiveness of these reserves depends on the extent to which they accommodate the full range of movements of the individuals they aim to protect. I started observing the team one year after Fred began collecting data, and just one week after Kyle started as Fred's field assistant. The case scientists belonged to the smaller, 20-person Coniglio-Ross Lab for Marine Ecology Research at Kinder (nicknamed the CR-Sea Lab), and were the only ones there at the time using GIS in their research. In fact, when I met Fred, he was just learning GIS because he knew the tools would facilitate his research.

I observed Fred and Kyle in three locations: (a) at the CR-Sea Lab; (b) *above* Fred's research site out on Cabezon Harbor (I went out on their research vessel the *Otter's Nest* but did not accompany them underwater on their scuba dives); and (c) inside the van they used to transport the *Otter's Nest* between these two locations. Although I focused my attention on Fred and Kyle's activities, I also captured some of their interactions with members of the wider Kinder community, including faculty scientists, technicians, and other graduate students.

## Scientific Practices Observed in the Laboratory

In my 40 hours observing and interviewing the case study scientists, I recorded the following 45 scientific practices. They are listed in Table 1 order of frequency logged, from highest to lowest. Since I did not visit the scientists on a daily basis, and was not able to observe them over the complete course of their five-year-long project, the practices on this list do not represent the complete repertoire of their work. As such, the corresponding frequencies should also be taken as relative indicators and a specific reflection of the days I chose to observe there. Following this list are discussions of the top 15 observed practices. (See Takeuchi, 2008 for descriptions of all 45 practices.)

Table 1. Scientific practices observed with the case study scientists

| Practice | Frequency | Nature | Practice | Frequency | Nature | Practice | Frequency | Nature |
|---|---|---|---|---|---|---|---|---|
| Use inscription | 34 | d | Connect study to personal exp. | 9 | e | Be meticulous/organized | 5 | d e |
| Maintain equipment | 20 | d e | Hypothesize | 9 | e | Communicate data/findings | 5 | d e |
| Divide labor/expertise | 18 | d | Partake of comm. resources | 9 | d | Compete for resources | 5 | d |
| Accomm. natural phenom. | 17 | d | Reason with others | 9 | d e | Discover/Achieve insight | 5 | |
| Identify pattern | 17 | d | Seek help | 9 | d e | Make meaning | 5 | d |
| Let tool shape research | 17 | d e | Seek new knowledge | 9 | d e | Put safety first | 5 | e |
| Apprentice | 15 | d | Strive for reliable data | 9 | e | Reframe problem | 5 | e |
| Follow ritual | 13 | d | Tweak tool/technique | 9 | e | Take risk | 5 | e |
| Save time/resources | 13 | d | Ask question | 8 | e | Be driven by ulterior motive | 4 | e |
| Accomm. misbehaving tool | 12 | d | Camaraderie | 8 | d | Deal with messiness of data | 4 | d e |
| Be committed/persistent | 12 | e | Modify plans/thinking | 8 | e | Ideate | 4 | e |
| Master routine | 12 | d | Participate in community | 7 | d | State limits of data/tool | 4 | e |
| Plan/Prep | 12 | d e | Appropriate new tool | 6 | e | Connect study to world issue | 3 | d e |
| Be uncertain | 10 | e | Tinker with tool | 6 | d e | Do politics | 3 | d e |
| Reason with tool | 10 | d | Apply background knowledge | 5 | d e | Invent | 3 | e |

Notes: d = Practice is a manifestation of or response to the *distributed* nature of work.
e = Practice is a manifestation of or response to the *emergent* nature of work.

### 1. Use Inscription (34)

Fred and Kyle used inscriptions (3) in nearly every task I observed, plus the ones that took place underwater. They printed waterproof maps of the harbor's depth to serve as underwater guides to the seafloor; analyzed individual fishes' home ranges on the GIS; and projected slides of fish tag expiration timelines on the lab wall to solicit help from advising professors, among other things. As the study's principal investigator, Fred spent much more time than Kyle did constructing and managing inscriptions for the planning, data collection, analysis, and communication activities they performed together.

## 2. Maintain Equipment (20)

While Fred took care of preparing inscriptions, Kyle was often occupied with maintaining the *heavy* equipment required to do their scientific work, including the 30-foot research vessel the *Otter's Nest*, the trailer that transported the *Otter's Nest* to Cabezon Harbor, and the rusty old van that towed the trailer 100 miles roundtrip to and from the harbor. Equipment maintenance involved packing up transport vehicles with equipment used on dives, filling vehicles with gas, fixing broken items, cleaning up and storing equipment, and making arrangements for regular servicing. Kyle also maintained the team's scuba tanks and the four buoys—each weighing 43 kilograms—that served as receivers for the acoustic tracking system set up in the harbor. I emphasize *heavy* above because the lighter equipment associated with inscriptional work—i.e., Fred's laptop, the lab's GIS desktop computer, and the GPS unit—for the most part fell under Fred's jurisdiction, as did the tiny and expensive acoustic tags that were surgically implanted into the fish for tracking by the telemetry system.

## 3. Divide Labor or Expertise (18)

Fred and Kyle often assumed responsibility over separate tasks in order to accomplish the maximum amount of work out of available time. Divisions of labor usually fell along lines of expertise, professional rank, location, or individual commitments. Fred, for example, managed the fish tag equipment because he possessed more specialized knowledge about the technology than Kyle did. And it was Kyle's job to load the van up each morning at 6:30 AM because this is the type of grunt work that field assistants are hired to do. On lab days—versus days spent in the field—Fred often worked inside completing paperwork, writing research grants, or working with software, while Kyle could be found outside in the storage sheds fixing or maintaining equipment. In many cases, work could only be accomplished on this two-man team if tasks were divided. Fred, for example, always steered to position the boat using his GPS unit as a guide while Kyle dropped anchor. Divisions of expertise also contributed to the efficiency of the work team, as when Fred had Kinder's resident geneticist run DNA tests on the fish eggs he collected.

## 4. Accommodate Natural Phenomenon (17)

As much as scientists attempt to maintain control over all aspects of their research, nature often evades management. Fred and Kyle had to adjust their plans, tweak their equipment, and redesign their investigation to accommodate the occasional unforeseen and uncontrollable behaviors of the fishes under study. In the spring, when Kyle was having no luck locating egg nests of the fishes they had tagged the previous summer, Fred decided to extend their egg hunts beyond his study site to untagged fish. Doing so would increase his sample size, but disassociate a set of genetics tests he wanted to run from the home range aspect of his study. The scientists' work was also at the mercy of the sea and the sky. Environmental events—e.g., high surf, cold water temperatures, algal blooms—regularly altered their course of action on a moment-by-moment basis.

## 5. Identify Pattern (17)

Scientists often craft visualizations of their data to reveal patterns that remain hidden in rawer formats. These patterns help them make predictions and make sense of the represented phenomena. In a laboratory meeting convened around the mysterious disappearance of several fish Fred had tagged earlier in the year, the participating scientists rarely referred to one of the displayed graphs, tables, or maps without extracting some less-than-obvious pattern from it. The three senior scientists in the room surfaced patterns in Fred's data that even Fred had never seen. They were so generative in this regard, in fact, that it was as though they couldn't look at an inscription without looking for underlying patterns. By meeting's end, their interpretations of the data led the group to the conclusion that Fred had perhaps ill advisedly constrained his study site to the published receiving range of the buoys, and needed to expand it to cover the region that his tagged fish actually inhabit.

## 6. Let Tool Shape Research (17)

The scientists often allowed the affordances and constraints of their tools influence how they designed or proceeded with their investigation. What Fred and Kyle managed to accomplish in a day's data collection expedition, for example, depended on the number of scuba tanks they brought with them on the boat (also limited by the size of the boat) and the oxygen composition of each tank. A tank holding 1,200 pounds of air gave each diver 45 minutes to complete a fish density or UPC survey of one reef in their study site. The oxygen-enriched tanks with a 20/80 oxygen to nitrogen mix allowed Fred and Kyle to perform more physically exerting tasks, such as underwater fishing (4), in the same amount of time, but were harder to obtain at Kinder. Sometimes Fred and Kyle's air supplies dictated their dive itineraries. As Fred once instructed Kyle just before their final dive of the day, "Let's just make sure that we come up with enough air to switch the buoy out, and if we catch one (a fish), that we come up with enough air to bring it back down."

7. Apprentice (15)

Fred hired Kyle as his field assistant just two weeks before I started observing them, so I got to witness a critical stretch of Kyle's on-the-job training. Very little time was set aside for direct instruction. Instead Kyle was expected to watch Fred perform a procedure once through, such as locating and unmooring the telemetry buoys, or preparing their rods and reels for underwater fishing, before taking responsibility for the task the next time. Although it was up to Kyle to direct his own learning—by asking Fred questions rather than waiting for Fred to provide lock-step instructions—Fred was fully cognizant of the training session in progress. In fact, when there were new techniques for Kyle to learn, Fred often made sure his apprentice stayed near enough to see him model the activity. These learning episodes were among the rare occasions that the teammates worked on the same task simultaneously.

8. Follow Ritual (13)

During the summer field season spanning July through October, the scientists ran scuba expeditions four days of the week to collect data and maintain their telemetry equipment on the harbor. Field days began at 6:30 AM loading up the boat and van at the lab, and included a 100-mile round trip drive to and from Cabezon Harbor, where they took three or four scuba dives over the course of four or five hours. Days often ended past 6:00 PM, after hosing down and storing all of the equipment. Between tasks, scientists participated in a number of social rituals to take the edge off of this grueling work. Morning trips to Emmy's Bakery for muffins and coffee, for example, were mandatory even when the scientists were running behind their on-the-road-by-7:00 schedule. Other social rituals included the "hot water bucket" that researchers would pour down their wetsuits after their last dive of the day to warm their bones, and chitchat on the long drives between Kinder and Cabezon Harbor. These commonly shared experiences helped build rapport within the Kinder community, and were passed down from old-timers to newcomers.

9. Save Time or Resources (13)

Fred and Kyle constantly sought to make the most of their limited time and resources. Some of these efforts were built into routines—as described in *divide labor* and *apprentice*, which are not included in this count—but others involved a conscious pursuit of the most efficient path through their work. Fred, for instance, spent a couple of days constructing and then printing 25 percent contours of the tagged fishes' home ranges so that on scuba dives they could more easily locate egg nests to collect samples. More time spent at the computer meant less time swimming around underwater in search of the nests, expending energy and oxygen stores. Kyle's efficiency-motivated acts include creating drop-down menus in an *Excel* file to speed up data entry and minimize error, and inventing a special belt holding eight large vials and cuticle scissors to make it easier to harvest fragile fish eggs while underwater.

10. Accommodate Misbehaving Tool (12)

Just as the scientists altered their plans or even goals in response to the unanticipated behaviors of the fish, the weather, or the sea, they also accommodated the equipment that broke down or failed to produce some desired outcome (Pickering, 1995). Small misbehaviors, such a leaky O-ring on a scuba tank, might alter the day's data collection agenda, but bigger ones affected changes at a greater scale. The disappearance of half of Fred's tagged fish from telemetry reception, for example, prompted him to spend several weeks catching more fish to tag and include in his study. It also prompted him to rescale his study site in order to monitor a wider region of Cabezon Harbor and, hopefully, to recover reception of those missing fish. Fred and Kyle eventually solved the mystery of the disappearing fish—the batteries in their tags had simply died—but the time, effort, and expense spent in making these adaptations were significant. In a final act of accommodating the faulty fish tags, Fred decided to set the end point of the data collection phase to whenever the batteries in his remaining tagged fish petered out.

11. Be Committed or Persistent (12)

Only the most devoted make it in this field. Based on physical demands alone, those who can't take five months of 12-hour field days and scuba diving in 54-degree waters are weeded out at the level of field assistant. Fred's acoustic telemetry system required that he cycle a charged buoy into the harbor every week of the year, including stormy winter months, so that it would continually monitor Fred's tagged fish without interruption. The considerable commitment of these scientists extended beyond physical work. The unpredictable and often unwelcome behaviors of their fish and tools *(accommodate natural phenomenon* and *misbehaving tool*) often required extra time, money, and exertion to put the study back on track. Patience and perseverance are necessary to deal with the uncertain outcomes and regular disappointments associated with this type of work (Edelson, 1998; Kurz-Milcke et al, 2004):

> Fred: All these tagged fish that I tagged last summer... I did it for two years, right, and they all stuck around for the entire two years. And so I did them all last summer thinking, "Oh, this summer I'll just jump right into manipulating all this stuff." And now I just came back and half of

> them are gone! Ahhhh! It's really disappointing. I mean, but that's part of it. And you get other data from it. But I can totally see like if you don't have that interest and commitment to it, you can get that stop-doing it attitude. It's definitely kind of long and ongoing and always changing.

### 12. Master Routine (12)

The scientists repeated many of the same routines—defined here as regularly repeated procedures—on a weekly, if not daily, basis. Weekly routines included the buoy switching mentioned above. This involved unmooring the least-charged of three telemetric buoys from the harbor floor and transporting it back to the lab for recharging and replacement the following week. Daily routines included loading up the van and boat with the necessary dive and data collection equipment each morning, and unloading it at the end of the day. Certain routines involved complicated procedures that both Fred and Kyle became more skilled at with practice, as they did with their underwater fishing techniques. Other routines, such as loading and unloading transport vehicles at the lab, were familiar practices among members of the wider Kinder community. On the day that Fred couldn't dive due to an ear infection, the field assistant he "borrowed" from another crew was able to step in and perform a number of these institutionalized routines with little instruction.

### 13. Plan/Prep (12)

Due to the tremendous material aspect of their work, along with the fact that it often took the coordinated actions of several people to accomplish a single task, the scientists spent quite a bit of effort orchestrating upcoming tasks. Poring over the minutiae of their data collection, analyses, and presentation activities beforehand helped Fred and Kyle obviate unwelcome complications. It also ensured that minimal time and money were wasted in the implementation. The scientists often spent far more time prepping for than executing target tasks, as examples cited in *save time or resources* suggest. Fred spent months preparing his dissertation proposal, which, once approved by his dissertation committee, served as the official blueprint for his study. But most of the planning I saw took place on a more impromptu basis—on van drives to and from the harbor, while suiting up in the parking lot, or just before putting their face masks before a dive. Fred and Kyle were in constant communication about how to best coordinate their upcoming actions.

### 14. Be Uncertain (10)

Never knowing what to expect next in an unfolding investigation—especially ones marked by *misbehaving tools* and *natural phenomena*—instills in scientists a comfort with uncertainty. The scientists demonstrated this comfort by openly admitting to colleagues what they didn't know, couldn't understand, or were willing to accept as unanswerable, in one-on-one and lab-wide meetings alike. They also demonstrated this comfort in their ability to carry on in their work and make important decisions despite unknown outcomes. Kyle, for example, spent several hours fabricating a special belt to facilitate their underwater egg sampling excursions using random materials he pilfered from around the lab. He had no idea if the belt would work—he had yet to try it out at the time of our interview—since the whole egg collection process was uncharted territory for Fred and Kyle. A common corollary to the scientists' uncertainty was a desire to bring clarity to a situation, and this required a high tolerance for risk. As Fred's advisor Joe pointed out while counseling Fred on whether to shift the scale of his study midway through the investigation, "It's just one of those things that you have to take a shot at and see what's going to happen. That's the way science is. It sucks! Ultimately [...] you're trying to figure out what's the best effort to put my time into."

### 15. Reason with Tool (10)

The scientists reasoned with tools when they used artifacts in their environment to (a) offload complex cognitive tasks or (b) extend their cognitive capabilities. In an example of the former, Fred used a dive watch to help monitor his oxygen usage so that he could instead focus on his underwater tasks. In an example of the latter, he calculated statistics using software. Fred reasoned with the GIS for both purposes. Here Fred describes the advantages the tool brought to his research:

> Well, one thing that it really does the most for me is just to think about all this stuff. To just sit in front of it and actually look at it instead of just having a number. And you can get these distributions of points where the fish is and then you calculate an area and then you know the home range is 500 square meters. But actually looking at the shape and seeing how that fits into the habitat, really that's a big help, I think. And kind of coming up with ideas, and thinking about, "Oh this looks interesting, I should actually do the stats on that."

The spatial and layering capabilities of the GIS freed Fred up from having to translate the text data into something meaningful, and inspired analyses that he wouldn't have come upon unaided by the spatial display.

## The Distributed and Emergent Nature of Science

In the process of sorting through the 45 observed practices, I characterized the science that took place at Kinder Marine Laboratory to be both *distributed* and *emergent* (see tags in Table 1, above). I also established a pattern of *efficient* and *adaptive* responses to the problems presented by distributed and emergent systems. Though these findings merely confirm what empirical research in science and technology studies documented in the 1980s and 1990s, they are worth discussing briefly here, as these constructs helped guide my analyses of the 8th-grade classroom case.

Science is no longer construed as the solitary endeavor of brilliant individuals such as Isaac Newton or Albert Einstein. Scientific research and progress is more readily recognized as the joint achievement of people, organizations, places, and tools, all of which are distributed across space and time (Goodwin, 1994; Dunbar, 2000). I observed Fred and Kyle participate in 28 practices that were manifestations of and/or responses to the distributed quality of their work. Twelve such practices describe social interactions (e.g., *divide labor/expertise, apprentice, partake of community resources, seek help, participate in community, communicate data/findings, compete for resources, reason with others, do politics*), and seven describe their relationships with artifacts (i.e., *use inscription, maintain equipment, let tools shape research, identify patterns, reason with tool, accommodate misbehaving tool*, and *tinker with tool*). This dispersion of knowledge, reasoning, and labor across individuals, artifacts, institutions, and spaces both facilitate and pose particular challenges to the accomplishment of work.

Fred and Kyle often responded to the challenges with efficient measures. Some of these efforts were built into their routines, such as dividing tasks and Kyle shadowing Fred in an apprentice style of learning. But others involved a conscious pursuit of the most efficient path through their work. In some of the examples cited above—e.g., mapping out dives on the GIS to spend less time underwater, or creating drop-down menus in Excel to facilitate data entry—the scientists "sacrifice short-term efficiency to retool [their] knowledge or context for the prospect of long-term gain," in what Martin and Schwartz call a "prospective adaptation" (in press, p. 5). Because Fred's investigation took five years from start to finish, the time investment on any prospective adaptation paid itself off many times over.

Efficiency in the form of procedural speed and accuracy benefits distributed work systems, especially when these systems are stable and see little change. But the work of Fred, Kyle, and most scientists are far from predictable. No matter how meticulously they plan out their investigations, circumstances beyond their control have a way of altering the science that gets done. Pickering (1995) attributes the "temporally emergent" structure of scientific research to the nonhuman or material agency of scientific practice. When a machine fails to produce expected outcomes, humans often accommodate the machine by revising their original goals, or by tweaking the machine or the investigation itself. Other researchers (e.g., Knorr-Cetina, 1981) have documented how the particularities of a research situation—material, personal, or otherwise—influence discoveries in unexpected ways. What becomes scientific fact depends, to a great extent, on the context in which the science is conducted.

This emergent quality of science is also revealed in the taxonomy, with 30 of Fred and Kyle's observed practices falling into this category. I observed the scientists adapt to unanticipated events (i.e., *let tools shape research, accommodate natural phenomenon, accommodate misbehaving tool, appropriate new tool*, and *tinker with tool*), and take action to either anticipate the unknown (e.g., *maintain equipment, plan, seek new knowledge, strive for reliable data, hypothesize, take risk*) or rearrange the environment to handle new problems or information (e.g., *seek help, reframe problem, ideate, invent*). The emergent nature of their work also elicited certain attitudes: *commitment* is what kept Fred and Kyle coming back to work day after day in the face of recurrent surprise and disappointment, and their comfort with *uncertainty* is what permitted them to do so.

## What else counts as scientific practice?

Once developed, I took this taxonomy into an oceanography classroom, where it guided my analyses of a pair of 8th graders' GIS-based investigation of Catalina Island's kelp forest habitats. The students participated in many of the same practices I observed at Kinder Marine Laboratory, suggesting that the GIS provided an authentic context for their science learning. However, they were less inclined to engage in practices classified as adaptive than the scientists were, with evidence indicating that aspects of the school setting steered students toward more efficiency-oriented patterns of response. For a more detailed discussion of the classroom case study vis-à-vis this taxonomy, see Takeuchi, 2008.

Although the 45-practice taxonomy was sufficient for the types of comparisons I drew between the laboratory and classroom settings, it represents just one year (elapsed) of the scientists' work and primarily the data collection phase of their investigation. I imagine that others in the science studies and science education communities might also find value in such a catalog, but to be useful to a wider audience, the list would need to capture the complete investigation cycle. I would enjoy returning to the field to expand and refine the current list by watching practicing scientists over a longer time frame, and by augmenting the data on marine scientists with observations of other types of natural scientists (e.g., seismologists, meteorologists, stem-cell researchers, astronomers). The resulting universal catalog of scientific practices would provide a powerful set of images that could be used for practical and theoretical purposes in science classrooms, research, and policymaking.

## Endnotes

(1) Science studies is a blanket term for the genre of research that examines what scientists do and the nature of scientific knowledge. Within this genre there are a number of disciplines with their own specific methodologies and epistemologies (e.g., sociological studies of knowledge, philosophy of science, postmodernism).

(2) A marine protected area (MPA) is any area of the marine environment that has been reserved by law (federal, state, or local) to protect endangered plant or animal species, ecosystems, and important historical and cultural sites.

(3) Scientists' representations of their objects/phenomena under study. Inscriptions are materially embodied in some medium, such as paper or computer monitors, and include maps, graphs, photographs, equations, diagrams, and hand-scribbled notes.

(4) To implant the fish with acoustic tags, Fred and Kyle had to gently capture them from the seafloor and bring them up to the boat's deck for surgery. They took 2-foot long fishing rods underwater with them and dangled hooks baited with live shrimp right in front of individuals of the target species.

# Analyzing Collaborative Knowledge Construction in Secondary School Biology

Vanessa L. Peters, James D. Slotta, Ontario Institute for Studies in Education, University of Toronto
252 Bloor Street West, Toronto, Ontario, Canada M5S 1V6
Email: vlpeters@gmail.com, jslotta@gmail.com

**Abstract:** This research investigates student collaboration in a high school biology curriculum that was based on the Knowledge Community and Inquiry (KCI) model. Using co-design, the researchers collaborated with three high school science teachers to design a curriculum where 112 grade-ten biology students collaboratively developed a community wiki about Canadian ecozones and biodiversity issues. Students then used the wiki as the primary resource for a subsequent inquiry activity. This paper analyzes students' contributions to the knowledge base, test performance, and student satisfaction to evaluate the efficacy of the KCI model. A new method of analysis for collaborative wiki artifacts was developed to measure student interaction in the wiki. We found that students who were higher contributors to the knowledge base performed better on a post-test than students who were measured as low contributors. Our findings suggest that the KCI model is a promising mechanism for supporting both collaborative and individual learning.

## Introduction

Increasingly, scholars are emphasizing the importance of preparing students for the complex problems of a "knowledge society" (Drucker, 1959; Bereiter, 2002). Such 21st century skills are important for students to become productive citizens in a technological and knowledge-oriented society (Lemke, Coughlin, & Reifsneider, 2009). Such skills cannot be taught in isolation; rather, they must be learned in the context of a knowledge community where individuals collectively pursue the advancement of ideas. Many educators have noted the mismatch between conventional school curriculum and the needs of citizens in a knowledge society (Tapscott & Williams, 2006; diSessa, 2000). While schools struggle to raise student achievement on basic skills, scholars have identified a full spectrum of cognitive and metacognitive skills that are not being addressed, including inquiry, critical thinking, design and collaboration (Slotta & Linn, 2009). Thus, the traditional forms of lecture and homework that still predominate in today's classrooms are not desirable models for the design of technology-enhanced learning (Collins & Halverson, 2009).

The domains of science and technology are particularly reliant on high levels of knowledge work, yet in classroom settings teachers routinely employ rote learning in an effort to cover the mandated curriculum content (Slotta & Linn, 2009). This is particularly the case in secondary school science, which covers more topics than any other subject, thus resulting in textbooks that have been described as being "a mile wide and an inch deep" (Schmidt, McKnight, & Raizen, 1997, p. 62). Secondary teachers are responsible for teaching specific content matter, making it difficult to design learning activities where students can pursue a deep understanding of science topics. All science lessons must fit within a tight schedule of content coverage, with outcomes that are assessable by conventional measures. The fast pace of most science courses leaves teachers little or no time to ask their students "big-picture" questions, or engage them in personally relevant topics.

This paper begins by considering the established research traditions of knowledge communities and scaffolded inquiry, as well as a recent pedagogical model that describes how these two traditions can be blended to create engaging new curriculum for secondary science students (see Slotta, 2007; Slotta & Peters, 2008). We discuss the important innovation of co-design (Roschelle, Penuel, & Sechtman, 2006), which offers a means for creating such curriculum in a way that meets teachers' expectations without undermining the researchers' objectives. We discuss an eight-week design study where a technology-enhanced curriculum was co-designed according to the Knowledge Community and Inquiry model. In our analysis, we evaluate students' contributions to the community knowledge base, the effects of such contributions on test performance, and student satisfaction with the curriculum unit.

## Theoretical Framework

A number of promising instructional approaches have already shown to engage students in deep collaborative inquiry. In the research program called Fostering a Communities of Learners (FCL), Brown and Campione (1996) scaffolded student learning within a peer community. The key components of FCL – research, information sharing (jigsaw), and consequential tasks (performing) – provide structure and support for students' collaborations within the learning community. When combined, these components form an effective instructional strategy that fosters critical reflection and deep understanding of disciplinary content. An important characteristic of FCL activities is that they are independently purposeful, yet they cohere to form a functional system. Although FCL is scripted, it must be emphasized that simply following a series of steps is not enough – teachers must understand the goals and philosophies that underlie the approach.

An important theoretical contribution of FCL is the notion of *diverse expertise*. In their classroom implementations of FCL, Brown and Campione (1996) found that students came to highly value the contributions of their peers. These contributions were not always about content, they were often related to using the computers or managing the group (Collins, Joseph, & Bielaczyc, 2004). This observation solidified the importance of information sharing for fostering a sense of community among learners. The students also offered suggestions for refining the design of FCL (Bielaczyc, 2006), such as recommending that information sharing occur sooner in the process rather than at the very end of the project. This suggestion resulted in an innovation called *crosstalk*, which involves students presenting their preliminary findings to the entire class. Crosstalk became a mechanism for a peer-review of ideas that would often result in students pursuing a new line of inquiry (Bielaczyc, 2006).

Another important consideration in the research literature is that of scaffolded inquiry. Researchers have developed a number of prominent pedagogical approaches that provide students with rich collaborative inquiry activities, many of which include technology-enhanced tools and materials (e.g., Linn & Hsi, 2000; Slotta, 2004; Songer, 2006). Broadly speaking, inquiry learning is an instructional approach where students research and investigate some phenomenon before making inferences about it (Kuhn, Black, Keselman, & Kaplan, 2000). For some educational researchers, the goal of inquiry learning is to teach students to work in ways that are similar to the way real scientists work. Students pose questions, formulate hypotheses, and then design investigations to test those hypotheses (White & Frederiksen, 1998). For other researchers, the experimentation cycle is just one of many possible inquiry patterns (Linn & Eylon, 2006). In all models of inquiry, the teacher does not assume the role of "sage on the stage" (King, 1993), but that of a facilitator who guides students in leading their own investigations (de Jong & van Joolingen, 1998). Students engaged in inquiry activities learn domain-specific content while developing their reasoning skills (Hmelo-Silver, Duncan, & Chinn, 2007) and their ability to understand and apply scientific principles and concepts (Schwab, 1962).

Both inquiry learning and knowledge communities emphasize the importance of collaborative knowledge construction. Here, collaboration refers to the coordinated efforts resulting from "a continued attempt to construct and maintain a shared conception of a problem" (Roschelle & Teasley, 1995, p. 70). Fischer, Bruhn, Gräsel, & Mandl (2002) describe four characteristics of collaborative knowledge construction: (a) individuals bring their prior knowledge to the learning situation, (b) there is a cause for a learning partner to share that knowledge, (c) a consensus is reached about the content or given facts, and (d) individual perspectives are integrated into a common understanding of the task or problem. This form of learning, in which students become productive knowledge workers, citizens and lifelong learners (Stahl, 2000), always occurs in a social context, either face-to-face or computer mediated. The essential element is the provision of a shared space for individuals to engage in social negotiation.

The two research traditions of scaffolded inquiry and knowledge communities provide mechanisms for deeply engaging students in science learning. However, despite widespread enthusiasm, these approaches have yet to make strong headway in science classrooms, as researchers have yet to determine how they can promote new cultures of learning while remaining sensitive to curriculum standards: What types of pedagogical and technological innovations are required to transform classrooms into learning communities? How can these innovations be designed? What supports do teachers need to enact new approaches in a manner that does not undermine the theoretical commitments of the design? These are questions that need to be addressed before inquiry-oriented instruction can pervade secondary school science curricula.

## Knowledge Community and Inquiry

In an effort to make headway on these problems, Slotta (2007) has developed the Knowledge Community and Inquiry (KCI) model which combines collaborative knowledge construction with scripted inquiry activities to target specific curriculum learning objectives (Figure 1). The model begins with a collaborative knowledge construction activity where students explore and investigate their own ideas as a community of learners, creating knowledge artifacts that are aggregated into a communal knowledge base. An important component of collaborative knowledge construction is that learning activities (such as inquiry-type investigations) must be guided by the community itself through the knowledge construction process (Scardamalia & Bereiter, 1996). Common themes, ideas or interests should emerge, reflecting the "voice" of the community. The instructor must listen to this voice and respond by designing activities that reflect students' interests. The latter process is critical, but also challenging to execute, since the design of any activity must also address the content expectations and learning goals of the curriculum.

It is no easy task to design activities that respond to community interests while addressing learning goals and adhering to time constraints. In the KCI model, scripted activities are co-designed by teachers and researchers only after the knowledge construction phase is complete, resulting in new activities that build upon the themes that were identified within the knowledge base. Students then work independently or collaboratively on the scripted activities, drawing on knowledge elements from the community knowledge base, producing new contributions to that knowledge base, and completing inquiry tasks that are directly connected to assessable content learning outcomes. KCI attempts to support the development of such curriculum by working closely with teachers to develop a carefully controlled flow of collaborative knowledge construction and scaffolded inquiry activities that are specifically designed to address the mandated curriculum.

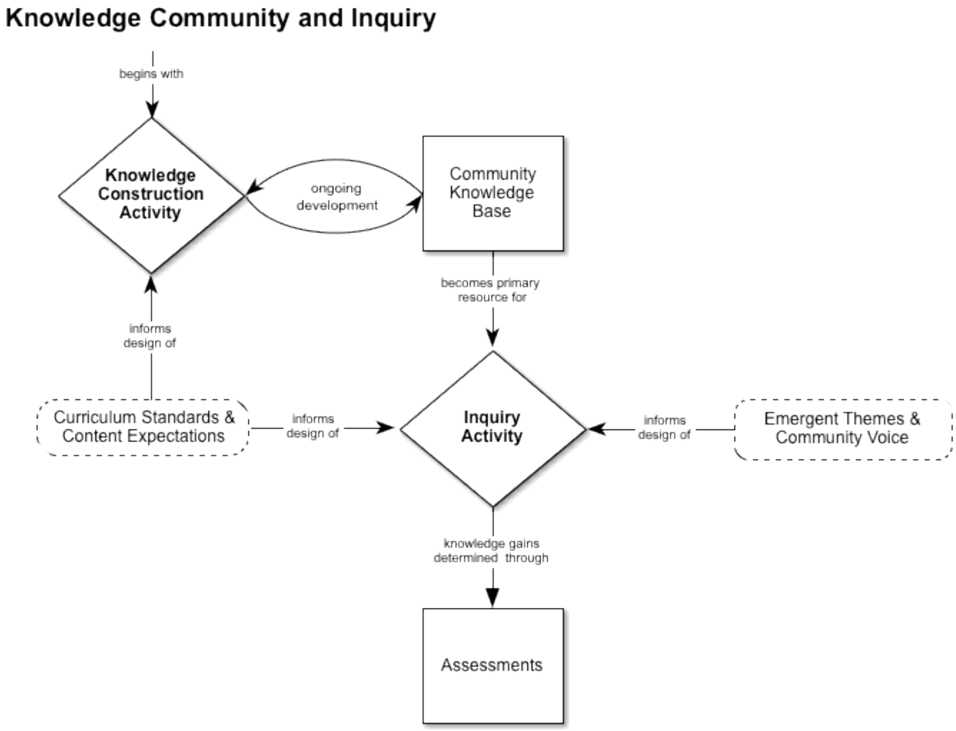

Figure 1. Flow diagram of a Knowledge Community and Inquiry curriculum.

## Methodology

The research discussed here was the second iteration of a design-oriented study that implemented the KCI model. Design research (Brown, 1992; Collins, 1992) was an appropriate methodology for this study as it supports multiple investigations across a number of contexts (McCanliss, Kalchman, & Bryant, 2003). Design research can be characterized by its iterative design cycles and formative research in authentic settings such as a real classroom (Edelson, 2002). Another important method used in this study was co-design (Roschelle, Penuel, & Shechtman, 2006), where teachers and researchers work in close partnership when designing all curriculum materials and activities. Since it was important that our biodiversity unit target the curriculum content expectations, the teachers' input was essential for creating relevant and ecologically valid materials.

### Participants and Data Sources

Participants included 112 grade ten biology students and three experienced science teachers. The co-educational school involved in this study provides specialized curriculum for high-achieving students in grades 7 through 12. Initially created as a laboratory school, this unique institution prides itself on new and innovative classroom practices. Admission to the school is competitive and based on students' score on the Secondary School Admission Test (SSAT), with 98% of new admissions being accepted from grade 6 students. The school population is ethnically diverse, with the majority of students coming from middle to upper-middle class homes. The school has a strong commitment to the liberal arts and sciences curriculum, and students are expected to fully engage in their academic program. There is a strong emphasis on community, and individual acceleration and early course specialization are discouraged. Assessment is ongoing throughout the school year and consists of formal progress reports and performance improvement plans.

### Design and Procedure

The teachers began the Biodiversity lesson by placing students into one of eight Canadian biome groups. Working in these groups, students could choose a geographical region from Canada for which they would create a wiki "Ecozone Page". A template was used to scaffold students to include specific biology content and to help them set up their wiki page. While it was important to preserve the open-ended feeling of collaborative editing that typifies wikis, it was equally important to our project that we provide students with a simple, structured way to create wiki pages that scaffolded their treatment of science concepts. We therefore created a new hybrid wiki environment that improved control over student accounts, groups, editing permissions and other features. This environment includes a special "New Page" web form (developed using Ruby on Rails) that collects metadata (e.g., with check boxes and text fields), and then generates a new wiki page with pre-specified headers to help scaffold students' wiki entries as well as the specified authoring and access permissions (see Figure 2).

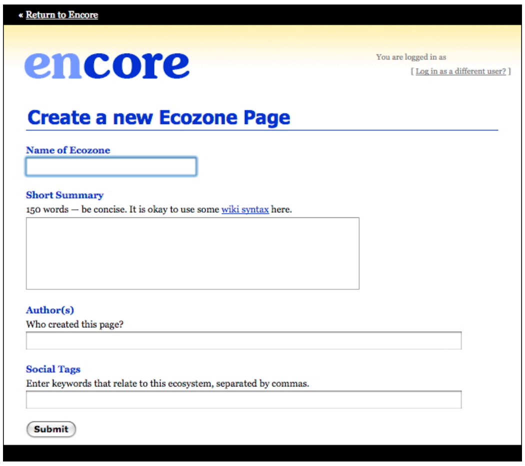

Figure 2. "New Ecozone Page" script.

Students in all four classes contributed to this same wiki repository, adding to and editing their peers' ecozone pages. After the knowledge construction activity, students were tested on their knowledge about Canadian biomes and ecozones. After working on the ecozone pages, students worked in pairs to create another wiki article about an issue or problem that posed an environmental threat to a Canadian region. Students could draw on their expertise by writing about an issue from the same ecozone they had written about in the first activity. Because biodiversity issues are not restricted to one ecozone, and to encourage synthesis of the wider knowledge base, students were asked to make connections between the different regions. Students were also asked to link to their peers' wiki pages wherever possible when referencing them in their biodiversity issue page.

## Data Sources and Analysis

Data for this study were drawn from the revision logs of students' contribution to the wiki resource, pre and post-test scores and student interviews. Content analysis was performed on a subset of students' wiki edits to gain insight into their authoring practices, and to determine the level of collaboration that was occurring. The pre and post-tests were used to gauge the effects of wiki authoring on students' test scores. Interviews revealed students' satisfaction levels with the wiki curriculum, including their perspectives of the co-authoring process. The use of multiple methods when studying collaboration is desirable since it provides a more complete picture of student engagement and interaction (Hmelo-Silver, 2003; Naidu & Järvelä, 2006).

Since there are no accepted guidelines for analyzing wiki contributions, we developed a method of content analysis to capture students' knowledge contributions to the wiki. To begin, we defined a unit of analysis for studying the wiki revision logs. The wiki technology employed in this study labels all contributions to the wiki as "changes"; however, this characterization is imprecise as it suggests that only a single change is occurring. We instead labeled such changes as individual "transactions", since it allows for multiple codes to be assigned to a particular section of the wiki (e.g., adding text, deleting text or moving text). Figure 3 is a screen shot of a revision history comparing two versions of a wiki page, and shows why this kind of segmentation (which is labeled as a single change by the wiki software), is inadequate for analysis purposes. Here, we can see two transactions: T1 and T2 (labeled as such on Figure 3). The upper portion of T1 (red text) shows a section of text as it appeared before the revision, and how it appeared afterwards (green text). The student who completed this transaction deleted some text from a paragraph (highlighted in dark red with strikethrough), and added new text (highlighted in dark green and bolded). In T2, the student added new text without altering any existing text. Referring to the content in this way enabled us to code wiki interactions without being overly reductionist in terms of the student's editing process, and permits a finer-grain analysis of wiki content.

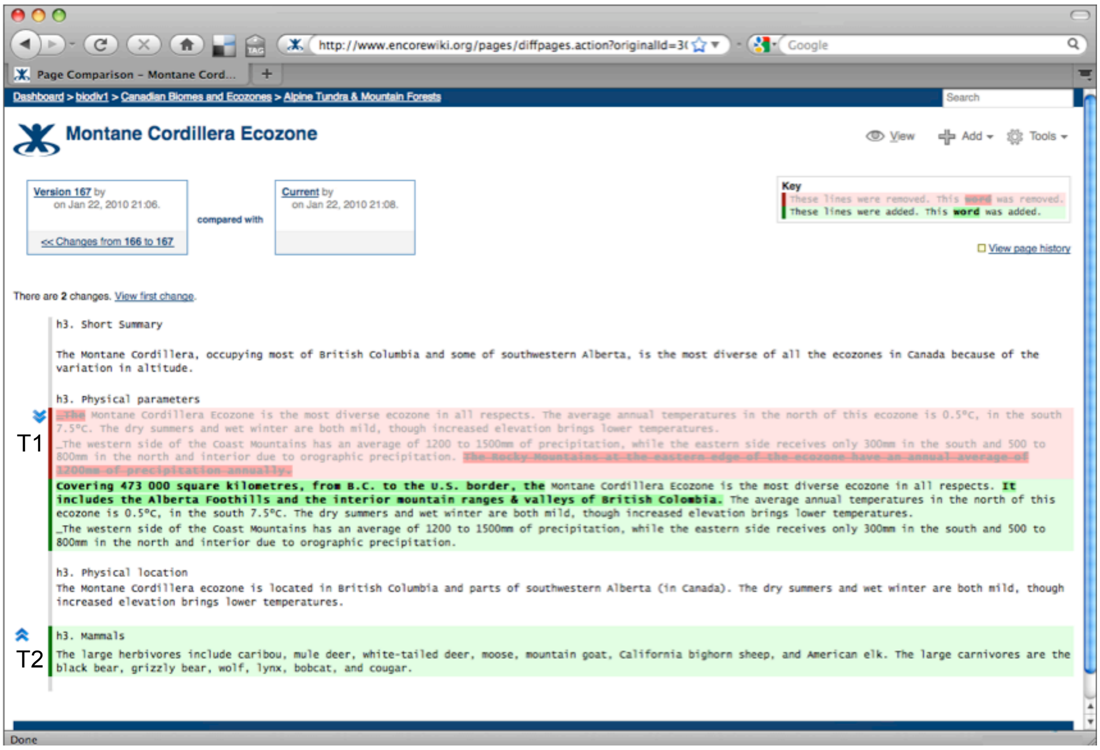

Figure 3. Screen shot of a revision history comparing two versions of a wiki page. In this comparison there are two "transactions". The first transaction (T1) contains text that was deleted and added into existing text. The second transaction (T2) contains newly added text.

We then developed a coding scheme to analyze the wiki contributions of a subset of students, coding all the transactions they made to every version of every wiki page. For the coding procedure, we first coded for "transaction type" (move, add, delete or format), then for "content type" (text, image, internal link or external link). Since substantive contributions would likely be written in prose, only text-based transactions were coded further – as either belonging to peer or self. If the edit was made to a classmate's text it was coded as peer, if it was made to one's own text it was coded as self.

## Results

Students were actively engaged in the construction of the knowledge resource within the wiki, creating 31 ecozone and biome pages, and 47 biodiversity issue pages that showed an average contribution of more than 1500 words per student ($M$ = 1651.55, $SD$ = 1700.40). Prior to analysis, each wiki page was run through Copyscape©, a web-based utility that compares web documents to check for instances of plagiarism. We found no cases that warranted concern. In the following sections we present our findings for performance gains, the collaborative knowledge construction activity and student satisfaction.

### Knowledge Construction Activity

To analyze how students were collaborating in the wiki, we applied our coding rubric to a subsample of students ($n$ = 8) to learn about their editing practices when co-authoring their knowledge artifacts. Overall, the students contributed an average of 38 transactions ($SD$ = 20.26), with high variability levels between students. Of these transactions, an average of 4.62 were images, 1.25 were internal links and 3.37 were external links. The total number of text-based transactions was 269 ($M$ = 33.63, $SD$ = 12.93)

We were interested in finding out how many of these text transactions involved *other* students text. That is, how often were students editing their own text, opposed to that of their peers? Of the students surveyed, the total number of self-based text edits was 151 ($M$ = 18.78, $SD$ = 8.87) and the total number of peer-based text edits was 118 ($M$ = 14.75, $SD$ = 9.44). The overall percentage of self vs. peer edits was roughly equal: 56.13% and 43.87%, respectively (see Table 1).

Table 1: Total text-based transactions per student: self and peer.

| | Total text edits | | |
|---|---|---|---|
| **Student** | **Self** | **Peer** | **Total** |
| Nick | 21 | 15 | 36 |
| Nathan | 22 | 31 | 53 |
| Patricia | 27 | 12 | 39 |
| Marion | 34 | 9 | 43 |
| Dave | 7 | 18 | 25 |
| Karen | 14 | 23 | 37 |
| Wendy | 15 | 10 | 25 |
| Brian | 11 | 0 | 11 |

## Performance Gains

We were interested in the effect of the knowledge construction activity on student test performance. We used only the test scores of two classes (*n* = 50) that were taught by the same teacher. We then placed these students into one of two groups based on their total number of text edits: "low contributors" and "high contributors". Students in the low contributing group were below the median for total words edited, and students in the high contributing group were above.

To find out if wiki contribution levels had an effect on test performance we conducted pre and post-tests. The difference in pre-test scores between the low and high contributing groups were not statistically significant ($t(48) = 0.2429$, $p = 0.809$), as shown in Figure 3. We did, however, find a significant difference between the two groups on a post-test ($t(50) = 4.68$, $p = <.0001$). Although this finding does not provide unequivocal evidence of higher learning gains for students who contribute more to the knowledge base, it does suggest that students who are more involved with the knowledge construction process are also engaging more with the subject content, resulting in higher test scores.

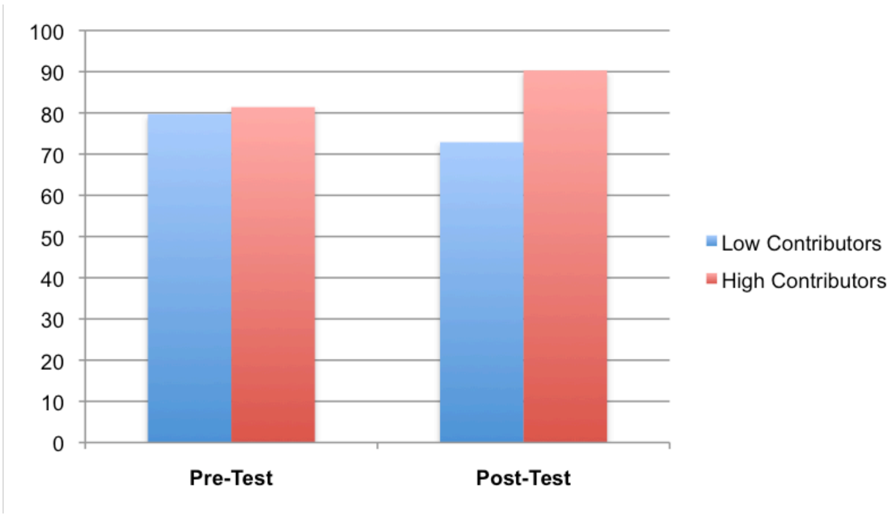

Figure 3. Test Scores from Low and High Contributing Students.

## Student Satisfaction

Student interviews were conducted in the beginning, mid, and end-point of the study. A total of twelve students participated in the interviews. Participants were interviewed in pairs in an informal environment, usually during the lunch break or after school. Since the students had never used a wiki before, we were interested in their perspectives of creating a wiki in their science class. All students responded that building a knowledge base was a fun and novel way to learn biology. One student, Marge, described her perspective of the unit as follows:

> I really enjoyed it because, like, I've never built a wiki site before and it was really cool because we actually got to make a webpage in a way – and I think it was a really interesting way of learning about Canadian biodiversity without just going on other peoples sites and memorizing all the information. Because here, I guess when you actually put the effort in

> creating a website you learn a lot more about it, or the subject itself, then when you just read it in a book – because when you're creating a site you have to do the research and then decide what information you need and what information you can leave out because it's either not relevant or it's too complicated. But in the long run you do the elimination process with the information that you get, so it's really interesting and makes you learn stuff.

Other students commented on the authoring process of their collaborative knowledge construction activity. For example, some students were against the idea that students could make deletions on their wiki page. They felt it was preferable for their classmates to leave comments or suggestions, but not actually edit the original text. They felt this would give them the opportunity to refute changes made by others, and avoid what they described as "wasted work". According to one student: "I don't agree with people making deletions right away on your own thing. I think it's better that they leave a comment and say 'you could just do this' but you don't actually change the original text." Other students, however, felt comfortable about their classmates making changes to their wiki articles. In Jason's words:

> Well, I don't really mind [people editing my ecozone page] as long as I know that everything is completely recorded in the editing history, but I guess if it was just easier to undo the changes, like a bit more immediate, then it wouldn't bother people... but I guess when you're posting something to a wiki you have to know that someone else is going to make changes, so you just have to be okay with that and move on.

Overall, the students enjoyed making wiki artifacts as part of their biodiversity unit, and felt confident about using their peers' work as a resource for later activities. Since the wiki environment was new to students, however, future implementations of this activity would need to consider the social aspects of wiki authoring such as accepted norms for editing, work distribution and possible role assignment.

## Discussion and Conclusion

Although still ongoing, the findings from this research provide support for the Knowledge Community and Inquiry model as a mechanism for engaging students in collaborative inquiry. The blended use of wiki-based knowledge construction and scripted inquiry activities enabled students to make productive use of their co-constructed community resource. Through co-design, we were able to establish a successful research partnership with teachers, resulting in curriculum materials in which the teachers had a strong sense of ownership. We see this partnership as a positive step towards the "hybrid culture" described by Bereiter (2002), in which researchers and teachers rely on each other when working towards an educational objective.

This research also raises new questions concerning collaborative practices in a wiki environment. For example, despite the relative success of the knowledge construction activity, we still know little about students' individual practices when working in a wiki: Why do some students contribute more than others? Are all wiki transactions of the same educative value? And what are the optimal conditions for encouraging students to work with the content contributed by their peers? These questions open up an important dialogue for further investigation – and characterization – of collaborative knowledge construction and inquiry.

**Abstract:** Spatial intelligence is deeply related to success in the STEM disciplines (science, technology, engineering, and math) yet teachers are unaware of the concept. This paper reports on a teacher, researcher, and designer collaboration focused on translating research shown to improve spatial thinking practice. This translation is supported through a spatial "toolkit" of activities designed to raise teachers' spatial intelligence awareness and improve spatial thinking practice.

## Introduction

In this paper we will describe the efforts of the Spatial Intelligence and Learning Center (SILC) to impact elementary school teachers' knowledge and incorporation of spatial content in the school day. These efforts face two interrelated sets of problems. The first is a central problem of education research: namely, how to translate research insights developed in the lab into classroom practices. The second relates to the unique nature of spatial intelligence: as a domain of research it has no named corollary in the school day, greatly exacerbating existing difficulties in bringing research to practice. Though spatial intelligence has important implications for success in the STEM disciplines (Science, Technology, Engineering, and Math), it is not itself an independent discipline. We have yet to find a school that has a class called "Spatial Knowledge"; rather, unexploited opportunities for spatial instruction are ubiquitous throughout the existing curriculum.

In the research literature models have been proposed to bridge the research/practice divide (e.g. Bryk & Gomez, 2008; Schoenfeld, 2009). These models describe a research effort that is vertically integrated and involves design collaborations between teachers and researchers. In this paper, we describe a design effort that substantially follows these approaches, but is modified to accommodate a domain in which the desired content is entirely unknown to teachers, and does not exist in the school curriculum. We do so by way of a spatial "toolkit" of activities, an innovation tailored to the unique circumstances of spatial intelligence research, by allowing teachers the flexibility to incorporate spatial elements in their curricula, without focusing on one specific domain.

## Spatial Intelligence in the Classroom

A central hypothesis of SILC is that particular experiences that occur early in life are important in laying the groundwork for spatial development. However, unlike other domains, notably language and literacy development, we currently know little about the preconditions for the development of robust spatial skills. SILC researchers have addressed this question through a number of studies examining the development of spatial language, engagement in spatial activities, and the relation of individual variations in these areas to the development of spatial skills themselves, along with a variety of domains of academic achievement.

Recent findings have shown that individuals who are more advanced spatial thinkers are more likely to major in STEM disciplines in college and to choose STEM career paths, even controlling for verbal and mathematical achievement levels (e.g. Hedges & Chung, 2008; Shea, Lubinski, & Benbow, 2001). Correlations specifically between visual-spatial ability and initial mathematical skills are even apparent as early as preschool (Robinson et al., 1996) and relate to middle and high school math achievement (Wolfgang, Stannard, & Jones, 2001). These relationships are not surprising, as spatial reasoning is central to many domains, not only explicitly in fields such as geometry, algebra, and calculus, but also as a foundational component in many domains (e.g., spatial reasoning is required for the construction of the nonverbal mental models that may underlie early arithmetical thinking and is critical to the ability to understand and create the physical models, diagrams, and visualizations used in fields such as science and engineering).

This reality highlights the importance of understanding the development of spatial thinking and its support. While it was long believed that spatial reasoning ability is biologically fixed, there is mounting evidence that training enhances spatial performance (Baenninger & Newcombe, 1989; Huttenlocher, Levine, & Vevea, 1998). Given this context, we would like to understand how the classroom environment and school content contributes to spatial reasoning, and perhaps more importantly, whether we can translate the rich spatial intelligence data we gather in the lab to classroom settings. Doing so would allow us to modify the classroom environment to enrich spatial input, which may enhance the spatial capacities of all students, and might perhaps provide particular benefit for those students who enter school with deficits in spatial reasoning.

## Initial Pilot Work: Identifying a Problem

That we need to modify the existing classroom context to enrich spatial input was made clear in an early pilot study. In this work we explored the spatial environment of a cohort of eight teachers' classrooms in an elite private elementary school. We began by cataloguing the representations found on the walls of the classrooms, as representations have the potential to contain a great deal of spatial information, such as the information contained in graphs, charts, maps, and measurement tools (e.g. rulers and thermometers, as in Figure 1). Because representations represent content visually and include explicit spatialization of data, they constitute an obvious opening for teachers to target spatial abilities, yet our pilot study demonstrates this is rarely the case.

Each classroom was photographed, and the representations were entered into a database where they were organized by representation type, subject area, and spatial content, among other factors.

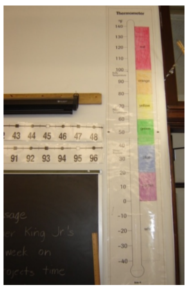

Figure 1. Thermometer Representation

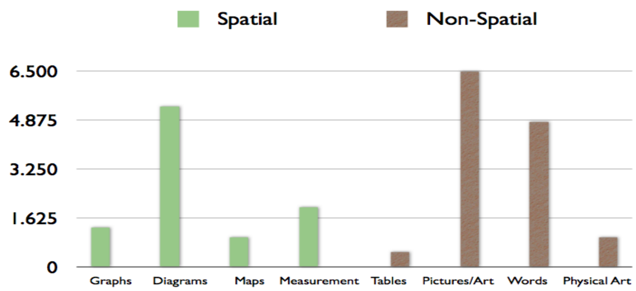

Figure 2. Average Number of Representations Per Classroom

Overall, there were more non-spatial representations than spatial representations (with an average of 12.9 per class to 9.7). As represented in Figure 2, diagrams constituted the only category of spatial representation frequently seen in classrooms. The majority of representations were decorative, displays of student work, or classroom guidelines, and very few required the use of spatial thinking (such as mental rotation, scaling, orientation, alignment, etc.), as even the diagrams (which do represent information spatially) did not make large spatial demands on students.

We followed up the representation catalogue by conducting clinical interviews with teachers in these classes. We tried to assess the degree to which they were aware of spatial intelligence and the degree to which they incorporated spatial elements in their classroom activities. For example, we gave teachers a sorting task, presenting them with more than 40 different pictures of real classroom representations. Teachers were asked to choose which of the assortment they would put on their classroom walls. We asked them to describe their decision-making process and to think about how they would utilize the representations. The following teacher's opening remarks as she sorted were typical of the responses we received:

> As I'm looking I'm sorting into what different programs require as resources for curriculum– that would be one pile. And included in those resources would be some things that implement our program… I would want to include things from different academic areas.
> I also think its really important to include children's work on display, some of these are hints about what to do when you're stuck… how to be prepared for school, I think it's important to have tips for kids, I also think in many of the classrooms there are class rules that have been generated by the class—those I like to post.

Over the course of the interview we pressed teachers to talk about representations that had explicit spatial content, such as the more spatially demanding charts and diagrams, and even in those cases teachers did not discuss spatial thinking. When asked to provide rationales for rejecting representations in their classes, teachers mostly cited aesthetics and the explicit relationship of the material to current curricular content (e.g. "too cutesy" or "low applicability to my class"). Thus, our pilot study demonstrated that even with respect to representations, which represent content visually, and often incorporate explicit spatialization of content, the teachers in our study rarely considered spatial elements or opportunities for spatial instruction within the existing curriculum

## Translating Lab Research

In the lab, researchers have had numerous insights into spatial learning, which, if translated to the classroom, could have an impact on students' spatial thinking. The problem, however, is that one cannot unproblematically translate lab research to the classroom. Even if we assume that our lab studies produce real insight that is relevant to classroom instruction, we must still struggle with the translation of that insight into something that has educational utility, a recognition that helped motivate the early development of design research (Brown, 1992). This is a problem that has been well articulated in the literature, as researchers have noted that laboratories are radically different environments than classrooms. In laboratory environments there is one-on-one interaction, with no outside noise or distraction, the intervention is heavily scripted so that experiments can be replicated, and the intervention is not embedded in any curricular context. Furthermore teachers are not researchers. Researchers develop deep expertise on very narrow problems, giving them the ability to devote time and energy to relatively small parts of the curriculum – a luxury teachers do not have. Often, teachers to not understand the interventions, or are unwilling to make changes to their practices, and in many cases they are deeply constrained by state, district, or school regulations.

A second set of problems is that, unlike other collaborative design projects, we needed to introduce teachers to entirely new concepts regarding intelligence, while having no pre-existing coherent curriculum to manipulate, improve, or change within the school curriculum. Improving and engaging students' spatial reasoning is important for a wide range of school content and skills, but it is not itself a learning domain; rather, it is an underutilized cognitive ability. Moreover, our pilot work indicated that teachers were entirely unaware of spatial intelligence as a concept. This challenge magnifies and makes more intractable some of the existing challenges to moving lab research into the classroom. The problem of acontextuality becomes much more profound when the lab studies do not concern themselves with school content, but with, for example, spatial alignment, and the problems of teacher impact become much more difficult, as well. Teachers do not have a baseline understanding of what spatial intelligence is, the way they do with content areas such as math, science, and reading. While it is true that many educational innovations are previously unknown to teachers, here we are not restructuring practices, reorganizing content, or devising new methods, but in essence raising awareness of an entirely new domain of intelligence, and asking teachers to act on that awareness.

To understand how these problems are magnified by the lack of content domain let us contrast them with substantial inquiry learning efforts. Early research, much of it based on lab studies, indicated that the deepest and most powerful learning takes place in context, and that acontextual learning was weaker and less meaningful. This insight (much simplified here) has led to a spate of programs to build curricula organized around meaningful activities, and more authentic organization of content. However while such programs may require pulling content from different areas of the traditional curriculum in order to organize that content along particular design principles, the basic content itself remains familiar. With spatial intelligence, however, there is no content that can be pulled from one place and reorganized; rather, many different content areas need to be taught with more and different information attached, and in some cases, in different ways.

## Overcoming the research – practice gap

In recent years, the literature has once again addressed the problem of the research-practice gap, and a growing body of literature has put forth a model of research to practice that addresses many of our first set of problems. This literature comes in response, however, to a different set of problems, posed by policy dictates that prioritize large randomized trials of educational interventions, and push for an understanding of "what works" in education.

In response to these mandates, a number of researchers (e.g. Bryk & Gomez, 2008; Burkhardt & Schoenfeld, 2003; Schoenfeld, 2009) have argued that in order for research to impact practice coherent institutions need to be developed that support multiple phases of development, from early trial research to broader testing, and finally to large controlled studies. They have pointed out that in other well-established fields a significant amount of research and development takes place well before any randomized trials begin, and that any randomized test of an intervention needs to be built on a solid theoretical base. In this literature design research is identified as an exemplar of the type of initial research that can help build theory, identify both *what* works and *why* it works, and can begin to flesh out the conditions under which interventions succeed and fail in practice. Accounts of this type share many similarities. They call for a vertical integration of the research effort, so that there is real coordination between the research and practice, a less fragmented infrastructure for research and development, with significant funds directed at the early, theory building stages, and a variety of research to practice models that begin with the iterative development of working prototypes and end with wide scale adoption and testing.

These models of a unified research effort that moves from existence proofs and design testing to widespread scaled-up interventions in schools also address the major problems with translating lab research to the classroom articulated above. Iterative, collaborative efforts between designers, teachers, and researchers are ideal for producing classroom interventions that work, as these collaborations, with focused effort, can overcome the gap between the lab and classroom, moving incrementally from one-on-one, scripted, a-contextual, researcher lead studies to dynamic classroom activities. This is necessarily an incremental process because the translation is so complex; it is rare that an intervention will be successfully translated in one session. Instead, multiple iterations take place, with teachers involved in the design and analysis, allowing the entire group to adjust to teacher difficulties, district mandates, and any other obstacles that may present themselves.

In our preliminary effort to move some of our spatial intelligence insights to the classroom, we envisioned a research to practice pipeline built on strong collaborations with researchers, designers, and teachers, much like the models described above. However, our second set of problems, that is, the unique constraints arising from the lack of target domain in the school day, and the total lack of teacher awareness of the concept of spatial thinking, forced us to modify the design effort to accommodate the special nature of the domain. In the next section we describe our design process, and how that design provided a flexible solution to these constraints.

## Resolving the curriculum gap: the spatial "toolkit"

To resolve these problems we adopted an approach that utilized the major collaborative features of an integrated research effort, while deliberately maintaining a broad flexibility that allowed us to work within existing school curricula and activities. Putnam and Borko (2000) describe two teacher support efforts, the SummerMath program and the CGI project, which combined intensive summer workshops with the support and involvement of researchers throughout the school year. Importantly for us, these projects were intended to change teachers' conceptions as well as their practices. Along those lines, we designed a summer work circle, bringing together nine lower-elementary public school teachers along with SILC researchers for intensive learning and design sessions, followed that up with sessions and support throughout the school year, and repeated the process again the next year, with 4 original teachers and 10 additional teachers. The nature of the support that we provided, however, was tailored to the nature of the material we were working with, and primarily took the form of a spatial "toolkit".

In an influential article on culture, Ann Swidler (1986) argued for two models of cultural impact, active in different historical circumstances. In one model culture provides a unified system that directs and orient behavior, and in another culture simply shapes a repertoire of tools, "habits, skills, and styles", which impact action indirectly, as people pick and choose from the toolkit in ways that may be fragmented and sometimes even contradictory. The notion of toolkit of resources has been adopted to talk about resources for organizational routines (Spillane, Gomez, & Mesler, 2009), as people select from available organizational resources to create strategies for action. This notion had great appeal for us. Traditional models of change, which implicitly assume a unified conception that is introduced to teachers, cannot function when there is no place in the school day or curriculum to direct action. Instead, we felt that we could work with the teachers to create an actual, literal, toolkit of practices and activities that draw on the insights we have developed in the lab, but are flexible enough to accompany teachers existing curricula. By working with the teachers on a toolkit we felt that we would be able to increase teacher awareness of spatial intelligence and its role in the classroom, and to help teachers design spatially rich activities to compliment their existing curricula.

Over the course of the first work circle in the summer of 2008 teachers and researchers co-produced the first iteration of a spatial toolkit. In this toolkit, teachers utilized the knowledge that they acquired in research presentations and applied it to their curricula, merging their expertise with that of the researchers. The teachers had free range to develop spatially rich projects on any aspect of the curriculum and classroom experience. For example, one pair of teachers developed a community mapping activity where the students built a map of their community, starting with the school at the center, and moving outward to the students' houses and other local landmarks, while another pair of teachers developed a technique for representing the daily schedule using spatial representations that were proportional to the length of time for each component of the schedule.

In order to understand how teachers were implementing toolkit items generally, during the year we maintained contact with the teachers, as they filled out a daily checklist of their use of spatial representations and activities, and reported back to us on their use of the initial items in the toolkit. We found that of the representations that teachers indicated that they used, 72 percent were used in an explicitly spatial way.

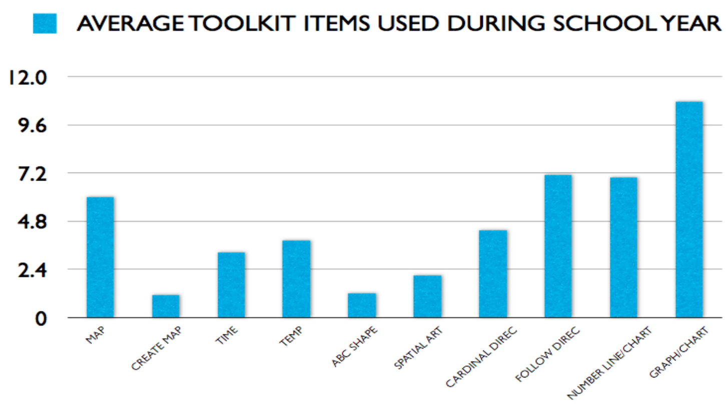

Figure 2: Distribution of Toolkit Items Used

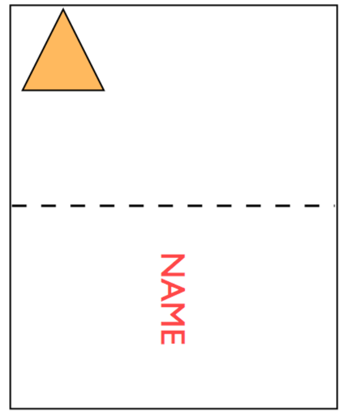

Figure 2a. Following Directions Example

We found that a domain did not need to be explicitly spatial for teachers to begin to incorporate explicitly spatial elements. One of the most frequently used toolkit items (Figures 2 and 2a, above) was an exercise that teachers use in the earliest grades to help students learn to follow directions. This activity could be done in any number of ways, but many teachers saw it as a perfect place for students to follow specifically spatial directions, such as folding a paper horizontally, putting a triangle in the top left corner, and writing their names perpendicular to the fold.

We also observed classes where the toolkit activities were being conducted. At points throughout the school year we held follow-up sessions where we had the opportunity to get additional feedback from teachers on the successes or failures of the toolkit activities. At these meetings we were also able to present teachers with new activity suggestions for them to tailor to their class use, based on our observations of their classes. For example, teachers expressed interest in a variety of puzzles, and SILC research has shown that puzzle play predicts children's performance on a mental transformation task (Cannon, Levine, Huttenlocher, & Ratliff, under review). We therefore developed a series of math puzzles (see Figure 3), such as a math domino game, a number grid puzzle ("What number am I?"), and a tangram math game, for the teachers to adopt in their classrooms.

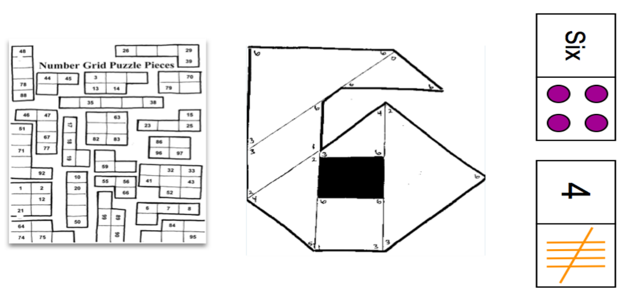

Figure 3. Math Puzzle Games

The toolkit format allowed us to modify and revise activities beyond the initial work circle, in order to accommodate teachers' needs throughout the year, and to insure that teachers were actively aware of spatial intelligence as a factor in their classrooms.

Teachers had the ability to pick and choose when and where the activities in the toolkit might be used, sometimes modifying them to fit their classroom needs. This design choice has numerous affordances particular to the material we were working with, but it also had some constraints. One constraint is that modified material sometimes changes such that the activity is no longer clearly representing the same concept as that in the lab activity. For example, a training study conducted in SILC labs (Levine, Kwon, Huttenlocher, Ratliff, & Dietz, 2009) demonstrated greatly improved ability to measure objects that are misaligned on the ruler when unit pieces are explicitly placed on the ruler (highlighting the space between hash marks as the unit, rather than the hash marks themselves), and when an item is first misaligned and then moved into alignment at the end of the ruler. In observing one 3rd grade class implementing a classroom version of this task, we noticed that the teacher had modified the activity to integrate with a number of different aspects of her curriculum. Instead of using the unit pieces to measure the spaces, and moving the measured item to the beginning of the ruler, she had the students use the units as part of a subtraction strategy, with some students putting units on all of the spaces up to the end of the item, and then removing those that did not align with the item. She explained this strategy to the students by saying "The turtle is four centimeters long because it ends at 6 and starts at 2; and 6- 2 is 4" (Figure 4).

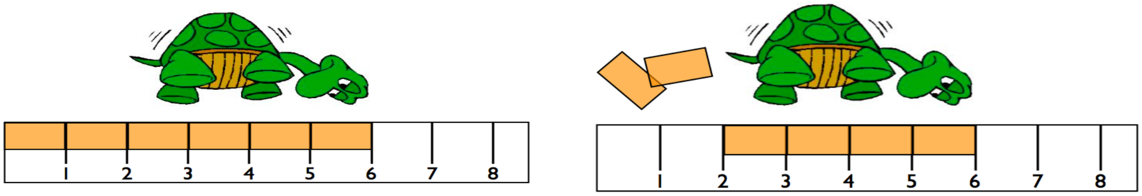

Figure 4: Classroom Adaptation of Measurement Training

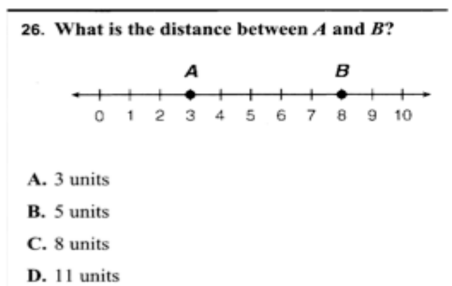
This strategy seems like a good strategy for solving misaligned ruler problems, and certainly takes advantage of spatial processes such as alignment; however, it is not the strategy that we had investigated in the lab. On the other hand, when provided with a sample of the practice ISAT standardized assessment that the students take in 3rd grade, we noted that there were explicit number line questions that demanded exactly the subtraction strategy that the teacher was urging the students to utilize (Figure 5). This example highlights the sort of interplay between research and practice the toolkit approach allows.



**26. What is the distance between *A* and *B*?**

**A.** 3 units
**B.** 5 units
**C.** 8 units
**D.** 11 units

Figure 5: ISAT Item Using Subtraction Strategy

## Multiple types of Toolkit Impact

We believe our spatial toolkit impacts teachers precisely because it does not attempt a unified curriculum to replace an existing curriculum; it is instead a product that contains a multiplicity of resources, the sum of which can impact teachers' understandings and practices as they choose those that work for them. As we built toolkit resources together with teachers and observed their classes we were able to see five different ways in which spatial resources were integrated into classes, each of which represents some aspect of growing teacher awareness of, and interaction with, spatial intelligence in the classroom.

**Coherent Independent Content:** Although the toolkit as a whole does not offer a unified curriculum some activities do independently mirror content that exists in the school day and can be used as replacements. For example, using a ruler is a skill that is taught in the early grades, and, as noted above, is also reflected in the toolkit. Although some teachers modified the activity substantially, other teachers used the activity without very many changes. This is a hallmark of the toolkit approach, which allows teachers to choose how and when they will implement activities.

**Reorganized Content**: Much like an inquiry based curriculum will be organized around a driving question, pulling from numerous content areas in the process, some toolkit items take existing content and reorganize it around an underlying spatial concept. For example, together with teachers, we designed a series of activities that explored the use of the number line as a tool to understand the concept of unit as a basic foundation for understanding a wide range of math content, from addition and subtraction, to fractions and decimals, to area and perimeter. In the toolkit, teachers were able to utilize these activities as a coherent unit, if so they desired.

**Standalone Games and Attachments:** One of the great strengths of the toolkit is the presence of numerous items that are flexible and compatible with a wide range of classroom environments and opportunities for use. For example, teachers have used spatial puzzles and dominos during free time, center time, and as attachments to math lessons.

**Classroom Methods**: Much of the understanding that we hoped to develop in the teachers did not relate at all to particular content, but to techniques and tools that draw on spatial resources. For example, during the work circle teachers learned about research regarding the use of gesture (gesturing helps children understand spatial translation, (Ehrlich, Levine, & Goldin-Meadow, 2006)) and spatial analogies (Gentner, Levine, Dhillon, &

Poltermann, 2009). These can be used in any context in the classroom, and their use reflects a deep awareness of the utility of spatial reasoning a range of circumstances.

We observed a notable example of this in one of our second grade teachers' classes during the 2008-2009 school year. During the work circle we discussed research by Gentner that demonstrated that differences between two items are more easily discerned by students when the two items are highly aligned – that is, are highly similar, and differ only in one area. In a unit on time and clocks the teacher, unprompted by the researchers, took this concept of high alignment and applied it to the classroom to show students the correct orientation of the hands on the clock. Holding up two clocks that were supposed to represent 3:30 with nearly identical configurations, she asked them to identify what was different about the two clocks. On one clock the hands were at the six the three, and on the other clock the hands were at the six and between the three and the four (Figure 6). This was a prime example of a teacher using a high alignment spatial analogy to communicate content in the classroom.

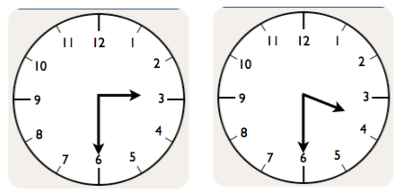


Figure 6: High Alignment of Clocks

**Language:** A major aspect of teacher uptake was in the use and incorporation of spatial language into the school day. This is one area that teachers immediately "got" and found ways to insert more, and more advanced, spatial language into their lessons. One teacher started using the cardinal directions when giving instructions to her students, and informed us during a feedback period that her students were no longer getting lost in the hallways of the school. Other teachers started to use more advanced terminology than they would have otherwise (for example: parallel, horizontal, diagonal, and symmetry were all mentioned by teachers).

## The Toolkit Approach as a Way to Change Teacher Thinking

In putting together a spatial toolkit we have been trying to introduce the concept of spatial intelligence to teachers, and to have teachers begin incorporating their understanding of spatial intelligence into their practices. Unlike a design for a new science curriculum or a new method for teaching fractions, many of the items in the toolkit might appear trivial—puzzles, games, following directions—but they serve an important purpose, and communicate a great deal of information. Because the activities are flexible, engaging, and teacher designed, teachers' perceptions of teaching have changed to include their awareness of spatial thinking as an important element of classroom instruction. Without any radical restructuring of the curriculum or of their methodology, teachers have been thinking more subtly about spatial content as they teach, and have been organizing their teaching around this thought process.

For example, teachers responded to an evaluation survey by uniformly commenting on how much their awareness had changed over the course of the study. One typical teacher wrote, "I have become much more aware of spatial intelligence and how to incorporate these things in my classroom". Nearly every teacher had some comment on the need to think explicitly about spatial intelligence while teaching (e.g. a sample of responses to "challenges I face": Being <u>very</u> explicit in spatial instruction; Thinking spatially about the lessons; Being aware of what I have in my classroom that ties into spatial thinking; Using specific spatial language, etc.). These responses reflect a reality in which teachers are using the toolkit as a resource that enables them to keep spatial intelligence in mind while constructing lessons and designing activities. This represents a major first step in impacting teacher practice.

## Final Thoughts

Spatial thinking is critically important for problem solving across the various sciences, as well as in many areas of daily life. Given recent evidence that spatial cognition is malleable, and hence that spatial learning can be fostered by effective technology and education (see Liu, Uttal, & Newcomb, 2008), we would naturally like to extend these findings to educational settings. The first steps in this process are making teachers aware of the existence of spatial intelligence, and impacting their practice to include activities that promote spatial reasoning.

In this study, we have tried to demonstrate some of the successes and challenges in introducing spatial intelligence to teachers and implementing change in the classroom. Because the concept is unknown to teachers, many areas that contain natural spatial learning opportunities are lost, and because spatial reasoning is not a subject taught in school we cannot easily build curricula to promote it. Many research-to-practice models encounter obstacles when there is no content in the school day matching the research in the lab. The development of the spatial toolkit helps fill in the gap, by increasing teacher awareness, and providing teachers with activities to supplement (rather than replace) their existing curricula. The toolkit approach allows teachers to pick and choose against a backdrop of resources and support, adjusting their understanding over time, and in concert with researchers.

As part of an ecology of events the toolkit can be an important early-stage product to spur the conversation between research and practice. After a number of work circle iterations we should have a good idea of what works and what doesn't, and under what circumstances different spatial activities will fit into the school day. A publishable end product could be produced and tried out more widely, giving a broader set of teachers the opportunity to build awareness of spatial reasoning through engagement in these activities. As teachers become more familiar with the concept, and more substantially adjust their teaching practices to include spatial content we can begin to test the impact of that content on students. Once we are certain that teachers "get it", in the sense of flexible integration with practice, we can explore how that translates to the students, and with that knowledge design even more targeted toolkit items to deepen student spatial ability.

# Personal Beliefs about Learning and Teaching: Comparison of student teachers in the sciences and humanities at different stages of their studies

Natalia Schlichter, University of Goettingen, DFG Graduate Research Program 1195 "Understanding and Enhancing Educational Fit in Schools", Waldweg 26, 37073 Goettingen, Germany, Email: Natalia.Schlichter@sowi.uni-goettingen.de

Matthias Nueckles, University of Freiburg, Department of Educational Science, Rempartstrasse 11, 79098 Freiburg, Germany, Email: matthias.nueckles@ezw.uni-freiburg.de

**Abstract:** The present project deals with teachers' beliefs as implicit, steady assumptions about learning and teaching and especially with 'participation', as the least investigated. This exploratory study analyzes (1) the representation of beliefs regarding 'participation' in student teachers' views, the impact (2) of the stage of their studies, and (3) of their discipline studied on the beliefs. Student teachers were interviewed regarding their views on learning and teaching (*N* = 30). The content analysis shows different multifaceted beliefs. The results reveal an alteration in the beliefs during the studies: At the beginning there is a 'transmissive-emotional' focusing which changes progressively to a more cognitive focus including 'construction' and 'participation', and still 'transmission'. Furthermore, the internal structure of 'participation' in the views of the interviewees does not correspond with the theoretical concept. On the basis of these results the possibility of developing a questionnaire for closer investigation of 'participation' is being discussed.

## Introduction

Teachers' beliefs have become a focal point of research in the hope of gaining a better understanding of teacher behavior. Furthermore, since the rise of cognitive psychology, an more and more attention has been paid in particular to the juxtaposition of two opinions (Anderson, 1997; Greeno, 1997): the view of teaching as a 'direct transmission' (Resnick & Hall, 1998), with learning seen as an 'acquisition' of knowledge; and a 'cognitive construction' view of learning. The current research shows typical patterns: 'transmission' vs. 'construction' views (e.g., Staub & Stern, 2002). In addition we find 'acquisition' vs. 'participation' metaphors (Sfard, 1998), and 'content-centered' vs. 'learning-centered' teaching (Kember & Kwan, 2000). Empirical research so far concentrates on the 'transmission' vs. 'construction' views (Dubberke, Kunter, McElvany, Brunner, & Baumert, 2008); 'participation' is still being neglected. According to Sfard (1998), the role of 'participation' in the learning process, which was introduced as 'situated learning' (Greeno, 1997), should be considered to a greater extent in research.

Therefore, the current project centers on teachers' beliefs in general and on 'participation' in particular. This study is an exploration of the self-reflected views of learning and teaching as they emerged in interviews with student teachers. The purpose of this paper is to create a better understanding of student teachers' beliefs regarding participation. First, the theoretical framework will be presented, defining the term "teachers' beliefs" and showing the relevant research as well as different views of learning and teaching. The research questions of this study will then be presented. Next, the methodological information will be described. Finally, the findings will be presented and the possible implications will be outlined.

## Theoretical framework

### The term "teachers' beliefs"

Beliefs are subjective and experience-based perceptions of learning and teaching. Martinez, Sauleda, and Huber (2001) use the metaphor 'blueprint of thinking' to illustrate the type of influence exerted by beliefs on perception and behavior. Beliefs about teaching are well established by the time a student gets to college (Pajares, 1992); they do not change easily or rapidly and are not independent of the discipline taught (Boulton-Lewis, Smith, McCrindle, Burnett, & Campbell, 2001; Staub & Stern, 2002; van Driel, Bulte, & Verloop, 2007).

'Belief' is still a 'messy construct', as Pajares (1992) called it. Among the terms used to describe teachers' thinking we find: beliefs, conceptions, orientations (Kember, 1997), perspectives, intentions, teaching approaches (Trigwell, Prosser & Taylor, 1994), and teaching perspectives (Pratt, 2002). Because of largely congruent contents all these work will be equally employed for the present study.

We define teachers' beliefs as implicit, steady, experience-based assumptions about the nature of learning and teaching: about the learner, the teacher, the learning and teaching process, instruction, classroom management, the genesis of knowledge and its growth.

## Research on teachers' beliefs

Before addressing the relevant studies, the theoretical background of different beliefs should be briefly outlined. As pointed out by Sfard (1998), the theoretical paradigms of learning can provide a suitable frame of reference on teachers' beliefs. The author differentiates between two basic metaphors: 1) individual acquisition of knowledge and 2) participation in the community of practice. Here, learning is regarded as a process of becoming a member of a certain community, which requires the ability to communicate in the language of the community and to act according to its particular norms. The learner is interested in participating in various activities rather than accumulating personal possessions. In contrast to this position, the individual acquisition metaphor considers learning as the result of a transmission process of information from the teacher to the student. Sfard (1998) describes both metaphors under the following aspects: goal of learning, learning, student, teacher, knowledge, knowing, and motivation. Kember (1997) also employs several dimensions to delimit the conceptions of teaching: teacher, teaching, student, learning, content, knowledge.

Sfard (1998) assignes behaviouristic and constructivistic notions of learning to the first metaphor and notions of situated learning to the second metaphor (Bruner, 1996; Greeno, 1997; Lave, 1987; Lave & Wenger, 1991). Contrary to this position, Martinez et al. (2001) differentiates three main metaphors: 1) learning as transmission of knowledge, 2) the constructivist metaphor, and 3) teaching and learning as a social process. According to the constructivist metaphor, learning is described as an active, constructive process which is influenced by the subject's prior knowledge and takes place in particular contexts (e.g., Bereiter, 1994; Staub & Stern, 2002). According to Trigwell and Prosser there is also the distinction between 'conceptual-change/student-focused' and 'information-transmission/teacher-focused' approaches of teaching (see also Norton, Richardson, Hartley, Newstead, & Mayes, 2005; Postareff & Lindblom-Ylänne, 2008; Trigwell, Prosser & Taylor, 1994).

Of equal interest is the research that takes into consideration more than two opposing beliefs: for instance Pratt, Collins, and Jarvis-Selinger (2001) and Alger (2009). Pratt et al. (2001) worked out five teaching perspectives: 1) transmission: Effective teaching requires a substantial commitment to the content or subject matter; 2) apprenticeship: Effective teaching is a process of students enculturation into a set of social norms and ways of working; 3) developmental: Effective teaching must be planned and conducted "from the learner's point of view"; 4) nurturing: Effective teaching assumes that long-term, hard, persistent effort to achieve comes from the heart, as well as the head; and 5) social reform: Effective teaching seeks to change society in substantive ways.

There is a growing consensus in research that teachers' beliefs affect the learning of the students. Teachers' beliefs influence their own perceptions, which in turn affect their practices in the classroom (Calderhead, 1996).

Empirical studies have already shown that the 'cognitive construction' view, which deals with the cognitive activation and constructive support of the learners, seems to be more promising in promoting a deeper understanding during students' learning than the 'direct transmission' view (Aquirre & Speer, 2000; Dubberke et al., 2008; Staub & Stern, 2002). In contrast to this, the 'participation' view has been addressed less, and there are no suitable questionnaires to measure teachers' beliefs about learning and teaching in terms of 'participation'. Therefore, in this study, we focus on the 'participation' aspects of teachers' beliefs.

## Research questions and hypotheses

We designed the present study to answer three main questions:

1. To what extent are the beliefs about learning and teaching described above represented in the views of student teachers?

It is necessary to find out more about what the student teachers' views of learning and teaching are in general and how important they regard 'participation' in the learning process in particular.

2. Are there any similarities among the student teachers at the same stage of their studies?

We want to compare the beliefs of the student teachers at the beginning, in the middle and at the end of their studies. This question should provide more insight into the assumption that the increased knowledge and practical experience which the students gather during their studies results in more sophisticated beliefs about learning and teaching.

3. Are there any similarities among the student teachers in the related disciplines?

This question should illuminate whether there are any similarities among the specific discipline communities. It can be assumed that differences will exist between the beliefs of student teachers in the sciences and student teachers in the humanities.

Consequently, the current study was designed to investigate the beliefs of student teachers with the aim of highlighting their opinions regarding the role of 'participation' in the learning process. Moreover, if the answers to the latter two questions should yield converging results, the design would provide an insight into the structure of beliefs of student teachers dependent on their knowledge and practical experience, related to the specific discipline.

# Method

## Sample and Design

The sample consisted of a total of $N = 30$ interviewees (11 male, 19 female, mean age: 23.7 years), who were all students undergoing their teacher preparation program at the University of Goettingen. Two discipline communities were represented in the sample: a) the sciences, e.g. mathematics, physics, chemistry, biology and geography ($n = 15$); and b) the humanities, e.g. languages, history and theology ($n = 15$). Furthermore, the participants were at different stages of their studies: a) at the beginning ($n = 10$, mean age: 20.9 years), b) in the middle ($n = 10$, mean age: 23.1 years), and c) at the end ($n = 10$, mean age: 27.2 years).

## Inquiry Method

For the current study, we used the methodology described by White and Gunstone (1992). We elicited the participants' views on learning and teaching by asking them to draw a picture which showed their concept or theory of learning and teaching. The participants were invited to the interview without much prior information about the topic of our study. The intention was to let them communicate their own thoughts with as little external influence as possible. After about 15 minutes of drawing, we asked the participants to explain the picture, thus describing their concepts of learning and teaching. When they had finished doing so, we asked them pre-designated questions on certain aspects that were of interest within our theoretical framework, like: Is the teacher or the learner at the center of the learning process? Who is more important in the learning process: the learner or the teacher? What is the role of the learner in the learning process?

The interviews were audiotaped and transcribed. In addition, in order to be able to analyze nonverbal information, we videotaped the participants together with their picture during the interview. All of the interviews were codenamed to ensure that the data (both verbal and videotapes) remained anonymous and inaccessible to third parties.

## Data Analysis

The method we used to analyze the data was based on Chi's "Quantifying Qualitative Analysis of Verbal Data" (1997). The author recommends the application of this method for verbal data such as explanations or reports. She emphasizes the main goal of this analysis method as understanding the representation of the knowledge. Further, we used the computer program MAXQDA, which supports the coding procedure of verbal data. As preparation for the coding, the interviews were first segmented into single coding units. For this purpose, we used a procedure originally suggested by Chi (1997). Each interview transcript was divided into segments so that each segment could be coded independently. The preferred segmentation technique was based on semantic futures, according to which the content of the utterances had to be interpreted to determine the segment boundaries, such as knowing that the topic of discussion has been changed. In general, it is a proposition or an idea. Mostly, one segment is one idea unit:

Example:

…and that I refer to my experiences that I gained when I was a pupil//

Furthermore, the granularity is referred to as a main point of analysis (see Chi, 1997). Grain sizes can vary from coarse to fine. For our interview analyses, we opted for the fine grain. Consequently, one segment is limited to one sentence, as in the above examples. However, the structure of the speech was often unclear and disorganized; sometimes, it took more than one sentence to express an idea to its conclusion. In this case, one segment might have been longer than in other interviews:

Example:

…for this purpose, I thought to myself, it should be some sort of old-fashioned seating arrangement, for example one pupil sitting on a bench at a table, then the next row, then the next, and the teacher standing here at the front holding the pointer in his hand and teaching at the blackboard//

The first step was to develop a deductive coding scheme. Therefore, we used aspects as 'goal of learning' or 'knowledge' (e.g., Kember, 1997; Sfard, 1998). The coding process was performed by two raters who were trained for this coding procedure. After discussing the category system, they coded the interviews independently. The inter-rater reliability as determined by Cohen's Kappa was good ($\kappa = 0.82$).

The results of this coding process revealed a quite accurate correspondence with the categories of the "Teaching Perspectives Inventory" (TPI) according to Pratt et al. (2001). In the following section, we present these categories as well as the results of the study.

# Results

## Category System

Table 1 shows the category system. Due to space restrictions, the description of each category cannot be presented in complete detail here. The table presents a small excerpt of all of the aspects from each category.

Table 1: The category system.

| Name of the category | Content description of the category |
|---|---|
| Transmission | • learning as gaining achievement and competencies by the individual<br>• teacher as an instructor of learning<br>• knowledge as substance and property by the individual |
| Nurturing | • productive without fear of failure<br>• teacher's responsibility to create an atmosphere without fear<br>• the importance of self-efficacy or self-esteem of the pupils |
| Participation | • learning as a process of enculturation of students into a set of social norms and ways of working<br>• teacher is an expert in his/her discipline and a moderator and supporter of learning processes |
| Construction | • learning as an active and constructive process, depended on the previous knowledge<br>• teaching from the learner's point of view<br>• suitable methods: experience-based and discovery-based learning |
| Social Reform | • collective as an object of teaching rather than individual<br>• encouragement of learners to take a critical stance<br>• learning as developing a world view and opinions |

To demonstrate two of these categories, the subcategories with anchored examples will be presented in the following:

> Subcategory of 'nurturing' – well-being:
> The school and the lesson must take place in a protected space, where the teacher creates emotional safety so that the children feel happy and comfortable and do not have any fears regarding learning.
> Subcategory of 'participation'- 'supporting class community':
> As a pillar of the classroom community, the teacher supports the development of the perception of the class as one community. He/she has to ensure that the pupils act as a group and not as individuals.

## Supplementary Categories

Also of interest are the categories that do not concern the theoretical learning paradigms, but rather address some supplementary influences on interviewees' thoughts during the interviews. For instance, there were ideas about learning, which could be described as naïve positive attitudes, for example about the effects of some specific teaching methods, as well as idealistic attitudes about the teaching profession.

> …so we can make the lessons very, very interesting if we use the new and creative teaching methods//
> The smaller the group, the better the learning//

The interviewees addressed their experiences as learners very often, but described their experience as teachers surprisingly rarely, although most of the student teachers were undergoing their school-based teaching practice during their studies. The focus of the present study is not on such aspects, so we will not address them further in our analysis.

## Internal Structure of Participation

In the theoretical presentation of the construct 'participation' (e.g., Sfard, 1998), there are many aspects that clarify the understanding of learning and teaching according to 'participation'.

The interviewees in the present study made their statements spontaneously. Consequently, it is conceivable that some aspects of their beliefs were not addressed. Hence, the view of the interviewees regarding 'participation' differs from the theoretical construct. For instance, some of the theoretical aspects were not represented completely. The figure below demonstrates the number of the interviewees who made some statements regarding the respective individual aspect (see Figure 1).

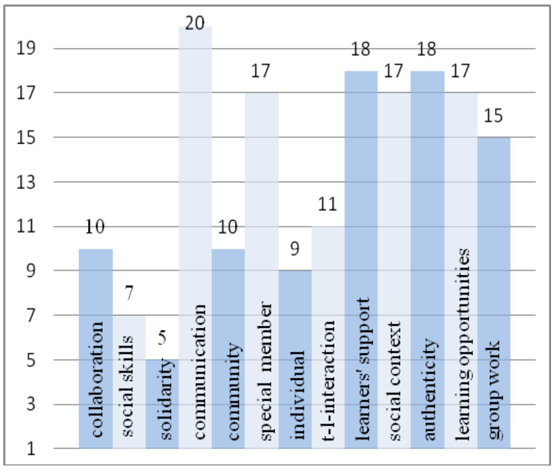

Figure 1.The internal structure of the 'participation'.

Most of the interviewees (*n* =20) commented on the communication process in the class. Communication, authenticity in learning, support by the learners, social context, the teacher as a special member of the class community, the teacher's responsibility to provide learning opportunities were also called often. Some other aspects as group work, interaction process close this list.

Of interest is also the fact that some aspects could be seen as overlapping with the category 'nurturing' because of their emotional value, for instance 'solidarity'. In conclusion, the first research question can be answered as follows: the beliefs of the student teachers in the present study contained five main beliefs and also some supplementary contents. Furthermore, the beliefs of interviewees contained 'participation', but the structure did not correspond to the theoretical construct. In the following section, a closer look will be taken at the different groups of the student teachers.

## Student Teachers' Beliefs

In total, the interviews yielded 2262 segments. 74.2 % of them were assigned to the main categories of beliefs about learning and teaching; the other 25.8 % were described in the section above (see Supplementary Categories). The following table (see Table 2) shows the means (in percent) and standard deviations for the values in the main categories for all the groups of student teachers.

Table 2: Descriptive statistics: Means (in percent) and standard deviations.

| | Whole sample (*N* =30) | Student teachers at the beginning of their studies(*n* =10) | Student teachers in the middle of their studies (*n* = 10) | Student teachers at the end of their studies (*n* = 10) | Student teachers in the sciences (*n* = 15) | Student teachers in the humanities (*n* = 15) |
|---|---|---|---|---|---|---|
| Total statements | 74.20 (29.13) | 73.30 (28.83) | 70.10 (20.76) | 79.20 (37.74) | 64.40 (30.21) | 84.00 (25.27) |
| Transmission | 25.77 (12.80) | 29.22 (17.34) | 23.93 (8.98) | 24.17 (11.26) | 26.07 (15.47) | 25.48 (9.99) |
| Nurturing | 15.18 (12.12) | 23.86 (12.85) | 11.01 (9.71) | 10.69 (9.40) | 13.47 (10.92) | 16.90 (13.37) |
| Participation | 23.9 (10.83) | 19.53 (7.39) | 29.85 (12.34) | 22.33 (10.37) | 25.70 (10.92) | 22.11 (10.81) |
| Construction | 19.25 (9.66) | 13.21 (9.68) | 21.35 (9.03) | 23.21 (07.91) | 27.30 (13.54) | 26.83 (11.94) |
| Social Reform | 03.65 (3.21) | 04.50 (3.34) | 01.10 | 0 | 00.12 (0.47)0.12 | 00.85 (2.24) |

## The impact of the stage of studies on the beliefs

The second research question concerned the different stages of the studies. Our sample contained students (a) at the beginning, (b) in the middle and (c) at the end of their studies to compare the influence of experiences from the studies on the beliefs. In order to examine the difference in each belief for each group, we conducted a multivariate GLM model (within subject design). The main effect of beliefs is significant: $F = 26.23$, $p < .001$, and reveals quite strong power, at $Eta^2 = .49$ as well as the interaction between beliefs and the stage of the studies: $F = 2.58$, $p< .05$, $Eta^2 = .16$. The findings are demonstrated in the figure below (see Figure 2).

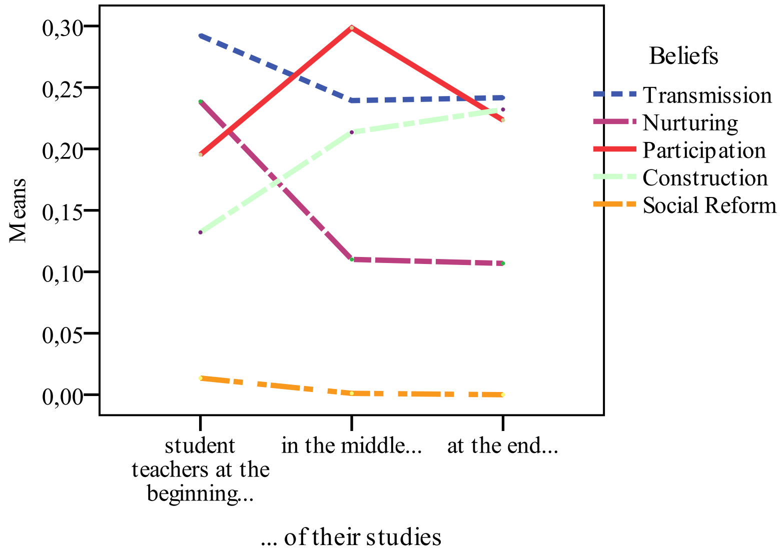

Figure 2. The distribution of the beliefs for each group of student teachers.

The difference between the student teachers at different stages in each belief was tested by means of univariate analysis of variance (ANOVA). The findings show a significant effect of the stages of the studies on the belief 'nurturing' at the .05 level: $F = 4.87$, $p < .05$, $Eta^2 = .27$. The test of contrasts shows a significant difference between the student teachers at the beginning and in the middle of their studies: $F = 23.25$, $p < .001$, $Eta^2 = .46$.

The difference in 'participation' is also significant. The effect of the stage of the studies on 'participation' is, however, significant only at the .1 level: $F = 2.71$, $p < .1$, $Eta^2 = .17$. The difference between the different groups of student appearances as follows: the student teachers in the middle of their studies show the biggest values compared with much lower values of the student teachers at the beginning and lower values of the student teachers at the end of their studies: $F = 62.11$, $p < .001$. This effect power is quite strong, at $Eta^2 = .70$.

Furthermore, the statistics reveal the differences in 'construction'. The effect of the stages of the studies on 'construction' is significant at the .05 level: $F= 3.57$, $p < .05$, $Eta^2 = .21$. The test of contrasts shows that the student teachers at the beginning of their studies have the lowest values in 'construction' compared with quite higher values of the student teachers at the end and also higher values by the student teachers in the middle of their studies.

For all the other beliefs, the differences were not significant. It is noticeable that in some categories, not all groups made statements: For 'social reform', none of the students at the end of their studies made any statements.

The following result could be already seen in the figure 2: The student teachers at the end of the studies possess the three beliefs 'transmission', 'construction', and 'participation' at the quite similar level; the belief 'nurturing' is also represented, but in noticeable smaller extend. This difference was tested by means of t-Test, computing for the beliefs 'transmission', 'construction', and 'participation' a common variable named 'cognitive focus' previously. The means (standard abbreviations) for 'cognitive focus' and 'nurturing' are respectively 23.23 (4.17) and 10.69 (9.40). This difference is significant at the level .05: $t = 3$ ($df = 9$), $p < .05$.

Due to the quite small groups of the students, all statistics were also reconsidered by means of non-parametric tests which carried out the findings like the above. Nevertheless, the conditions for ANOVA are fulfilled: the normal distribution and the homogeneity of variances are given.

To summarize, the student teachers at different stages of their studies have significant different beliefs. The development of the beliefs during the studies changes from the 'transmissive-emotional' focus including 'transmission' and 'nurturing' toward a 'cognitive' focus including 'construction', 'participation', and still 'transmission'.

### The impact of discipline on beliefs

To examine hypothesis 3, namely that the beliefs of student teachers in the sciences differ from those of student teachers in the humanities, we conducted analysis of variance (ANOVA), which proved to be insignificant. To sum up these final results, it can be stated that the expected differences between the beliefs of the student teachers from the two disciplines were not found.

## Conclusions and implications

In this paper, we described a study conducted recently at the University of Goettingen. It was designed with the aim to highlight how the different beliefs are represented in the thinking of the student teachers and what differences there are in these beliefs at various stages of their studies and in different disciplines.

At the beginning of the present study we did not have any expectations as to which beliefs would revealed by the interviews. In a first analysis, we expected two main paradigms such as 'individualistic' vs. 'social' paradigms in learning sciences (Sfard, 1998) or perhaps a 'transmission' vs. 'construction' view on learning and teaching (Staub & Stern, 2002). In the end we found not just one or two, but five different beliefs. These results could be seen in a positive light. An increasing number of researchers are calling for plurality in looking at the beliefs about teaching and learning. Pratt (2002) warns against the "one size fits all" notion of good teaching. Even Sfard (1998) points out the "dangers of choosing just one" of the two metaphors.

In keeping with the recent theoretical framework and empirical research that researchers and educators should pay more attention to the concept of 'participation' in the field of the learning science (Alger, 2009; Lave &Wenger, 1991; Sfard, 1998), our study set out to investigate student teachers' beliefs regarding 'participation' in more detail. In so doing, we analyzed the internal structure of the notion of 'participation' found in our interviews. This analysis showed that the understanding of learning as 'participation' by the student teachers in our study does not correspond to the theoretical concept. This can possibly be explained by the fact that the interviewees spoke spontaneously. Consequently, it is conceivable that some aspects of their beliefs were not addressed. The overlapping areas relate to emotional aspects of group processes like solidarity, which reveals that the future teachers value the idea of 'participation', not only from the perspective of advantages for learning but also in terms of the emotional advantages. In addition, many aspects concern social aspects of group processes. There are no didactic aspects or statements about specific learning processes in a 'learning community', with the exception of 'providing learning opportunities by the teacher'. The constitutive point of 'participation' – learning as enculturation – is lacking. Thus, this indicates that a one-sided view should be changed, and that the teacher education should be able to initiate such a change.

Furthermore, the present study confirmed the hypothesis of underlying similarities among the beliefs of the students at the same stages of their studies. But, the experimental design of the present study was cross-sectional, which is why the differences between the student teachers of different stages of their studies cannot be interpreted as definite changes in beliefs, but should at present rather be understood as hint thereof. Additionally, the teacher preparation program included not the same contents, because of the present system of Higher Education in Germany. Indeed, especially the clear preference of the student teachers in the middle of the studies for 'participation' emphasizes this fact. This especially preference may be a cohorts effect. In addition, the student teachers at the beginning of their studies understood learning primarily in terms of transmission of knowledge from the teacher to the pupil, seeing the main responsibility of the teacher in preparing and presenting of the contents of his/her discipline as well as creating an atmosphere without fear in order to secure of self-efficacy and self-esteem of the children. While the student teachers at the beginning of their studies show this 'transmissive-emotional' focus on the learning and teaching, the beliefs by the student teachers at the end of their studies tend toward the 'cognitive' focus. Thus, this alteration in the beliefs might be attributable to the increased knowledge the students gather during the studies and practical experience from the internships allowing to evaluate the role of teacher training a little deeper. We hope that these findings will be fruitful for educators who work in the field of teacher preparation program.

The sample also comprised student teachers from various disciplines. The recent research confirmed similarities in the beliefs in the same or relative disciplines (Boulton-Lewis et al., 2001; Norton, 2005; Pajares, 1992; Pratt et al., 2001; van Driel et al., 2007). Contrary to this research, in the present study differences between the student teachers in the sciences and the humanities were not found. In the Higher Education program in Germany there are two disciplines which must be studied. Thus, there are students in the sample who study for instance physic and language. The assignment of the students to each group was made according to the favorite discipline named by the student. This method of assignation seems to be not selective enough.

The aim of our study was to highlight the beliefs and how they are represented in the thinking of the interviewees. Restrictions were kept as more as possible. Due to the restrictive nature of questionnaires, we decided to work according to the inquiry method of White and Gunstone (1992). The next step could be to use the results of the present study to develop a questionnaire to measure 'participation' even more closely. Furthermore, a future study could interview other groups of people. Beliefs of experienced teachers seem to be of particular interest in the light of the present project. As a conclusion of the present study we must bear in mind that our investigation reveals not actual beliefs, but rather, in the best case scenario, the 'blueprints of beliefs' in the particular interview situation.

# A Longitudinal Approach to Appropriation of Science Ideas: A Study of Students' Trajectories in Thermodynamics

**Abstract:** This article provides an empirical analysis of data collected during the implementation of a teaching proposal on thermodynamics in a class of 20 students (17 year-olds) of a scientifically-oriented secondary school in Italy. During the activities, each student made evident progress in gaining intellectual autonomy as they took part in the teaching/learning dynamics of the classroom. Although the research had, up to now, an empirical orientation, this paper aims to provide a contribution for advancing theory development in physics education research. The study gives an example of the application of a specific model of teaching/learning (the Model of Longitudinal Development) that acted as "framework for action" in the design of the learning environment as "properly complex territory." The data analysis gives indications for how to develop a theoretical understanding of the concept of "personal learning trajectory" and it provides a basis for exploring the factors that can trigger intellectual autonomy.

## 1. Introduction

This article focuses on an empirical analysis of data collected during the implementation of a teaching proposal on thermodynamics in a regular 12th grade class in a scientifically-oriented secondary school in Italy.The study is an example of application of a specific model of teaching/learning (the Model of Longitudinal Development, described in Section 2), that acted as "framework for action" (diSessa & Cobb, 2004) in the design of a learning environment as "properly complex territory."

A framework for action is intrinsically and self-consciously heuristic. The purpose of a framework for action is to provide some useful focus and direction for the design of learning environments. However, because frameworks for action may involve multiple, diverse design elements and plans (some of which may have inexplicit underlying assumptions), frameworks for action are not themselves "theories of teaching and learning" that can be tested or falsified. The results of a design that is informed by the heuristic principles of a particular framework for action are iterative in nature, and often involve making explicit and gaining a better understanding of the initial choices made by intuition or guess-work and guided by previous design experiences. This is what happened also in this study: through feedback from our students, we progressively gained a refined awareness of both basic features and the potential of the materials we had designed. In sections 3 and 4, we document this progress by stressing what we had explicitly planned before and during the implementation and what became, to our surprise, evident in the monitoring of the classroom activities.

Although empirical in orientation, this study intents to go beyond purely heuristic findings and aims to provide a contribution to the enterprise of advancing theory development in physics education. The choice of focusing the study on the specific concept of "learning trajectory," known in the research literature of design studies (Confrey, 2006), did indeed allow us to find important hints in the data for developing the research from a more theoretical point of view. In particular, by working on real examples of learning trajectories constructed by the students themselves, the fairly abstract and mainly evocative word "trajectory" seems to gain specific and operatively recognizable properties. These properties appear to be good candidates not only for defining it, but also for potentially including it in a "local theory" (diSessa & Cobb, 2004), aimed at explaining the connections between individual and collective growth and individuating the factors that can trigger intellectual autonomy through the construction of personal learning trajectories.

Section 5 is devoted to implications for future research and stresses the need to point out such theoretical foci of attention on which future studies can be carried out.

## 2. The Model of Longitudinal Development (as a framework for action)

The Model of Longitudinal Development (MLD) is the main product of the Italian PRIN project *"F21 - Teaching and learning pathways in physics for the 21th century, in both "formal" and "informal" education"* (2004-2007). This project involved nine Italian research groups in physics education and was coordinated at national level by Paolo Guidoni.

MLD is comprised of a set of shared criteria for designing teaching materials that allow the cognitive potential of the pupils to be progressively exploited and tuned to the construction of physics knowledge along the pre-university curriculum (from Kindergarten to upper secondary school) (Guidoni & Levrini, 2008; Levrini et al., 2009).

According to the model, the longitudinal development of physics teaching/learning is schematically seen as a continuous widening of phenomenological evidence correlated to more and more powerful modelling along 3 macro-levels of development:

- Level one (K-8) - phenomenological "appropriation" of common life experience;

- Level two (grades 9-10, the first two years of upper secondary school) - re-arrangement of phenomenologies into pre-theory structures (nets of physical concepts);
- Level three (grades 11-13, the last three years of upper secondary school) - re-arrangement of the previously acquired knowledge in terms of physical theories, up to the basic concepts and formal insights of "modern" physics.

The structure of physical knowledge as discipline (i.e. its organization in terms of theories roughly corresponding to the traditional "chapters" in which physics is usually taught) is not taken in the model as the basis on which the whole long-term curriculum can be organized. Rather, the disciplinary structure of physical knowledge is considered to be a high cultural goal to which students will be progressively and consciously guided in the last years of upper secondary school.

In this study, MLD acted as framework for action. The experiment on teaching/learning thermodynamics, described in the next section, concerns the level Level 3 ($L_3$) and has been designed according to the following criteria, assumed within MLD as general orienting principles for the design of the experiment:

a. *The role of productive complexities in a physics reconstruction for all students (physics as culture).* The teaching/learning process is assumed to be meaningful if it tunes, in a productive way, three very complex systems: Real world, physics and cognitive dynamics. Because of the involved forms of complexities, hyper-simplified instructional descriptions and explanations, by making the material seem easy, can dangerously distort the learning process as well as the content. On the contrary, once useless complications are avoided, forms of unavoidable complexities can be exploited as productive for creating learning environments rich enough to enable each student to exploit his/her potential and to follow the route more congenial to his/her cognitive style and/or cultural interest. In the proposal on thermodynamics described below, the two main sources of productive complexities considered are: (1) The comparison between different approaches to the same content (a multi-perspective approach) and (2) the plurality of the dimensions tuned in the proposal (a multi-dimensional proposal). Such forms of complexities have been investigated by our research team for several years, in particular in studies about teaching/learning modern physics (special relativity and quantum physics) (see, for example, Levrini et al., 2008).

b. *The distinction between classroom corridors and students' individual trajectories.* The two terms "corridor" and "trajectory" are taken from the work of Confrey (2006) who asserts the necessity for research to develop teaching paths in actual classrooms in collaboration with researcher-teachers in order to reach two kind of goals: i) To provide teachers "of guidance (…) to organize corridors (…) as intellectual spaces through which students progress" realizing "a particular conceptual trajectory through the corridor", "with variations among students", and ii) To allow the researchers to identify the invariants inside the different paths and to use them in "the articulation of domain-specific guidance illuminating conceptual corridors" and in "engineering and identifying multiple means for constructing" corridors that can be successfully navigated in different ways by different classes.

In short, according to the MLD, the criteria used for designing the teaching materials and strategies are strongly oriented by the aim of fostering the creation of the learning environment as a *properly complex territory*, that is:

- able to outline a wide, coherent perspective where productive complexities are exploited (*corridor*);
- suitable to be "navigated" by the students along different *trajectories* according to different cognitive styles and/or cultural interests.

## 3. The study

### The context

The study concerns a teaching/learning experiment carried out during regular activities within a class of a science-oriented secondary school (Liceo Scientifico "A. Einstein") in Rimini, Italy. The class, composed of twenty 17-year-old students (9 girls; 11 boys), was attending the 4$^{th}$ year of upper secondary school (12$^{th}$ grade) and had studied physics from the first year (9$^{th}$ grade). Following the MLD, during the first two years (Level $L_2$), the teacher (PF, one the authors) carried out activities strongly focused on the problem of guiding students to construct pre-theory structures (nets of physical concepts) suitable to manage classes of phenomenologies (concerning motion, heating, light and vision, waves). The re-arrangement of the acquired knowledge in terms of physical theories ($L_3$) was the general aim of the activities carried out from the third year (11$^{th}$ grade). Before the teaching of thermodynamics as a theory, the curriculum had covered classical mechanics and special relativity. The thermodynamics corridor implemented in class was designed by a research group made up of researchers in PER, experienced teachers and undergraduate students.

According to the MLD criteria, the design of the thermodynamics corridor was characterized by the following basic choices:

- to present the same contents from different approaches. In this case, the two approaches were the macroscopic and microscopic ones, treated consistently as two different models, that can be compared by confronting the complementary explanations the two models give of the same phenomenology;

- to develop a critical-epistemological reflection on the peculiarities of the two approaches through specific activities (a questionnaire where students were asked to analyze and discuss excerpts of epistemological texts on the distinction between the two approaches, submitted at the beginning of the thermodynamics study; two collective discussions about the questionnaire performed at the beginning and at the end of the whole work);
- to emphasize the comparison of thermodynamics with the theories previously studied (classical mechanics and special relativity), so as to support learning as a continuous process of refining, re-investing, revising the models and the formal structures already acquired by looking at what was already known from new and more powerful perspectives.

The previous experiences of the group in designing teaching materials of modern physics (Levrini 2002) have provided interesting results about both students' understanding of the physical concepts (Levrini & diSessa, 2008), and the development of students' intellectual autonomy in properly complex territories (Levrini et al. 2008).

Following the research results of many years of investigation about teaching/learning modern physics, the design of the thermodynamics proposal was explicitly shaped by the following two research-based assumptions:

1) A multi-perspective approach can foster deep understanding of the physics concepts.
   In particular, the model of coordination class of learning and conceptual change (diSessa & Sherin, 1998), used as theoretical framework for analyzing a complex classroom episode, provided a theory-based explanation of *why* explicitly exposing, managing, and relating multiple classes of projections of a physical concept (the concept of proper time in special relativity), also elicited by the comparison between the geometrical and operational approach to special relativity, seems to be a good instructional technique to work around documented difficulties in conceptual change (in special relativity) (Levrini & diSessa, 2008);
2) The multiple dimensions (phenomenological, formal, conceptual, metacognitive) tuned by the analysis of historical-epistemological debates on the interpretation of the formalism of modern physics can foster the creation of a complex learning environment where the students are stimulated to reflect on the intricacies of the opinions and their personal involvement with them.
   A heuristic study on the implementation of a teaching proposal on quantum physics enabled us to point out that the multi-dimensional learning environment fostered students' intellectual autonomy by encouraging them to generate the questions that puzzled them and find out explicitly productive answers by themselves (Levrini et al., 2008).

The main methodological feature that distinguishes the research on thermodynamics is the focus on student's individual trajectories. The pieces of evidence about students' trajectories collected in our previous studies on different topics mainly came from classroom discussions and therefore the elements of intellectual autonomy emerged from the occasional individual contributions. In this study the aim of pursuing the individual trajectory was clear from the beginning and specific activities and instruments were designed for this purpose.

## Aims, data sources and methodology

The study here presented focuses on a selection of the data we collected during the whole experiment on teaching/learning thermodynamics. We focus on the transcripts of the individual semi-structured interviews that were conducted at the end of the whole work. The interviews were specifically performed for addressing some research questions that had arisen from the previous study on quantum physics: Are the properly complex territories defined above really suitable to be navigated by the students along their own learning trajectories in an explicit and conscious way? If so, is it possible to point out what identifies an individual trajectory with respect to the classroom corridor? What features of corridors, teaching strategies and/or collective activities can trigger the construction of personal trajectories?

The first two questions will be answered fairly precisely by means of the data analyzed so far, whilst as far as the third question is concerned, the study will provide a preliminary answer in terms of hypotheses about the possible factors that enabled students to construct their own trajectories.

Out of the 20 students of the class, in order to avoid interfering too much with the regular classroom activities, 10 students (5 boys and 5 girls) have been selected for interviews so as to represent students' variety as far as motivation to study physics, special interest in thermodynamics, contribution to classroom discussions, level of performance in regular physics tasks are concerned.

The interview protocol included:

- general questions like: *What did you find more and less interesting in the work you did on thermodynamics? Why? What did you find easier and what more difficult?*
- specific questions addressed to the individual student for clarifying something he/she had said during the classroom activities, like: *During the last discussion in class you mentioned the existence of an interesting relation between thermodynamics and the theories you previously studied (like mechanics). Would you mind telling us more about this?*

The interviews have been conducted by a masters student (GT) in the presence of a researcher (OL) and another masters student (MS). They have been audio-recorded and transcribed. In the first step of the heuristic study, we decided to select 5 out of the 10 interviews so as to analyze a reduced amount of data and to make the search for criteria to analyze the whole set of data easier (Glaser & Strauss, 1967). The analysis of the 5 interviews produced 5 profiles that are illustrated in the next sections. The analysis allowed us to better define the nature of the trajectories that characterize each student's way of navigating the classroom corridor.

## Results

Confrey's distinction between "corridors" and "trajectories" is strongly evocative in pointing out the different roles of the teacher and the students in the teaching/learning episodes. In the design phase of the study on thermodynamics, the distinction was taken as a synthetic way to emphasize the need both of assuring an active role to the students in constructing their own learning trajectories, and of dedicating research and teaching efforts in designing learning environments (corridors) able to foster a resonance between the growth of the individual intellectual autonomy and the collective classroom progression.

A major research product of the construction of the students' profiles was the tentative redefinition of the concept of trajectory that appears to enable us both to extract deeper information from data and to contribute to the development of a theoretical frame of analysis.

At the present level of the analysis, in order to share and discuss with other researchers the results of our attempt at better defining the concept of trajectory, we think it useful to report the 5 profiles reconstructed from the interviews with the students. For this purpose we also include whole original sentences from the students' protocols so as to respect to the extent possible, the students' style of argumentation.

### Michele: Actuality of real life and curiosity for "how things work"

Michele, at the end of his interview, summarizes very clearly his position: "*I like Physics because it explains <u>how reality works</u>, so to say, I'm very curious about <u>how objects work</u> and natural events…*".

Next year Michele will start Engineering at the university. His interests are already precise. The topics that were most impressive for him were the definition of temperature and the kinetic theory of gases that "*better explains the causes, that is what temperature is, the very word, whereas in the macro* [approach] *we study the effects without being able to give a satisfactory explanation of the word*", but even more the Carnot Cycle: "*real life is there, let's say, these processes, the engines working through these cycles, therefore I was more interested in connecting it to real life than in knowing exactly what it is*".

He had previously been highly interested in classical mechanics, getting very good marks on it: *"we were looking for causes there"* as he said, it was a *"framework"* for understanding *"things of the real world"*, like engines, he was very keen on. While studying thermodynamics he was very quick in dealing with formal steps for expressing ideal gas laws at microscopic level and in studying heat engines. His out-of-school interests and his personal objectives have driven also his school-work that gives him satisfaction.

Also because of his very precise motivation, Michele played an important role in the classroom dynamics by taking a very clear position both in favour of the microscopic approach to the first law and in favour of the macroscopic approach to the second law: He became a stable and respected reference, often opposed to Matteo's position.

In spite of his precise preferences, Michele expressed his interest in the whole teaching path, because "the two ways led to reality" and gave an example of how "scientists work":

"*It seemed to me very interesting for understanding…. these two different ways to manage to arrive to principles, to how reality was investigated. It was very interesting to me also for understanding how scientists work, how Einstein, Poincaré worked…"*

### Matteo: The pleasure of speculating and the search for approaching science from a "humanistic" point of view

The sentence that better summarizes Matteo's position is: "*I take for granted that <u>it is fundamental to speculate on reality and life</u>, because when you see phenomena and you get formulas out of that, then you have nothing, no foundation on which to stand. […] I believe that in order to find a way to understand a method to reach a reality […] it is fundamental to build a basis and <u>to speculate on how theories are found</u>, how concepts are elaborated. These concepts will certainly last longer than some formula."*

Matteo appears to like neither the formal elements of physics, "*too abstract*", nor the science claim to arrive at the truth: "*In my opinion Physics should not aim at truth, it should only […] be useful for mankind […]. To try to believe it possible to find in phenomena the foundation of truth is, I believe, an assumption out of the physics domain*".

The main point of his argument is that, in doing science, "human" and "far from reality" frameworks are projected on the world: *[…] <u>the sciences seem to me mainly human constructions</u>, I mean the way man has to investigate nature, to try to explain, may be without understanding that we cannot explain nature because we* *are human, we can only explain by the means we have… [and these] in my opinion are not powerful enough to catch the laws of nature… they are all human constructions that seem to me very inaccurate*".

Matteo played a role in the discussions similar to that of Michele, taking very precise and opposite positions to Michele's ones by criticizing the kinetic theory of gases and the microscopic approach in general: "*yes, the approach I prefer, you may already know, is the macroscopic one, because it stops at observing what happens and does not try to investigate reality, does not aim to understanding how these things happen from the inside, like the microscopic theory does by probing the bodies and finding some particles that move the same way… strange things*".

His opinion of science takes a positive turn when Matteo judges the epistemological activities carried out in the classroom. The topic he particularly enjoyed was the concept of irreversibility connected to the time arrow: "*yes, it is exactly this about entropy, where it develops a way of looking at the world which is a little less naive, because we see that the world is becoming, that some things that happen cannot be transformed… taken back to how they were: people get older, the table falls over, the cup breaks… cannot be put together again and here is a key concept to manage to accept even somehow reality, trying to explain everything following the path we went with these laws of mechanics, which is an odd idea, because mechanics laws are reversible and therefore there is no reason for a time line and for the time to go ahead; this may be a too philosophical way of looking at reality, because this way of refusing the becoming of being, of wishing to explain everything, the fact we understand that something cannot be explained, that there is this time advancing, this becoming that cannot be reduced to a being, may be this is something I enjoyed, I mean I enjoyed it*".

**Lorenzo: The pursuit of a unified consistent view of physics**

Lorenzo makes his position explicit by saying: "*One can see that everything is resumed, it is <u>not divided in topics</u> each with its own laws, instead everything can be <u>connected, unified</u>; the argument becomes <u>wider, more uniform</u>*".

Lorenzo appreciated the macroscopic construction of the ideal gas equation because of its unifying nature: "*It was rather quick, with those three laws [Boyle's and Gay Lussac's ones] we quickly arrived to the ideal gas law"* and its link to mechanics ("*trying to explain again temperature by referring to particle dynamics*). He confirms his position when talking about the comparison of the two approaches: "*that in the end I managed to understand which elements I prefer of one and of the other… I preferred one for some features and the other for some others, in the end I managed to make everything uniform, therefore I understood the whole argument rather clearly, thanks to these two ways*".

"Understanding" means, for Lorenzo, "connecting", "unify in a general framework". His focus of attention is the systematic pursuit of consistency: to solve contradictions, to get rid of spurious elements, by bringing everything back to the simplest possible framework (in his opinion mechanics is the simplest theory).

Lorenzo admitted to have met serious difficulties in completing the questionnaire at the beginning of the teaching path: the key was lacking for giving a unified structure to the lot of information contained in the excerpts. The comparison between the two different approaches proved very satisfactory to his needs: "*…when I read it again (the questionnaire) […] I immediately associated microscopic thermodynamics to the constructive type of theory, at once did it come to me….. and I read them (the excerpts) in an altogether different way, … and it was all clearer than the first time, I managed to connect and realized immediately that something had changed… […] and I felt satisfied… because I had then only to read… whereas the first time it had been hard, it took the whole afternoon, I had to read it many times, many passages were obscure….*".

He concludes by saying: "*[…] I noticed a big difference between reading it at the beginning and at the end, I mean that hadn't I read it at the beginning I might not realize all the work we have done*".

Lorenzo played indeed a fundamental role in the final discussion about the questionnaire: his need for consistency was a basic support to reflection and an incentive toward pointing out "contradictions" of the overall reasoning (the "jarring notes").

**Chiara B.: "Understanding as seeing" and the systematic effort of widening "one's own views" looking for and testing "new points of view"**

In the final discussion on the questionnaire Chiara said: "*We have analyzed thermodynamics from both perspectives, <u>looking</u> at differences and similarities, I mean we have two different <u>points of view</u> ... it may be more complete to try to analyze a phenomenon, or whatever is around us, from two different <u>points of view</u> rather than from one and therefore this teaching path widens what we've done. It widened <u>my view</u>*".

"To understand", for Chiara, means "to see". Her interview is full of this metaphor. The comparison between the two approaches, the two "points of view", as she says, takes a more general, social and cultural meaning. In learning physics, the comparison has been very interesting because it gave various opportunities to "play" between the real and the ideal and to use her metaphor of "seeing": from empirical observation of reality to the investigation through the microscopic approach, of what can only be seen with the "mind's eyes".

"*Talking of the concept of temperature... one* [approach] *is more tangible, more real, because you see it with a thermometer, you measure, you say «yes, there is a change in temperature, I see it, I understand it», but* *also the microscopic one is useful [...] The particle movement, for instance, I cannot see it in a thermometer, only going to the micro can I see this movement*".

Therefore the microscopic approach has been useful from a personal point of view: "*Not so much for better understanding the macro, that I found easier, but because it gave me a different point of view*".

Her attitude towards physics comes out also when she speaks about irreversibility. In the following sentence Chiara expresses her surprise in finding also in the concepts of irreversibility the overturn of reality that allows physics to go beyond appearance: "*[I liked] entropy because it was interesting this business of irreversibility and reversibility of phenomena, ... I told to myself «what a strange thing: phenomena are irreversible, there is a before and an after, but I take them for reversible and also here I make another ideal model, I consider them through other processes», I mean.... it's* <u>*some kind of overturn*</u> *always in physics and that's what I like...*"

Chiara plays an important role in both classroom discussions on the questionnaire because of her passion for "*seeing other people's points of view*", for "*widening one's own view and avoiding getting fixed on some issues*".

**Chiara C.: Focus on details and search for "not obvious details that are taken for granted"**

"*I like physics because I sometimes happen to ask myself... I mean I am rather curious about how things happen*". What Chiara seems to like the best of physics is that "obvious things are not taken for granted".

Of the thermodynamics corridor she enjoyed everything "<u>*that made me notice something I had not noticed before*</u>", like the meaning of measuring an apparently obvious quantity like temperature or the fact that "*a true theory is the one, like thermodynamics, that manages to give the same results from both approaches* [... I believe that] *a theory that really works is the one that manages to compare the two ways that can be verified*".

Chiara pays attention to the smallest details that she keeps under control to be sure that the constructed model of reality is not too idealized or unfounded. "*In the microscopic I liked and disliked at the same time this business of the model of a discrete gas, ideal, rarefied...*". What she dislikes of the model is the idea of "perfection" that appears to give a too ideal and simplified image of reality, neglecting too many details. What she likes is "*to be able to think to a model we can make experiments on and to create such a perfect model that everybody would be able to imagine a thing like that*".

Once she has been reassured that the model is rooted in reality, she can appreciate it for making her notice details she had not noticed before: "*I liked the macro best because* <u>*it made me think of things that I took for granted*</u>*, whereas I liked the microscopic because there is this model that makes you think, because if you focus on all the passages to arrive to the final law, we had to take into account a lot of things*".

Chiara played an important role in classroom dynamics because of her attention to details that, when recognized by all students, became catalysts of the discussions.

The idiosyncratic nature of the way each student reacted to the teaching proposal is evident from the excerpts as well as his/her ability to move within thermodynamics showing confidence and competence on the topic (appropriation).

What features of the profiles allow us to say that they constructed their own trajectories within the classroom corridor?

Looking again at the profiles in order to answer to this question we identified a set of criteria that we implicitly used in tracing the profiles and that could be used as an explicit tool for re-analyzing the whole set of data in terms of students' trajectories:

- the line of thought is *explicit* in the words of the student;
- the line of thought is *consistent* across the whole interview;
- the specific approach to disciplinary knowledge is *not occasional* (it can be traced back to the student reaction in various classroom activities);
- the arguments are *on-task*, referring to selected aspects already present in the classroom corridor;
- the keywords, around which the student constructs her/his arguments, reveal personal engagement, by being *genuine* and *emotion-laden*.

## 4. Final reflections and implications for research

The heuristic study here presented started from a "framework for action" (diSessa & Cobb, 2004) that we developed according to the MLD produced within the Italian project F21. Such a framework oriented us in designing and managing the learning environment as properly complex territory. As far as the research questions are concerned, the study presented here shows that the learning environment really proved to be able to foster students' intellectual autonomy. More specifically, the profiles outlined from 5 interviews allowed us to point out specific features that characterize the individual trajectories with respect to the classroom corridor. In this sense the results, although preliminary, represent an advancement in knowledge on design studies. The results moreover illuminate some foci of attention for analyzing the data and they point out the need for programmatic and iterative investigations over time along different directions:

1. *Re-shaping the framework for action in more detail* and designing future experiments on teaching/learning thermodynamics as "successive iterations that can play a role similar to systematic variation in experiment" (Confrey, 2006). At present, two new experiments are planned: Experiments where the same corridor and the same tasks are proposed to 17-year-old students by different teachers in a different school. This will be the opportunity for testing the effects that the new awareness about students trajectories can have: Their existence can indeed encourage teachers to foster their construction by the students but it can also affect the deeply genuine character of the trajectories described here. In any case, we expect the comparison of these variations of the same experiment to provide new hints for studying the classroom dynamics by cutting the process on the joint that lies between corridors' and trajectories' features.
2. *Analyzing trajectories within the more general problem of conceptual change* and, more precisely, within the problem of *a longitudinal approach to "appropriation" of science ideas*. Meaningful learning of a topic requires, in a quite obvious way, a long-term process of appropriation. By appropriation we mean the process leading to enter a topic deeply – and extensively – enough to see that topic in a personal version. In other studies about appropriation, concerning teachers coping with innovative research proposals (De Ambrosis & Levrini, submitted), it has been pointed out to what extent an appropriation process, that requires one to find one's own point of view, is a problematic task because of the complex dynamics of finding criteria for coherence between (critical) details and a global perspective (Viennot et al., 2005). The students' trajectories described above seem to have all the features of an appropriation process, because of the personal, genuine, character as well as the coherence they have in situating contents details in a global framework sensible to them. The specific point of how, why and under what conditions the construction of personal trajectories is connected to deep understanding (conceptual change) deserves future research studies, both on the data examined in this study (by strictly crossing the personal trajectories and the contents comprehension), and on other data where, for example, the personal trajectories seem to distort the learning of a concept and where the process of appropriation and/or conceptual changes seem to be problematic and/or unsuccessful.
3. *Individuating the factors that can trigger intellectual autonomy* by the construction of personal learning trajectories. A study on "personal excursions"[1], in spite of their different features with respect to students' trajectories, inspired us in the search for those factors that can made the trajectories' construction possible (Azevedo, 2006). In agreement with Azevedo, we think that such factors need not to be identified at a too general level: They have indeed "to operate at a level of specificity that allows for a satisfactory explanation of the dynamics patterns characteristic of personal excursions [personal trajectories, in our case]". Following his suggestions, we think that, as a preliminary answer to the third research question ("What features of corridors, teaching strategies and/or collective activities can trigger the construction of personal trajectories?"), the following factors can be identified:
    - *the specific feature of the content reconstruction* that, by means of the comparison between two different approaches (macro and micro), is able to create a collective dynamics where students are involved with different roles (as partisans, opponents, moderators, disrupters, facilitators, …). Such a dynamics seems to have a productive power in making each student to find her/his more congenial path and progressively to test and refine it.
    - *the features of the activities specifically addressed to activate an epistemological meta-discussion* of the peculiarities of the two approaches. Although unusual, unfamiliar and demanding, the design of such activities has been always carried out in such a way that students could find themselves in their "regime of competence" (diSessa, 2000, quoted in Azevedo, 2006): Activities where they could approach the new epistemological language by applying it to physics domains previously studied.
    - *the choice of the teacher*, made explicit to the students, *to evaluate* their performance in the epistemological activities, by taking into account not "what they wrote or said in specific", but *their level of involvement*, the *coherence of their thinking* and the *contribution they are able to give in the collective discussions*.

All these factors deserve further studies specifically addressed to improve our theoretical understanding of students' trajectories. So far they seem to suggest that students' trajectories are stimulated and become evident in contexts where the whole teaching proposal is systematically developed and managed by the teacher through actions directed to move the learning problems from a plan where only “right-wrong”, “yes-no”, “bad-good” answers are possible, to a plan where the problems themselves, although respecting the shared disciplinary knowledge, admit an analysis in terms of critical evaluation of different possible, consistent, “points of view”.

## Endnotes

(1) Personal excursions are defined by Azevedo as self-initiated, self-directed, self-motivated and relatively long-term activities, belonging to a student’s trajectory but task-off with respect to the classroom corridor. They represent “key events whereby students connect, in a deep and personal way, to the subject matter and overarching goals [of the unit proposed to them]” (Azevedo, 2006).

# Designing Assessments to Track Student Progress

Namsoo Shin, Shawn Y. Stevens, & Joseph Krajcik
University of Michigan, Ann Arbor, MI
Email: namsoo@umich. edu, sstevens @umich. edu, krajcik@umich. edu

Learning scientists have embraced the idea of using learning progressions for the development of assessments to monitor learning over time. Using LPs to develop assessments requires an iterative, process-oriented approach, and involves design products that work in real contexts. This proposal illustrates a design research process, Construct-Centered Design, for the development of assessment tasks to track the long-term development of student learning for a core idea in science – the transformation of matter. Fifty-six items of various types were designed to measure student understanding along the lower levels of a LP. We iteratively collected cross-sectional data from 500 middle students for developing, piloting, and revising the assessment items. We conclude the paper by discussing the strengths of and weaknesses of this process for measuring students' understanding across levels of the LP. The ultimate value of this work will propose the design process of assessment to track student learning.

Learning scientists have emphasized the importance of intensive research for addressing theoretical questions about the nature of learning in context and producing *evidence-based claims* to support their theoretical questions (Collins, Joseph, & Bielaczcy, 2004). Moreover, for valid evidence-based claims, researchers need to consider student learning over an extended period of time because learning challenging content takes years to develop (Stevens, Delgado, & Krajcik, 2009; Duschl, Schweingruber, & Shouse, 2007). Such research requires the development of assessment tasks (e.g., interview protocol, test item, observation instrument, survey) that can track student progress over time in real contexts rather than simply examining isolated variables within laboratory contexts (Brown, 1992; Barab & Squire, 2004) or memorized fragmented pieces of knowledge. However, to develop such assessment tasks is challenging. The learning science community needs models that illustrate principled and systematic ways of doing so. Recently, the science education and learning science communities have embraced the idea of learning progressions (LP) to provide a guide for monitoring student learning over time (see for example, Smith et al., 2006).

Learning progressions are research-based descriptions of how students may build their knowledge, and gain more expertise within and across a core idea over a broad span of time (Duschl, Schweingruber & Shouse, 2007; Smith et al., 2006). They illuminate how learners can develop and connect concepts within and across disciplines as they progress towards a more sophisticated understanding of the key concepts and skills necessary. As such, LPs can provide a potential path for students to develop understanding of core ideas over time, and can guide the alignment of instructional materials, instruction and assessment in a principled way to support the development of integrated learning (Duschl, Schweingruber, & Shouse, 2007; NRC, 2006 & 2007; National Assessment Governing Board, 2006a & 2006b). A LP contains three key factors: a lower and an upper anchor to define the range of content within a core idea and defined levels of understanding between the lower and upper anchors (Smith et al., 2006; Stevens, Delgado, & Krajcik, accepted). The levels of a LP specify not only the order in which students develop understanding of the important concepts, but also how they *interconnect* and *reason with* the important concepts between related ideas.

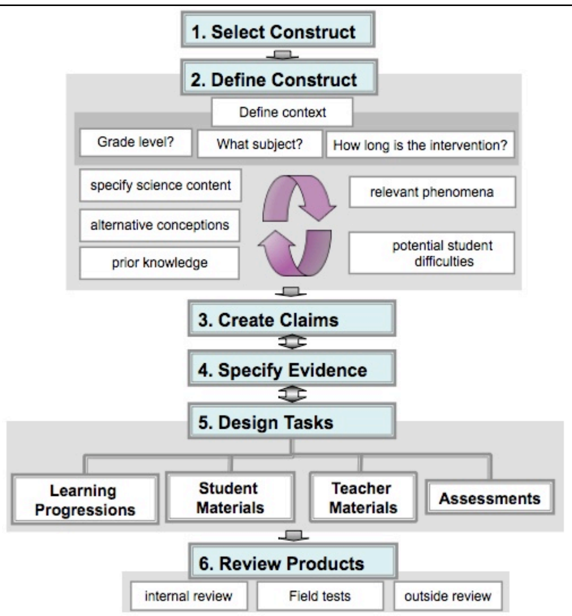
However, developing assessments that align with a LP requires an iterative, process-oriented approach, and involves designing products that work in real contexts. Because there are no such ready-made LPs, an iterative process of building, validating, and revising LPs and associated assessments using exemplary instructional materials is critical. Because learning is a complex process, many factors affect the path that students may follow as they build understanding, including the learning context, instructional materials, instruction, and students' prior knowledge and experiences. Thus, in order to build LPs and associated assessments, empirical data need to be collected from students who have experienced curriculum materials that were developed following LPs and learning principles. This helps us to ensure that students' lack of understanding is not because of inadequate learning experiences, but because of the developmentally challenging ideas students are expected to learn. Well-developed coherent curriculum materials and associated assessments based on a LP should be designed, implemented, and tested iteratively throughout the process of refining a LP. In addition, intensive research is needed to better characterize student understanding because gaps in learning research still exists. These gaps need to be filled prior to building LPs. In sum, developing assessment tasks using LPs is a complicated process and requires thorough, longitudinal studies related to how students learn core ideas over time in diverse contexts. A principled research design process should guide the complex, iterative process of developing assessments along an LP.

In this paper, we illustrate a research design process that can be used to develop assessment tasks to track the long-term development of student learning for a core idea in science – the transformation of matter.

We explore the following research question: *How can assessment tasks be developed that monitor student learning over time and that assign where student understanding lies along the LP?* Based on our previous work, we propose using Construct-Centered Design (CCD) (Shin, Stevens, & Krajcik, 2010; Pellegrino, et al., 2008) to develop assessments based on LPs. Because CCD focuses on the construct that students are expected to learn as well as what researchers and teachers want to measure, the CCD process provides a flexible and systematic approach for guiding product development, monitoring the development process, and examining the effects on learning outcomes. Next, we describe the foundation of CCD and present how the CCD process applies to the development of assessment to track student understanding in a LP. Finally, we conclude by discussing the strengths of and weaknesses of the process.

## Research Design Process: Construct-Centered Design

A research design process to guide learning research and the development of products should provide flexibility for (a) mapping out the constructs associated with core ideas and (b) developing assessments and instructional materials that support and measure how student understanding develops over time. Thus, a design model should emphasize both defining constructs for instructional material development and specifying evidence for assessment development. By modifying and adapting the learning-goal-driven design (LGD) process for developing construct-focused curriculum materials (Krajcik, McNeill, & Reiser, 2008) and the evidence-centered design (ECD) model for developing assessments (Mislevy & Riconscente, 2005), the CCD process provides such a model. The CCD process begins with specifically defining the focus of the construct. We define the construct as the core ideas that students are expected to learn and researchers and teachers want to measure (Messick, 1994; Wilson, 2005). Because the foundation of the process focuses on the description and explicit specification of content that lies within constructs, the process is termed construct-centered design (CCD). In describing the process, we do not mean to imply this is a linear process. In practice, the process is interactive and highly recursive, with information specified at one step clarifying and often modifying what was specified earlier. Figure 1 illustrates the CCD process. A detailed description follows.



<u>Claim:</u> Student should be able to distinguish between matter and non-matter and justify their conclusions

<u>Evidence</u>: Students' evaluations and justifications should include the following criteria:

- Matter takes up space and has mass (has weight in a gravitational field)
- Matter can exist in three different states–solid, liquid and gas. The same substance can exist in all three forms under specific conditions

<u>Assessment task (multiple True or False item)</u>

Do you consider the following to be matter?

| | Yes | Not sure | No |
|---|---|---|---|
| a rock | | | |
| an idea | | | |

(…grain of salt, heat, a wish, air, a tree, a shadow, particle of chalk dust, beam of light, image in a mirror, smoke, helium inside a balloon, a cloud)

Which criteria are true of all matter?

| **Criteria** | **True** | **Not Sure** | **False** |
|---|---|---|---|
| Whether you can see it | | | |
| Whether you can touch it | | | |
| Whether it takes up space | | | |
| Whether it is alive | | | |
| Whether it is a solid | | | |

<u>Figure 1.</u> CCD process, Claim, Evidence, and multiple True or False Item example

### Select and Define the Construct

The first step in CCD is to choose the construct and define the target learners (see Figure 1, step 1). The construct is essential as it identifies the set of ideas for which learners will study and develop understanding. Because students at different grade ranges have different knowledge and experiences that influence their learning, defining the target students helps define the construct appropriately, and also guides preparation of level-appropriate instructional materials, instruction and assessment. The construct of our LP is the transformation of matter and includes core ideas associate with the atomic model and the interactions between atoms and molecules as they undergo various transformations. To help define the range of content that needs to be unpacked, the lower and upper anchors for the LP were defined. In this case, the lower anchor was defined using the learning progression for atomic molecular theory for grades K-8 (Smith, et al., 2006), and additional empirical research. The upper anchor of the LP was defined based upon national standards (AAAS, 1993; NRC, 1996), ideas required as a foundation for nanoscale science and engineering learning for grade 7-12 students (Stevens, Sutherland, & Krajcik, 2009) and current learning research related to those ideas.

The next step is to define the construct based on expert knowledge of the discipline and related learning research (see Figure 1, step 2). This process, called unpacking, involves defining the ideas contained within the construct. By unpacking, we mean breaking up the construct into smaller components to explicitly specifying the concepts that are crucial for developing an understanding of the construct. Being related to the construct is not enough; the concept must be necessary for building understanding of the construct. The depth of understanding that is expected from students is also clearly defined in this step. As a step towards defining *how* students should know the content, the prior knowledge that is required both within and from other related constructs is also specified. The unpacking process also includes: identifying potential difficulties students might have learning the content; specifying and clarifying non-normative ideas that might interfere with students learning the content; providing possible phenomena that may help student learn ideas and develop their understanding; and identifying strategies for effectively representing the concepts based on previous learning research. The concepts within the constructs were then unpacked to define what it means to understand them at levels appropriate for grade 7-14 students.

<u>Characterizing How Students Develop Understanding</u>

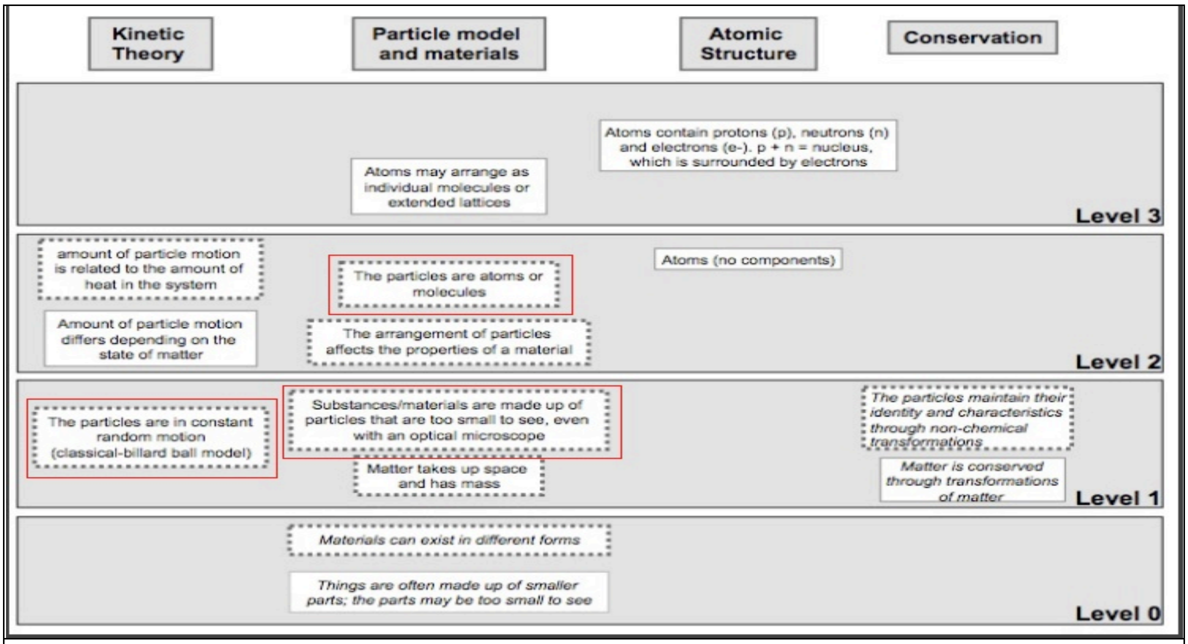
In the process of unpacking the construct, the current evidence-based learning research was not sufficient to completely define the levels of student understanding, possible non-normative ideas, and difficulties related to the developing understanding of the construct. To help fill gaps in the learning research related to the construct, an interview protocol was developed based on the CCD claim and evidence steps to characterize how ideas related to the transformation of matter developed as grade 7-14 students passed through the current curriculum (see claim and evidence sections for further details). A cross-sectional sample of students (N=79) representing the range of grades in our target population was interviewed. In this case, seventh grade students and high school students from the same district or school system were interviewed individually. At each level, we chose students who provided a mix of gender and a range of achievement levels. A 20-30 minute semi-structured interview was conducted with each student to characterize understanding related to sub-constructs of the transformation of matter. The interview questions required students to apply their knowledge to explain real world phenomena. The interviews were conducted in several phases. After each phase, student responses were evaluated and the protocol was revised to better characterize student understanding of the construct. The results of this study inform the strategies that may help students move along the LP. They provide information about how students develop understanding of the construct, and where they have incomplete knowledge. We used the results to describe prior knowledge about student learning using current instructional materials, and identify difficulties and non-normative ideas students hold regarding the content. Understanding students' ideas is critical in determining when and how it might be appropriate to introduce the concepts to students. In addition, knowledge of non-normative ideas aids the development of assessments that measure students' progress (see Stevens, Delgado & Krajcik, 2009 for detailed results).

## Create Claim(s) and Specify Evidence

A set of claims is generated based upon the unpacked construct and student data. Claims specify the nature of knowledge and understanding expected of students regarding a particular construct (see Figure 1, step 3). In constructing a claim, vague terms like *to know* and *to understand* are not used. Rather, claims specifically define what cognitive activities students will need to apply to respond to the task (e.g., Bloom's taxonomy; Bloom, 1956). For example, students should be able to provide examples of phenomena, explain patterns in data, construct explanations, or develop and test hypotheses. An important part of student learning involves the ability to connect ideas and apply knowledge to new situations (Bransford, Brown & Cocking, 1999). Therefore, it is important that the claims specify how students should connect ideas both within individual sub-constructs, and among related sub-constructs in order to describe how students build integrated understanding of the construct. The evidence specifies the aspects of student work (e.g., behaviors, performances) that would be indicative that a student has the desired knowledge to support a specific claim or set of claims (see Figure 1, step 4). In particular, this step explicitly defines the expected level and depth of understanding that the target learners should demonstrate. The understanding defined by the evidence provides a guide for specifying levels in the LP.

## Design Tasks

The tasks, which are generated based on the claims and evidence, provide a response that offers appropriate evidence to support the relevant claim (see Figure 1, step 5). The tasks can be either learning products that will help learners develop the knowledge in the claim, or assessment products that measure whether learners hold the knowledge stated in the claim. The assessment tasks are designed to elicit or generate students' performances to allow for a judgment to be made about whether sufficient evidence exists to support the learning *claim*. A single assessment task may provide evidence for more than one claim; multiple tasks may be necessary to assess a single claim. A single task or set of tasks can be associated with a claim or a set of claims assigned to multiple levels on the LP. An individual claim, its evidence and corresponding task may link to a single level on the progression. The right column in Figure 1 provides an example of a claim, its corresponding evidence and assessment tasks. Based upon the claims and evidence, we developed the first version of a LP (see Figure 2 for a portion of the LP).



**Likert-type item: The following are possible characteristics of atoms and molecules. Mark whether the statements are true or false.**

| Statement | T | PT | NS | PNT | NT |
|---|---|---|---|---|---|
| 1. At 75°F (~24°C) molecules and atoms are always moving. | | | | | |
| 2. Molecules are all the same size. | | | | | |
| 3. Molecules that make up ice cream are very cold. | | | | | |
| . | | | | | |
| 21. A balloon is filled with water. When squeezed the balloon changes shape. The pressure from squeezing also changed the shape of the water molecules. | | | | | |
| 22. The atoms in solid copper metal are hard. | | | | | |

T: true, PT: pretty sure it is true, NS: not sure, PNT: pretty sure it is not true, and NT: not true

Figure 2. A portion of LP and Likert-type item for measuring Level 1 and 2 of the LP

## Develop Assessment Items to Measure Levels of Understanding in a Learning Progression

The claims and evidence specify how students should be able to connect ideas both within a sub-construct, and among related sub-constructs in order to describe how students build integrated understanding. The claims and evidence can be used to refine the levels. Figure 2 illustrates part of the LP for the transformation of matter. In figure 2, the dashed boxes represent the content for which we are developing assessment tasks. The red color boxes correspond to the assessment item in the figure. The levels in the LP represent a set of ideas that describe a path towards developing a more complex understanding of the construct. The set of ideas within a level connects to explain a range of phenomena; higher levels describe the phenomena with greater scientific sophistication and completeness. In this way, the levels of the LP describe increasing levels of understanding. Further research is required to examine whether the order in which students learn concepts within a single level is important.

Based on the LP, we developed assessment items to locate the level of student understanding in the LP. Because the development of assessment items is a challenging activity, our design process will take several iterations to develop assessment tasks that will track student from the lower anchor to the upper anchor. In the first iteration, we focused on the development of assessment items for the lower level including levels 1 and 2. When possible, we selected previously published items that supported claims and evidence appropriate for the target students and modified them as necessary; otherwise, we designed and developed new items. We evaluated the items using the criteria of sufficiency, necessity and age appropriateness (Deboer, et al., 2008). We then revised the item stems, answer choices, and associated representations to ensure they support the claims and evidence associated with the lower levels of the LP and to ensure that text and representations were level appropriate. Fifty-six items using various item types (e.g., two-tiered, multiple true and false, complex multiple-choice, and Likert-type scale) were designed to measure how well students apply ideas within and across the sub-constructs. Although in future iteration, we will develop open-ended items, in the first Iteration, various item types as listed above were employed to develop assessment items that measure carefully and efficiently student understanding across grades 7-16 (Scalise, & Gifford, 2006) (see Figure 1, 2 and 3 for example).

## Review Products

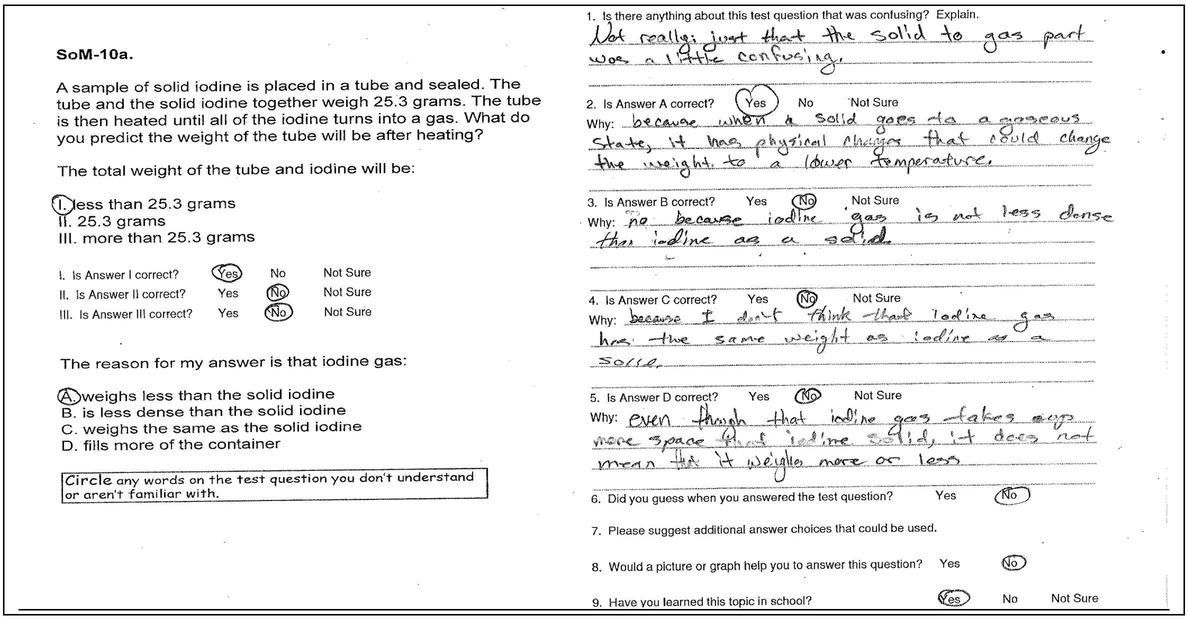
The next CCD step is to review the products. For each step within this iterative process, the products are reviewed internally and when appropriate, externally (see Figure 1, step 6). The internal review focuses on critique and revision of the products to ensure that they align with the claims and evidence. External review includes feedback from teachers of the target students or from content or assessment experts. Conducting pilot tests and field trials with target students is an essential component that provides invaluable information about the products.

### Pilot Study

In order to ensure that students interpret the questions and associated representations as intended, we piloted the items with 479 middle school students (grades 6-8) from three schools in two distinct communities representing a range of race, ethnicity and SES. The cross-sectional design ensures that items measure the understanding of students with a range of knowledge and abilities. A range of different types of assessment items can provide information about students' understanding. The different types of items vary in complexity (e.g., matching < categorizing < ranking and sequencing < assembling proof) and in the amount in which learners' responses are limited or *constrained* (e.g., traditional multiple choice vs. open-ended essay; Scalise & Gifford, 2006). Items that are more constrained are easier to score, but likely provide less information about student understanding and higher-order reasoning. In this pilot study, we investigated "*what are the advantages and limitations of different item types for measuring student understanding across Levels 1 and 2 of the LP?*" Each student was given a test form containing four to five items. We piloted each test item with 30-35 students. The piloted items were each accompanied by a set of questions to explore how students interpreted the item (Deboer, et al., 2008). Figure 3 illustrates the questions that accompanied the two-tier multiple-choice questions; slightly different sets of questions accompanied different item types.

We analyzed each item using a simple descriptive analysis, a classical item analysis and an Item Characteristic Curve analysis that focused on identifying item clarity. For the descriptive analysis, we created five categories: confusing words in an item, confusing item stem, reasons for choosing their answer, percent who correctly answered an item, and helpfulness of representation. We carefully reviewed the items that students answered correctly more than 80% and approximately less than 30% in order to investigate whether the items are too easy or difficult for target students, or are written poorly. Figure 3 provides an example of student responses to an item. In this case, students answered correctly 24% in the first-tier question and 33% in the second-tier question. This item posed conceptual and literacy difficulties for students. Because the item involved not only the idea of conservation of matter but sublimation as well, we judged that it might be a level 3 item, as students did not seem to understand the phenomenon of sublimation described in the item. Other students did not know that "iodine" could be a solid. In addition to ensuring that our pool of items were written clearly and at an appropriate level, student responses helped ensure that there is only one correct answer and provided an evaluation of the distractors. After the initial descriptive analysis, we then conducted an additional review of the two-tier multiple-choice and multiple-choice items using classical item analysis and Item Characteristic Curve (ICC). For the classical item analysis, we focused on the correlation between the individual item score and the total score of the test. Then, we reviewed the ICC of each item to investigate how well an item differentiates between students having ability below and above the item location using dichotomous data (1=correct, 0=incorrect), and how students respond to the distractors of the items using polytomous data (raw responses = 1, 2, 3, 4). These analyses helped us to revise each item stem, as well as the distractors for each item. For example, the results indicate that the two-tier item type was not appropriate for measuring middle-school students understanding because the students were confused about how they should answer the question, and the item did not provide additional information than when only using the second part of the two-tier question. We speculate that middle school students are not developmentally ready to interpret the structure of such an item type. We decided to conduct a future investigation for this item type because our finding is inconsistent with Treagust's study using high-school students (Treagust & Chandrasegaran, 2007)

We conducted an additional analysis to investigate the characteristics of the item types on measuring student understanding along the LP. First, we developed items using two different item types (multiple-choice and multiple True and False (T/F)) to compare how students perform differently on the two item types and whether the two item types provide similar or different information. We assessed student understanding using a Multiple T/F list as opposed to a series of multiple-choice questions for gaining insight into connections and/or the complexity of student understanding (see Figure 2). The results show that most high-ability students responded that the multiple T/F item type is more difficult than multiple-choice items. They reported that they have to think carefully before responding to the item because they need to respond to every answer rather than to select a single correct answer. Therefore, the multiple T/F item type may better assess student understanding because they cannot rely on test-taking skills such as answering a multiple-choice item. In contrast, a majority of low-ability students responded that the multiple T/F is easier than the multiple-choice item because they is not just one correct answer.



SoM-10a.

A sample of solid iodine is placed in a tube and sealed. The tube and the solid iodine together weigh 25.3 grams. The tube is then heated until all of the iodine turns into a gas. What do you predict the weight of the tube will be after heating?

The total weight of the tube and iodine will be:

I. less than 25.3 grams
II. 25.3 grams
III. more than 25.3 grams

I. Is Answer I correct? Yes No Not Sure
II. Is Answer II correct? Yes No Not Sure
III. Is Answer III correct? Yes No Not Sure

The reason for my answer is that iodine gas:

A. weighs less than the solid iodine
B. is less dense than the solid iodine
C. weighs the same as the solid iodine
D. fills more of the container

Circle any words on the test question you don't understand or aren't familiar with.

1. Is there anything about this test question that was confusing? Explain.
Not really; just that the solid to gas part was a little confusing.

2. Is Answer A correct? Yes No Not Sure
Why: because when a solid goes to a gaseous state, it has physical change that could change the weight to a lower temperature.

3. Is Answer B correct? Yes No Not Sure
Why: no because iodine gas is not less dense than iodine as a solid.

4. Is Answer C correct? Yes No Not Sure
Why: because I don't think that iodine gas has the same weight as iodine as a solid.

5. Is Answer D correct? Yes No Not Sure
Why: even though that iodine gas takes up more space than iodine solid, it does not mean that it weighs more or less.

6. Did you guess when you answered the test question? Yes No

7. Please suggest additional answer choices that could be used.

8. Would a picture or graph help you to answer this question? Yes No

9. Have you learned this topic in school? Yes No Not Sure

Figure 3. Two-tier type item and accompanying questionnaire with student response.

Second, we analyzed the relative difficulty of the Likert-type and multiple T/F items to explore how they measure the range of understanding for each level of the LP using Item Response Theory (IRT). We used a series of 14 T/F questions to measure how well students distinguish between matter and non-matter (See Figure 1). We treated each statement as a separate individual item of the multiple T/F item for the analysis. We reviewed the difficulty level of the items by examining a Wright map (Wilson, 2005) and an item fit output to ensure the items measure across Level 1 and 2 of the LP. The Wright map showed that item difficulty ranged between logit -2 and 1 out of a range from – 6 to 6. The – 2 to 1 range is consistent with our intention of measuring Level 1 and 2. A logit takes into consideration both the ability of respondents as well as the item difficulty in assigning a task to a particular location on the Wright map. In addition, we found that virtually all students classified the solid forms of matter–rock, a grain of salt, a tree and a particle of chalk dust–as matter. The item difficulty levels are very similar between logit -1 and 0. In the revision of the item, we streamlined the list by removing three of these objects since they were not providing additional information. The other part of the question was designed to gain information on students' reasoning as they distinguish between matter and non-matter. Students were asked about the criteria necessary for something to be classified as matter. Students in the first pilot suggested the "whether it's a solid" as a possible criteria. We found in subsequent administration of the item that it proved to be an effective distractor. We created a Likert-type item that surveys a range of ideas related to the atomic and kinetic theories based on a survey created by Harrison and colleagues (Harrison, Kease, & Voss, 2006) to efficiently measure students' models of the structure of matter (see Figure 2). Their difficulty levels are between logit -1.5 and 1.5, which is the range for Levels 1 and 2. Twenty-one statements were spread evenly across three logits on the Wright map. From the findings, we conclude that the Likert-type and multiple T/F type items can be used to measure a range of student understanding along the LP without spending significant testing administration time or giving up probing student reasoning.

## Interview Data

After data analysis, we selected problematic items where the difficulty was not clear (e.g., whether the problem resulted from students' lack of understanding or the item itself). The five selected items included a multiple-choice item with a picture, a two-tier item, a Likert-type item, a graphic representation item, and a model representation item. We developed a semi-structured interview focusing on the selected items and interviewed 19 middle school students to ensure the accompanying items adequately measured students' understanding. We analyzed the student data using the five categories described above.

In the case of the two-tier item, the interview confirmed that most students did not know what was "iodine." Their responses were similar to students in the pilot study. However, they could guess that it is a chemical substance and that it can be liquid and solid. We initially decided to use "iodine" in the question because the students could answer the question correctly without knowing is the meaning of "iodine." In addition, the interview results about the two-tier item confirmed that middle school students have difficulty understanding the structure of the item. They had to spend time trying to understand how to answer the item rather than how to apply their knowledge to answer it. From the pilot and interview data, we conclude that we will not employ the two-tier item type for future development of assessment items for middle school students. For the Likert-type item, students felt comfortable responding to the item, but felt it was more difficult than a multiple-choice item because they had to think about the degree of the correctness of each statement. Based on the pilot and interview data, the results confirmed that the Likert-type item is appropriate for measuring middle school students' level of understanding. The results from the graphic and model representation items provided detailed information about student's interpretations of the item stems, distractors' representations, and graphical representations to guide revision of the items for the next iteration. Overall, the results from the survey instrument and interview data were consistent, which means that in the future, we can use a survey instrument to collect data about items instead of collecting intensive, time-consuming qualitative data.

From the first iteration of data collection and analysis, and further expert and internal review, we are revising 11 problematic items for the next iteration. The important task of the next iteration is to analyze the relative difficulty of the items to gain insight into the relationship between the students and the assessment items using Item Response Theory (IRT). We will collect a student data set, approximately 100 students per item to analyze the relative difficulty of the items. This item analysis will confirm that the items measure student understanding corresponding to Levels 1 and 2 of the LP.

## Conclusion

We have described the iterative CCD research design process that researchers can use to develop assessment items that align with a LP to track learning across time. These items will provide a scale that can locate students on the lower levels of the LP. Ultimately, we will use these items to collect longitudinal data to evaluate student learning as they experience three years of coherent instruction that supports learning of the nature of matter.

A number of researchers have discussed the value of developing learning progressions to track students learning (Wilson, & Berenthal, 2006; Smith et al., 2006; Duschl, Schweingruber, & Shouse, 2007). However, there are still critical challenges to overcome in the process of developing and refining LPs and valid associated assessments to measure the level of student understanding across time (Pellegrino, Chudowsky, & Glaser, 2001; Smith, et al., 2006). First, because of the complexity of building LPs, we need to use a research design process that is iterative, process-oriented, and involves designing products that work in real contexts that extend our understandings of the nature and condition of learning and development as well as promote student learning (Barab & Squire, 2004; Brown & Collins, 1992; Collins, Joseph, & Bielaczcy, 2004). However, the typical strategy for this type of learning research employs naturalistic methodologies to investigate how learning occurs and the product development process for building evidence-based claims (Barab & Squire, 2004). A fundamental challenge for such research is the extensive quantity of qualitative and quantitative data that must be collected and organized in order to provide appropriate evidence to support the research claims (Collins, Joseph, & Bielaczcy, 2004). Second, although LPs offer a promising framework, limited validated assessment items exist which connect assessment items and the developmental progress of student understanding to illustrate conceptual growth. Prior to using the LP to track student progress, extensive research is needed to validate assessment items.

As we have illustrated, CCD can be a valuable process for learning research that may overcome these challenges. In particular, the CCD approach focuses on clearly defining the construct to focus the research and development strategies. Another critical characteristic of CCD is the explicitly specified evidence based on the unpacking of the construct that links directly to the claims. Specifying the claims and evidence supports the development and alignment of a range of products. The systematic process outlined by CCD provides guidance for the collection, organization and analysis of data by defining what data is essential for supporting the learning claims we hope to make about student learning. CCD can be considered a component of an iterative development process that is constantly being refined and revised to accommodate the needs of learning researchers. We still have much work to accomplish to make CCD a usable design model for other researchers. We need to further develop the guidelines and examples for each step of CCD to provide guidance on how researchers can use CCD to accomplish a variety of design-based research goals. To do this, researchers need to apply the CCD process to design various research, instructional materials, learning progressions and assessments tasks in order to articulate the subcomponents of the various CCD steps more clearly. As we and other researcher use CCD to guide a greater amount of research and development products, the process will become articulated better.

# Discourse as a lens for reframing consideration of learning progressions

Alicia C. Alonzo, Michigan State University, 330 Erickson Hall, East Lansing, MI 48823, alonzo@msu.edu

**Abstract:** Learning progressions – descriptions of increasingly sophisticated ways of thinking about a topic – have generated much interest in the science education community, as a means of bridging the chasm between cognitive science research and methods for supporting and assessing student learning. In order to fulfill this promise, learning progressions must be developed and refined based upon a rigorous process that explores the match between the learning progression and available evidence of student learning and is complicated by the nature of students' thinking. This paper explores the implications of reframing consideration of learning progressions using Gee's notion of discourse. This reframing is posited as a means of making sense of students' use and interpretation of words that have both everyday and scientific meanings and their apparent inconsistency in responding to assessment items. Data collected about students' understandings relative to two learning progressions is used to explore this approach.

Learning progressions – descriptions of increasingly sophisticated ways of thinking about a topic (National Research Council [NRC], 2007) – have generated much interest in the science education community. The National Science Foundation (NSF) has issued special calls for projects focused on learning progressions (NSF, 2005, 2006, 2009); the National Research Council has advocated for their use to inform science curricula (NRC, 2007) and assessments (NRC, 2006); and the National Assessment of Educational Progress (NAEP) science framework called for the inclusion of learning-progression-based items (National Assessment Governing Board, 2008). Learning progressions have been promoted as solutions to wide range of current educational issues, including a lack of curricular coherence (Gotwals & Songer, 2008), the developmental inappropriateness of current curricula (Stevens, Shin, Delgado, Krajcik, & Pellegrino, 2007), misalignment between instruction and assessment (Black & Wilson, 2007), and weaknesses in support for valued teaching practices (Alonzo, 2009; Furtak, 2009). Learning progressions are viewed as a means of bridging the chasm between cognitive science research and methods for supporting and assessing student learning.

In order to fulfill this promise, learning progressions must be developed based upon existing research and refined based upon a rigorous validation process. The central question guiding this work is the extent to which the learning progression (as a hypothesis about student learning) matches available evidence. This evidence necessarily relies upon methods for eliciting and interpreting student responses relative to the learning progression. Thus, the iterative process of developing and refining a learning progression must involve simultaneous consideration of both student learning and the means by which that learning is assessed. Both the learning progression and its associated assessment items are influenced by assumptions that are made about what is progressing and the goal of learning.

This paper explores an alternative framing of these assumptions, as a means of addressing two current challenges in work to describe and assess student learning through the use of learning progressions. The paper first provides an overview of these challenges. Second, the paper describes an alternative framing – a different way of considering what is progressing – drawing upon Gee's (1991) notion of discourse. This framing is then applied to consider evidence of student learning. The paper concludes with a discussion of implications for future work on learning progressions.

Throughout this paper, two learning progressions are used to illustrate these ideas. The first was designed to describe the learning that might take place during students' first formal study of *Force & Motion* (*FM*; Alonzo & Steedle, 2009), typically in a middle or high school physical science course. It focuses upon students' ability to make predictions about situations involving force and/or motion: predicting the force(s), given information about an object's motion, and vice versa. The second learning progression describes elementary school students' learning about *Plant Nutrition* (*PN*; Alonzo, Benus, Bennett, & Pinney, 2009). It is comprised of three "progress variables" (Wilson, 2005): *Food for Plants*, *Energy for Plants*, and *Plants as Producers*. The discussion in this paper is limited to the first two progress variables, which pertain to students' explanations surrounding the source of plants' food and energy, respectively.

## Two Challenges in Current Work on Learning Progressions

Work to develop learning progressions (and associated assessment items) must grapple with the nature of student thinking. Prior work (Alonzo & Steedle, 2009) explored two characteristics of students' thinking that pose challenges to efforts to describe and assess their learning. Each of these challenges will be briefly described here and illustrated with examples from the two learning progressions.

## Students' Definitions for Words with Scientific and Everyday Meanings

In many areas of the science curriculum, students encounter words that have both "scientific" and "everyday" meanings. For example, the word "force" has a variety of everyday meanings (Halloun & Hestenes, 1985) across a range of different contexts. A sports fan might consider ways in which this word is used as a verb – for example, forcing a double play [in baseball], a game four [in a playoff situation], or a turnover [in basketball or football] – and as a noun, referring to a player as "a force" [such as a defensive lineman in football]. These examples might lead one to conclude that force has a meaning like "making something happen" (or stopping something from happening), a much broader definition than that of a physicist. Ioannides & Vosniadou (2001) explored the ways in which children from 4 to 15 years of age used the word "force". They identified four well-defined, internally consistent meanings for this word and found that students' use of these definitions varies with age. Thus, it seems likely that students' ideas about the word "force" change along with their ideas about the content of the *FM* learning progression: the relationship between (the scientist's definition of) force and motion.

Revisions to the *FM* learning progression (Alonzo & Steedle, 2009) included consideration of the way in which students' definitions for the word "force" were treated. Students in the target population were expected to hold an "acquired force" (Ioannides & Vosniadou, 2001, p. 26) or "impetus" view of force (Buridan, as quoted in Halloun & Hestenes, 1985, p. 1057): the idea that moving objects have some internal property, imparted to them by a push or a pull. Typical physics textbooks (e.g., Hewitt, 1997) introduce a scientific definition for force and then assume students will use that definition to make sense of subsequent discussion of the relationship between force and motion. Similarly, initial versions of the learning progression first addressed students' definitions for the word force, such that a lower level (Level X on the left side of Figure 1) was reserved for students who hold an impetus view of force. Higher levels of the learning progression (Levels X+1 and X+2 on the left side of Figure 1) described increasingly sophisticated ideas about the relationship between force and motion, assuming that students at those higher levels hold a scientific view of "force".

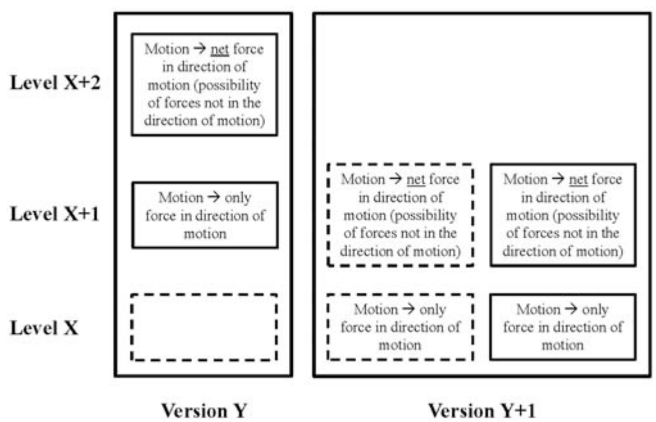

Figure 1. Revisions to the *FM* learning progression, reflecting students' definitions for the word "force". Dashed boxes represent an "impetus" view of force: solid boxes represent a scientific view of force.

Perhaps not surprisingly, interview data revealed that students with an impetus view of force could have different ideas about the relationship between force and motion (Alonzo & Steedle, 2009). For example, when asked to identify the forces acting upon a ball thrown up into the air, students might say that only the throwing force is acting on the ball or that both the throwing force *and* gravity are acting on the ball. The first response is consistent with the view that the only force acting on an object is one in the direction of its motion. The second response is slightly more sophisticated, recognizing the importance of *net* force and the possibility of forces acting on an object that are not in the direction of its motion. Both of these ideas about the relationship between force and motion could also be held by students with more scientific views of the word "force". Thus, as shown on the right side of Figure 1, the learning progression was revised to reflect the possibility of students with two different views of "force" making progress in thinking about the relationship between force and motion, such that students' ideas about "force" and their use and interpretation of this word were treated as two separately progressing entities.

Work on the second learning progression was similarly complicated by students' definitions for words such as "food" and "energy". A review of the literature indicated that students often use these words interchangeably (Leach, Driver, Scott, & Wood-Robinson, 1996) to describe things that are necessary for plants to be healthy. Students who do differentiate "food" and "energy" tend to equate food with things that are "eatable" (Wood-Robinson, 1991; Simpson & Arnold, 1982). Initial data collection surrounding this learning progression elicited evidence of students' definitions for these words, along with evidence of their thinking about plant nutrition (Alonzo et al., 2009). Once again, it appeared that students could make progress with respect to underlying ideas about *Food for Plants* and *Energy for Plants*, while holding a range of different definitions for words such as "food" and "energy". The work reported in this paper was motivated by an interest in this central problem: the way in which students' definitions for words (particularly those with both everyday and scientific meanings) impact their learning and expression of scientific ideas.

## Apparent Inconsistency of Students' Thinking

In physics, students' inconsistency in approaching problems addressing the same underlying principles is well-documented. Chi, Feltovich, and Glaser (1981) demonstrated that a key characteristic differentiating between novices and experts is the way in which they categorize physics problems, with experts viewing problems in terms of underlying principles and novices attending to surface features. Halloun and Hestenes (1985) and Finegold and Gorsky (1991) identified frameworks that college-level students used to reason about motion and force, respectively; however, students did not apply these frameworks consistently across different problem situations.

Reinforcing these findings from the literature, inconsistencies were observed in student responses elicited to explore the *FM* learning progression (Alonzo & Steedle, 2009). For example, a student might describe the forces acting on a stationary object (such as a book on a table), by explaining that "gravity is always acting." Yet this same student might respond that only a throwing force is acting on a ball tossed into the air, rejecting the notion that gravity is acting on the moving ball. Reliabilities for sets of items assessing understanding with respect to the learning progression were all moderate. In addition, a relatively low percentage (59%) of student responses were at the same level across pairs of items that asked essentially the same question in two different contexts. Similarly, in interviews designed to inform revision of the *PN* learning progression (Alonzo et al., 2009), inconsistencies were observed in the way in which students discussed the source of food for plants. At the beginning of the interviews, students were asked to describe the different parts of a plant and to explain what each part did "to help the plant live and grow." Many students began by explaining that the roots take in food for the plant. Yet later in the interview, these same students might express the idea that plants "make" or "produce" their own food.

Thus, listening to students discuss a set of force and motion problems or talk about "food for plants", it can be easy to conclude that students' thinking simply doesn't make sense. Although the work described in this paper was not undertaken to address this puzzle, as will be discussed below, attempts to make sense of students' use of language had the unexpected, but fruitful, side effect of also suggesting an alternative interpretation for the apparent inconsistency of students' thinking.

## Reframing Thinking about Learning Progressions in Terms of Discourse

Gee (1991) defines discourse as "a socially accepted association among ways of using language, of thinking, and of acting that can be used to identify oneself as a member of a socially meaningful group or 'social network'" (p. 3). Elizabeth Moje and colleagues (2004) have explored the implications of this perspective for literacy and content instruction in science classrooms; this paper explores implications for describing and assessing student learning via learning progressions.

Returning to a consideration of everyday meanings for the word force, it becomes evident that these definitions, while inconsistent with a scientist's definition, are completely consistent with one's everyday experiences with force and motion. In everyday experience, forces are required to keep objects moving. A force is, indeed, required to make something happen (in this case, the motion of an object). One might conceptualize the whole "package" of one's ideas, experiences, and ways of talking as comprising an "everyday discourse" with respect to force and motion. We know a lot about words such as "force", "food", and "energy" by virtue of the way in which we use them to talk about experiences in our everyday lives. Those definitions do not exist in isolation; rather, they are a part of how we "are in" and interact with the world and, thus, inform the way in which we think about related ideas (such as the relationship between force and motion or plant nutrition). While these ideas are perhaps not a central part of our identities, the particular experiences we have in the world – by virtue of being, for example, a sports fan – do influence our thinking about words that have both everyday and scientific meanings and, thus, are tied up with how we make sense of the world.

This "everyday discourse" can be contrasted with a "scientific discourse".[1] The latter includes the use of words consistent with their scientific definitions, as well as the application of a set of scientific ideas derived from those definitions to very specific sorts of situations. In many cases, this means accepting a narrower view of words and ideas than those in one's everyday experience. For example, a physicist would not say that forces make "something" happen. He/she would use force only to apply to case in which "something" refers to a change in motion (speed and/or direction). The scientific discourse also requires – to a certain extent, at least in physics – that one reside in a fairly idealized world: one in which friction and air resistance are usually ignored.

Taking a discourse perspective recasts what is progressing in a learning progression in terms of a transition between "everyday" and "scientific" discourses. In their current forms, the *FM* and *PN* learning progressions describe the evolution of students' thinking about a scientific topic. Students' definitions for relevant words, such as force, food, or energy, are treated as existing separately from their understanding of the scientific topic and as a challenge to accessing the real focus of the learning progression. Taking a discourse perspective puts students' definitions and ideas back together again. This reframing also permits a reinterpretation of students' seemingly inconsistent responses as struggles to reconcile their everyday and scientific discourses. Sometimes there may not be a conflict between these two discourses. However, where everyday and scientific discourses yield different ways of interpreting and reasoning about a given question, students must choose how they will consider the question being asked. Subtle aspects of the situation – such as the context in which questions are being asked, the particular problem context involved in a given question, and even particular wording of a question – might influence the extent to which students draw upon their everyday and scientific discourses in making sense of the situation.

## Reconsidering Evidence of Student Learning

In this section, data collected with respect to the *FM* and *PN* learning progressions are reconsidered in light of the discussion above, in order to answer the research question, "Does a discourse lens help to interpret students' responses with respect to the two learning progressions?" This is intended as a "proof of concept" exploration, as the data were not collected specifically to test the ideas above. Rather, the intent is to explore the fruitfulness of this reframing, in order to inform future data collection that might more directly evaluate these ideas.

### Evidence with Respect to the *FM* Learning Progression

The data considered in this section was collected as part of two separate studies, both conducted in the Midwestern United States. Study 1 involved students from a middle class rural high school who answered questions about force and motion directly following a unit on this topic in their physical science classes. Data included 58 students' responses to ordered multiple choice (OMC; Briggs, Alonzo, Schwab, & Wilson, 2006) items. Study 2 involved 1088 students from six high schools, representing a mix of rural and suburban communities. By virtue of their course enrollment, students were expected to have learned about force and motion concepts (either in their current science course or one taken in a previous year). Data included students' responses to a set of OMC force and motion items, plus one question that asked students to indicate whether they had learned about the content of those items before.

The source of students' reasoning about the OMC items was not evident in their responses. However, one might hypothesize that students who have access to the scientific discourse are more likely to reason using that discourse in situations further removed from their everyday experiences. The available data permits a small exploration of this hypothesis. In particular, the set of 16 items presented to students in both Study 1 and Study 2 include three pairs of items in which an almost identical question is asked in a familiar and an unfamiliar context. Questions A and B ask students to describe the motion of an object, first under the influence of a constant force and then once that force is no longer being applied, respectively. These questions are asked both in the relatively familiar context of pushing a car (albeit across a frictionless surface) and the less familiar situation of a rocket traveling in outer space. Question C asks students to describe the forces acting upon a stationary object, both a boulder resting upon the ground (familiar context) and a mysterious blob suspended in the air in a scientific laboratory (unfamiliar context). Analysis of responses to these six questions involved the 58 students from Study 1 and 798 students from Study 2 (those who indicated that they had learned about force and motion concepts before). Students who had not studied force and motion were excluded, as these students may not have access to the scientific discourse and, thus, would not be expected to exhibit variation in the discourse used to reason about the different problem contexts.

Table 1 shows the percentage of students in each study choosing the option corresponding to the highest learning progression level (as an indicator of the use of scientific discourse) for each item. Shaded cells indicate statistical significance ($p < .05$), using the McNemar test. For all comparisons, students selected the highest learning progression level at a similar or higher rate in the familiar context, as compared to the unfamiliar context. However, these rates were statistically significant for only two pairs of items (Question B in Study 1 and Question C in Study 2). Thus, across the two studies, students who had studied force and motion concepts seemed somewhat more likely to apply scientific discourse to analysis of unfamiliar contexts, lending a small degree of support to the proposed reframing.

Table 1: Percentage of students selecting the highest learning progression level for a given item.

| | Study 1 (N=58) | | Study 2 (N=798) | |
|---|---|---|---|---|
| | Familiar Context | Unfamiliar Context | Familiar Context | Unfamiliar Context |
| Question A | 17.2% | 22.4% | 16.5% | 17.3% |
| Question B | 31.0% | 53.4% | 40.4% | 40.2% |
| Question C | 43.1% | 53.4% | 37.8% | 60.0% |

## Evidence with Respect to the *PN* Learning Progression

In order to inform revisions of the *PN* learning progression, semi-structured interviews were conducted with 30 students (grades 1-6) who attended a suburban elementary school in the Midwestern US. Because of its proximity to a large research university and hospital, the school enrolled many children whose parents were associated with these institutions. The school was located on the edge of town and, thus, some of its students lived on surrounding farmland. A small houseplant was used as a prop during the interviews, and efforts were made to elicit students' ideas about words such as "food" and "energy", as well as their school-based and everyday experiences with plants. However, the richest interview data came from students who spontaneously explained their answers in terms of their own experiences and everyday discourses.

Interviews were labeled with the gender and grade level of the student, as well as the order in which they were conducted. For example, 04-M1 indicates the fourth interview, conducted with a male first grader. All interviews were videotaped, and the videotapes were transcribed prior to analysis. For the purposes of this paper, interview transcripts were coded to identify instances in which students explicitly provided evidence of their everyday or scientific discourses; this evidence included explicit use of the words "food" and "energy" as well as students' discussion of related ideas. Students' examples of how they used words such as "energy" in their everyday lives, descriptions of out-of-school experiences with plants, and explanations for personal experiences that informed their thinking about plants were all considered to be evidence of everyday discourse. Students' discussion of ideas explicitly identified as having been learned in school or from a science text were considered to represent their scientific discourse. The surrounding interview transcript was then examined for ways in which students' ideas about plants' sources of food and energy may have been influenced by these two types of discourse. Themes emerged with respect to each of the two progress variables and are illustrated with examples from the interview transcripts.

### Food for Plants

Consistent with findings from other research (e.g., Cañal, 1999), the students in this sample often expressed the view that plants manufacture their own food along with the view that plants take in food from the environment. Some students expressed each idea separately, at different points in the interview, while other students stated that plants get food both from sources. Although the latter position is represented in the current version of the *Food for Plants* progress variable, a student who exhibits the former type of response to the interview questions appears to be at one level of the progress variable at some times and at a completely different level at other times. Such a student poses challenges to current conceptualizations of learning progressions, which assume that a given student will hold a consistent set of ideas that can be used to diagnose his/her level. However, since each view about the source of food for plants is consistent with a different discourse, students' thinking may be reinterpreted as struggles to reconcile two different ways of thinking and talking about food for plants.

Although most students did not explicitly address the source of their ideas about plants manufacturing their own food, this is unlikely to be a part of most students' everyday experiences and, thus, may be interpreted as representing a scientific discourse. For example, a second grade boy's interview (20-M2) included the following statement about the role of the sun in plants' growth: "I think plants use the sun to make their food… I think in the photosynthesis they do that." Later in the interview, he explained that he had read about photosynthesis in a science book. Through their school science experiences, many students in the interview sample had developed a discourse surrounding seeds and their source of food. For example, a third grade girl (02-F3) explained that she had learned in school that "the seed doesn't need food 'cause they have already food… they have food in their shell."

Many of the same students also had everyday discourses surrounding food and, in particular, plants' source for food. Consistent with Roth's (1991) interpretation of student thinking, some students brought in ideas about human nutrition to explain their ideas about plant nutrition. For example, a third grade girl (17-F3) said, "We grow because we eat healthy food… Like, if we ate candy bars, like, every single day, like ten a day. We would get really, really sick. And we wouldn't, like, be very healthy. And we wouldn't grow as well." She went on to explain that it wouldn't be healthy for plants to take in "a kind of bad soil that's really sugary." Two students (04-M1 and 21-M5) discussed food for plants in terms of experiences with Venus flytraps, which "eat bugs" that they fed to the plants. The first grade boy (04-M1) had difficulty reasoning about food for regular plants, which he recognized did not eat bugs. Most students' out-of-school experiences with plants were situated in a discourse about plants needing things from people and those things constituting food for plants. For example, a third grade girl (02-F3) described in vivid detail her experiences planting trees on her family's farm over the weekend preceding the interview. She had provided the new trees with both "special food" and water (that "carries food in it"). For other students, including another third grade girl (17-F3), the water itself, as something that was required for life, was also food for the plant. She explained that this saying, "'Cause just like people, they need water to survive." For these students, ideas about human nutrition and human interactions with plants (part of their everyday discourse) fairly straightforwardly informed their ideas about plants.

However, the interviews also offered numerous examples of students who appeared to be using different discourses to make sense of the different questions being asked about food for plants. Many of these students appeared to be struggling to reconcile everyday and scientific discourses. Often, student's scientific discourses did not appear to be robust enough to support detailed reasoning about food for plants. Students seemed to have learned a phrase, such as "plants produce their own food" without details about this process. For example, consider the following segment of interview transcript involving a second grade girl (02-F3):

> 02-F3: [Plants] produce the food.
> Interviewer: Do they use any of the food that they produce?
> 02-F3: What do you mean "they produce"?

The idea of plants producing food seems to have limited meaning to the girl. When her ideas about plants' source of food was probed further in the interview, she seems to have combined ideas about plants taking in food and water (provided by people such as herself) to explain that "The water actually goes to the leaves and the leaves can turn it into food. The leaves could have to make the food out of the soil. The water too." Thus, like many students in the sample, she appears to be reconciling her ideas about plants taking in food and water from the environment (to serve as food) with the idea of plants making their own food.

## Energy for Plants

Perhaps not surprisingly, students in the interview sample seemed to have limited access to a scientific discourse surrounding energy. However, they provided many examples of their everyday discourse about energy, allowing examination of the way in which this discourse informed their thinking about energy for plants. Students expressed three main ideas about energy – associating energy with movement, electricity, and the sun – all of which were contained in a segment of an interview with a third grade girl (17-F3):

> Well, energy can come from the sun. Energy is, like, a thing that makes you move. Like, if you're really hyper you can have a lot of energy so you can, like, run around a lot. And energy is, like, batteries have energy in them. And electronics. And, energy from the sun also, like, it has vitamins in it. Kind of. So that, like, when it comes down and hits stuff, it makes it healthy.

Thus, consistent with other research (e.g., Nicholls & Ogborn, 1993), students' everyday discourses about energy often involved movement. These students then tried to make sense of energy for plants in terms of this way of thinking about energy. One second grade girl (14-F2) used her ideas about energy ("Like if you run then you kinda get your energy") to conclude that plants would not have energy "unless someone moved it… If someone picked it up and ran with it, maybe it would have energy." A third grade girl (02-F3) explained that plants have energy "not in order to, from here, this plant to move from here to here. Not that type of energy." She later explained that plants needed energy so "the roots can move around to get the food." Thus, she associated plant's energy with motion of its roots. Other students invoked the movement of substances such as food or water to explain how plants use energy. For example, a fourth grade boy (01-M4) explained that plants might use energy "to get the food to the, everywhere it needs to go… Like the leaves."

Students also drew upon their own experiences in thinking about where plants might get energy. For example, the third grade student above (17-F3), like other students in the sample, believed that the sun was a source of vitamins for both people and plants. She also explained that people get energy from healthy food:

> You get your energy from food. Like, carrots, and celery, and, um sugar gives you energy, but it's a bad kind of, well, it's not really bad, but it just, like, doesn't last very long. So, it's not, like, true energy. But, food that has, like, vitamins in it, I think it has, like, the vitamins and the calcium combined, that gives you energy. So, that, like, if you eat a bunch of carrots, and celery, and vegetables, and fruits, that you'll be really energetic because then you have a lot of… you have a lot of nutrients in you. And so then you're like, really healthy."

She went on to explain that plants needed healthy food and vitamins for their energy as well. A second grade girl (05-F2) explained her knowledge of energy in terms of her mom's position as a track coach:

> [Energy] means exercise and fit, so you can stay in shape and stuff. 'Cause I know all this stuff because… my mom's a track coach so she teaches about 85 people in this team. And she has to tell them about keep fit and stay in shape and stuff.

Later in the interview, she explained that she knew plants get energy from water (as well as sunlight) "'cause we get energy from water, 'cause yesterday I ran a mile. And I needed a lot of water."

The students in the interview sample had not had many formal learning opportunities surrounding the concept of "energy", but they drew upon rich everyday discourses to make sense of energy for plants. This led them to make connections between plants and humans, some of which are consistent with a scientific discourse about energy for plants and some of which are not. Thus, we might predict that their subsequent learning about plants will involve some struggle to identify aspects of their everyday discourse that are and are not consistent with scientific discourse.

## Conclusions & Implications

The reframing presented in this paper takes as an underlying assumption that science learning involves students' reconciling their everyday and scientific discourses and that this process will occur whether or not it is acknowledged in efforts to describe, support, and assess student learning. While students' prior conceptions are commonly acknowledged, this perspective takes a broader view of students' ideas, explicitly including ways in which students draw upon both language and experiences to make sense of phenomena. The preceding sections of this paper explored whether this assumption was reflected in existing data surrounding students' understanding of force and motion and food and energy for plants. Although the data was not collected to explicitly address students' everyday discourses, the available evidence seems to support the interpretation that students draw upon this discourse in making sense of questions about scientific topics, often in conjunction with the scientific discourse. This interpretation helps to make sense of both students' use of language and their apparent inconsistency in responding to assessment items and interview questions.

This perspective has several implications for the design of learning progressions. First, treating students' ideas about and language surrounding scientific topics as both falling under the "umbrella" of discourse helps to address the perhaps false dichotomy between ideas and language. This helps to resolve the problem of how to "treat" students' definitions for words as part of a learning progression. Second, this approach means reframing what is progressing in a learning progression from ideas about a scientific topic to changes in the extent to which students draw upon scientific discourse in reasoning about scientific questions. It is important to recognize that this process is not one of replacement, in which students make progress by gradually discarding their everyday discourses in favor of a scientific one. Instead, one might view this as a process by which students gradually understand their everyday discourses in light of a scientific one: narrowing definitions and ideas where necessary and adding additional interpretations to explain existing experiences. As students make progress with respect to the learning progression, they may draw upon everyday and scientific discourses to varying degrees; part of what is progressing is students' reliance upon scientific discourse in appropriate situations. Thus, in this view, one does not expect students to consistently rely upon scientific discourse to answer all questions and – to both describe and support student learning – a challenge becomes figuring out the circumstances under which students might be more likely to draw upon everyday discourse and to help them to utilize scientific ways of thinking in appropriate circumstances. The reframing proposed in this paper has the potential to help learning progressions to more accurately reflect the nature of students' thinking and, thus, to be more useful tools for describing, assessing, and supporting student learning.

## Endnotes

(1) This discussion is not meant to imply that everyday and scientific discourses are fully dichotomous. Scientific discourse emerges from and attempts to explain everyday experiences, and, indeed, one would expect a scientist (or expert student) to have access to both types of discourse and to flexibly draw upon some mixture of the two, depending upon the context. One might view these two types of discourse as two ends of a continuum (where the continuum is shorter or longer, depending upon the degree of similarity between everyday and scientific discourses in a particular area).

**Abstract:** Collaboration is an essential component of many project-based learning environments; however, verbal interactions within groups can be ineffective. Extending previous research, this study investigated verbal interactions within teams of high school students as they solved a prototypical design-task called the Earthquake task. Videotaped performance assessments of high and low performing teams were analyzed in depth. Teams were categorized as high and low performing using two different methods: (1) highest successful structure built and, (2) percentage of successful designs. Results suggest that teams engaged in three different patterns of verbal interactions: *Accept-Build*, *Accept-Build-Discuss-Modify*, and *Discussion*. High performing teams most often engaged in, and were most successful when, their verbal interactions followed the *Accept-Build-Discus-Modify* pathway. The instructional implications of these results for promoting productive group collaboration and future research directions are discussed.

## Background

With the renewed interest in instructional approaches emphasizing the connection between knowledge and the context in which it is to be used, there has been resurgence in the use of project-based learning in K-12 science classrooms. The enthusiasm and belief in the efficacy for project-based learning has waxed and waned over the years, resulting in only a handful of teachers adopting the approach consistently (Barron et al., 1998). There is strong evidence that problem-and project-based learning can be successful (e.g. Cognition and Technology Group at Vanderbilt [CTGV]. 1994, 1997; Collins, Hawkins, & Carver, 1991; Schauble, Glaser, Duschl, Schulze, & John, 1995). Yet, there are several factors that are important for the design of problem-or project-based learning environments that can influence their impact on student learning outcomes.

Collaboration is an essential component of many project-based learning environments and can greatly impact student learning. It provides opportunities for students to extend their thinking, share ideas, and draw on the expertise of others (Krajcik et al., 1994). Yet, we have much to learn about how to best foster collaboration for learning (Barron, 2003). Simply having students work together to complete prescribed procedures for an investigation or task does not constitute collaboration (Marx, Blumenfeld, Krajcik, & Soloway, 1997). Rather, collaboration involves the construction of shared meanings (Webb & Palincsar, 1996) through the exchange of ideas.

Unfortunately, collaboration that is productive and leads to the development of shared understanding is not always guaranteed (Barron, 2003). Not all verbal exchanges within collaborative groups lead to the solving of problems or the construction of shared meanings. Rather, productive verbal interactions within a group require that: (a) ideas are presented clearly and explicitly so that they may become shared, (b) group members elaborate on their own and others' ideas, and (c) reasoning and evaluation of the ideas is done collaboratively (Hoek & Seegers, 2005; Mercer, 1996).

The nature and structure of the task can also shape the collaborative process (Hoek & Seegers, 2005). Tasks that are likely to benefit most from collaboration are those that require group work and deal with ill-structured problems (Cohen, 1994). Design is a practice that deals with ill-structured problems that have no clearly predefined path leading from the problem specification to the final design solution (Fortus, Krajcik, Dershimer, Marx & Mamlok-Naaman, 2005). For tasks, such as design tasks, productivity will depend on the interaction that happens within the group (Cohen, 1994).

In order to better foster productive collaboration within groups, we need to understand the characteristics of interactions that lead to productive group collaborations (Barron, 2003). Much like Barron (2003), this research is focused on understanding how verbal exchanges between collaborators influences the collective achievements of the group. While Barron focused on the interaction between collaborators while solving mathematical problems, this paper reports on the verbal interactions that occur within teams of students as they work to solve a design challenge. Design tasks provide an interesting context in which to study group collaborations because unlike math problems, which are well-structured, design problems are characteristically ill-structured, with ill-defined goals, states or operators (Goel & Pirolli, 1992). Thus, a goal of this research is to understand the verbal interactions that occur when students collaborate to solve a design challenge. Studies such as this are necessary if we are to begin to help practitioners and researchers create learning environments that can take full advantage of collaborative learning in project-based or design-based learning environments.

## The Study

This study is situated within the context of a larger study that examined student learning in an 8-week high school design-based learning curriculum unit. Design-based learning is a particular form of project-based learning. In design-based learning, the activity that is meant to promote learning is a design-project; students are required to use and extend their knowledge of science and math to develop a technological solution to a problem using available resources.

The research in this study focused on understanding how verbal interaction within teams affects performance in a design task. The analysis was motivated by prior research done within this context that examined the strategies students use to solve a prototypical design task, the Earthquake task (see Apedoe & Schunn, 2009). Results suggested that students use both science reasoning strategies (e.g. control of variables) and design-focused strategies (e.g. adaptive growth). However, the strategies commonly associated with success in science (e.g. control of variables) did not necessarily lead to success in design. In addition, while both science reasoning strategies and design-focused strategies led to content learning, the content learned was different. In this study, we extend the analyses to investigate the influence of verbal interactions on team performance on the Earthquake task.

The research questions of primary interest are:

1. What verbal interaction patterns are evident as teams collaborate to complete the Earthquake task?
2. What verbal interaction patterns distinguish high and low performing teams, as defined by the highest successful structure built?
3. What verbal interaction patterns distinguish high and low performing teams, as defined by the percentage of successful design trials?

### Research Design and Methods

#### Research Design

This study utilized a high-low extreme case design to analyze student team performances on a design task called the Earthquake task, which was adapted from Azmitia and Crowley (2001). Extreme-groups comparisons provide greater statistical power without bias, and are particularly useful for labor-intensive studies such as those involving video-data coding. Teams of students completed the task, and the most successful and least successful performances were analyzed in detail. There were two criteria used to categorize teams as high or low performing: height of structure, and percentage of successful designs trials regardless of height. Teams that were considered high performing based on the highest successful structure built may have taken more risks with their designs, whereas teams that had a high percentage of successful designs, but not necessarily tall structures, may have been more conservative in their approach. Thus it was of interest to see if the verbal interactions within teams would differ based on these two different categorizations.

#### The Earthquake Task

Students were given 54 wooden blocks to build as high a structure as possible that would withstand (i.e. no blocks fall from the structure) a 20-second simulated earthquake (see Figure 1). Students were allowed to build and test as many structures as they wanted and were given approximately 20 minutes to complete the task.

The Earthquake design task was chosen based on two important criteria. First, the Earthquake task has the three elements that Cross (1994) describes as being common to all design problems: (a) a specified goal, (b) constraints within which the goal must be achieved, and (c) criteria for recognition of a successful solution. Akin to the design problems described by Goel & Pirolli (1992), the Earthquake task is ill-structured and requires creativity to move from the start state to the goal state. Secondly, the task did not require students to have any discipline-specific knowledge about the domain beyond elements of everyday experience.

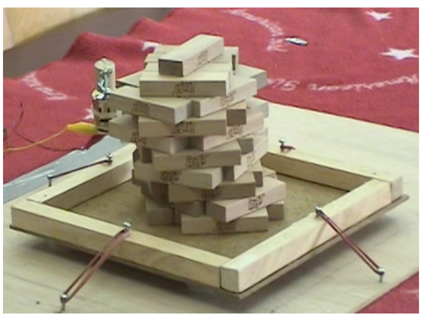

Figure 1. Sample student-designed earthquake-proof structure on earthquake simulator

## Context & Participants

This research was conducted as part of a larger study that examines student learning in high school design-based learning units. As part of an effort to reform teaching and learning in high school science classrooms, teachers from a large urban area in the northeastern United States were invited to implement a design-based science learning unit in their classrooms. Teachers held design competitions within their classrooms to identify the top student team design projects, as part of the unit implementation. These top student teams were then invited to participate in a *Regional Design Competition* (See Reynolds, Mehalik, Lovell, & Schunn, 2009 for more details). During the *competition event*, while teams waited for their projects to be judged, they were invited to participate in this study, and complete the Earthquake task. A total of 191 students (42% female, 58% male), drawn from urban high schools with a moderate proportion of traditionally underserved students, participated in the study. Participants included 9th, 10th, 11th and 12th grade high school students enrolled in a science course (e.g. spectrum science, biology, chemistry, or physics) that implemented a design-based learning unit. Participants worked in pre-existing groups of same or mixed gender teams of 2-5 students.

## Data Collection & Sources

The primary method of data collection for this study was performance-assessment interviews. Data were collected during the *Regional Design Competition* in both 2007 and 2008, with 29 teams of students participating in the 2007 session and 30 teams participating in the 2008 session. Student teams were videotaped while completing the Earthquake task. During the task, students were asked to explain their designs (e.g. Why did you build your structure this way?) to help clarify the design choices and problem-solving strategies they used. The data set analyzed for this paper included videos of 16 teams of students that represented both the highest and lowest performing teams based on the highest successful structure built. This sub-set was drawn from a larger dataset of 59 teams of students.

## Data Analysis

Video-data was analyzed in multiple passes by the researcher (Miles & Huberman, 1994). A coding scheme was developed to establish verbal interaction patterns within teams as they completed the design task. A set of 17 videos, that were not included in the final analysis, were viewed and coded. The final coding scheme developed showed that with the initial presentation of a design idea, the verbal interaction patterns within a team typically followed one of four pathways: *Accept Build*, *Accept Build-Discuss-Modify*, *Discussion*, or *Reject* (see Figure 2).

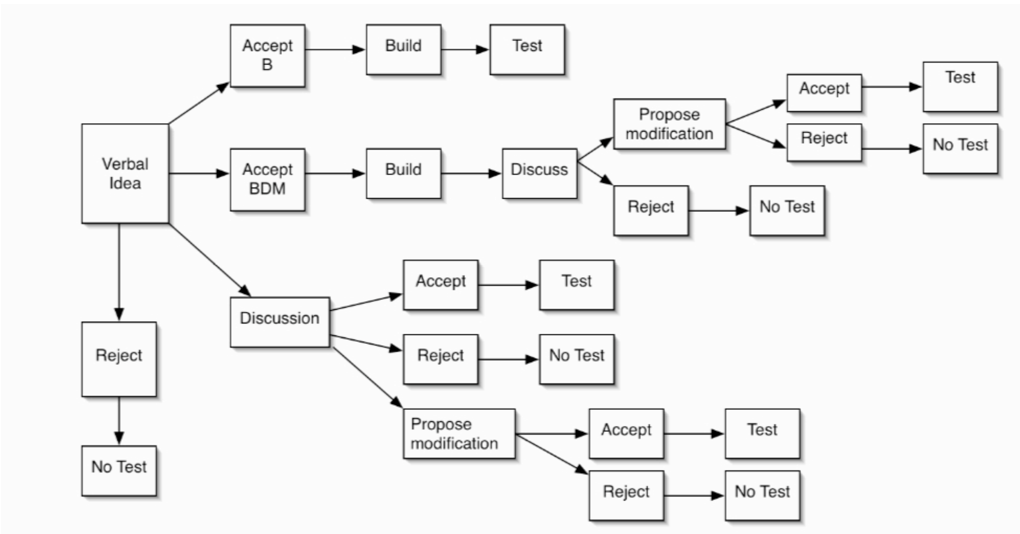

Figure 2. Possible Verbal Interaction Pathways

The first pathway, *Reject* describes the situation wherein a design idea is presented by a team member, but is immediately rejected by the rest of the team. The second pathway, *Accept Build (B),* describes instances wherein the initial design idea is immediately accepted and the team builds a structure.

The third pathway, *Accept Build-Discuss-Modify (BDM)*, describes instances wherein teams immediately begin building a structure. However, during the building of the structure, discussion ensues, often regarding the worthiness of the current design. At this point, either the current design idea is *rejected*, or a *modification* is proposed. This *proposed modification* is either accepted or rejected until an acceptable modification is proposed, and building resumes or a structure is tested. If an acceptable modification is not found, building stops, and the structure is never tested.

The fourth pathway, *Discussion*, begins with a design idea that is discussed by the team prior to physically building the structure. There are three sub-paths in the Discussion pathway: Discussion-Accept, Discussion-Reject, and Discussion-Proposed Modification. Discussion-Accept describes instances when a team member provides a design idea for the structure that is automatically accepted without any further discussion or modification prior to building and testing the structure. Discussion-Reject refers to the dismissal of a design idea after a discussion. In these instances, no structure is built until a new design idea is proposed and accepted. Discussion-Proposed Modification describes instances where a modification to the current design idea is suggested. These proposed modifications are either accepted or rejected. If accepted, the accepted proposed modifications are eventually tested after (n) accepted proposed modifications are made. If the proposed modification is rejected, then the team would continue to build the structure without any alterations, or until a new modification was proposed and accepted. All verbal interaction pathways end when the structure is finally tested to determine whether it could withstand the 20-second simulated earthquake.

Using the developed coding scheme, two coders independently coded the 16 teams' performances. Overall agreement between the two coders was 95.5%. In instances where there was a disagreement in coding, the discrepancy was discussed and resolved.

## Findings

### Verbal Interactions Used

All verbal interactions within teams were codable as one of the aforementioned pathways. Other logical possibilities, a *Reject* pathway and two sub-paths, the Discussion-Accept and Discussion-Reject, were never used by teams. Teams used the remaining verbal interaction pathways with varying frequency. The mean proportion of trials in which teams' verbal interactions followed the *Accept BDM* pathway was much greater than those that followed the *Accept B* or *Discussion* pathways. The average number of modifications made per trial during the *Accept BDM* pathway was 6.5, while during the *Discussion* pathway there was an average of 9 modifications per trial. Table 1 provides a summary of the overall trends in verbal interaction pathway use. Figure 3 shows the verbal interaction pathways used by teams.

Table 1: Summary of verbal interaction pathway use.

| Pathways | Mean Proportion of Use (all trials) | Mean Proportion of Successful Designs when Used (all trials) | Mean Proportion of Successful Designs (pathway specific trials) |
|---|---|---|---|
| Accept B | .23 | .18 | .53 |
| Accept BDM | .63 | .21 | .37 |
| Discussion | .14 | .40 | .50 |

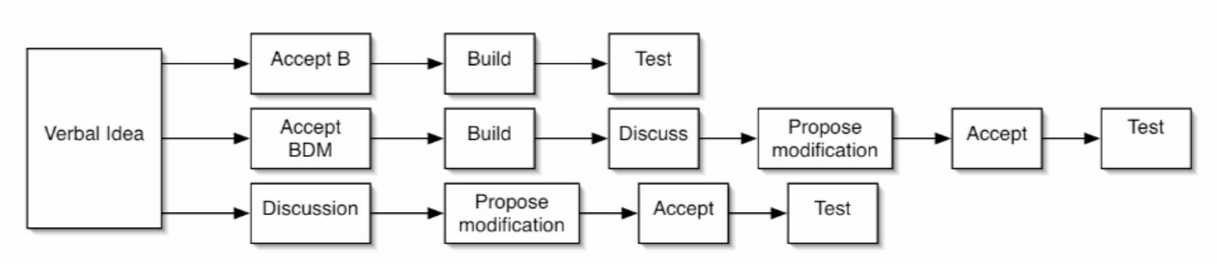

Figure 3. Observed Verbal Pathways Actually Used by Teams

### Distinguishing High & Low Performing Teams

#### Highest Successful Structure Built

Teams were categorized as high performing or low performing based on the highest successful structure they were able to build. Using a median split teams were divided into high and low groups, with the high groups' highest successful structures ranging between 13-45 stories tall, while the low group structures ranged from 0-10 stories tall.

High performing teams' verbal interactions followed the *Accept B* pathway significantly more frequently than did the low performing teams, $t$ (15) = 1.94, $p$ = 0.04. However, there was no significant difference in how frequently high and low performing teams' verbal interactions followed the *Accept BDM* pathway, $t$ (14) = -1.04, $p$ = 0.16 or the *Discussion* pathway, $t$ (8) = -0.44, $p$ = 0.33. Table 2 provides a summary of the verbal interaction pathways used by high and low performing teams.

With regard to design success, high performing teams had marginally significantly more successful designs across all trials when using the *Accept B* pathway, *t* (14) = 1.43, *p* = 0.09, as well as within trials that used the *Accept B* pathway, *t* (10) = 1.46, *p* = 0.09. High performing teams also had marginally significantly more successful designs when their verbal interactions followed the *Accept BDM* pathway over all trials, *t* (14) = 1.50, *p* = 0.08. When the analysis was narrowed to focus on only successful designs within trials that had verbal interactions following the *Accept BDM* pathway, high performing teams performed significantly better, *t* (14) = 1.90, *p* = 0.04. However, there were no significant differences in the amount of successful designs over all trials, *t* (14) = 0.83, *p* = 0.21, or within pathway only trials when verbal interactions followed the *Discussion* pathway *t* (14) = -0.61, *p* = 0.28. Table 3 provides a summary of the design success and its relation to verbal pathway use.

Finally, as part of the *Accept BDM* and *Discussion* pathways, the number of modifications proposed by team members was coded (see Table 3). There was no significant difference between high and low performing teams in the number of modifications made per trial when their verbal interactions followed the *Accept BDM* pathway, *t* (14) = 0.82, *p* = 0.21. There were also no significant differences in the number of modifications made per trial when their verbal interactions followed the *Discussion* pathway, *t* (12) = 0.59, *p* = 0.28.

## Percentage of Successful Designs

Although success on the Earthquake task was defined as building as tall a structure as possible that would withstand a 20-second simulated earthquake, it was of interest to know whether teams who may not have built the tallest structures, but still had a high proportion of successful trials were engaged in different types of verbal interactions. Teams were once again evenly split into high and low performing groups, this time based on the percentage of successful designs they built and tested. The high performing group consisted of teams with a percentage of successful trials within the range of 38%-100%. The low group was comprised of teams with a percentage of successful trials within the range of 0%-33%. This categorization scheme resulted in a number of teams changing high/low status. Of the 16 total teams, 6 teams (38%) changed high/low status.

There were no significant differences between high and low performing teams in the frequency of use of the *Accept B, t* (14) = 0.19, *p* = 0.43, the *Accept BDM, t* (14) = -0.63, *p* = 0.27, or the *Discussion* pathways, *t* (10) = 0.61, *p* = 0.28. Table 4 provides a summary of the verbal interaction pathways used by high and low performing teams.

With regard to design success, there were no significant differences between high or low performing teams in the percent of successful designs over all trials when their verbal interactions followed the *Accept B* pathway, *t* (9) = 1.13, *p* = 0.14. However, there was a marginally significant difference in the proportion of successful trials within *Accept B* pathway only trials, *t* (8) = 1.44, *p* = 0.09. There was also a significant difference in the percent of successful design trials when the verbal interactions followed the *Accept BDM* pathway over all trials, *t* (10) = 3.62, *p* = 0.00. When the analysis was narrowed to focus only on the proportion of successful designs within trials that had verbal interactions that followed the *Accept BDM* pathway, high performing teams did significantly better, *t* (14) = 2.20, *p* = 0.02. For verbal interactions that followed the *Discussion* pathway, there was a marginally significant difference in the percent of successful designs over all trials, *t* (9) = 1.72, *p* = 0.06, however, there were no significant differences with the success of trials within *Discussion* pathway only trials, *t* (14) = 0.61, *p* = 0.28. Table 5 provides a summary of the design success and its relation to verbal pathway use.

Finally, there were no significant differences between high and low performing teams in the number of modifications made per trial when the verbal interactions followed the *Accept BDM* pathway, *t* (10) = 0.34, *p* = 0.37, or the *Discussion* pathway, *t* (10) = 0.61, *p* = 0.28, (see Table 5).

Table 4: Verbal interaction pathway use by high and low teams as defined by % of successful designs.

## Discussion

The verbal interactions within both high and low performing teams followed one of three pathways, *Accept B*, *Accept BDM*, or *Discussion*. Overall, teams' verbal interactions followed the *Accept BDM* pathway. That is, once an initial design idea was posed, teams tended to begin building a structure that encapsulated the initial idea, and then as they were building, engaged in verbal exchanges wherein proposals for ways to modify the structure were made. Eventually, after a number proposed modifications were accepted or rejected, teams arrived at a structure that they deemed worthy of 'testing' to determine its ability to withstand the 20-second simulated earthquake. Overall, there was no statistically significant correlation between the verbal pathways used and the percentage of successful designs teams built.

However, when team performance was analyzed by looking at high performing and low performing teams, there appears to be a relationship between the verbal interaction pathway followed and how successfully teams were able to complete the design task. Teams that were considered high performing based on the highest successful structures they built engaged in verbal interaction that followed the *Accept B* pathway more often than did the low performing teams. In addition, the high performing teams had marginally significantly more successful designs when their verbal interactions followed the *Accept B* pathway than did the low performing teams. This result suggests that the verbal interaction pattern of: (1) proposing a design idea, (2) accepting the design idea, and (3) building the design idea without further discussion or modification of the idea prior to testing, can result in productive collaboration and success on the Earthquake task. The fact that the teams did not further discuss or modify the original design idea is the distinguishing difference between this pathway and the *Accept BDM* pathway during which modifications were made.

At first glance, this result is counter-intuitive because it would suggest that accepting and implementing ideas without discussion is a good strategy. However, we must be cautious when interpreting this result, as it is possible that high performing teams began with "better" ideas, and thus discussion or modification of those ideas was not necessary. In addition, teams that were considered high performing based on the highest successful structures they built, engaged in verbal interactions that did not follow the *Accept B* pathway the majority of the time. Rather, high performing teams most frequently engaged in verbal interactions that followed the *Accept BDM* pathway. Interestingly enough, high performing teams also experienced great success when their verbal interactions followed the *Accept BDM* pathway. High performing teams had significantly more successful designs when their verbal interactions followed the *Accept BDM* pathway. The primary difference between the *Accept B* and *Accept BDM* pathway is that within the *Accept BDM* pathway, teams engage in a cycle of proposing modifications to the initial design idea – and either accepting or rejecting those proposed modifications – before completing building of the structure and testing it against the simulated earthquake. Thus, it would appear that the added benefit of engaging in verbal interactions that are characteristic of the *Accept BDM* pathway is that the initial design ideas become more refined and consequently "better" which results in the building of more structures that are stable enough to withstand the simulated earthquake. Success on the earthquake task appears to be related to the articulation and modification of design ideas within the group. However, results suggest that it is not the number of proposed modifications that matters, as these were essentially the same for both high and low performing groups. Rather, it is likely that the quality of the proposed modifications is what makes a difference. Additional analyses will need to be done to explore this possibility.

If we look at the verbal interaction patterns of teams that were considered high performing based on their percentage of successful designs, a somewhat similar pattern emerges as is seen when teams are considered high performing based on the highest successful structure they built. While teams that had a high percentage of successful designs verbal interactions did not use the *Accept B* pathway more frequently than did the low performing teams, they did have marginally significantly more successful designs. This suggests that regardless of the definition of "high performing" that is used, verbal interactions that follow the *Accept B* pathway lead to success on the Earthquake task, and in turn, are characteristic of productive collaboration. This pathway suggests that the process of "rapid-prototyping," building and testing design ideas with minimal discussion of those ideas can be effective and lead to success in on this design task. Based on this finding, perhaps a helpful strategy would be to encourage teams employ this "rapid prototyping" process, to take advantage of the unlimited opportunities for testing. In addition, the *Accept BDM* verbal interaction pathway appears to be one that is characteristic of verbal interaction that leads to productive collaboration. Teams considered high performing due to their percentage of successful designs, had significantly more successful designs when this pathway was used, than did the low performing teams. Again, the number of proposed modifications made does not appear to make a difference to the effectiveness of this verbal interaction pathway to lead to productive collaboration.

Surprisingly, verbal interactions that are characteristic of the *Discussion* pathway do not appear to foster productive collaboration or success on the Earthquake task. The only significant difference between the *Discussion* pathway and the *Accept BDM* pathway, is that prior to building a structure the design ideas are discussed amongst the group members. Once the initial idea has been discussed and proposed modifications considered, building of the structure commences until it is ready to be tested against the simulated earthquake. Overall, teams rarely engaged in verbal interactions that followed the *Discussion* pathway. However, when teams' verbal interactions did follow the *Discussion* pathway, those that were considered high performing based on their percentage of successful designs, had marginally significantly more successful designs than did the low performing teams. This was not the case for teams that were considered high performing based on the highest successful structure built. Because all teams used the *Discussion* pathway minimally it is difficult to assess whether verbal interactions of this type do indeed lead to productive collaboration.

The results of this study lend support to the claims in the literature that successful verbal interaction while collaborating involves: (a) clear presentation of ideas, (b) elaboration on ideas by group members, and (c) reasoning and evaluation of ideas collaboratively (Hoek & Seegers, 2005; Mercer, 1996). Teams that were high performing engaged in verbal interactions that allowed them to engage with each other's ideas, refining and improving upon them, until an ideal solution was reached. In some regards, the Earthquake task was an ideal task for promoting productive collaboration, because the physical component of the task allowed individuals to make their ideas clearly visible to their team members simply by building their idea. Barron (2003) highlights the creation of a "joint problem-solving space as being particularly important for achieving productive collaboration. It can be argued that the Earthquake task in particular, and design-based learning tasks more generally, are particularly effective at facilitating this process for students because it requires the creation of an artifact that represents the thinking of the team. Teams that were highly successful on the Earthquake task were likely able to take advantage of being able to make their thinking "visible" through their design. This explanation may also help account for why teams did not make extensive use, and had less success with, verbal interactions that followed the *Discussion* pathway.

## Future Research

While it was already noted that the average number of proposed modifications did not differ between high and low performing teams for either the *Accept BDM* or *Discussion* pathways, it is possible that there was a qualitative difference in the modifications proposed that may have contributed to the overall success of the team. What types of modifications were proposed during the verbal interactions of the high performing teams and did the types of proposed modifications influence the outcome of the trials? Alternatively, it is possible that high performing teams began with "better" ideas, and thus discussion or modification of those ideas was not necessary. These questions will need to be answered to provide greater understanding of the verbal interactions that foster productive collaborations.

Finally, in an effort to further understand collaboration within teams, an additional future study could look more closely at specific team participants who may have dominated a team's overall performance by verbalizing more than others. Examining the group dynamics, and the influence it has on the teams' overall performance will help further elucidate the characteristics of teams and their verbal interactions that lead to productive and successful collaborations.

# Implementing a Lesson Plan Vs. Attending to Student Inquiry: The Struggle of a Student-Teacher During Teaching Science

L. T. Louca, M. Santis & D. Tzialli, Department of Education Sciences, European University Cyprus,
6, Diogenous Str., Engomi, 1516 Lefkosia, Cyprus

**Abstract**: Despite calls for student-centered, inquiry-based instruction in science, science teacher preparation remains mostly teacher-centered, with the underlying assumption that novice teachers need to form a teaching identity before attending to their students' inquiry. In this paper, we use the idea of framing to analyze a 42-minute science lesson of a senior kindergarten student-teacher. Findings suggest that the student-teacher struggled for balance between teaching science as implementing a lesson plan, and as attending to her students' inquiry. We use this evidence to suggest that novice teachers can attend to students' inquiry as early as in their student-teaching experience, which suggests additional pressure on the need for preparation in teaching science. Thus, the role of science methods courses should be to help students understand the different interpretations of teaching within the different frames and provide them with strategies for entering more productive frames during teaching.

## Introduction

Despite decades of calls for promoting students' inquiry in science in grades K-12 (NRC, 2000; 2007), this agenda has been slow to become established in instructional practice (Minstrell & van Zee, 2000; Osborne et al., 2004), possibly for a number of reasons. First, despite a wide consensus regarding the importance of inquiry in science learning, the education community has yet to agree on precisely *what* is important in scientific inquiry (Anderson et al, 2000). For many, inquiry is a method for learning science "content," while for others, inquiry is a part of science and an objective in itself. Secondly, there is no agreement regarding what "productive" inquiry should include, especially in the early grades. Answers have varied from general appeals for "messing about" to more specific targets for developing "concrete" abilities such as controlling variables (e.g., Metz, 1995).

In contrast to the tangible and more straightforward objectives of traditional content, when considering these ambiguities, the difficulty of sustaining instructional attention to student inquiry is understandable (Hammer, 1995). Regardless of the particular account of children's inquiry, there always exists the challenge of diagnosing student progress in any classroom situation (e.g., Goodwin, 1994). Developing such diagnostic abilities for identifying and responding to students' scientific inquiry depends largely on teachers' professional development (both pre- and in-service) in teaching science. While a number of studies have looked into how teachers in primary and secondary education teach science (e.g., Kuiper, 1995), little is known about how kindergarten teachers implement the science aspects of the curriculum (e.g., Kallery & Psillos, 2002). To make progress in promoting student inquiry especially in early grades, science education needs to develop a better understanding of how teachers perceive and respond to student inquiry in classroom settings and what struggles they encounter to implement inquiry-based teaching.

The purpose of this case study is to contribute towards this understanding and development, by proposing and applying a specific methodological approach which helps to describe how a senior student-teacher conceived her role in the class and how her behavior reflected a struggle to balance between teaching science as implementing a lesson plan she had developed and received approval for by her tutor, in contrast to attending to her students' scientific inquiry. We use the idea of framing (Goffman, 1974; Tannen, 1993; Schank, 1990) to analyze a 42-minute science lesson of this student-teacher. In doing so, we seek to show how using the idea of "framing" in the context of analyzing student-teaching may prove useful in understanding the process of novice teachers' professional development and in identifying areas in which teacher education may support this. We also argue that it is not unrealistic to expect novice teachers to be able to attend to and respond to students' inquiry during real-time teaching.

## Theoretical framework

### Emphasis of science education in inquiry-based, student-centered approach

Following recent changes and reforms in curricula, science has become established as part of the early primary curriculum (The Curriculum Guidance for the Foundation Stage QCA/DfEE, 2000). The National Research Council (2007) strongly recommended the development of an approach for teaching science in kindergarten through eighth grade, in which science is viewed as providing opportunities for both learning and development, or to lay down the foundations in preparation for future learning in science (Kamii & DeVrie, 1993). In this context, considerable attention is given to children's own explorations and inquiry (QCA/DfEE 2000), with a number of researchers emphasizing the importance of engaging young children in hands-on science experiences which support the development of an early interest and knowledge base in meaningful scientific themes, and which provide children with an introduction to and support for developing science inquiry skills (e.g., Chen & McNamee, 2007; Kamii & DeVries, 1993).

Current emphasis in science education highlights among other things the support of student inquiry (NRC, 2000; 2007), promoting it as the central strategy for teaching science. The National Science Education Standards (NRC, 1996) has provided a definition modeled after the work of scientists where scientific inquiry refers to the diverse ways in which scientists study the natural world and propose explanations based on the evidence derived from their work. Inquiry also refers to the activities of students in which they develop knowledge and understanding of scientific ideas, as well as an understanding of how scientists study the natural world. Numerous other definitions can be found in the literature, which vary in their emphasis (e.g., Barman, 2002; Flick, 2002; Crawford, 2006). Taking all these into account, for the purpose of this paper, we take student inquiry to mean the pursuit of causal, coherent explanations of natural phenomena (Hammer, 2004) which may take many forms, both experimental and theoretical. Regardless of the form, the instructional agenda is to help students learn to engage in that pursuit for themselves. In this view, science inquiry supports the development of problem solving, communication and thinking abilities as students pose questions about the natural world and seek the evidence to answer them (NRC, 2000).

## Preparing teachers for inquiry-based teaching in science: approaches and challenges

Despite NRC's (2000; 2007) current emphasis on "student-centered" instruction in science education, only a few programs have been designed to support pre-service teachers in developing their knowledge about scientific content and inquiry (e.g., McDevitt et al., 1995). On the whole, teacher preparation for teaching science remains largely teacher-centered. Science methods courses focus on the things teachers (should) do, on instructional methods (Tobin & Fraser, 1990), management strategies (Feiman-Nemser & Parker 1992), questioning skills (Fleer & Hardy, 2001), evaluation procedures (Jarvis et al., 2001), and planning processes (Lenton & Turner, 1999), putting much of the emphasis of teacher preparation programs on helping teachers form a teaching identity (e.g., Freese, 2006).

The teacher-centered approach of preparing pre-service teachers to teach science has been strongly influenced by stage-based accounts of teacher development (Kagan, 1992). Teacher developmental stages refer to the stages through which teachers progressively gain professional knowledge, abilities and beliefs (Nimmo, 1994). This approach proposes that during initial stages of their development, novice teachers need to clarify and construct their self-image as a teacher by developing routines related to classroom management and instruction. Beginning teachers' concerns tend to focus primarily on self and self-image as a teacher, rather than on students' learning. Consequently, the level of effort and skill required by beginning teachers to teach science using inquiry-based approaches may not be achievable for many. Therefore the tendency in these instances is to revert to authoritarian, teacher-directed approaches (Harlen, 1996). In this context, activities or units that work are seen to be effective partly because they engage students, in the sense that they keep students interested. Although this approach results in teachers focusing on their own behavior before they can attend to student learning, it is seen as a crucial step early in their professional development (Kagan, 1992). Once they have "resolved" an image of themselves, novice teachers can then shift their attention to attending to and responding to their students' inquiry. Thus, the challenge to integrate aspects of teaching science as inquiry, into their planning and instruction maybe frustrating for novice teachers.

Conversely, Crawford (1999) suggests that it is not only possible, but it is also realistic to expect that at least some novice teachers design and carry out inquiry-based instruction. Novice teachers can be capable of articulating an emerging knowledge of teaching science as inquiry, and they may espouse philosophies aligned with this kind of pedagogy (Crawford & Lunetta, 2002; Windschitl, 2003), but they may be incapable of, or unwilling, for various reasons, to enact teaching science as inquiry in their classroom (McGinnis, Parker, & Graeber, 2004; Newman et al., 2004).

Levin, Hammer and Coffey (2009) provide an extensive review of the challenges to stage-based accounts of teacher development, indicating that this view may be misleading and steer teacher education in science in unproductive directions. They suggest that in a number of studies, pre-service teachers were able to reflect on several issues related to the content of teaching (Grossman, 1992), and to attend to the substance of their students' thinking (Davis, 2006), although Davis questions pre-service teachers' abilities to reflect-in-action. Despite stage-based accounts implying that after having developed classroom routines teachers focus their attention to student reasoning, Zeichner and Gore (1990) showed that novice teachers rapidly shift from progressive, student-centered attitudes formed during pre-service to traditional, teacher-centered approaches when confronted with the realities of the workplace. Furthermore, studies showed that teachers often become satisfied with their teacher-centered approach to teaching and are less likely to question their chosen routines (Grossman, 1992). Finally, Olsen (2007) indicates that such stage-based models focus on implementation and not necessarily on decision-making processes that take place during teaching and learning, and that such work has been primarily conducted with in-service teachers.

We agree with these challenges and we highlight that the ability to attend to students' inquiry is one of the critical aspects of the pedagogical content knowledge (PCK) that novice teachers need to develop as part of their pre-service preparation (e.g., Davis & Smithey, 2008). Even though helping pre-service teachers develop rich pedagogical content knowledge prior to substantial teaching experience is not an easy task (van Driel, De Jong, & Verloop, 2002). We agree with Davis & Smithey's suggestion that it is possible to provide pre-service teachers with enough experiences to prepare them to develop "PCK readiness" – that is the requirements for developing abilities to attend to their students' inquiry. Davis & Smithey use the following analogy to illustrate the idea of "PCK readiness": Kindergarten teachers spend most of the school year helping students develop "reading readiness" i.e., the skills students need to develop before they can read. None of these skills (how to hold a book, which direction to turn the pages, the letters and their sounds) is technically "reading," but every reader needs these skills. Similarly, they suggest that pre-service teachers can learn about the content, how to represent this to learners, and common ideas learners bring to the science class. Even if this initial knowledge is in pieces, this forms the building blocks for well-developed and usable PCK.

### The idea of framing and how we transfer it to student-teaching

Though substantial gains have been made in understanding teachers' professional knowledge development (e.g., Munby et al., 2001; Calderhead, 1996; Borko & Putnam, 1996), little is known about the difficulties novice teachers encountered during teaching science as inquiry (Anderson, 2002), raising questions about how to support learning and to enact teaching science as inquiry (Newman et al., 2004; Windschitl, 2003).

To contribute towards this end, we have adopted the term "framing" based on previous work in sociology (Goffman, 1974), sociolinguistics (Tannen, 1993), and cognitive science (Schank, 1990). Framing is used to describe the idea that people use knowledge from past experiences to make sense of what is going on in situations they perceive to be similar. In this sense, individuals are accomplished at attending to what is happening around them, searching for signals that indicate the type of activity and making alterations to their behavior when it appears appropriate (MacLachlan & Reid 1994). For instance, when entering an unfamiliar restaurant people immediately interpret what kind of restaurant it is based on activities around them: Are customers waiting for a waiter to take their order or are they standing at a counter ordering food? In this manner framing influences one's expectations about what is going on as well as their interpretations of what they see or expect to happen in particular situations, so influencing the way they act.

We can parallel the manner people frame daily activities with the way pre-service teachers frame their role in science classrooms. There are many aspects to framing, including how to manage teaching time, maintain student control and introduce new activities. Additionally, the consideration of whether or how teachers respond to their students' inquiry may also be an aspect of framing. Their understanding of successful teaching should include the issue of responding to students' inquiry or not, and in which ways this is done. This perspective may help to better understand student-teachers' enactment of teaching during the early phases of their careers.

Our purpose in this paper was to describe how the a senior student-teacher conceived her role in the class and how her behavior reflected a struggle to balance between teaching science as implementing a prepared lesson plan, and as attending to her students' emergent inquiry, seeking to identify different ways of teacher acting during teaching. While it is inconceivable to focus only on implementing a lesson plan with total disregard of student inquiry in a student-centered setting, it is also "unacceptable" for a student-teacher to ignore an informed lesson plan. This dilemma has implications for what is seen as the role of science teaching preparation and how educators support their student teachers' struggle to balance both criteria. In this paper, we seek to show that the student-teacher was able to attend to her students' inquiry during her teaching early in her career, despite stage-based accounts of teacher development.

## Methodology

This is an interpretive case study focusing on a single science lesson of a senior kindergarten student-teacher. We recorded and transcribed this lesson in March 2009 as part of the student-teachers' requirements to have five of their science lessons videotaped, which they subsequently reviewed and discussed with the faculty teaching science methods, their teaching supervisors and their peers.

For her last semester of student-teaching (Spring 2009) Mary (the study's participant) was assigned to an urban public kindergarten school and carried out her nine-week student-teaching practicum in a class of 17 students (age ranging: 4.5 - 5.5 years old). The lesson we analyzed for this paper was her first science lesson during this student-teaching phase and concerned the solubility of various substances in water. We chose to analyze this specific lesson because it was easy to identify instances in which Mary followed her lesson plan or not, as she had an elaborated version of her lesson plan and when following it she would literally read from it.

For this paper, we used the lesson video and its transcript as our primary data source. Using Videograph software, we coded all the episodes during which Mary talked during whole class discussions. The coding was based on whether she was following her lesson plan, or making "teaching moves" for which she had not planned. We used four codes for this analysis where Mary: (1) read directly from her lesson plan, (2) did not read from her lesson plan, (3) followed an open-ended discussion activity that she had planned for (that is she did not read from her lesson plan, but she was following a pre-planned activity) and (4) students talked. The coding was carried out by the second and third authors (Cohen's Kappa=0,945) and the resulted differences were resolved through discussion.

When agreement was reached, in order to have participant check of our interpretations of the findings, the first author carried out an open-ended interview with Mary, during which the video of the lesson was reviewed, pausing it at various points that had been selected based on the findings of the analysis. At those points, he asked Mary about her thinking and purpose for specific "teaching moves". In some cases, she requested to watch the episode under discussion once more. Eventually, she was able to identify the elements of the students' thinking to which she was responding. In this way, we verified or made alterations in our interpretations of the findings of the code-based analysis.

## Findings

For about 14 minutes of the lesson (out of the total 42 of the entire lesson – 33.3%) Mary read directly from her lesson plan, obviously following an elaborately prepared plan. Out of the total 483 utterances coded, this time corresponded to 86 utterances (17.8%). We refer to these instances as working within an *implementing-a-lesson-plan frame* (Frame 1). Conversely, for about nine minutes, (21.42% of the total lesson time) Mary spoke spontaneously without searching to read what to say. This time corresponded to 125 utterances (25.87%). Within these nine minutes of spontaneous talk, we identified two distinct sub-frames where Mary either a) responded directly to her students' thinking or conversational contribution (*attending-to student-inquiry-frame* – Frame 2) or b) she was following an open-ended discussion with her students within her lesson plan's general structure (*lesson-plan free-talk frame* – Frame 3). The second frame consisted of 49 utterances (10.14%) and lasted for about 4 minutes (9.5% of the total time), and the third frame consisted of 76 utterances (15.73%) and went on for about 5 minutes (12.5% of the total time). The remaining 217 utterances corresponded to student talk in the conversations, while the time unaccounted for was taken up by the children's experimentation (about 9 minutes). Figure 1 represents a timeline graph of the lesson's discourse. From this it is clear that, while there are instances where Mary worked primarily within one of the three frames identified (e.g., utterances 0-13; 81-145; 416-449), there are also instances when she shifted to and from between the frames over a short period of time (e.g., 14-80; 140-231; 350-455). The analysis of the transcript and the subsequent interview with Mary, allowed us to define the characteristics of the frames identified. Below we describe in detail those characteristics for each of the frames we identified.

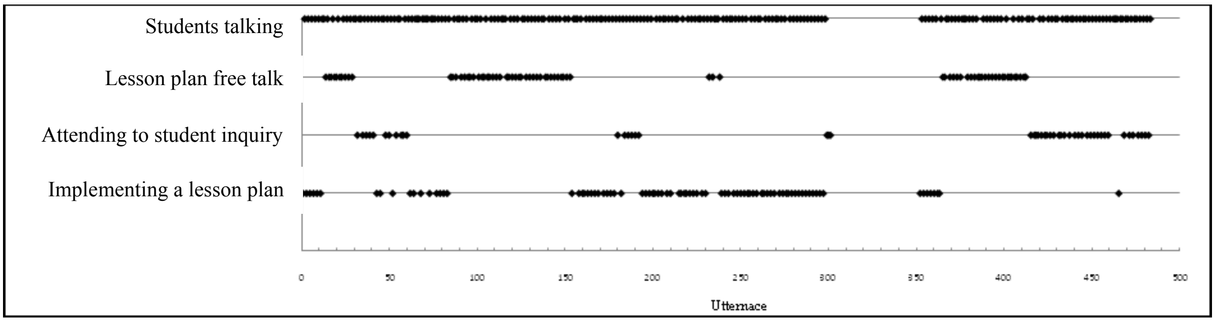

Figure 1. Timeline graph of the student-teacher's discourse

### Working within the implementing-a-lesson-plan frame

For most of her teaching time, Mary worked within the implementing-a-lesson-plan frame. She began her lesson within this frame, and in almost all cases returned to this frame after having shifted to the other frames. From the interview, it was clear that Mary was very conscious of the fact that the lesson plan she had prepared included prescribed activities from the teacher's official guide for teaching science in kindergarten, and for which her tutor had given approval thus, she felt that "these are the steps we have been taught to follow". Her sense of urgency to fulfill each outlined step was also apparent as she proceeded with the sequence of activities, paying little attention to her students' responses and understanding. Her questioning, as she turned from one student to the next, was characterized by the search for the correct, predefined answer. The conversational exchanges that took place in this frame lasted longer than the other two frames, with each of her utterances lasting for an average of 10s – (the duration in frame 2 was about 5 seconds and about 4 seconds in frame 3.) Consequently, her questioning sessions during this frame labored for as long as it took to find the answer required. One of the most salient aspects of this frame was the jarring changes from one activity to the next when Mary felt she 'had' to move on.

In the example below we see Mary cutting short a discussion in order to move on to the next activity. This discussion, in which students were articulating their hypotheses relating to what had happened to the sugar in the water, was carried out in attending-to-student-inquiry frame. In this excerpt, Mary reverted back to the lesson plan's next activity (frame 1) without linking it to her students' on-going discussion, giving the impression that it was the lesson plan, not Mary 'running' the lesson.

*Mary:* Harry says the sugar fell into the water, so what might have happened to the sugar? [as it cannot be seen]
*Student 1:* It turned into water
Mary: What do you mean it turned into water?
*Student 2*: It melted
*Mary*: It may have melted…
*Student 1*: It became sugar
*Mary*: OK, now I am going to give you each something, OK? You can touch it, smell it, but you mustn't taste it, [hands out substances with which the children will experiment]

## Working within the attending-to-student-inquiry frame

Our analysis showed that Mary shifted from following her lesson plan to directly responding to her students' thinking, and in this attending-to-student-inquiry frame, she did not read from her lesson plan. Rather, she attended and responded to her students' thinking, even if this led her outside of what she had planned. In these instances, she spontaneously provided her students with some feedback, comment or conversational direction that was not part of her lesson script. This frame usually lasted for short bursts of dialogue when Mary responded directly to her students' inquiry and then she quickly reverted to frame 1. For instance, after the children's various predictions of what would happen to the substances in water, during which Mary followed her lesson plan, the different children's predictions caused Mary to abandon her lesson script.

*Mary*: How can we be sure what is right? I see we have some disagreements… how will we know for sure if our materials will dissolve or not? What should we 'scientists' do?
*Student 3*: We can sit at our tables and see…
*Mary*: See what? Do what at our tables?
*Student 3*: Scientific things!
*Mary*: Scientific things! Well done, and what do we call these scientific things?
*Student 4*: Experiments!
*Mary*: Well done Nancy! We're going to do an experiment!

After this short discussion (frame 2) , Mary shifted back to following her prescribed lesson plan (frame 1) and brought out a chart for noting down the predictions prior the experiments. We suggest that the relatively brief duration of these exchanges in frame 2 (an average of 5 seconds per teacher utterance) was due to two factors. First, the fact that the dialogue during this frame was not part of the "official script" seemed to cause Mary anxiety and a desire to return back to the security of her lesson plan. Second, it became apparent during the interview that Mary somehow underestimated the real value of these activities regarding them as only perfunctory steps in the process towards understanding the concept of dissolving. Nevertheless, during this frame there was cohesion not only within the frame as Mary's questioning directly addressed the children's conversational contributions, but also as she moved from this frame to a different one. These moves were characterized by a natural flow which did not disrupt the rhythm of the lesson nor disorientate the children.

## Working within the lesson-plan free-talk frame

During analysis we identified a third, somewhat intermediate, frame to the previous two. This frame was observed (1) during the discussion of the problem presented (where was the sugar which had fallen into the water?), (2) while the children identified the materials with which they would experiment, and (3) immediately following their experiments, when they announced their results to the rest of the class. In this lesson-plan free-talk frame, Mary also responded to the children without reference to her lesson plan, but on these occasions she was clearly working within a particular activity she had noted previously as a sub-heading but had not scripted for in the lesson plan. She responded less specifically to the children's conversational contributions compared to the second frame, often reflecting their answers back at them when these were wrong (e.g., "is it sugar?") or repeating their correct answers, meanwhile using more closed questions than when working within the attending-to-student-inquiry frame. This frame always followed on from the implementing-a-lesson-plan frame and it was apparent that Mary was aware of the pedagogic objective for these activities which, to some extent restrained her responses to students' inquiry in her attempt to fulfill the objective. On two occasions, when she moved from this third frame to the attending-to-student-inquiry frame, this occurred when the children encountered difficulties in responding appropriately to Mary's more restricted questioning and Mary seemed to instinctively and effortlessly change her framing to accommodate for this factor and respond directly to the children's comments, building on these comments to guide the children in their discovery.

The following is a short excerpt in which the children announced their conflicting results for whether flour dissolved in water or not. In this excerpt, Mary shifted from working in the lesson-plan free-talk frame (during which she guided students to present their results) to attending-to-student-inquiry frame.

*Mary*: Let's look at your results for flour. What happened to the flour? Did it dissolve or not dissolve?
*Student 5*: It dissolved!
*Student 2*: No, it didn't dissolve!
*Mary*: What did you discover? Let me come and see [what they had noted on their charts]
*Student 1*: We discovered that sugar….
*Mary*: But what happened to the flour now. […] Did it [the flour] dissolve or not?
*Student 1*: It dissolved.
*Mary*: Has another team noted something different? Do you agree?
*Student 4*: Andy's team discovered that it didn't dissolve.

While working within a lesson-plan free-talk frame for some time, Mary "saw" that at least two groups of students had different results for whether the flour dissolved in the water or not. A possibility is that this disagreement is related to how one defines solubility (e.g., something is considered dissolved if it is not visible any more, or when one cannot identify two separate substances). While Mary did not clarify this definition, she addressed the disagreement between the groups, because, as she indicated in the interview, students acting as scientists need to reach consensus about an experimental result. To do that, she shifted to the attending-to-student-inquiry frame. Mary also indicted that when she reverted back to following-the-lesson-plan frame, it was specifically to move to the next activity in the lesson either guided by time restraints or believing that she had fully addressed the children's questions. These moves back to the following-the-lesson-plan frame were marked by abrupt changes in the discussion's direction and lesson activity.

### Themes emerged across the three frames

Despite the differences between the three frames that we described above, we have identified at least two emerging themes relevant to all the frames. These include Mary's need for "teaching security" and her role in the classroom, which we describe below.

Mary explained that the lesson plan offered her security by knowing "where [she was] in the lesson and how to proceed." She indicated that "I feel secure that I know now I do this and then I do that." This had an impact on the duration of the various activities: During the lesson implementation, Mary felt justified to allow e.g., the questioning to last for a long time, until the children gave the 'correct' answer, resulting in her paying little attention to alternative answers offered. Conversely, she was aware of the time pressure during the frames outside of the lesson plan stating emphatically, "the discussion flowed and the lesson progressed but it took too long." Her view that these activities did not contribute substantially to the learning added to her need to return to the safety and validity of the lesson plan, and was evident in her abrupt jumps from the lesson-plan free-talk back to the implementing-the-lesson-plan frame.

Mary also indicated that while working within the implementing-a-lesson-plan frame she "just let the lesson plan roll and didn't respond to them [her students]", supporting our own findings that in this frame Mary "automatically" moved from one activity to the next. She conceived her role as following an approved plan, and thus her main concerns were to finish the activities culminating in the correct answer, though she described her role as that of a guide, providing the stimuli with which to develop the children's knowledge and discovery in the direction she saw as relevant. In contrast, while working within the attending-to student-inquiry-frame or the lesson-plan free-talk frame, she indicated that the children had made comments she had not predicted and thus responded intuitively addressing the issues raised. Likewise, when asked why she had not scripted for all the activities in the lesson plan, she said that during these activities "I knew [what needed to be done]".

## Discussion

Our purpose in this study was to describe in detail a science lesson of a senior kindergarten student-teacher in order to gain better understanding of how she conceived her role in the class and how her behavior reflected a struggle to balance between teaching science as implementing a lesson plan she had developed and received approval for by her tutor, in contrast to attending to her students' scientific inquiry.

Our first contention is that our findings show that the idea of "framing" (Goffman, 1974; Tannen, 1993; Schank, 1990) as a methodological approach used for analyzing teaching may prove useful in understanding the processes that novice teachers go through during their first attempts to teach. Framing is used to describe the idea that people are accomplished at attending to what is happening around them by searching for signals that indicate the type of activity and making alterations to their behavior when it appears appropriate (MacLachlan & Reid 1994), and by using past experiences to make sense of what is going on in situations they perceive to be similar. This helped us define different ways of teacher acting during teaching and their characteristics and so identify several issues that caused Mary's struggles during student-teaching in science.

The need to follow an approved lesson plan, to feel confidence in what she was doing, the restriction of the time, and her understanding of her role as a teacher in the classroom were some of the factors that guided Mary's behavior during the lesson we analyzed.

Second, we argue that it is not unrealistic to expect novice teachers to be able to attend to their students' inquiry during actual teaching. Despite views suggesting that novice teaches may be incapable of enacting teaching science as inquiry (e.g., McGinnis, Parker, & Graeber, 2004), our findings suggest that the student-teacher in this study was able to attend to her students' inquiry at times and successfully integrate aspects of teaching science as inquiry into her teaching. Of course, we do not suggest that she was expert in teaching science as inquiry, in fact, there are several respects in which it is evident she was not. Our conclusion, then, is that novice teachers come to their student-teaching with some possibly nascent abilities for inquiry teaching, that they may invoke these spontaneously, directly in line with the abilities that teacher educators have described as important to impart. That Mary actually shifted frames, suggests having the ability to make these transitions. From the interview it was clear that these shifts were not always done consciously, but intuitively.

Agreeing with challenges to stage-based accounts of teacher development (e.g., Levin, Hammer & Coffey, 2009; Grossman, 1992; Davis, 2006; Sherin, 2004), we suggest that an important role of undergraduate methods courses is to help students make clear distinctions between alternative teaching frames, understand the different interpretations of teaching within each frame and the characteristics of the teaching resulting from each. At the same time it is important to help pre-service teachers develop strategies both for (a) entering the attending-to-student-inquiry frames during early stages of their careers, and (b) working within that frame more reliably. This will help pre-service teachers to develop "PCK readiness" (Davis & Smithey, 2008) which they can then use for developing abilities to attend to their students' inquiry.

# "I study features; believe me, I should know!" The mediational role of distributed expertise in the development of student authority

Jennifer M. Langer-Osuna, University of Miami
222 Merrick Building, Coral Gables, FL, 33124 USA, jlangerosuna@miami.edu
Randi A. Engle, University of California, Berkeley

**Abstract:** This paper examines the development of student authority in a case of one student assigned the role of topic expert in a classroom that utilized distributed expertise as a participation structure during collaborative projects. Using video data of a heated student-led debate, we show how this student successfully positioned himself with greater authority than recognized adult experts, despite the fact that his evidence was often weak given classroom norms. He was able to do so for two reasons. First, he utilized his role as topic expert to position himself with authority and discredit others, including the recognized adult experts. Second, he drew on student allies that supported his position. We conclude with implications of this paper for how participation structures may mediate the development of powerful student identities, and function in concert with other interactional factors in the classroom.

## Introduction

Many math and science classrooms have shifted toward a sociocultural view of education, in which learning occurs through interactions among students, and between students and the teacher. A central feature of such classrooms is to have students work collaboratively in structured ways designed to support their engagement in disciplinary ideas and practices. Participation structures, such as using a "round robin" to share ideas (Langer-Osuna, 2007; Saxe et al., 2005), the jigsaw method for sharing expertise (Brown & Campione, 1994), or the use of student group roles (Cohen & Lotan, 1995; Herrenkohl & Guerra, 1998) afford students opportunities to think through and debate ideas, to judge ideas as reasonable, and to gain a sense of ownership over their learning. Participation structures are also designed to support more equitable engagement in collaborative tasks (Cohen & Lotan, 1997). If each student is expected to contribute ideas in a structured fashion, then it is less likely students will become privileged in or marginalized from group discussions.

Recent studies, however, have shown that the goals of equitable, collaborative learning are difficult to accomplish even with such participation structures because students tend to construct inequitable relations of authority among themselves (Bianchini, 1999; Kurth, Anderson, & Palinscar, 2002). For instance, Esmonde and Langer-Osuna (2009) found that relational power among students—including social authority such as friendship and popularity, and academic authority such as being considered smart—still played a large role in how students negotiated group discussions despite classroom norms valuing multiple competencies. Engle, McKinney de Royston, Langer-Osuna, Bergan, and Mazzei (2007) found that some students illegitimately gained more influence and authority over others in a discussion in part by differentially making use of tactics to gain greater access to the discussion despite classroom norms designed to promote equitable turn-taking.

Understanding how students become positioned with authority is important to the goal of supporting productive student-led discussions (Engle & Conant, 2002; Gresalfi, Martin, Hand, & Greeno, 2009). Students positioned with authority participate more frequently in small groups, are more able to gain access to and hold the conversational floor, decide what is correct, be seen as contributing more meritorious ideas, and become more influential than students perceived as having less social or academic authority (Cohen, 1997; Inglis & Mejia-Ramos, 2009; Langer-Osuna, 2009). Being positioned with authority supports engagement because the student is in a position to judge what is correct or incorrect, and to initiate or close down group discussion (Esmonde & Langer-Osuna, 2009). Such privileged engagement and influence can occur not only in classroom using participation structures, but even when the students positioned with authority make claims that are not as objectively meritorious as those made by others (Engle, et al., 2007; Kurth, Anderson, & Palinscar, 2002).

This paper focuses on how a particular participation structure, the role of being a local expert mediated the assigned student's position of authority in coordination with his and other students' actions. The classroom used a participation structure called *distributed expertise,* in which students were assigned particular topics to research and become experts in, and then teach what they have learned to other students (Brown et al., 1993). In particular, we explain how this student, Brian, ultimately became positioned with authority because: (a) he utilized his role as features expert in order to position himself with greater authority than other students and even adult professionals; and (b) he made use of potential allies who took up his position of authority.

## Data Collection and Analytic Strategies

In classrooms that utilize distributed expertise, students are treated like researchers who gather, analyze, and share information about a particular topic, gradually developing expertise in that specialty area (Brown et al., 1993). Our paper is situated in one such classroom, in which students were researching different endangered species. Students in this classroom established their expertise when they showed that they could provide a legitimate answer to any reasonable question about their topics (Engle & Conant, 2002).

We analyze a case of nine fifth graders who engaged in a student-led debate (Engle & Conant, 2002; Engle, et al., 2007) that arose unexpectedly the day after a field trip to Marine World, then a science learning center. During the orca (i.e., killer whale) show one of the trainers stated that orcas were not whales, but rather the largest member of the dolphin family. Soon before going to Marine World and after a long struggle, this particular group of fifth graders had finally proven themselves to have sufficient expertise about whales to be allowed to create a bulletin board about their research for the rest of the school. As part of that, Brian had been established as the local expert on the anatomical features of whales. Thus, when the Marine World trainers mentioned the orca's large dorsal fin as being relevant to their assertion that orcas were not whales, this was taken up as a direct challenge to the group's, and especially Brian's, hard-fought authority. In the face of what is typically a greater source of authority – adult professionals – Brian stood firm on his position as an "expert" on whale features. Thus he sought to position himself as *more credible* than the adult professionals.

We view the case of Brian as a revelatory case (Yin, 2001) as it is more dramatic than typical student-led discussions, thereby highlighting how issues of authority are negotiated vis-à-vis student roles in interaction. Indeed, the student-led debate was loud and intense, and Brian successfully utilized his role as features expert to convince all but one student that he was a more credible source of information than the Marine World trainers and, later, the author of a science book about whales. The dramatic nature of this debate illuminates the ways in which such participation structures as distributed expertise can mediate not only the participation of a particular student in a given role, but also the interactions among students, and how students get positioned as a result. The processes of mediated student interactions and positioning occur in collaborative discussions that utilize participation structures. Our goal, then, is to explore the relationship between these processes, and how they explain the development of positions of authority.

The primary data source utilized here is a 27-minute videotape of the student-led debate. Video was recorded by a mostly fixed Hi-8 camcorder that captured the circularly arranged group from the side and was connected to a radio microphone placed in the center of the group. Video data were coded and organized into an analytical transcript that was divided into columns (Barron & Engle, 2007; Jordan & Henderson, 1995) for words and actions relevant to: (a) making claims about whether orcas are whales or dolphins, and (b) indications of being influenced by particular students; (c) type of evidence used to support those claims, and (d) the perceived authority of sources of evidence; (e) the management of the conversational floor and interactional space; and (e) a miscellaneous column for all other words and actions. Multifunctional words and actions were included in multiple columns. This analytical transcript was originally used for previous analysis that considered multiple factors explaining students' differential influence during this student-led debate (Engle, et al. 2007; Engle, Langer-Osuna, & McKinney de Royston, 2008). Of the four explanatory factors, students' negotiated levels of authority were particularly central. This, in this paper, we go beyond previous analyses to unpack exactly *how* Brian developed a position of authority vis-à-vis other students during this student-led debate.

To understand how Brian developed a position of authority, we coded for events that signaled a shift in each student's position with respect to authority. A person was considered to be positioned with authority on a topic to the degree that he or she was evaluated, acted, or was treated as being credible. A shift in a student's perceived authority could be signaled by statements that contained explicit evaluations of his or her credibility (e.g., "He's features expert, he should know"), statements or actions that evidenced that student being treated as an authority (e.g. one student asking another to give them the correct answer and recording it without request for justification), or the student acting like an authority without anyone contesting it (e.g., "Believe me, I should know" with no one else objecting). For each shift in students' perceived authority, we then noted the student interactions that preceded the shift. Patterns of interaction were compiled into categories (Guba & Lincoln, 1982), which served as a basis for characterizing the interactions that explained the development of Brian's position of authority in this student-led debate.

## Characterizing Changes in Brian's Authority During the Student-Led Debate

We begin with an analytical narrative (Angelillo, Rogoff & Chavajay, 2007) based on the coded, analytical transcript. The narrative describes the key events of the debate relevant to characterizing how Brian's authority developed. Because another student, Samantha, was the most vocal opponent to Brian, changes in her authority, which increasingly became oppositionally paired with Brian's, are also described.

### Early in the Debate, Both Brian and Samantha Positioned with Similar Levels of Authority

At the start of the debate, both Brian and Samantha were generally oriented to as having higher authority than other students in the group. Brian was recognized as the expert on whale anatomical features, his assigned role for the project. In contrast, Samantha was often oriented to by the teacher and other students as a good student who knew things, which was evidenced by another student's comment at one point in the debate that "we all goin' against Samantha; we better be right." (line 420). Samantha's authority also may have been strengthened given her recent influence in the hallway debate about whether to include orcas on their bulletin board. Early in the debate (through line 97), Brian's authority was given additional boosts by the teacher who represented him as having "serious points" that should be considered.

### Brian's Authority Was Challenged

During the next phase of the debate (lines 97-180), Brian's authority was challenged on three occasions when the quality of his evidence was evaluated as being low. First, Brian's and Samantha's credibility were both challenged when the teacher declared that only one student, Jonah, had thus far presented evidence. His arguments had used documentary sources (lines 50-52) while theirs had not. Brian and Samantha then argued back and forth for opposing positions with no resolution while each implied that the other had lower credibility. This started to put their positions of authority in opposition. Next, Brian's authority received an additional downgrade by the teacher who required him to provide a more well-justified argument before she left the group to attend to other groups. As the teacher left, a next student, Toscan, took up Brian's role as features expert by asking him for key facts about whales' anatomy. However, Brian's role as expert was weakened further as Jonah used new documentary evidence to contradict Brian's claims, which Toscan subsequently acknowledged.

### Brian's Authority Steadily Increased

A transition occurred during the next episode (lines 181-379) when Samantha began defending the authority of the trainers. Brian then began arguing for his superior authority on the topic due to his role as features expert. Toscan defended Brian as having greater authority than the trainers, and presumably anyone else who might wish to argue against Brian. Several other students joined Brian's side of the argument during this time. Later, after having difficulties getting selected for turns, Samantha interrupted to argue against Brian's presumptions that he was a scientist and that the trainers were not, but was stopped first by Brian and then Toscan.

In the debate's climax (lines 380-435), Brian made a point against the trainers' authority that was oriented to as high quality and in response three more students publicly declared allegiance to Brian's side while one strengthened her commitment to it, with Brian and his allies celebrating after each success. It began with a rolling chorus of student agreements to Brian's point about the trainers not being experts as one of them confused how many teeth orcas have as compared to dolphins. At this point in the debate, most students had aligned with Brian. Jonah then got the floor and argued that the book he was using as documentary evidence to challenge Brian's credibility offered contradicting information, discrediting the book's authority. Gaining Jonah as an ally was interpreted by Brian and Toscan as meaning they had "won" the argument. Finally, Brian got Jonah to call on a still unaffiliated student, Sione, who also declared allegiance with Brian's side. The teacher then called to the group to wrap up the debate, and Brian concluded, "I rest my case."

## Analyzing the Development of Student Authority

Our analyses, described below, show that Brian became positioned with and sustained relatively greater authority primarily because: (1) he utilized his role as "features expert" to mediate his position of authority vis-à-vis others; and (2) he made effective use of potential allies who took up his position of authority.

## The Role of Expert as a Resource that Brian Used to Position Himself with Authority

Brian engaged in particular forms of interactions that served to maintain his position as expert on whale features and become positioned with relatively greater authority than others: (a) he highlighted the relevance of his role, while (b) personalizing his expertise beyond the role itself; and (c) he simultaneously redefined the trainers as non-scientists, and then (d) linked the discredited trainers with Samantha, which reduced her credibility.

### The Relevance of Brian's Role as Features Expert Was Made Central to the Debate

Brian's role as features expert was germane to the debate that erupted among students after the Marine World fieldtrip. That is, to decide whether orcas were actually whales, an understanding of the anatomical features of whales would be critical. However, other sources of information contradicted his conclusion that, because of similarities of anatomical features, orcas were indeed whales. Students drew on these sources of evidence, which included a book on whales, to argue against Brian's conclusions. Because classroom norms valued backing up arguments with sources of evidence, the information offered in the book became more central to the debate. Indeed, early in the debate when the teacher was still present, she stated that only one student, who had drawn on information from a book, had thus far used any evidence despite the fact that Brian had cited particular features of orcas that were similar to whales. In doing so, Brian's "knowledge" of anatomical features became less central than the information gleaned from the book or even from the trainers during the field trip.

Thus, in order for Brian to claim a position of authority, he needed to make his role as features expert just as central a source of information as books or the trainers. In the excerpt below, Brian positioned his role as features expert as a central *source of information*:

51 Brian: Oh . . it's . . it's kinda it seems like it's not true [*that orcas are dolphins*]
52 because . . um in all the research
53 everything I've done on/ on killer whales . . . .
54 it points to that they are whales
*(+ signifies Brian's gestures for emphasis)*
55 the +blubber . . the+blowhole . . the +eyes . . the +teeth
56 it points out . . that they're a whale

Brian's phrases "in *all* the research" and "*everything* I've done" (lines 52-53) emphasize that he had done a lot of work on his route to becoming an expert and had gathered much information, such that his conclusions (lines 54, 56) ought to be considered credible.

However, his conclusions were challenged by some of the other students who drew on other sources of evidence that suggested that these similarities also extended to dolphins. Thus, as in the following statement, and in many other moments (included in other sections below), Brian positioned his role as features expert itself as making him a central *authority* in the debate:

199 Brian: I study FEATURES . . believe me I should know . . I should know . .

When other students, in particular Samantha, asserted that the trainers were also in positions of authority on the topic by virtue of their profession, Brian sought to expand his expertise by personalizing it beyond the classroom role to Brian *himself* being an authority on the issues relevant to the debate.

## Brian personalized his expertise beyond the role itself

Brian personalized his expertise so it transcended his classroom role as features expert by claiming that he as a person was an authority on issues pertinent to the debate:

226-7 Brian: I've known a lot about whales . before I started researching . .
…
498-9 I:: . know .a lot about whales personally before I even started researching this . .
500 so nothing's that new to me . . . .

Brian defended his position of authority by claiming that his expertise went beyond the role of features expert to include the contents of his individual mind (line 290), which existed prior to the assigned role (lines 498-500), and was inaccessible for critique (line 291-2).

## Brian redefined the trainers' role to that of non-scientist

At the same time, Brian simultaneously defended his position of authority by *redefining the trainers' role* to that of a non-scientist. Brian's role as classroom expert on the anatomical features of whales gave him particular tasks to complete, which included researching, documenting, and sharing information about whale features with his group, the class as a whole, the rest of the school, and any adults who might engage with the class (see Engle & Conant, 2002). Brian's specific tasks were well-defined and easily defended to the other students as engaging in "real research." Brian thus argued that the role of Marine World trainers included little more than performing with dolphins and included little of the real work of scientists like himself.

In the excerpts below, Brian contrasted his and the trainers' roles, asserting that they were not comparable in expertise:

221-3 Brian: I study FEATURES . . believe me I should know . . I should know . .
224-5 they TRAI:N whales . . there's a BIG old difference . .
…
369-70 Brian: okay I'm gonna change and be one of the persons who works at Marine World
371-3 for the whale training . . [ I apply for a job . um . and then my boss tells me
374-6 . . take this stick . . tap [ the water . . and then the whale will come up
…
387-8 and I know a LOT about whales, AND I've REsearched it . .
…
478-9 Brian: like they're really sci:entists /they just apply for a job one day
480 got told a little bit about it .
481 and they've been working with the whales ever since . .

In lines 221-225, Brian directly contrasted the two roles and asserted that he, unlike the trainers, actually studied the anatomical features of whales. The trainers, instead, were simply employees who were told by their employers what to do to make the whale come out of the water during the show, and perhaps told also a "tiny bit" about whales (lines 224, 379-381, 480). Toward the end of the debate, Brian directly challenged their expertise by sarcastically stating, "like they're really scientists" (line 478).

By engaging in such interactions with the group, Brian positioned himself as a more valid source of information than the trainers by virtue of their contrasting roles. Brian's role as features expert positioned him as a "real scientist", while the trainers' role was redefined to include little more than following directions

### The discredited trainers became linked to Samantha's credibility

In the course of the student-led debate, Samantha became the most vocal supporter of the trainers' credibility. She was considered to be someone who gave evidence-backed arguments. Indeed, prior analysis of this data (see Engle, et al., 2007, Appendix A) indicated that Samantha's arguments during the focal student-led debate were more objectively meritorious than Brian's arguments. Thus, in order to reduce Samantha's credibility as a student with valid arguments to consider in the debate, Brian (and his allies) effectively linked Samantha's credibility with that of the discredited trainers. Because the trainers' authority was, in essence, directly in opposition to Brian's, Samantha's authority became oppositionally linked to Brian's.

In the following excerpt, Samantha was positioned as knowing less than Brian, even though at the start of debate, and throughout the year, Samantha was considered to be a student with high academic status.

| | | |
|---|---|---|
| 410-1 | Samantha: | I see (your point of view) but still . . is . that [*the trainers know better than us*] |
| 412-3 | Jonah: | still what? [*Toscan puts hand down, Jonah's is still up*] |
| 414-5 | Brian: | *(to Samantha)* At first you're TOtally convinced that a killer whale is a whale . . . |
| 416-7 | | THEN you find out just from ONE person . from ONE moment . |
| 418 | | that it's a dol]phin. |
| … | | |
| 447-8 | Brian: | [*the trainers know better than*] you do . . better than . YOU do . . |
| 449 | | I::: know what I:'m talkin' about |

The excerpt above followed after Samantha asserted that the students should believe the trainers because they likely knew more about whales and dolphins than the students did. Some of the students then pointed out mistakes they recalled the trainers making during their performance in order to discredit them. Samantha conceded their point and had begun formulating a counter-response (lines 411-412) but was then interrupted and criticized for believing, not an expert, but rather "one person from one moment" (lines 416-417). Brian then shifted the nature of the criticism to be about Samantha herself, stating that the trainers, if anything, knew more than she did (lines 447-448) but not more than he did (line 449). In doing so, Brian first linked Samantha's and the trainers' credibility, and then demoted Samantha as knowing less than even the discredited trainers.

## Allies Took Up and Supported Brian's Position of Authority

Brian's moves to position himself with greater authority than even adult professionals could not be successful by themselves. Other students could have rejected his attempts to position himself in such ways, negotiated an alternative positioning with him, or taken up his proposed positioning as having greater authority (Clark, 1996).

In order to encourage the latter to occur, Brian engaged in several kinds of interactions that served to gain and maintain allies, including taking credit for arguments stated by others, and rousing students' desires to be his ally rather than foe. We then see evidence that students rallied in support of Brian's credibility, joining in the criticisms of the trainers, Samantha, and even the book author, while aligning with and building on Brian's arguments or the arguments of others that Brian had claimed as his.

### Brian gained authority by taking credit for others' points that supported his side of the debate

Brian often positioned himself with authority during the debate, which was at times taken up or challenged by the other students. Brian was able to increase uptake of his position of authority by aligning with, and taking credit for, points made by others that had been oriented to as compelling in the debate. In the following excerpt, Brian claimed another student's point and was later credited with that point by a third student:

| | | |
|---|---|---|
| 213-4 | Jonelle: | if . if they're dolphins why do they call them killer whales? . . |
| 215 | | why don't they call them [ (killer dolphins?) |
| 216 | Brian: | My point exactly . . |
| … | | |
| 234 | Toscan: | ok, Brian has a very good point . . . . |
| 235-6 | | when . . the killer whales, if they're called . |
| 237-8 | | and Jonelle, if the killer whales are called killer whales . |
| 239 | | why are they saying NOW that they're dolphins |

Jonelle argued that orcas, also known as killer whales, were likely to be whales because their name includes the term "whales," not "dolphins" (lines 213-215). Brian immediately then exclaimed, "my point exactly" (line 216) claiming the idea as his. Moments later, Toscan attributed the point to Brian (lines 234) and repeated the argument, mentioning Jonelle as linked to this point only in passing (line 237).

During the debate Brian frequently used the phrase "my point exactly" or later simply "exactly" (lines 41, 44, 216, 620-621, 659, 695, 721) in response to others' points for the orcas-as-whales view and then got the last word at the very end of the debate, saying, "I rest my case" (line 836). In essence, Brian successfully took ownership of many of the arguments offered by others that supported his side of the debate, positioning himself as the leader of the "orcas as whales" side, and the other students as merely supporting *his side* of the debate.

### Brian created in students a desire to align with him rather than against him

In addition to gaining allies by essentially becoming the figurehead of successful points, Brian also created in students a desire to align with him by dramatically celebrating when students took up his position through cheers and high-fives while also creating an intimidating climate for disagreeing.

Brian loudly and excitedly celebrated when students announced either switching to or confirming support for his side of the student-led debate. For instance, in response to a claim that supported Brian's attempts to discredit the trainers, Brian loudly and excitedly exclaimed, "Yup, yeah you're right! You're right! You're hecka right!" Moments later, Brian exclaimed, "whooo!" in support of another student contributing arguments that also positioned her on the orcas-as-whales side. Directly after this, several students shot their hands up to speak next. From that point on, the majority of students in the group shared cheers, high-fives, and animated talk as they contributed to the orcas-as-whales side of the argument, creating a snowball effect of support for Brian's position of authority in the debate (Anderson, et al., 2001).

For instance, in the excerpt below, Brian dramatically celebrated after Jonah read information from the book *Album of Whales* that could be understood to support the claim that orcas are not dolphins:

647-8 Jonah: *(holding up book)* it says right here . that um . wha/ that . um
649-50 that wha/ . that um dolphins are beaked wha/ . beaked whales . . a family
651-2 *(looks up from book)* killer whales are not even/ . don't even have have a beak
653 Brian: A::::::::::::::::::::H *(screeches; Brian jumps up and down, in and out of chair)*
654 *(Brian high five's Toscan and Sione)* . . . . We WON!
…
665-7 . . we convinced him . we convinced him we convinced him
…
672 *(Brian jumps up from chair, turns around dancing in place three times, lifting right and left arms in air alternately, and says in sing-song voice)*
673 HALLELUIA, that's the way

Jonah offered evidence that dolphins are considered "beaked whales" (lines 647-650) and noted that orcas do not have a beak (line 651-652). This was Jonah's first contribution supporting the orcas-as-whales side; his previous contributions, which all used high-status and high-quality documentary evidence, tended to support the opposing view. Brian dramatically celebrated Jonah's contribution, which he interpreted as signaling that Jonah had switched sides. Brian jumped in and out of his chair, screamed, gave high-fives to nearby students, danced around, and even yelled out, "Halleluia" in praise of gaining a new ally in Jonah, also a high-status student.

These celebrations were coupled with harsh responses to Samantha's challenges of Brian's position of authority, which may have dissuaded other students from also challenging him. For instance, Brian often groaned in protest, or aggressively pointed or gestured to Samantha when she challenged his credibility. Over time, other students, as examined below, even jumped on the bandwagon of trying to intimidate Samantha.

### Allies tag-team in a snowballing increase of support for Brian's credibility and against others

Most of the students ultimately supported Brian's position of authority in the debate. They positioned his role as features expert as central, discredited the trainers and the book author, and took up his arguments.

For instance, in the excerpt below, Toscan defended the centrality of Brian's role as features expert:

253 Toscan: if Brian is studying features . .
254 why didn't HE get the information before Jonah did . .
255 because he was studying it a lot more and . .
256 every book that he got said whales and now they're saying . .
257 "OH yeah they're dolphins" . .

Toscan challenged the credibility of Jonah's argument, based on evidence he found in a book, by drawing on Brian's role as features expert. He claimed that Brian, as features expert (line 218) had researched far more than Jonah (or other students) had (line 220), and had considered more than just one book (line 221). In doing so, he took up Brian's role as features expert as central to the argument, and Brian as a credible source of information.

Students also joined Brian's attempts to discredit the trainers. In the excerpt below, Liana built on Brian's assertion that the trainers were not really experts and therefore not believable:

607 Liana: [OH! . . oh . . oh . . *(raising her hand excitedly)*
608 A:::ND . she probably didn't even know .
609-10 because she was probably just there, for a little whi::le .

612 and then she just made it [up

Liana contributed to Brian's effort to re-define the role of the trainers as non-scientists. She claimed that the trainer "probably didn't even know", had been there for just "a little while", and had "made up" the information offered at the show (lines 608-610). Finally, the other students joined Brian in trying (though unsuccessfully) to intimidate Samantha to change her position. In this excerpt from late in the debate, Samantha was hassled in multiple ways for continuing to disagree with Brian:

425 Samantha: okay . so . well . I still don't believe it
426-7 becu:z . I don't think she said that, "I think" . . . ]
428 Jonah: [she did too]
429 Samantha: [what I remember is .
430-1 her saying that . . that "we have figured out that . . . . . .
432-3 Brian: *(holding tape recorder to Samantha)* Talk! . . . . talk . . . . ]
434 Sione: *(holding microphone within inches of Samantha's face)* [Talk! . .
435-6 Brian: *(to Samantha)* C'mon, just forget it.
437 Samantha: the whale/ ok . the killer whale
441 is a probably . a dolphin becuz .
442 I think they know better what they're talking about than we do/]
443 Jonah: [PRO:BABLY?
444-5 Brian: NO! . . (MAKE THAT BETTER THAN . YO::U! DO! . . ]
446 Jonah: [*chuckling*] probably

Samantha was frequently interrupted here (lines 428, 432-436, 443-445) and earlier, but she successfully reclaimed the floor (lines 419-425, 429-431, 437-442). In response, Brian and his allies sought to intimidate Samantha by placing the researchers' microphone directly in her face, spatially crowding her, and yelling at her to "talk!" (lines 432-434, and later), while Brian then calmly and almost dismissively urged her to "c'mon, just forget it" (line 435-436). When Samantha persevered (lines 437-442), Jonah and Brian ridiculed her.

As dramatic as these interactions may have been, once the students were regrouped as a class with the teacher, opportunities to address Brian's domination arose. In the ensuing weeks of the unit as the students continued to debate the question, the teacher continually emphasized the importance of considering evidence and discouraged students, including Brian, from declaring victory. Students found additional evidence for Samantha's side. By the end of the unit when Brian wrote about the controversy in his part of the group's report, he represented it as a stalemate with evidence for both sides. This made sense given that orcas can be considered to be both whales and dolphins (orcas are in the "dolphin" [delphinidae] family, which is itself within the sub-order glossed as being the "toothed whales" [odontocetes]). Thus Brian's strong position of authority, perceived as even greater than the authority of the trainers and the book author within this one debate, did not prevent these students from productively engaging in the issue over the long haul (see Engle & Conant, 2002 for more)

## Discussion

Participation structures, such as student roles that make use of shared expertise, not only mediate students' engagement in collaborative work, but also their positions of authority in relation to other students and beyond. In the case of Brian, he was positioned with authority on whale features because of his assigned role, but it went beyond simply this to afford a positional identity as not only a central and credible student, but also as a "real" expert on par with adult professionals (Langer-Osuna, 2009; Wortham, 2004).

This paper explored how particular participation structures, such as distributed expertise (Brown et al. 1993) can support the development of student authority, and identities of power. These identities may be critical to support valued learning processes, such as students becoming authors of ideas, debating and coming to consensus on student-authored ideas, and using sources of evidence from adult professionals to think through the reasonableness of ideas without passively aligning to the authority of such sources (Inglis & Mejia-Ramos, 2009). However, student identities as authorities can also lead to bad outcomes when students do not sufficiently hold themselves accountable to others and disciplinary norms (Engle & Conant, 2002), resulting in the propagation of invalid ideas and reasoning (Brown & Campione, 1994).

But participation structures are not the only factor to consider with respect to how student authority becomes constructed in classroom interaction. Engle, Langer-Osuna, and McKinney de Royston (2008) offer a model that depicts the dynamic interactions of four negotiated factors that affect how students gain influence over others, based in part on the student-led debate discussed here. These factors include students' perceived authority, but also the perceived merit of their arguments as well as their access to the conversational floor and interactional space. For instance, when Brian's authority was challenged early in the discussion, he was less frequently chosen to speak. However, Brian then worked to increase his access to interactional space through dramatic gesturing, and otherwise spatially gaining attention. In doing so, he gained access to the discussion, which he then used to strengthen his position of authority in the ways we have analyzed here. We believe that such dynamics within and between authority and other factors will also be relevant to other student discussions .

**Abstract:** This paper presents empirical evidence concerning the application of digital video technologies for creating design-based learning environments for middle school students. In three studies we show how the affordances and constraints of digital video technology can support for students their (a) cognitive (b) action related and (c) socio-cognitive learning processes in the domain of history. We present both quantitative and qualitative data. We also present initial evidence for the role of complementary support by explicit instructional guidance. Results are discussed with regard to practical implications.

## Introduction

Audiovisual media provide an important resource for classroom learning. Yet, films and videos are often used in 'suboptimal' ways (Hobbs, 2006). For example, they are shown to classes in a passive, TV-like manner, without clear-cut educational goals and without fostering students' learning activities, dialogue, knowledge construction, or critical thinking. From a psychological perspective, this kind of usage limits the effectiveness of audiovisual materials for learning, and promotes instead a tendency towards superficial cognitive processing (Salomon, 1984) and oversimplification (Spiro, Collins, & Ramchandran, 2007; Spiro, Feltovich, Jacobson, & Coulson, 1991). While this might be only unfortunate in some cases, it can actually be problematic in others, such as in the complex domain of history (Spiro, et al., 2007). In history learning, media sources including historical films, newsreels, TV-products and videos can help to reconstruct historical processes and events (e.g., Wineburg, 1991). Yet, the sources themselves - rather than merely presenting "facts" - are themselves parts and results of the historical processes from which they have originated, and as such they reflect certain perspectives (sometimes subtley as in news shows or educational films, sometimes obviously or even deliberately as in propaganda films). Hence, historical films and videos need to be understood by students exactly in this way: as historical "constructs" (Wineburg, 1991).

How can such an understanding be achieved? Educators have suggested domain-specific strategies, such as "de-construction and re-construction" of historical films (Krammer, 2006). Taking a general theoretical stance in his important work on cognitive flexibility, Spiro has suggested using hypermedia technology as a supportive tool for multithematic exploration and processes of active and constructive work with video in ill-structured domains. Likewise, in a similar cognitive-constructivist framework for the use of video in education (Goldman, Pea, Barron, & Derry, 2007), video analysis activities with advanced digital video tools have been acknowledged as supporting "perspectivity" (Goldman, 2004), inquiry, and specific (socio-)cognitive processes of students (Smith & Blankenship, 2001). This advanced category of digital video tools (some of them originally created for professional research purposes) refers to software applications which provide a variety of possibilities for editing, contextualizing or analyzing digital videos (cropping, annotating, commenting, tagging, or integrating hyperlinks). Such functions could be restructured for youthful learners in classrooms so that they could either produce their own videos or remix video contents (as, for example, from YouTube).

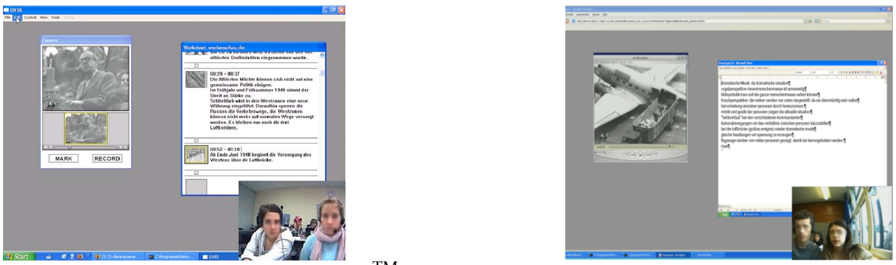

Figure 1. Screenshots of a DIVER™ worksheet (left) and the video player plus text editor condition (right) including video feed of dyads' interactions (bottom right).

In this paper, we present empirical research on the meaningful integration of digital video tools into history education in secondary school. We conducted a series of three empirical studies with 11th grade students in Germany. Our research rests on two assumptions: (1) the assumption that the affordances and constraints of digital video technologies—particularly constructive video tools allowing for annotating, editing (e.g., zooming and cropping), and re-sequencing—have opened up new vistas for making video accessible to constructivist learning in school-based education and beyond (Zahn et al., 2005) and (2) the general assumption that framing such video tools in constructivist design tasks can be effective (Zahn, Krauskopf, Pea & Hesse, in press). We worked with a video tool which has been created specifically to support both cognitive processes and collaborative learning with digital videos (the DIVER/WebDIVER™ system, Pea et al., 2004, see Figure 1). It supports cognitive processes such as focusing attention within a complex and dynamic visual array. It includes a set of specific editing capabilities which enable users to extract, rearrange and comment on scenes or video segments aiming at the support of important visual analytic skills of learners, such as focused observation. The selected and commented items are called *dives*, based on users "diving" into a video by zooming in on scenes and details of the video by controlling a selection frame or "virtual viewfinder". A dive consists of re-orderable "panels", i.e., clips and corresponding comments that are shown in a separate column next to the source video. As a result, sequences and details of a video are not only being cognitively selected, but these video selections and interpretive annotations become new, replayable artifacts that have persistent references as URLs. This is why the system is also considered a *collaborative* tool: These replayable artifacts can be collaboratively produced and shared with others for joint reflection, analysis and discussion ("Guided Noticing"™). In transferring these design rationales underlying the DIVER/WebDIVER™ system or similar tools to the classroom (Zahn et al., 2005), we investigate in our research both the new opportunities and the new challenges arising for students, and ultimately teachers. From our point of view , there are many opportunities to create better conditions for active learning with video materials and relate them to effective processes of knowledge building (Scardamalia & Bereiter, 2006).For instance, students may work creatively with digital videos, which are already available as audio-visual sources online. They can suggest new ways to approach these media and thus enable subsequent users to integrate the reflections of others, which ultimately leads to the development of core competences, such as historical reasoning, advanced expertise (Scardamalia & Bereiter, 2006) or new media literacies (Jenkins, Clinton, Weigel, & Robison, 2006). The main challenge is to frame these collaborative tools with the right tasks to create powerful learning environments, in order to reach the learning goals during classroom- based instruction.

## Visual Design to Frame Learning with Digital Video Tools

To investigate both the opportunities and the challenges of using advanced video tools for constructivist learning in history lessons, we apply design approaches to learning, i.e., concepts of learning by creating artifacts (e.g., learning through design, Kafai & Resnick, 1996; learning by design, Kolodner et al., 2003). We consider the design approaches especially suitable in our case, because they call for activity- and project-oriented learning with media. In this process, students can autonomously create something that seems authentic, meaningful and consequential for them, which gives them the opportunity to experience themselves as competent and intrinsically motivated learners (Beichner, 1994). In addition, from a cognitive perspective, a deeper understanding of the complex topic area and video content can be expected: Acting as designers, students are creating a new video-based information structure. This requires them to select, compare and reflect on the content they wish to present and on how to present it, which results in a positive influence on knowledge acquisition for a complex topic, as in writing (Hayes, 1996). Based on the work of Lehrer and Erickson (Erickson & Lehrer, 1998; Lehrer, Erickson, & Connell, 1994), the ideal structure of a design process includes planning, transformation, evaluation and revision. Design projects thus should support the development of general problem solving skills as well as specific skills related to media competence. Learners not only need to plan the information structure they are going to create, they also must creatively integrate different media formats in order to combine them effectively for a sensible form of the information presented. In an attempt to integrate the cognitive models of writing and design with constructionist perspectives, and in order to apply them to the case of video-based design, we proposed elsewhere a tentative model of collaborative visual design as a process of joint dual space problem solving (Zahn, Krauskopf, Hesse, & Pea, 2009). In this model, we hypothesize visual design to be a collaborative problem solving process involving intensive interactions between video content and form (audience-related goals), in a rhetorical problem space. Based on this model, we shaped our research around the following research questions:

- How do the affordances of advanced digital video tools impact (a) cognitive (b) action related and (c) socio-cognitive processes of students learning a historical topic?
- How do students approach visual design tasks in a real history class?
- When and how can explicit instructional processes optimize the implementation and utilization of digital video technologies?

For the purpose of our empirical research, we developed a prototypic visual design task for German history lessons, where students were asked to rework a video source showing an historical newsreel on the 1948 Berlin blockade. With varying digital video tools at hand, learners elaborated on the video source by integrating additional information provided, with the goal of creating an artifact that could be published online for future (peer-)learners. The task included critical reflection and comments on the historical content as well as on newsreels as a means of propaganda in former times, based on examples from the source video. Whether the affordances of digital video tools used in the context of our creative task would clearly have a positive effect on student understanding in a real history class was an open empirical question. It was also an open question whether the affordances and constraints of different digital video tools differentially influence student learning and if so, whether they would affect specific task elements. In general, we assumed the visual design task and the affordances of digital video tools would have an impact on three levels: (a) the cognitive impact was assessed by multiple choice items tapping historical knowledge and transfer tasks for critical film analysis. We investigated the design products of participants as indicators of (b) action-related outcomes by considering their number of selected scenes and sequences, precision (length of sequence and size of detail), and structuring (deviations from the source video's chronology). Finally, we analyzed the dyads' taped interactions as indicators of (c) socio-cognitive effects by using a coding scheme that captures students' problem solving behaviors (planning, executing, evaluation, revision), collaborative behaviors, and content discussed (the original newsreel-video, the historical events, or their design task). In addition, we analyzed selected case examples of dyads' interactions to provide empirical evidence for the impact of the affordances of the advanced digital tools on collaboration.

The visual design task was tested in a lab-experiment (see Zahn, Pea, Hesse, & Rosen, in press) under controlled conditions to investigate its general effectiveness. Also, the specific effects of the affordances of the digital video tool WebDIVER™, in contrast to a control condition using "simpler" technology (video-player & text-editor) had to be proven before we took the procedure into studies with high school students in the classroom. The sample of this first study consisted of 24 dyads of psychology students (mean age = 22.2, *SD*= 4.8, 68.8% female). Generally the results revealed high appraisal of the task and significant positive mediating effects of the WebDIVER™ video tool on all three levels of outcomes described above: Dyads supported by WebDIVER™ showed higher factual knowledge and film analysis skills, design products of higher quality, and more communication time devoted to task relevant content (historical context and design decisions). In sum, the results showed that the influence of the video tools extended to the learners' socio-cognitive processes and focused their interactions on the task. Qualitative case analysis provided evidence for direct effects of the video tools on conversations, i.e., tool affordances implicitly guided learners' elaboration on the source video.

## Field Study in Class

Following up on the results from this preliminary laboratory study, we took the experimental design into German secondary classrooms. The experimental sessions were conducted in schools spanning over two subsequent 45 minute units using a portable "notebook classroom" we provided for the study. The students were alerted by teachers that our task would be integrated into the current history curriculum. In this study we manipulated two experimental between-subject factors in a two-way factorial design. The first factor (technology) was the digital video tool provided to the students (digital video tool DIVERTM vs. simpler software solution, i.e. video player combined with text-editor). The first factor was chosen to test the ecological validity of the results found in the prior lab experiment on the specific effects of the affordances of the digital video tool WebDIVER™. By investigating effects of tool affordances, we wanted to address the important issue of whether or not an editing tool originally designed for researchers and educators, when reapplied as a tool for learning in the classroom, would be beneficial for students in comparison to a common (and maybe more familiar) technology. The second factor (metaphor) was the appeal to students' media-related rhetorical concepts –their rhetorical concepts were either in line with or different from the system architecture of the digital video tool). By introducing this second factor, we wanted to tap into the question of explicit instructional support of the complex design task as opposed to the implicit guidance by the digital tools. We based this factor of metaphor on the work of Stahl and Bromme (2004), who investigated students designing hypertexts and reported that, due to the novelty of the medium hypertext, student designers cannot be assumed to have firmly established media-related rhetorical concepts which form a design goal. Therefore, in the first condition we prompted students with a metaphor of "video dives" epitomizing the concept of a medium for selecting ("diving into") visual information. In the second condition we prompted students with a metaphor of "annotated movies" epitomizing the concept of a medium for integrating information elements.

Altogether 234 students from 8 classes in 4 German secondary schools participated. Due to technical problems, data of 24 participants (12 dyads) could not be saved and were not included in the analyses. In the end, data from 111 dyads of students were analyzed (mean age =15.9, *SD*=0.78, 60.9% female). We are aware that our data has a multilevel structure; however, due to the sample size and small number of classes, we based our analyses on the dyadic level. Gender composition of the dyads was equally distributed over the four conditions. Furthermore, experimental groups did not differ with regard to their experiences with digital media, personal computers, or prior knowledge of post-war German history. However, the groups using the DIVER™ tool reported higher initial interest in post-war German history. Thus, all reported analyses were additionally run with interest as covariate without changing the results.

In general, the design task was rated by participants as being interesting in general and proved applicable in the classroom. Also, with regard to cognitive outcomes, all students improved in their factual knowledge of the historical content, measured by a multiple-choice test before ($M$= 45.20% correct, $SD$ =15.50) and after the design task ($M$= 65.00% correct, $SD$=8.20), $F(1, 107)=230.83$, $p<.05$, partial $\eta^2= .68$. However, there were no differential effects of the independent variables. The manipulation tapping students' media concepts showed no effects on either outcome variable, nor were there any significant interactions ($F<1$).

With regard to the action-related outcomes, students using the advanced digital video technology (DIVER™) created more sophisticated design products. They selected significantly more scenes and more details within these scenes compared to the control group. Furthermore, the DIVER™ tool increased the number of deviations from the chronological order of the source video when students made the selections, which indicates more autonomous design in the experimental compared to the control condition. Altogether, this indicates that the advanced digital video tool fostered a higher quality of the design products.

In line with these findings, dyads using the DIVER™ tool seem to have acted more autonomously during collaboration: In order to analyze the socio-cognitive impact of the affordances of digital video tools on collaborative design, the interactions of a random subsample ($N$=14 dyads) were coded for (a) content of collaborative talk and (b) problem solving behavior. 20% of the videos were coded by a second rater and according to Asendorpf and Wallbott (1979) we computed Cronbach's α for ratio scales (here the aggregated time of students spent on the different activities) as the agreement measure. Overall, high inter-rater reliability was found, all αs > .81.

The proportions of content discussed during the design task, relative to overall collaboration time, show a beneficial influence of the advanced technology. Dyads working with DIVER™ discussed the historical content more substantially ($M$=14.22% of time, $SD$=7.37) and their actual design task ($M$=16.45%, $SD$=5.96), than did dyads in the control condition ($M$=5.33%, $SD$=6.56), $F(1, 107)=6.42$, $p< .05$, partial $\eta^2= .39$, respectively ($M$=7.23%, $SD$=6.55) $F(1, 107)= 7.78$, $p< .05$, partial $\eta^2= .44$. In contrast, students working with the less sophisticated video player and text-editor showed a tendency to discuss the source video itself more ($M$=18.64%, $SD$=8.36) than did students using DIVER™ ($M$=3.49%, $SD$=18.03), $F(1, 107)=3.37$, $p< .10$, partial $\eta^2= .25$. Overall, this indicates that the affordances of the advanced digital video tool influenced the dyads' collaboration on a socio-cognitive level and may have fostered task-relevant discussion about historical content and design.

Students' general problem-solving behavior, however, was influenced neither by the design tools nor the prompted metaphors. All dyads directly engaged in executing the task (80.5% in general) and devoted less than 4% of their time to planning and evaluation. Analyses revealed a tendency for students to request help less often when using DIVER™ (1.63% time working on task, $SD$= 2.13) than in the control condition ($M$=5.32%, $SD$= 4.04), $F(1, 10)= 4.21$, $p<.10$, partial $\eta^2= .26$). We interpret this as an indicator for a stronger implicit guidance of the advanced digital tool in situations when a task is not explained step by step but determined by the goal. The coding of the video interactions also showed that overall "other" activities of learning dyads made up less than 5% of the time on task. These activities included off-task behavior, such as chatting ($M$=3.90%, $SD$=3.58) and problems concerning the technology ($M$=3.67%, $SD$=2.82) and did not differ between the four conditions, all $F$s < 1, ns. Therefore, any differences in students' learning behaviors cannot be attributed to differences in the difficulty of operating the two technologies.

However, especially taking into account the limited time that students could spend on the design task, the quantitative indicators for learning outcomes document effects, *not* processes. In order to provide evidence windows to substantiate our assumptions (see above: advanced digital video tools may support collaboration on a socio-cognitive level), we conducted additional case analyses focusing on giving what Barron (2003) calls a "localized account" on how the dyads integrated technology affordances in their conversations for their design-related interactions. Such evidence was already found in the prior laboratory study (Zahn et al., in press), where we identified processes of "guided noticing" (Pea, 2006), which emerged as interactional patterns in dyads elaborating on a newsreel with WebDIVER™. In the present paper, we provide evidence for similar findings under the conditions of the real "noisy" classroom setting. We compare two exemplary episodes for processes in two dyads working with either DIVER™ (see Table 1) or the simpler technology of the control condition (see Table 2). These dyads performed similarly well on the task and the post-tests. The episodes illustrate how the students from each dyad collaboratively work on the *same* scene in the historical newsreel video, but with *different* orientations: Dyad 1 (Students A and B working with DIVER™) discusses a design problem thereby elaborating on historical content, while dyad 2 (Students C and D working with a video player combined with a text-editor) discusses descriptive features of the source video while also sticking to its chronology.

In dyad 1, during most of the episode the two students skim through the dive panels they had created earlier, which results in several cycles of "guided noticing" (Pea, 2006). The transcript provided in Table 1 illustrates how A guides attention to a previously selected picture. The joint attention of students A and B is also implicitly guided by the technology's affordances: In the beginning of the episode (lines 1-9) the students seek a picture as a focus of their joint attention and select it for their design product (while deleting another prior selection). In the middle of the episode the question of student B about a necessary design decision (where to assign the caption "Air Lift", line 11), initiates a short discussion (lines 12-16), which ultimately leads to meaning-making about what "Air Lift" means (line 12) and what "Candy Bombers" are (lines 14-16). In other words: understanding of the historic event (the aim of supplying the population separate from the planes as a means of reaching this aim and their name "Candy Bombers") results from a simple question (line 11), which resulted from the necessity to write and place a caption. This provides an example of how the tool's affordance impacts socio-cognitive processes, joint meaning-making and the establishment of common ground, finally leading to creating a design product. There is an additional factor suggested by the excerpt presented here: While the dyad diverges from the central goal in this episode—specifying what is meant by the term Air Lift—the dive panels created earlier repeatedly guide joint attention back on this goal. Students A and B finally record the different ideas emerging during their conversation, in other words, they arrive at closure, manifested in their design product as a replayable artifact.

Table 1: Exemplary Episode of Dyad 1 (Working with DIVER™)

| **Line** | **Student** | **Utterance** | **Actions and written comments** |
| 1 | A | Where is the picture?<br>There it is. | B scrolls up to the specified dive |
| 2 | B | Yes. … | |
| 3 | A | What's that? | |
| 4 | B | That's … [inaudible] … write "Air Lift" | |
| 5 | A | I would leave that the way it is. | |
| 6 | B | What is that? | |
| 7 | A | Yes, that is a good picture. …<br><br>But you can delete the one below. | A refers to a selected detail of an image showing a group of men carrying bags of supplies |
| 8 | B | Too bad, actually. | B deletes the indicated image |
| 9 | B | Um … (verbalizes while typing) Supplies provided by the Allied Forces? | B selects a dive showing two men unloading a truck with supplies and types "Supplies provided by the Allied Forces" |
| 10 | A | Mmhmm | |
| 11 | B | And where do we write "Air Lift"? | |
| 12 | A | Well, Air Lift means the supply with … carried out by the airplanes. | |
| 13 | B | But it has to be mentioned somewhere. | |
| 14 | A | Well no. … Because everything is about the Air Lift … Nee! … Well, or we add "Candy Bomber" to a picture of a plane. | |
| 15 | B | Were they all named like that? | Screens through the selection |
| 16 | A | Well no, but this is what they were called … well, colloquially. | |
| 17 | B | All of them, really? | |
| | | | A selects a dive of a still showing a group of airplanes on the ground. |
| 18 | A | Yes. … | |
| 19 | A | Ah … I thought you had deleted that. | |
| 20 | B | I did. | |
| 21 | A | Ah, you it is not possible to go down here like this.<br>What is that? … people …<br>That one, we can also delete. | A deletes a dive |
| *Timestamp 15:53 – 16:09* | | *Experimenter announces that everybody should write their final comments and prepare to proceed to the following tasks.* | |

In comparison, as can be seen in Table 2, the conversation of dyad 2 is focused on describing the source video's surface features instead of dealing with design issues and the historical content. The episode starts with C guiding D's attention to the music on the audio track (line 1). After an initial affirmative reaction (line 2), D draws the joint attention away from the music towards the pictures, and states that the airplanes are shown from different camera angles (line 2). C writes down this discovery and continues D's initiation of a deeper interpretation (lines 4-6), which D incorporates in the written comment (line 5). Next, D focuses their discussion on the word choice (lines 10-12), draws the focus away from interpretation back to the observable surface level (line 6), and C corrects his former writing. They then return to the issue of the music (line 8) with which they started out, and they describe the accompanying video images (lines 9-11). Continuing to refer to the music accompanying the final scene, D suggests an interpretation (line 14), yet C objects. In sum, while the two students from dyad 2 initiate meaning-making twice in this episode, they do not succeed in achieving true common ground or finally in recording the ideas that emerged during their conversation. In other words, the dyad does not arrive at agreed-upon meanings to be manifested in their design product. Furthermore, they do not elaborate on content or design, but their discussions remains on a descriptive level with a strong orientation towards the surface features of the original source video. This is in line with the quantitative findings reported above (proportions of content discussed during the design task). Moreover, with regard to the socio-cognitive effects of the control condition technology, we found another aspect. As suggested by this excerpt of this dyad's conversation, the technology affords the students to *proceed according to the chronology* of the source video. This contrasts with the conversation of dyad 1, in which the students skimmed through the source video *following an idea.*

| **Line** | **Student** | **Utterance** | **Actions and written comments** |
| 1 | C | Military marches. | C stops the video |
| 2 | D | Mhm [affirmative]<br>Let's write that the planes are being shown from many different angles [incomprehensible] concentrate | C starts to type "planes are shown from many different angles" |
| 3 | D | Now you typed perp. [laughs] | C corrects the typing error perp. to pers. |
| 4 | D | „in order to" ..., come on, say something | |
| 5 | C | „in order to ...<br>make people concentrate on them" | C continues to type "in order to make people" |
| 6 | D | Yes …<br>„in order to highlight them" is better. | C changes the comment into "in order to highlight them." |
| 7 | C | An what do we write here? | |
| 8 | D | „military marches" | C types "military marches" |
| 9 | C | "while …" do you get that? | |
| 10 | D | Yes, I do. Do you see that?<br>There [incomprehensible] are being distributed. | D points to the monitor.<br>C starts to type "while supplies are being distributed" |
| 11 | C | "while [incomprehensible] are being distributed" | |
| 12 | D | [incomprehensible] Oh, crap!<br>[incomprehensible] No, no, it does not work somehow. How embarrassing.<br>What's happening? You are clicking correctly, aren't you? | C is struggling with positioning the cursor at the word that needs to be corrected<br><br>They continue to watch the video to the end |
| 13 | D | "Joyful music, because the supply with food is ensured." | D moves the head in the rhythm of the music. |
| 14 | C | No, that's crap. | |
| 15 | D | So, what do you wanna write? „because [incomprehensible]"? | C types "Freudenmusik" [joyful music] |
| *Timestamp 00:25:12* | | *Experimenter announces that everybody should write their final comments and prepare to proceed to the following tasks.* | |

In conclusion, the results indicate that the digital video tools as "collaborative" tools supported students' understanding of historical sources in *different* ways during the visual design task.

## Discussion

Taken together, our quantitative and qualitative results indicate that advanced digital video technologies applied to classroom learning can be useful in supporting the socio-cognitive processes of student dyads performing complex visual design tasks in the history domain. The findings suggest, when explicit instructional guidance is limited, technological affordances and constraints can implicitly guide and support students' task-related and socio-cognitive activities. We found indications that the implicit instructional support of specific tools constitutes an important complement for learning with design tasks. However, students focused on applying the different technologies, but spent little time on planning and evaluation during task completion. This latter finding might explain why using instructional metaphors did not prove to be salient enough when combined with different digital video tools on students' learning: Metaphors are important during planning. When planning is limited, metaphors have limited impacts on design and learning.

The results of this field study are in line with the earlier findings from the lab study (Zahn, et al., in press), where the affordances of the advanced digital video tool impacted the quality of participants' design activities and extended to learning outcomes and learners' socio-cognitive processes focusing their discussions in very similar ways. Thus, we conclude that the effects of implicit guidance by technological affordances and constraints may constitute an important factor in computer-supported learning that needs to be considered with regard to educational goals and possible instructional strategies. Affordances and constraints of advanced technologies already in use can be seen as potentially supportive to implicit instructional aspects. Studying them means providing valuable information for effective integration in the classroom. However, explicit instructional aspects need to be considered, too, during learning with digital video. This is especially true when addressing issues such as optimizing learners' problem solving within the joint problem space of a complex visual design task, and successful integration of these tasks into instruction for a whole classroom. Further research is needed into these issues. In an initial step to look further into the role of explicit instructional support, we went back to a more controlled environment by inviting 201 students from 9 school classes to our research lab. In this study we manipulated two between-subjects factors: The first factor was the instructional support of either the design problem or the collaborative aspects of the task, which was derived from the theoretical model of design as problem solving. At the beginning of the collaboration phase, students were either prompted to consider the future audience of their design product and to make clear the main messages they wished to convey with their reworking of the source video (support of design), or they were asked to write down rules to ensure good communication within their dyad and to think about how to divide the task into sub-tasks and how to distribute these among them (support of collaboration). For the second factor, we manipulated the video tools, by contrasting two web-based applications: WebDIVER™ and Asterpix (http://www.asterpix.com). This manipulation was based on our considerations that we had found different technological systems to differ on a generic level in enabling users to acquire different cognitive skills (Zahn, et al., 2005): Some digital video technologies focus on integrating associated information, like the Asterpix system. Others focus more on observation and analysis, like WebDIVER™. We were especially interested in whether the specific socio-cognitive functions of the two prototypic tools would differentially influence student learning on the three levels described above (cognitive impact, action-related outcomes, socio-cognitive effect). Furthermore, we wanted to investigate whether our explicit instructions fostered students' planning behavior, and, indirectly, other important sub-processes of our model. Finally, we wanted to learn more about the interaction between the instructions and the tool-specific affordances, in order to provide more evidence for the need to frame digital video tools when integrating them into classroom instruction. Results from this study indicate significant effects for explicit instructional support, as well as the interaction with implicit guidance by the tools' affordances.

Taken together, such results provide initial evidence for the importance of instructional framing of visual design tasks. With our research we hope to deepen our understanding of how to foster students' video-related learning activities, dialogue, knowledge construction, or critical thinking when working with historical sources. We hope, too, to pave the way for constructivist approaches to using audiovisual media in the classroom.

# THE EPISTEMOGRAPHY OF JOURNALISM 335: COMPLEXITY IN DEVELOPING JOURNALISTIC EXPERTISE

David Hatfield, David Williamson Shaffer, University of Wisconsin-Madison, 1025 West Johnson Street, Madison, WI 53706
Email: dhatfiel@wisc.edu, dws@education.wisc.edu

**Abstract:** As bloggers and mobile phone eye-witnesses increasingly supplement the 'news,' it is more important than ever to understand how professional journalists develop their expertise. In this paper, we examine an intermediate level reporting practicum course to explore the learning processes therein. Using a new method called Epistemic Network Analysis, we also explore emergent relationships within developing journalistic expertise. Understanding these relationships should be useful for journalism education as well as the design of research on learning environments.

## Introduction

Increasingly, bloggers and mobile phone eye-witnesses seem to provide the public with all the news that's fit to see. At the same time seemingly each year, reports (McDonnell et al., 2008) document the decline in newspaper readership, speculating that for the few people who still care about the news, Google and other online services are increasingly the destinations of choice.

We argue that despite commercial pressures and in light of the explosion of online information technologies, it is more important than ever to understand how professional journalists develop their expertise. It matters because that expertise is focused on the work Kovach and Rosenstiel (2001) describe as journalism's primary purpose: "to provide citizens with information," gathered and produced through "a discipline of verification," necessary "to be free and self-governing."

In this paper, we examine one of the ways journalists develop expertise through an ethnographic study of Journalism 335, an intermediate level reporting practicum course at a large Midwestern university. The main goal of the study was to explore the learning processes experienced by the students in the course. Using a new method adapted from social network analysis called epistemic network analysis (Shaffer et al., 2009), we also explore emergent relationships within developing journalistic expertise. Understanding these relationships should be useful for journalism education as well as the design of research on learning environments.

## Theory

In the professional practicum, novice professionals engage in simulations of professional work. Guided by reflective interactions with more experienced mentors, they "learn by doing," developing the "complex ensemble of analytic thinking, skillful practice, and wise judgment upon which each profession rests" (Sullivan, 2005, p.195). As Schon (Schon, 1983, 1987) argues, for most professions this "complex ensemble" is developed in capstone courses and/or professional practicum experiences.

Shaffer (2004, 2005a), extending Schon, calls this ensemble an *epistemic frame*, emphasizing that what makes professional expertise uniquely powerful are the relationships between the elements within the ensemble. In other words, the particular set of knowledge and skills that is the focus of most "hands-on" approaches is interconnected with a particular set of values and identities, forming a coherent and integrated perspective that professionals use when making professional judgments in the world. Thus, a professional journalist has mastered a body of writing and reporting knowledge and skills, sees herself and is seen by others as a journalist, and frames her efforts according to a set of journalistic values and norms.

Shaffer (2005b) argues that the practicum is designed to help develop this professional epistemic frame through its participant structures, or the "recurrent patterns of involvement that structure a particular kind of situation within a given practice." In his study of Journalism 828, an advanced reporting capstone course, Shaffer (2005b) explores three such participant structures: interactive copy editing of stories with peers and the professor, news meetings in which participants shared progress and received feedback on their reporting, and war stories from the professor or guest journalists providing lessons learned from past experience. Each participant structure "links identity and practice with particular knowledge and values of a domain" (Shaffer, 2005b) for one of three professional abilities: writing to formula, writing for story, and writing as a watchdog.

The ability to write to formula reflects the highly prescribed nature of journalistic writing (Shaffer, 2005b). From capitalization and punctuation rules in the Associated Press (AP) style guide to innumerable how-to guides for story organization and structure, being able to appropriately use formula is critically important (Murray, 2000; Edgerton, 1997). But this skill is also bound with knowing a particular set of principles concerning appropriate usage and application of this skill. It also involves adopting a particular kind of voice, or identity, within the writing as a way of asserting certain values of neutrality, objectivity, if not truth (Kovach & Rosenstiel, 2001; Stewart, 1998).

Writing for story, on the other hand, focuses on the practices of reporting and developing the particulars of stories in order to realize the broader significance of specific characters and details (Shaffer, 2005b; Franklin, 1986). It employs knowledge about various reporting techniques and tools, skill in their use to capture key details, as well as knowledge and skill with narrative techniques to most effectively use those details in stories. It emphasizes the reporter's identity as a "professional pest," tenaciously seeking out information, and the value of letting the voices of real people carry the story.

Finally, writing as a watchdog organizes the various elements involved in the journalist's role as "watchdog for the public trust" (Shaffer, 2005b). This involves developing skills to "monitor power and offer voice to the voiceless" (Kovach and Rosenstiel, 2001) through knowledge of the normal activities of institutions and individuals, both powerful and humble, and it is guided by the profession's ethical value of public accountability.

Each of these abilities thus constitutes its own "complex ensemble" within the broader professional frame of journalistic expertise. They constitute, in other words, epistemic *sub-frames* in which particular kinds of knowledge, skill, identity, values and epistemology are bound together, and which should also feature linkages to other sub-frames as part of an overall integrated epistemic frame.

Shaffer (2005b) argues that each ability is developed separately and then integrated with the others through the epistemic discourse of the professor, as for example in discussions of how the different practices constitute "smart reporting." In this study, we explore an alternative possibility, that these abilities may each exhibit different patterns of internal development and integration with the others, and we describe a technique for quantifying these patterns called the Integration-Cohesion index below.

Here, we extend Shaffer's study by examining a similar journalism education context to investigate whether these three sub-frames manifest within a transitional practicum course. We then use epistemic network analysis to examine how these sub-frames become integrated into a unified professional perspective. I argue that epistemic network analysis can provide a quantitative measure of the complex linkages within and between ensembles of knowing, being, acting and valuing that comprise a professional perspective. Finally, I discuss how the results of this study may contribute to the design of learning environments.

## Methods

### Setting

As part of the University's School of Journalism and Mass Communication "Reporting" track, J335 occupies a key transitional role between highly structured introductory courses and more open advanced writing and reporting courses, thus providing an opportunity to study an early practicum environment.

J335 was a four-credit course that met twice a week for 75 minutes throughout a 15-week semester. Students also met outside of class in small groups while working on two different group reporting projects, the first occurring midway through the semester and the second occurring at the end of the semester. The specific sequence of assignments is described in the results section.

### Participants

The class was comprised of 13 students. There were six seniors and seven juniors, all journalism majors. No other demographic information was collected about the students. The professor, John, is a prize-winning journalist. The class also had five guest speakers, each of whom was a reporter, editor, or publisher at local or regional newspapers or radio organizations.

### Data collection

Data was collected about the course in several ways. Twenty six of the 30 class meetings were observed. During the semester, students worked on two team reporting projects, and one group was observed for the second project. This team included four seniors and one junior. Copies of all e-mail messages sent by the professor to the class and also of messages exchanged among members of the project group were collected and analyzed. Copies of all story assignments including both the story text and the professor's feedback were also collected and analyzed.

Classroom data was collected in digital audio recordings and supplemented with field notes. Recordings were transcribed to provide a detailed record of interactions, and field notes were used to capture meaningful non-verbal aspects of the context and supplement the transcripts. Out-of-class group meetings were documented via field notes.

## Data analysis

The data was segmented into interactive units, which were defined as strips of activity with a consistent interactional structure and topical focus. The boundary between strips was marked by either a change in topic or a change in interactional structure. In other words, when either the focal point of discourse or the social arrangement changed, one unit ended and another began. For in-line story feedback, comments targeting the same passages in a story were treated as occurring within a single unit while comments targeting different parts of a story were treated as occurring in separate interactive units. Specific examples of classroom interactive units are provided below in the results section, but in the class the transition was clear and often explicitly marked by professor comments like "Alright, we're going to change gears now and focus on [something new]."

Strips were coded for particular practices, knowledge, identities, and values of each of the three epistemic sub-frames of entry-level journalism identified previously: 1) writing to formula; 2) writing for story; and 3) writing as a watchdog. Following Shaffer (2005b), segments were coded for writing to formula when participants "discussed or referred explicitly to the methods of journalistic writing, including specific rules of journalistic style and forms or formulae of traditional journalism." Segments were coded for writing for story when participants "discussed or referred explicitly to journalism as a process of telling stories: stories about particular people encountering problems or conflict, the thoughts and actions of those people, and the specific events that happened and the unique details surrounding them." Segments were coded for writing as a watchdog when participants "discussed or referred explicitly to informing the public about important information and events, drawing attention to inequities, monitoring people and institutions in positions of power, or offering a voice to those without power." Table 1 provides a brief description and example for each category used in this analysis. If a strip represented more than one category, it was coded for all applicable categories.

Table 1: Coding scheme for observations and stories using the elements of an epistemic frame

| Code | Description | Example |
|---|---|---|
| Writing to Formula | | |
| Practices | Using journalistic writing formula | "A terrific job of drawing readers into the lead by setting the scene and mixing a little action with quotes." |
| Identity | Invisible authorship | "No need to state your conclusions in the ending. Just let your sources and docs carry the story." |
| Values | Writing with a neutral voice | "Interviews where you speak the most will probably be the most fun and the most worthless." |
| Knowledge | Knowledge of journalistic style | "Please review AP style; his title wouldn't be capitalized unless it immediately precedes his name." |
| Writing for Story | | |
| Practices | Skills of smart reporting | "Couldn't we get the police report and search warrant return to give readers this powerful piece of info?" |
| Identity | Identity as a professional pest | "Part of your job is to assess credibility. It's not just to get that good quote, but it's to aggressively assess whether your source really knows the issue." |
| Values | Importance of providing an individual face | "Strive to use character development, description, narrative storytelling and use of key details and facts to grab readers' attention. For example, the story could focus on John Doe with a little additional reporting." |
| Knowledge | Knowledge of reporting tools | "There's more information more readily available to journalists today than ever in history. … The challenge is knowing which kinds of information to acquire and what to do with it." |
| Writing as a Watchdog | | |
| Practices | Recognizing important patterns | "You found ways to bring readers inside the world of students worrying about being admitted …. And officials shared insights into how things are supposed to work." |
| Identity | Acting as a watchdog | "Would be even better with interviews with some of the candidates and election officials. Still, this is an important issue and I applaud you for tackling it." |
| Values | Importance of public accountability | "Given the recent revelations about this charity's financial woes, would be important to include a graph or two about that." |
| Knowledge | Knowledge of journalistic ethics | "a good attempt to use data. But wouldn't it be far more fair to compare the campus ethnic mix to that of the state and city rather than the U.S. as a whole?" |

The result was a database of interactive units showing the presence of epistemic frame elements organized by epistemic sub-frames for entry-level journalism as well as the times during which they occurred. The relationships among these different components were then analyzed using epistemic network analysis.

### Epistemic network analysis

Epistemic Network Analysis (ENA) adapts the framework of Social Network Analysis (SNA) for use with cognitive, rather than social, elements (Shaffer et al., 2009). As Shaffer argues, while SNA was developed to provide insight into the relationships between individuals and groups, it also provides a robust set of analytic tools for representing and studying networks of relationships in different domains. In ENA, these tools can be useful for understanding the kinds of linkages between and across elements taking place over time.

For this study, each epistemic frame element was considered to be a node in the epistemic network representing the interaction captured in each interaction unit or strip. Links were defined as the co-occurrence of two or more epistemic frame elements within any strip. Links between the elements of a single sub-frame were defined as intra-frame links, while links from elements in one sub-frame to those in another were defined as inter-frame links.

In order to capture the strength and changes of these links over time, we developed an Integration-Cohesion (IC) index. The IC index measures the degree to which a given sub-frame or sub-frame element emphasizes cohesion, by linking more often to elements in the same sub-frame, or integration, by linking more often to elements of other sub-frames (see Table 2).

Table 2: Intra-frame and Inter-frame linkage formulae

| | |
|---|---|
| $Intra-frame = \sum \sqrt{(L_{in})^2 / (M_{in}-1)}$ | $Inter-frame_{sub1} = \sum \sqrt{(L_{sub1})^2 / (M_{sub1})}$ |
| Equation 1: intra-frame linkage | Equation 2: inter-frame linkage |

As provided in Equation 1, the strength of intra-frame linkage for any frame element was calculated by first summing the squared values of the links between that element and the other frame elements in that element's sub-frame ($L_{in}$), then dividing by the number of elements in the sub-frame ($M_{in}$) minus one, and finally taking the square root of the resulting number. As provided in Equation 2, the strength of inter-frame linkage for any frame element was similarly calculated by first summing the squared values of the links between a given frame element and the frame elements in one of the other sub-frames ($L_{sub1}$), then dividing by the number of elements in that other sub-frame ($M_{sub1}$), and finally taking the square root of the resulting number. The inter-frame calculation was repeated for each of the two sub-frames in which each frame element was not a member. These values were then summed at each successive interaction unit, producing one intra-frame and two inter-frame linkage values which reflected the accumulated link behavior to that point in time. Finally, the ICI was calculated as the difference between the inter-frame linkage value and the intra-frame linkage value at each successive interaction strip, with positive values indicating integration across two different sub-frames and negative values indicating cohesion within a single sub-frame.

## Results

Journalism 335 (J335) was an intermediate reporting class designed, according to the syllabus, "to develop reporting and writing skills." As a pre-requisite for several advanced writing courses, this course provides "practical training in a wide range of reporting techniques, including interviewing, use of public records and research methods" to help students "learn how to become better watchdogs over powerful individuals and institutions and how to provide a voice for the voiceless."

Our observations of J335 are described below. We describe the epistemic sub-frames, *writing to formula*, *writing for story*, and *writing as a watchdog*, that emerged during the course. Then, for each sub-frame we describe the Integration-Cohesion index relationships that manifested between the sub-frames.

### Epistemic sub-frames

Shaffer (2005b) argues that journalism reporting courses are organized around at least three "critical elements in the skill set of an entry-level journalist: the ability to write to formula, the ability to write for story, and the ability to write as a watchdog" (p12). In turn, each of these three abilities comprises an interlinked and integrated set of particular journalistic knowledge, skill, value and identity relative to that ability. These three epistemic sub-frames played an important role in organizing the experiences of students in J335 as well.

## Writing to formula

As the syllabus suggested, part of the emphasis in J335 is to help students develop journalistic writing skills. In one interactive unit during class, for example, John and the students discussed different kinds of leads and when it is appropriate to use them in stories. John asked, "Blind leads, where are they helpful?" Carol replied, when the news is "important but people don't know the organization." "Right. The issue is interesting, but the group isn't well known," John said,

> "Something should be going off in your mind right at that point saying, maybe this is the right structure for this kind of story. Now generally if you do go with the blind approach, that's going to also suggest to you very quickly usually within a couple sentences, you'd better circle back in and start filling this in with some of that detail you omitted from that first graph cause you don't want to leave your reader hanging too long."

In this brief excerpt, John showed the students a particular journalistic writing *practice*: when "the issue is interesting but the group isn't well known," a blind lead may be "the right structure for this kind of story." He cautioned about a potentially conflicting journalistic writing *value*: "you don't want to leave your reader hanging too long." And he used specific journalistic writing *knowledge* to suggest ways of avoiding this problem, by "circling back in and filling this in with some of that detail you omitted from that first graph." In other words, he articulated an interconnected sub-frame of values, practices and knowledge journalists use to *Write to Formula*.

Using epistemic network analysis (ENA) to quantitatively look across all of the strips of activity for the semester as shown in Figure 2, the *Writing to Formula* sub-frame demonstrated relatively strong internal cohesion, particularly for its epistemic frame knowledge and skill elements. In other words, interactions throughout the course worked to develop rich intra-connections within this sub-frame, focusing in particular on binding understanding of journalistic writing formula with skill at its use.

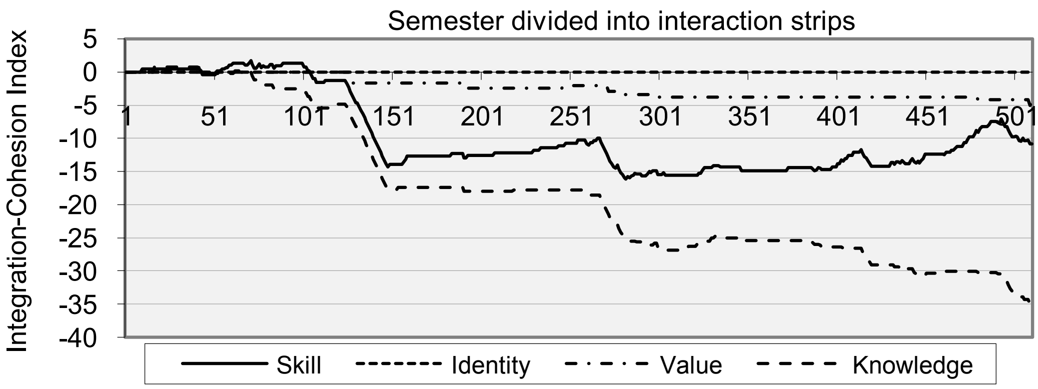

Figure 1. Writing to Formula Integration-Cohesion Index

## Writing for story

As a reporting class, J335 was equally concerned with helping students learn to develop reporting skills. In an example from another class session later in the semester, John was reviewing Susan's education story in front of the class. "One thing I liked about this story," he commented

> "was instead of just saying it's a poor school district, there were some good supporting numbers. [Median household income for the town, median for North Carolina.] … There's also a description - the interior is shabby … Then we get down here, this different view that visitors would see at Randall Elementary. … So you get some idea of the disparity in what they look like as well as then disparities in the teachers."

Susan responded, "that was one of the interesting things about going to North Carolina. They were saying that they were taking teachers that weren't even certified. … I assumed that you needed to be certified." John then wrapped up the review by commenting,

> "one thing that I think works here that is a good story telling device that you could think about for your own future work is, if you have a visual element that you think would help people understand and you have some important issue like the qualifications of teachers which is kind of an abstract concept, think about starting with the visual because that's more comprehensible, more tangible for your readers to describe things and point out disparities, visual disparities. Then when you've softened people up and you've gotten them interested in it, then talk about the disparities with teachers. … And in your own work, just keep looking for disparities like this. You can never go wrong by looking at situations involving the have's and the have-not's, whether you're talking about education, housing, whether you're talking about safe neighborhoods or unsafe neighborhoods. And these are issues that are ripe for journalists too ... Because they are open to us, few institutions point these things out, so that's part of our job is to explore these situations."

In this example, John showed the students a particular reporting *practice*: gathering and using "good supporting numbers," the median household income for the two communities in the story. This practice was guided by a particular reporting *value*: "You can never go wrong by looking at situations involving the have's and the have-not's," and connected to a particular reporting *identity*: "that's part of our job is to explore these situations." In other words, he highlighted the connections between a particular sub-frame of values, practices and identity journalists use to *Write for Story*.

Similar to the *Writing to Formula* case, using ENA to look across all of the semester's strips of activity, as shown in Figure 3, reveals developing internal cohesion for the epistemic frame elements of the *Writing for Story* sub-frame. In addition, the cohesion shown for this sub-frame is stronger than that for *Writing to Formula*, as shown by the relatively larger negative movement in the I-C index, and all of the elements are involved. Finally, the identity element of *Writing for Story* was also substantially more cohesion oriented in contrast to identity in *Writing to Formula*. These data suggest again and perhaps even more strongly that interactions throughout the course worked to develop rich intra-connections within this sub-frame, mobilizing the reporter's identity as an interviewer and storyteller along with developing skills and knowledge of techniques.

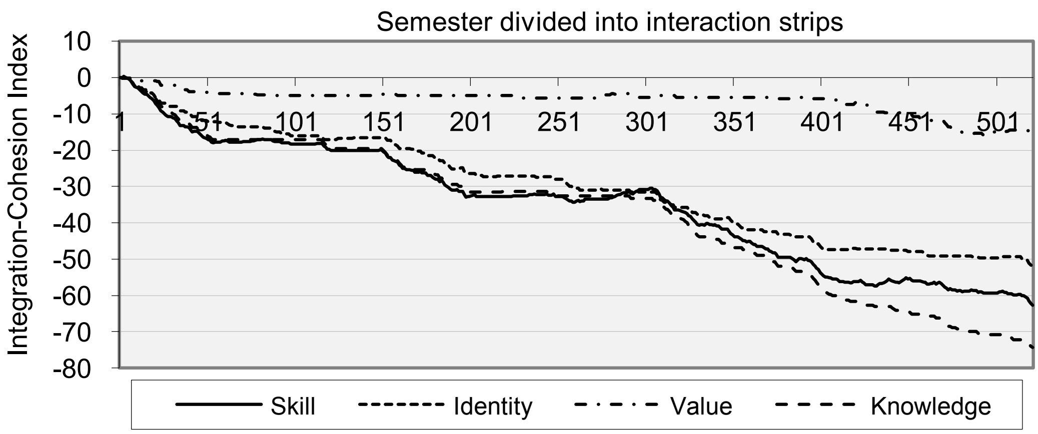

Figure 2: Writing for Story Integration-Cohesion Index

## Writing as a watchdog

In J335, students were developing reporting and writing skills in order to "learn how to become better watchdogs over powerful individuals and institutions and how to provide a voice for the voiceless." After taking the class to meet with the County Clerk, the Police Department spokesperson, and the Mayor, John and the class discussed their interactions with these powerful institutions. One of the students, Sean, said, "as far as what [the Police spokesperson] was saying about be accurate and fair, seemed he stressed be nice to them. Isn't there a point where you don't want to be so accommodating to them? … His whole message to us was 'be nice to us and do what we tell you to do.'" John replied,

> "Right. And through your whole career you're going to get that attitude, especially from people in law enforcement and paramilitary organizations – they're used to dealing with

> hierarchy. Journalism breaks down hierarchy. Journalists seek to understand hierarchies, and then seek to penetrate those hierarchies. People in charge of those hierarchies often resent those efforts. You're exactly right-there's a tension there. I think the challenge for us as journalists is how to achieve the balance. It's possible to be both polite and aggressive. It's possible to be nice but yet firm. To articulate our point of view in a respectful manner, but keeping in mind that we have a different point of view and a distinctly different role than a public agency does. Our responsibility should be to whom? Who are we serving? The public, right."

In this case, John showed the students how a particular watchdog *identity* was connected to a particular set of watchdog *practices*: "Journalists seek to understand hierarchies, and then seek to penetrate those hierarchies." This linked identity and set of practices required a particular watchdog *understanding* guided by a particular watchdog *value*: how to achieve a balanced articulation of the journalist's point of view "in a respectful manner" while keeping in mind "our responsibility" to the public. In other words, he focused on the particular ways of understanding and valuing that guide journalistic practice and perspective when journalists *write as a watchdog*.

The ENA picture that emerges for the *Writing as a Watchdog* sub-frame, shown in Figure 4, is quite different from the other two sub-frames. In this case, all of the elements are revealed to be linking either neutrally (neither more internally nor externally linked) or strongly externally as in the case of the skill element, integrating this sub-frame with the others. These data suggest that interactions throughout the practicum used *Writing as a Watchdog* elements, and particularly the practices of pattern recognition central to this sub-frame, to tie together the developing sub-frames of formulaic writing and story reporting.

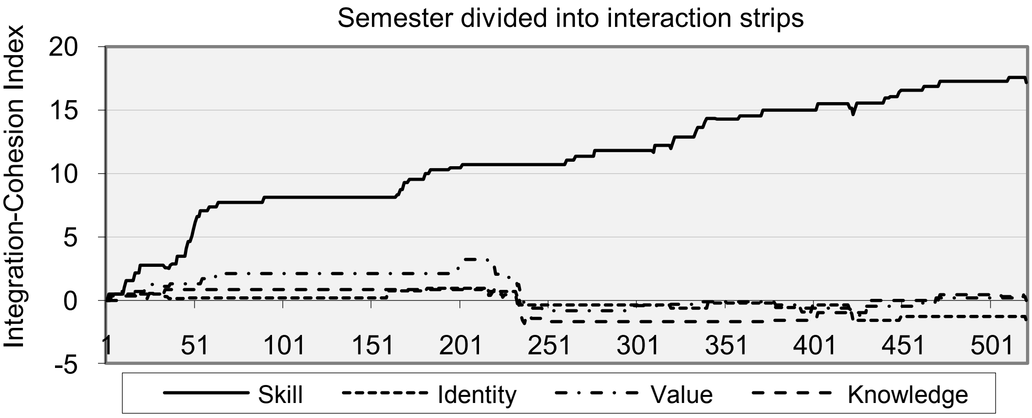

Figure 3: Writing as a Watchdog Integration-Cohesion Index

As described earlier, Shaffer's epistemography of the advanced reporting capstone course Journalism 828 (Shaffer, 2005b) provides a compelling account of the development of these abilities through the learning practices of the Journalism 828 practicum. While not surprising, the results of this study do suggest that these epistemic sub-frames organized student experience throughout the course in ways quite similar to those of the advanced practicum course. In addition, the ENA data provides a new perspective on the ways in which pedagogy was instantiated on the ground in course interactions

## Discussion

These results suggest that over the course of Journalism 335, distinct elements of journalistic expertise were drawn out and linked together, helping to develop and integrate the epistemic sub-frames of *writing to formula*, *writing for story*, and *writing as a watchdog*. This confirms similar observations in Shaffer (2005b), suggesting that, despite being a transitional course, J335 provided an important practicum experience for its journalists in training.

In addition, the results of this study indicate that different sub-frames for specific areas of expertise can exhibit different developmental patterns, sometimes emphasizing the development of stronger connections with other elements of the same sub-frame, and sometimes emphasizing stronger connections with elements from other sub-frames. This in turn suggests an area for future study might be exploring the ways in which developers of learning environments might best align different kinds of participant structures to take advantage of the different developmental patterns touched on here.

These results also suggest that the epistemic network analysis method can be productive way of studying interactions within learning environments. Building on Shaffer (2009), this study adds the *Integration-Cohesion* index to epistemic network analysis, to uncover particular linkages patterns occurring across sometimes difficult to see interactions. Epistemic network analysis suggests a powerful set of techniques for studying the traces of cognitive development through social interaction, and it points toward a promising new way of observing the translation of pedagogy into practice in various kinds of learning environments.

The study presented is of course limited. As observations of a single seminar, these results obviously can't generalize to all instances of journalism practica or capstone courses. Further, as an intermediate-level course, there was significantly less student-initiated interaction than might have been observed in more advanced courses. At the same time, these findings do suggest a more complex relationship within and between these epistemic sub-frames can emerge during the overall development of journalistic expertise, the details of which deserve future study. They also suggest that the method of epistemic network analysis may be useful for future investigations of learning environment interactions for a deeper understanding of cognitive development.

# Which science disciplines are pertinent? –Impact of epistemological beliefs on students' choices

Porsch, Torsten & Bromme, Rainer, University of Muenster, Fliednerstraße 21, 48149 Muenster,
Email: t.porsch@uni-muenster.de, bromme@uni-muenster.de

**Abstract:** The growth of scientific and technological knowledge in modern societies has lead to an increase of specialization of knowledge and expertise. Most socio-scientific issues are far too complex to be understood deeply by laypersons. From various disciplines we have to choose pertinent ones if we want to rely on expert advice. Epistemological beliefs might be helpful to cope with this challenge. Furthermore it is necessary to have realistic awareness of one's own fragmentary understanding and to avoid the "illusion of explanatory depth" (Rosenblit & Keil, 2002). In order to research on adults' capability to choose between disciplines who might be relevant for a science topic, N = 520 secondary school students were asked to choose, which of 22 scientific disciplines (e.g. math, geology, biology) should contribute to a book about tide and float. They were also asked to assess their own knowledge about the theme. Influence of epistemological beliefs has been tested by an epistemological sensitization in an experimental design. The epistemological sensitization significantly influences students' self-assessment of knowledge and discipline rating. Students with sophisticated epistemological beliefs were more critical about their own knowledge about tide and flow, chose significantly pertinent and -by tendency- potential pertinent disciplines more and declined non-pertinent disciplines more.

## Introduction

### Division of cognitive labor

The enormous growth and importance of scientific and technological knowledge in modern societies entail various consequences. Knowledge is unevenly distributed and we are laypersons in most knowledge domains. Dealing with various problems demand different and diversified knowledge backgrounds. Most socio-scientific issues (chemical additions to food, genetic engineering; Zeidler, Sadler, Applebaum & Callahan, 2009) are far too complex to be understood deeply by laypersons, but it is nevertheless necessary for laypersons to reason and to decide about these issues with regard to personal health or with regard to civic participation. Laypersons must rely on experts based on their own fragmentary understanding of such issues (Bromme, Kienhues & Porsch, 2009). Even children learn from the very beginning that they have to rely on others in order to get information, to answer a question, or to solve a problem (Bergstrom, Moehlmann, & Boyer, 2006). Children know that they can ask parents and peers if they need to know something. They differentiate who to trust (Harris, 2007), they are aware that people have different areas of expertise, and know how knowledge is clustered in the minds of others (Keil et al., 2008). For instance, in a study by Lutz and Keil (2002), 56 children of different age (3-, 4-, and 5-year-olds) had to judge which of two experts (a car mechanic or a doctor) would know more about a specific topic. Results show that the 4-and 5-year olds were able to attribute knowledge correctly based on scientific principles, whereas the 3-year olds performed better than chance merely on stereotypical role items. Even children have an early notion of the division of cognitive labor, they have an assumption which experts might know something about what. In the following we will call this knowledge about the "disciplines` pertinence" to certain issues.

An understanding of the pertinence of different knowledge fields to different issues must be based on an understanding of the structure of knowledge. Scientific knowledge has been developed in and is taught in academic disciplines, for example in school or at universities (Stevens, Wineburg, Herrenkohl, & Bell, 2005). We all grow up with and learn knowledge being structured into different disciplines. But not all issues and problems could be clearly and unambiguously assigned to one and only one discipline. Some issues are multi disciplinary and do not belong to only one discipline. Especially new, emerging problems and complex socio-scientific issues fell into the domain of several disciplines. Furthermore, the academic canon of disciplines is subject to continuous change. While it would be desirable if layperson would know who (which expert?) would be pertinent to which issue, it can be difficult asses which disciplines are more or less relevant for a theme. It is an open empirical question if secondary school students are able to identify disciplines which are pertinent to a complex scientific issue.

### Epistemological beliefs

Research on epistemological beliefs, i.e. beliefs about the nature of knowledge and knowing, has expanded considerably in recent years (see, for overviews, Buehl & Alexander, 2001; Hofer & Pintrich, 1997, 2002). Epistemological beliefs include beliefs about the structure and variability of knowledge (Stahl &

Bromme, 2007). We can assume that someone conceiving knowledge as static, (if it has been found once it will not be changed anymore) and as a collection of clear, but separated facts that could be “found”, would have less elaborated ideas about the pertinence of disciplines to issues. Naïve or better to say “straightforward” epistemological beliefs might come along with a less elaborated awareness about the possibility to have different kinds of knowledge about the same issue (object of reference). We assume that such a person might have less well elaborated ideas about the pertinence of disciplines to topics, because she or he might tend to identify the knowledge with its objects of reference. In contrast, a person holding more sophisticated beliefs about knowledge (i.e. conceiving knowledge as dynamic and interrelated and more constructed than “found” ) might have more elaborated ideas about the pertinence of disciplines to issues. Furthermore he or she might include more disciplines when asked which discipline might be pertinent to a certain topic. We expect therefore the following relationship between epistemological beliefs and judgments about the pertinence of disciplines to complex issues: Sophisticated epistemological beliefs go hand in hand with a better (more realistic) assessment of disciplines pertinence. Dealing with a complex scientific issue, sophisticated beliefs should foster the inclusion of various disciplines.

### Knowledge self-concept

In informal settings it is necessary to have realistic metacognitive awareness of one’s own fragmentary understanding and to avoid the “illusion of explanatory depth” (Rosenblit & Keil, 2002). It is an open question if the self-assessed knowledge about the topic impacts on layperson’s assumptions about the pertinence of disciplines to complex scientific issues. Such an impact could be all the more probable as students self concept about their own knowledge differs between different school subjects. Even more, research on students’ self concepts has shown that students tend to overestimate the differences between their knowledge and abilities within different school subjects (Marsh & Hau, 2004). These findings of self-concept research argue for a cognitive and emotional impact of the disciplinary structure of school subjects on academic self concept, and as we conclude, they point to the possibility that the assessment of one’s own knowledge is relevant for judgments about the pertinence of disciplines to topics.

There is broad evidence for gender differences in self-concept (e.g. Marsh & Craven, 1997; Jacobs et al., 2002). Dealing with knowledge in school context boys tends to have higher self-concepts in subjects like math, whereas girls show a higher self-concept in language arts. Dealing with a complex scientific issue with a main focus on natural science, male students are supposed to have higher knowledge self-concepts. It is an open empirical question if the self-assessed knowledge about a theme moderates the rating of discipline’s pertinence and if this is also influenced by gender.

### Research questions

In this study we address the following research questions: First, do students know which disciplines are pertinent? Based on the division of cognitive labor we expect that students are able to identify which disciplines are pertinent. Second, is the rating of discipline`s pertinence impacted by student’s epistemological beliefs? We expect that sophisticated epistemological beliefs foster the ability to assess discipline`s pertinence. Third, is the rating of discipline`s pertinence moderated by student’s knowledge self-concept? Furthermore, the influence of gender on knowledge self-concept and thereby also on pertinence ratings will also be considered.

## Method

### Procedure

Data collection was done on personal computers. During the session all students read an introduction text about tide and float. Students were randomly assigned to two sub-samples that received two versions of this introduction text about tide and float. Before and after reading the introduction text, an epistemological beliefs questionnaire has been conducted. Subsequently, students assessed their own knowledge about “tide and float”. In the main part of the study, students had to evaluate 22 disciplines regarding to their pertinence to the theme “tide and float”. The whole session took around 20 minutes for each student. Due to the computer supported session we have not to deal with missing data on the depending variables. When a question has not been answered, students have been pleased to do so before proceeding.

### Participants

Secondary school students were randomly recruited during an open day at the university ($N$ = 520). Mean age was around eighteen ($M$ = 17.95; $SD$ = 1.01). The majority of the participants was female (132 male, 382 female, 6 unstated).

### Materials

<u>Epistemological Beliefs Questionnaire</u>

The success of the epistemological sensitization was determined by administering an instrument based on a semantic differential. The instrument was administered before and after reading the introduction text. The CAEB (Connotative Aspects of Epistemological Beliefs; Stahl & Bromme, 2007) consists of two scales of connotative adjective pairs: CAEB-texture measures beliefs about the structure and accuracy of knowledge on 10 items (sample item: "structured – unstructured") and exhibited satisfactory reliability pre-instructionally (Cronbach's $\alpha = .78$) as well as post-instructionally (Cronbach's $\alpha = .85$). CAEB-variability measures beliefs about the stability and dynamics of knowledge on 7 items (sample item: "dynamic – static") and exhibited medium reliability preinstructionally (Cronbach's $\alpha = .64$) and satisfactory reliability post-instructionally (Cronbach's $\alpha = .83$). The dimensions "texture" and "variability" are similar to the factors simplicity, structure and certainty from the Hofer model (Hofer & Pintrich, 1997, 2002) and the "source" dimension as described e.g. by Schommer (1990), but are named and conceptualized partly different. Texture encompasses beliefs about the structure and accuracy of knowledge. This factor includes beliefs from the dimensions "simplicity" and "source", and from "certainty". Variability encompasses beliefs about the stability and dynamics of knowledge. This dimension ranged from beliefs that knowledge is dynamic and flexible to beliefs that it is stabile and inflexible. This dimension mainly encompasses the dimension "certainty" but also the dimension "source". Several studies have shown that the CAEB is a quite reliable and valid instrument (e.g. Stahl, Pieschl & Bromme, 2006; Pieschl, Bromme, Porsch & Stahl, 2008; Kienhues, Bromme & Stahl, 2008). For the measurement of epistemological beliefs in this study, it has been used in a topic related way, i.e. it had to be sensitive to the knowledge about the theme "tide and float" and students had to refer their answers just to their beliefs about knowledge from this theme. This takes into account, that such beliefs can be topic-specific (e.g. Trautwein & Lüdtke, 2007).

## Introduction text

Ideas about pertinence of disciplines can be related to more and less sophisticated epistemological beliefs (see above). To consider these claims experimentally it is necessary to manipulate epistemological beliefs systematically: Two versions of an introduction text to "tide and float" were randomly administered to the students as an instructional intervention that we termed epistemological sensitization. In a recent study it was possible to successfully sensitize subjects reading science texts for an advanced epistemological stance by a comparable method (Kienhues, Bromme & Stahl, 2008). The two sub-samples did not differ with regard to age, gender, level of education, and school performance (measured by grades). One sub-sample ($N = 258$) read an introduction which was "straightforward" because it was enriched with statements that indicate a more structured and static view on the knowledge about tide and float (e.g., "models about tide and float fit well"; "water level forecasts are accurate even in the long run"). The other sub-sample ($N = 262$) received an introduction text that was enriched with comments on the epistemological nature of selected facts (e.g. detailing scientific controversies) and thus should elicit a more "sophisticated" view on the knowledge. Results show that the epistemological sensitization heavily impacted the ratings on the (Post-) CAEB-Questionnaire (repeated measure ANOVA for Texture: $F(1, 518) = 148.56$; $p < 0.00$, $\eta^2 = 0.22$ and Variability: $F(1, 518) = 301.94$; $p < 0.00$, $\eta^2 = 0.37$). The epistemological sensitization impacted the ratings into the assumed directions. For example, students in the straightforward instruction group rated their knowledge about tide and float as more structured and static in the Post-Questionnaire. In the sophisticated group students rated their knowledge as more unstructured and dynamic. Instruction groups are included as independent variables in subsequent analyses. For our research questions it is not important if this change is a fundamental and lasting modification of epistemological beliefs or a temporal effect on context-dependent epistemological resources (Hammer & Elby, 2003). We hereby acknowledge that our epistemological sensitization might only have changed epistemological beliefs during the session (in situ).

## Knowledge self-assessment

Students rated their own knowledge about "tide and float" on 5 Items (e.g.: "I already know very much about tide and float" or "There is not much more, that I can learn about tide and float" (reversed)). Students answered each item on a 5-point-Likert-scale (from "I totally disagree" to "I totally agree"). The scale exhibited satisfactory reliability (Cronbach's $\alpha = .84$). Students rated their knowledge above mean ($M = 3.08$; $SD = 0.88$). The individual results of the knowledge self-assessment scale are admitted in further analysis. Due to the above mentioned results, gender will be included as an independent variable in subsequent analyses.

## Discipline evaluation

To measure how students assess the pertinence to difference disciplines, the following scenario was established. We told the students that all the knowledge about tide and float is going to be gathered in a book. They had to decide which disciplines should contribute to this book. Each discipline had to be rated on a 5-point-Likert-scale (from "should absolutely not contribute" (1) to "should absolutely contribute"(5)). The result of the discipline evaluation is admitted in further analysis as a depended variable. Twenty two different disciplines were listed (randomized for every student): forestry, meteorology, geo science, life sciences, landscape ecology, information technology, electro technology, business informatics, e-business, information management, physics, chemistry, biology, math, medicine, orthopedagogy, museology, astronomy, oceanography, engineering, geology, and hydrology. The disciplines have been collected from the domains "environment", "general knowledge", "computer" and "health". There are some clearly pertinent disciplines (e.g. oceanography) but there are also cases where the relevance for the topic is less obvious.

# Results

## Do students know which disciplines are pertinent?

This question was investigated by using an external criterion. Disciplines` pertinence is not as obvious at it seems to be (see above). On way two consider the gradual pertinence of several disciplines to one theme, is to embrace the public perception. The combined appearance of theme and discipline in newspapers, journals and web databases provides an indication of pertinence. This approach is based on the assumption, that disciplines are more often mentioned together with a specific theme, if they are pertinent ones. The following approach uses a methodology transferred from the calibration paradigm (Nelson & Dunlosky, 1991): First, a measure for quality of the students discipline ratings was determined. Objective values were computed from the relative frequency of the co-occurrence of the theme ("tide and float") and each discipline ("e.g. physics") within Lexis Nexis, a large text data base. By reason, that the co-occurrence is just a frequency's subset of the theme and of the discipline, the value was divided by the sum of the overall frequencies. The strength of association between theme and each discipline has been used as an indicator of "objective" pertinence of the discipline to the topic. (Note that it is only 'objective' in the sense that it is reflected in the thousands of documents which make up the data base, and that we use it here as the norm for a comparison with of our students' assessments). The systematic relationship between student's discipline ratings and the objective value was determined by computing within-subject Goodman-Kruskal Gamma correlations ($G$). These were subsequently Z-transformed into indices. Median of indices overall students was $G = 0.58$ ($t(518) = 16.21$, $p < .001$).

The results can also be considered in a descriptive manner. Student's ratings differed between disciplines (Figure 1). An empirical trichotomy of the data gets obvious. Seven disciplines (oceanography, physics, astronomy, geo science, geology, life sciences, biology) with a mean rating above $M = 4.0$ are highly associated with the theme. The pertinence of five disciplines (meteorology, math, landscape ecology, hydrology, chemistry) is much more graded ($3.0 <$ mean rating $M < 4.0$). All other disciplines are mostly declined (mean rating $M < 2.0$). To sum up, student's ratings correlate significantly with the associations of disciplines and theme in a text data base. Furthermore, students clearly identify disciplines which have to contribute, maybe should contribute and definitely should not contribute.

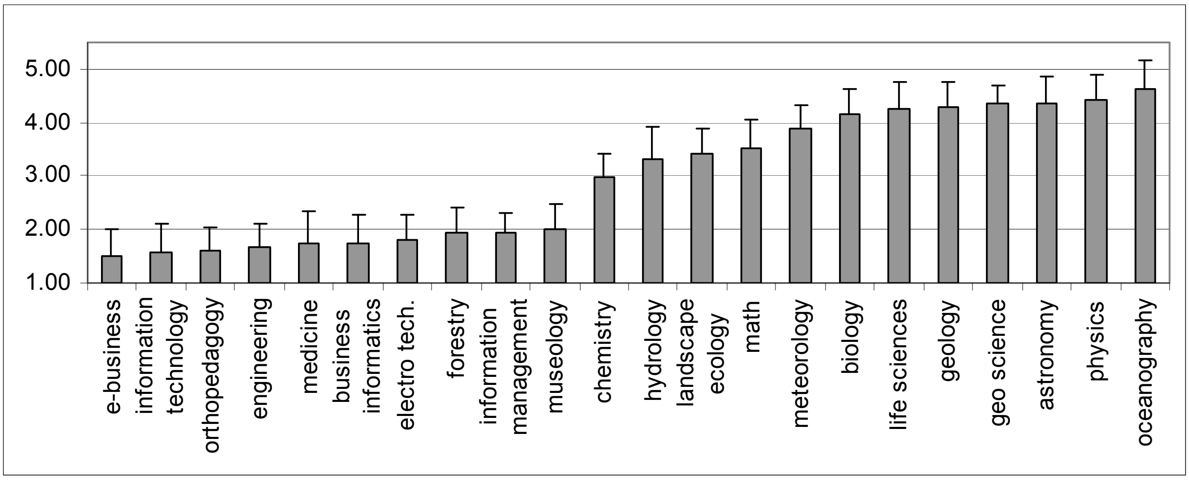

Figure 1. This figure visualizes the mean discipline ratings.

## Are discipline ratings impacted by epistemological beliefs and knowledge self-assessment?

In order to answer this question the experimental groups (straightforward versus sophisticated instruction text) as well as gender were included as dichotomous factors in a measurement model (linear regression). To account for the trichotomy in discipline ratings three dependent variables have been computed: "Mean rating of pertinent disciplines (RD)" (*N* = 7, *M* = 4.35, *SD* = 0.49), "Mean rating of disciplines with graded pertinence (GD)" (*N* = 5, *M* = 3.42, *SD* = 0.63) and "Mean rating of non-pertinent disciplines (ND)" (*N* = 10, *M* = 1.76, *SD* = 0.55). Interactions between errors of these three variables (RD, GD and ND) are accepted in the model. Furthermore, the knowledge self-assessment scale (KSA) was included in the measurement model. Fit indices indicate a sufficient model fit (Byrne, 2001). Relative chi-square ($\chi 2/df = 1.57$) and the comparative fit index ($CFI = 0.98$) exhibit an acceptable fit between the hypothetical model and the sample data as well as the point estimate of the root mean square error of approximation ($RMSEA = 0.03$). No significant interactions between independent variables (experimental group and gender) have been found. As shown in Figure 2, introduction text ($r = -.42$, $p < 0.001$) and gender ($r = -.29$, $p = 0.003$) significantly impacted knowledge self-assessment (KSA). Students who read the sophisticated introduction and female students significantly stated to know less about "tide and float". The independent variable "introduction text" also impacted significantly the "Mean rating of pertinent disciplines (RD)" ($r = .27$, $p = 0.002$). Students in the group with the sophisticated introduction text agree significantly stronger to the pertinent disciplines (RD). By tendency, students who read the sophisticated introduction agree also stronger to the disciplines with graded pertinence (GD) ($r = .17$, $p = 0.058$) and decline non-pertinent disciplines (ND) more ($r = -.05$, $p$ = n.s.). No relation between knowledge self-assessment (KSA) and discipline rating as well as between gender and discipline rating has been found.

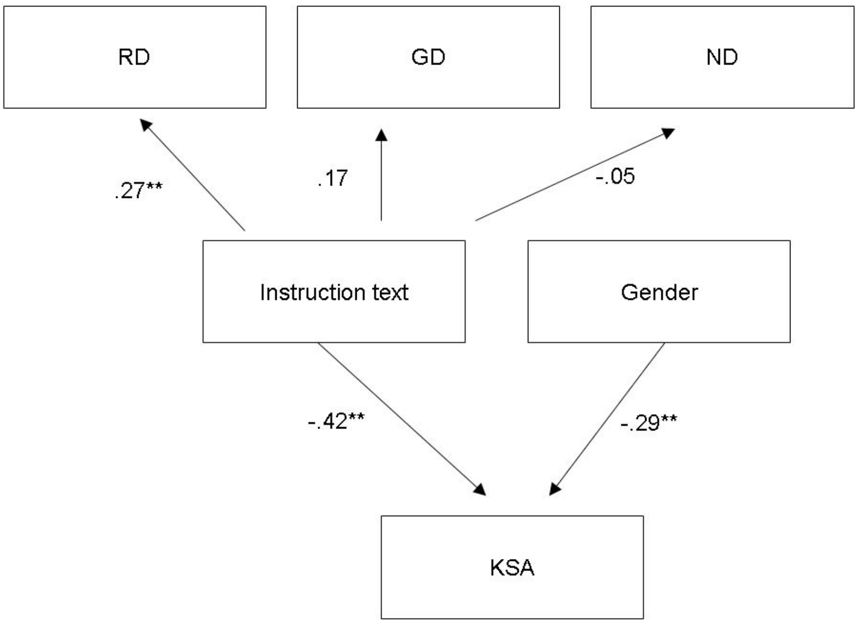

Figure 2. This figure visualizes the results of the measurement model ($N = 520$). (RD = Mean rating of pertinent disciplines, GD = Mean rating of disciplines with graded pertinence, ND = Mean rating of non-pertinent disciplines, KSA = knowledge self-assessment).

## Discussion

To rely on others gets increasingly important in modern society (Bromme, Kienhues & Porsch, 2009). A realistic view on own knowledge as well as knowledge about pertinence of disciplines are helpful requirements in academic and informal settings. Results of this study indicate that students are aware of discipline's pertinence and know which disciplines are pertinent to the theme "tide and float". They are able to assess disciplines' pertinence in a meaningful way. Student`s ratings are significantly correlated with findings in a large text data base. The pertinence ratings of the used disciplines to "tide and float", are concordant with the appearance of the combination of disciplines and theme in newspapers, journals and web databases. The descriptive consideration of the data reveals that next to pertinent and non-pertinent disciplines, some disciplines exhibit a graded pertinence to the theme. Empirically three groups of pertinence (pertinent disciplines, disciplines with graded pertinence and non-pertinent disciplines) could be established. The discipline pertinence ratings of these groups are partly explained by the epistemological sensitization. The results show that all students assume that there are some disciplines which are pertinent (oceanography, physics, astronomy, geo science, geology, life sciences, biology) or graded pertinent (meteorology, math, landscape ecology, hydrology, chemistry). But students who read the sophisticated introduction text agree stronger to the pertinent and graded pertinent disciplines. Students who read the straightforward introduction text preferred these disciplines less. This result indicates that students in the sophisticated sensitization group have more elaborated ideas about the pertinence of disciplines: They tend to include the pertinent and graded pertinent disciplines more when asked which discipline might be pertinent to a certain topic. The given topic is a quite multidisciplinary one. Students with strong ideas of the connectedness and variability of knowledge might tend to transfer their beliefs on ideas about the pertinence of disciplines. The results indicate that students are able to do this in a meaningful matter. Instead of assuming a general pertinence of all disciplines, students with more sophisticated beliefs made a better choice. The sophisticated epistemological sensitization induces a more differentiated choice between the disciplines. All disciplines which seemed, even only rudimentarily, pertinent were appraised higher.

The expected influence of the knowledge self-concept on disciplines' pertinence rating has not been found. Students concept about own knowledge about the topic doesn`t impact their ability to assign pertinent disciplines to the topic. We conclude (cautiously because it is a speculation based on the lack of empirical relationship) that ideas about who knows what (knowledge about the division of cognitive labor) are relatively independent from knowledge about the reference issue itself. Our cautious conclusion is in line with Keil et al, (2008) who reported awareness about the division of cognitive labor held by young children who clearly lack deep knowledge about the reference issue.

Gender influences the knowledge self-assessment independent from epistemological beliefs. Female students stated to know less. This result is in line with findings about gender specific self concept in academic contexts (e.g. Shaalvik & Rankin, 1990; Marsh & Craven, 1997; Jacobs et al., 2002). The theme "tide and float" is contextualized in school in the subjects as "physics" or "geography". Gender differences in self-concept in context of these "natural scientific" subjects are as expected. But these differences did not impact the rating of discipline's pertinence. Neither knowledge self-assessment nor gender itself has impacted student's choices.

The analyses uncovered further results. With regard to the content used here, the sophisticated epistemological sensitization causes students to asses more cautiously their own knowledge about the issue at stake. But this is not necessarily a misjudgment. Their knowledge self-assessment could be simply more realistic. Even if they have already superficial knowledge about the theme, most of the students have not dealt with the underlying mechanisms before. With regard to the research by Rosenblit & Keil (2002), we assume that the straightforward sensitization contributes to an "illusion of explanatory depth". In this study, the confrontation with epistemological uncertainties ("texture" and "variability") e.g. by detailing scientific controversies, might have helped the students to relativize their own knowledge about "tide and float" in a realistic way. Further studies should also take qualitative methods into account to provide an insight into why more sophisticated epistemological views make students more critical about their own knowledge.

There are, however, some limitations of this study: We did not capture underlying reasons for preferring a discipline but rather ask for student's spontaneous judgments. Additionally, we acknowledge that our epistemological sensitization might not have resulted in a sustained change of the students' epistemological beliefs. Within this study we focused on the relationship between epistemological views and pertinence assessments and the question, if the epistemological views which we have established within our experiment will be stable or not can be postponed to further studies. Nevertheless, our finding that it is possible to induce such an epistemological sensitization by a rather sparse intervention has interesting educational implications. The intervention which was used here for experimental reasons could be also used for educational aims. Of course, such sensitization might only work with specific topics. The implementation of the epistemological sensitization has to be tested further to use it in more real life settings (e.g. classrooms and textbooks) with more diverse populations. In everyday problem solving and decision making it is a quite common task to decide about disciplines pertinence in context of mostly unknown knowledge topics, but the capabilities which are necessary here have not been researched intensively so far. While our results are clearly confined to our sample (secondary school students) they do nevertheless demonstrate how such capabilities could be studied.

# Free, open, online, mathematics help forums: The good, the bad, and the ugly

Carla van de Sande, Arizona State University, carla.vandesande@asu.edu

**Abstract:** Free, open, online, help forums link students with volunteer helpers who have the time, knowledge, and willingness to provide assistance with specific problems from coursework. Some forums endorse a select learning theory, whereas others do not espouse any one approach. This study shows how student activity differs in a forum that supports Cognitive Load Theory (CLT) and one that does not embrace the practice of any single learning theory. A sample of 100 exchanges on the calculus concept of limit were collected from the archives of a forum of each type and compared for student contributions to the construction of the solution and student initiative in expressing resolution. The results show that the forum supporting CLT evidences lower levels of student activity (both initially and following helper intervention), and favors weak over strong expressions of resolution. The designation of the good, bad, and ugly depends on the reader's epistemological stance.

Today's students are using the Internet as a resource for completing their assignments through participation in open, online help forums. Many such forums, covering a wide variety of school subject areas, are found on websites that are accessible to the general public (open) and allow students everywhere to communicate anonymously and asynchronously with volunteers around the world who have the time, willingness, and experience to help them. Students post queries (usually problem-specific questions from assignments) on these forums when they are seeking help constructing a solution to a problem or when they are seeking verification of a solution that has been constructed. In order to help students construct solutions to their problems, some forums allow any member to respond to the student (e.g., as a helper) and participate in ongoing exchanges. Help is this case is a spontaneous activity, and we refer to these sites as Spontaneous Online Help (SOH). In short, these forums afford convenient, accessible, efficient help to thousands of students, while, at the same time, they transform help seeking and helping from a private, one-on-one activity bounded by physical walls into a public, communal endeavor that spans geo-political boundaries (2007). This contribution to the democratization of education is part of "the good" (Larreamendy-Joerns & Leinhardt, 2006); what constitutes "the bad" and "the ugly" depends on the epistemological stance of the reader.

These forums exist primarily for the purpose of helping students. How do they then tackle the monumental and ill-defined task of defining *what it means to help* within their community, especially given the diversity of the members? The answer is that some forums explicitly endorse a select learning theory, whereas others do not espouse any one approach. The purpose of this paper is to explore the nature of student activity in a mathematics forum that uses Cognitive Load Theory (CLT) as its modus operandi (Cramster) versus another forum that does not advocate any particular theory of learning (FreeMathHelp). In both cases, the community of helpers is not required to adhere to any mandated pedagogical practices, but rather the corps of helpers has self-selected a forum in which to volunteer. Regardless of enforcement, however, the position taken by the forum administration and helpers on theories of learning and instruction is expected to show up in the manner in which students use the forum as they seek help completing assignments.

## Conceptual Framework

### Help seeking

These problem statements that students post on the help forums generally stem from routine exercises, commonly referred to as closed tasks. However, if a student is unable to solve such a task without assistance, then the "exercise" has become a "problem" from the student's perspective (Selden, Selden, Hauk, & Mason, 2000). In this way, the forums are instantiations of help seeking, an activity that no longer carries the stigma of incompetence or stupidity (Nelson-Le Gall, 1981). In fact, quite the opposite may be true, as students engaged in help seeking can be proactively taking responsibility for acquiring new knowledge and skills (Resnick & Nelson-Le Gall, 1997, p. 150). Help seeking, *with appropriate performance goals*, has strategic value in the learning process. Nelson-Le Gall (1985) distinguished between "executive" or dependency-oriented help seeking that is associated with performance goals ("Just tell me the answer") and "instrumental" or mastery-oriented help seeking ("Give me a clue!"). Now, given that students are seeking help using open, online, homework help forums to construct solutions to routine exercises, the question is: In what ways are students acquiring the knowledge and skills that allows them to complete their assignments?

Alternative learning theories advocate different definitions of what type of help is conducive to learning. I now turn to one learning theory that has a lot to say about how students learn.

## Cognitive Load Theory (CLT)

CLT is a theory of learning developed by Sweller (1988) that is based on the limited capacity of working memory and emphasizes the need for instructional design to minimize cognitive processing or load. Determining pedagogical practices that are consistent with this theory has therefore been a central part of the research agenda (Kirschner, 2002). The use of worked examples is one such practice that has been extensively researched (Atkinson, Derry, Renkl, & Wortham, 2000). The provision of worked examples as a study tool has been shown to facilitate near transfer, require less acquisition and performance time, and require less mental effort than engaging in problem solving or exploration (Paas & Van Merriënboer, 1993; Sweller & Cooper, 1985; Tuovinen & Sweller, 1999; Van Merriënboer, Schuurman, De Croock, & Paas, 2002), at least for students who are really unfamiliar with the material (Kalyuga, Chandler, Tuovinen, & Sweller, 2001).

Of course, no self-respecting cognitive load theorist would claim that worked examples are, in and of themselves, a magic bullet. It is the way in which students engage with worked examples that determines how much help they provide. For instance, students who self-explain worked examples learn more deeply than students who simply read through them (Chi, Bassok, Lewis, Riemann, & Glaser, 1989) or copy them (Chi, 2009).

The Cramster forum advocates providing worked examples as an effective means of providing help. Drawing explicitly on CLT, they claim that this is the best and most efficient way of helping students with their homework assignments.

## Methods

The objective of this project was to investigate the nature of student activity on sites with differing adherence to theories of learning. Two open, online, mathematics help forums were chosen, one that espouses CLT and one that does not endorse any given learning theory. In addition, Cramster.com has a reputation system (Dellarocas, 2003) in place that allows students to rate the contributions of helpers, whereas FreeMathHelp does not. Associated with this distinction is the fact that Cramster offers subscription levels that increase the weight of ratings for others' contributions.

Because of the exploratory nature of this work, an observational methodology was adopted (Goodyear, Jones, Asensio, Hodgson, & Steeples, 2005). In order to draw comparisons across the two sites, I gathered 100 exchanges from the archives of each forum on a single calculus concept, the limit, by conducting a search on "lim*." Although there are arguably many concepts in calculus instruction that surface on the help forums and that could have served my purpose, the limit concept took precedence, being both foundational and poorly understood by students (Cornu & Tall, 1991; Szydlik, 2000; Tall & Vinner, 1981). The Cramster postings were first gathered in December, 2008 and the search was performed on exchanges dating back from November, 2008. These dated back to September, 2008 and were compared with a set of analogous exchanges from the archives of FreeMathHelp that had been gathered for previous research. The FreeMathHelp corpus dated from April, 2008 to January, 2007. The differing time spans covered by the searches (3 months for Cramster versus 15 months for FreeMathHelp) reflects the relative popularity of the two sites; Cramster receives much more traffic than FreeMathHelp. Because Cramster offers subscription and FreeMathHelp operates strictly gratis, the Cramster search specified that only exchanges initiated by nonpaying Cramster members be included. However, the Cramster sample may include some students whose status changed between the time of posting and the time of data collection.

## Site Descriptions

### Cramster

www.cramster.com (Cramster) is a global study community for help in many subjects, including physics, math, science, and engineering. The site was launched in 2003 by Cramster, Inc., a private company headquartered in Pasadena, California. The site advocates CLT and has been recently endorsed by well-known educational theorist, John Sweller, who is also a member of the Cramster Academic Advisory Board: "Cramster provides an effective learning environment for difficult and complex concepts. I strongly recommend to any student."

In addition to the discussion forum or Q&A board, the site provides access to study materials such as textbook solutions, topic notes, sample problems, and practice exams that were created by the administration, indexed from the web, or contributed by members. Although general membership is free, participants can elect to subscribe monthly ($9.95/month) or annually ($49.95/year) to enjoy additional site benefits and access. Members have access to user profiles that include self-volunteered information on school, major, and expertise. In each contribution, members are characterized by a self-selected username, an optional avatar (static or animated picture that represents the user), board level (ranging from Rookie to Oracle), and "karma."

Karma is acquired through participation in site activities (such as answering queries on the Q&A board, submitting solutions to textbook problems, challenging others' solutions, providing notes, quizzes, outlines, etc., and referring friends to become members) and is based on an intricate point system. For the Q&A board that is the focus of this study, karma points depend on the rating awarded by the member who asked the question (Lifesaver, Helpful, Somewhat Helpful and Not Helpful), their membership status, and the difficulty level of the board. Karma points can be redeemed for gift certificates and prizes. On the part of students, rating responses is voluntary but does affect the student's "respect score" (the number of answers the student has rated divided by the number of answers provided to that student).

In addition to standard Terms of Use for activity on the Internet, Cramster has an Anti-Cheating policy posted: "Copying solutions or posting unexplained final answers on the Q&A Board promotes completion without comprehension, and that's something we don't support on this site."

### FreeMathHelp

www.FreeMathHelp.com (FreeMathHelp) is an advertisement-supported mathematics help portal established in 2002 by Ted Wilcox, who was, at the time, an enterprising high school junior. The site contains 10 homework help forums organized by subject area (ranging from arithmetic and pre-algebra to calculus and differential equations). The sole requirement for becoming a forum member is registration (which entails agreeing to abide by terms for permissible content and/or conduct, providing a username and e-mail address, and selecting a password). Forum members can initiate threads in a discussion forum (e.g., as students posting mathematics questions) and can respond to others' posts (e.g., as helpers). Forum members also have access to user profiles that include self-volunteered information on occupation, residence, contact information, as well as statistics on discussion board activity.

This site does not espouse any one pedagogical approach. At one time, a lengthy and passionate debate was held in the community forum by prominent helpers concerning the nature of the assistance that helpers should be allowed to provide. The suggestions covered a wide range of possibilities, from banning helpers who provided "copy-ready" solutions to creating a separate forum for those who wished to provide worked solutions. The final decision, made by Ted as forum administrator, was to allow helpers to practice any form of pedagogical assistance, with a request for helpers to respect and not interfere with the helping strategies employed by others in the community.

Forum "netiquette" (Shea, 1994) is located in a "sticky" that is the lead posting within each help forum. Although the forum does not ascribe to any particular learning theory, students are encouraged to show all of their work. The rationale is that, by doing so, helpers are more able to detect the source of student difficulty and the forum can operate efficiently. If, for instance, no work is shown, then helpers may assume that the student only needs help getting started, or, if only partial work is shown, then helpers will not be privy to errors in undisclosed portions of the solution.

### Analyses

The objective was to illuminate differences in student behavior depending on the forum. Analyses of student activity were designed to capture the trajectory of understanding from the perspective of the student over the course of a given exchange: initial and post-intervention (during), and final. Each exchange was therefore examined for the presence of student assertions and proposals of mathematical actions, both in the *initial* posting in which a query was presented as well as following helper intervention *during* the ensuing thread. Examples of actions that were taken as evidence of student activity included suggestions of a solution procedure, proposals of solution steps, and follow-throughs on others' proposals. In order to be inclusive in this analysis of help-seeking activity, even instances that were hedged or offered in a hesitant manner, were counted. The last contribution made by the student in each exchange and the ratings provided by students on the Cramster forum were used as indicators of the *final* state of understanding, that is, as an expression of how the student felt about the resolution of the problem. The strength of resolution was further characterized as "weak" (expressions of gratitude) or "strong" (reflection on why or how interaction was helpful). These overt activities (contributing to the construction of the solution and initiative for expressing resolution) reflect student agency (Greeno, 2006) and characterize interactive activities (Chi, 2009).

## Results

### Contributing to the construction of solution

Figure 1a shows the percentage of threads in each forum according to the presence of student suggestions and proposals for action in the initial posting and subsequent thread: [0 0] (no student activity), [1 0] (student activity only in the initial posting), [0 1] (student activity only after the initial posting), and [1 1] (student activity in both initial and subsequent postings in the thread).

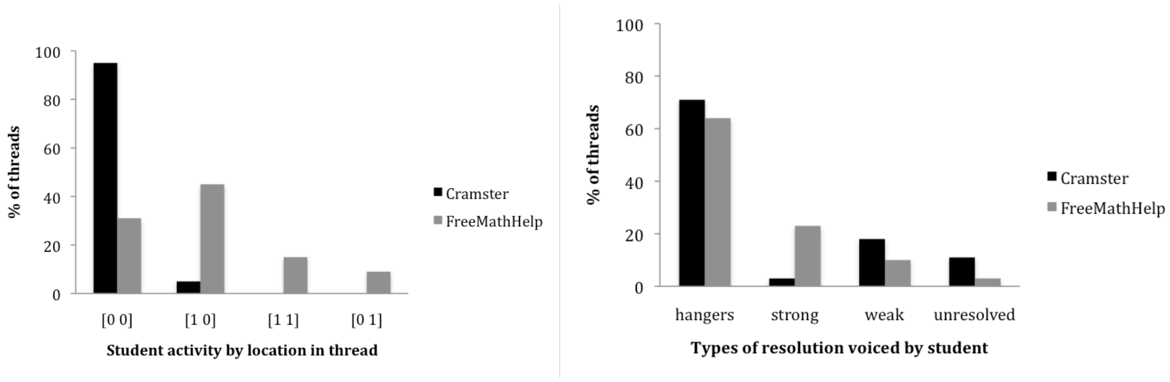

Figure 1. a) Student contributions to construction of solution; b) Student expressions of resolution by type

There are two noteworthy results here: first, Cramster contained *no* threads in which student activity increased following helper intervention ([0 1]) or in which student activity was present throughout the exchange ([1 1]), and second, *virtually all* (95%) of this site's exchanges were completely devoid of any student mathematical activity ([0 0]). On this site, students pose their queries without showing work and the helpers almost exclusively contribute worked solutions (see Figure 2). In contrast, the majority of the exchanges (69%) in FreeMathHelp contained evidence that students were actively contributing to the construction of the solution, either in the initial post or in response to helper assistance (see Figure 3).

The most sensible explanation for these results can be found in the differential nature of the help provided on the two forums. On Cramster, 98% of the helpers' first interventions (the first response received by the student) consisted of a full worked solution; not surprisngly, there was no need then for students to contribute to the construction of the solution. On FreeMathHelp, however, only 23% of the first interventions could be classified as a worked solution. Thus, in many cases, a worked solution was not provided by a helper, and students could still contribute to the construction, if they chose to do so.

## Initiative for expressing resolution

There are several ways that a participant can indicate that an issue has (or has not) been resolved. First of all, participants can be silent and opt not to further contribute to an exchange. Silence in computer-mediated exchanges may indicate acceptance or rejection of another's contributions and does not offer evidence for (or against) the achievement of resolution. Thus, in the forum discussions, if a student does not return to the exchange following helper interventions, it is not clear whether the student feels that the issue has been settled or not. I refer to exchanges of this type as "*hangers*" since other forum participants are, in some sense, left hanging regarding the helpfulness of their contributions. On the other hand, when a student does explicitly acknowledge helpers' contributions, they can do so in either a *weak* or *strong* manner. For instance, an expression of appreciation, such as "Thank you," indicates a weak level of resolution on the part of the student since this may simply be a residual of polite manners, that is, a customary response to receiving assistance. Also, if a student simply rates the quality of received help, then this rating is indicative of weak resolution since it does not signify how the interaction was helpful. In contrast, the contribution of mathematical actions (e.g., the presentation of a solution to the problem) and assessments (e.g., reflections on the ways in which the intervention helped) are stronger indications that the issue has been resolved to the satisfaction of the student. Finally, an exchange can evince a lack of resolution or be *unresolved*, when a student receives no response to a query or receives a refusal from forum tutors to provide further assistance.

Figure 1b shows the percentage of exchanges for each forum in which resolution could not be determined (hangers), in which resolution was evident and the strength of the expression (weak versus strong), and in which the issue was unresolved.

Given the informal and transitory nature of these interactions, it is not surprising that the majority of exchanges were characterized as hangers in both forums. However, those that did evince some degree of resolution showed a different pattern in Cramster versus FreeMathHelp. First of all, in Cramster 11% of the exchanges were unresolved, with 4% demonstratively unresolved following helper intervention. In contrast, in FreeMathHelp, only 3% of the exchanges were unresolved, which is the worst outcome of forum participation from a student's perspective. Also, although the expression of resolution is promoted in Cramster because of the "respect score," there was a higher percentage of expressions of resolution on FreeMathHelp (33% versus 21%), as seen by collapsing over resolution strength. A distinction between strong and weak resolution showed an additional difference in this aspect of student activity across the two forums. In Cramster, expressions of weak resolution (18%) were more prevalent than strong (3%), whereas this trend was reversed in FreeMathHelp, in which strong resolution was indicated in 23% of the exchanges, whereas 10% showed weak resolution. It appears that Cramster favors the demonstration of weak resolution (if any), in which students either provide a rating or express thankfulness, but fall short of remarking on the way in which they received useful help and gained understanding (see Figure 2). In contrast, something about the interaction in FreeMathHelp encourages students to express resolution, with no incentive, reflect publicly on the way that the help received contributed to their understanding of the mathematics in question (see Figure 3).

## Examples

### Cramster

Figure 2 shows a prototypical example of a Cramster exchange derived from the in-depth analyses of student activity. The student, **Ali**, did not contribute in any way to the construction of the solution ([0 0]) and gave the helper, **fatbuddha**, a lifesaver rating (weak resolution) following the provision of a (sparsely) annotated worked solution. **Ali** typed in the text of the exercise, **fatbuddha** constructed the solution, and **Ali** evaluated the reply. The entire transaction took only 11 minutes, where the median length of time until a student received a first reply in the Cramster sample of 100 exchanges was 26 minutes. The exchange is remarkably impersonal and devoid of social interaction.

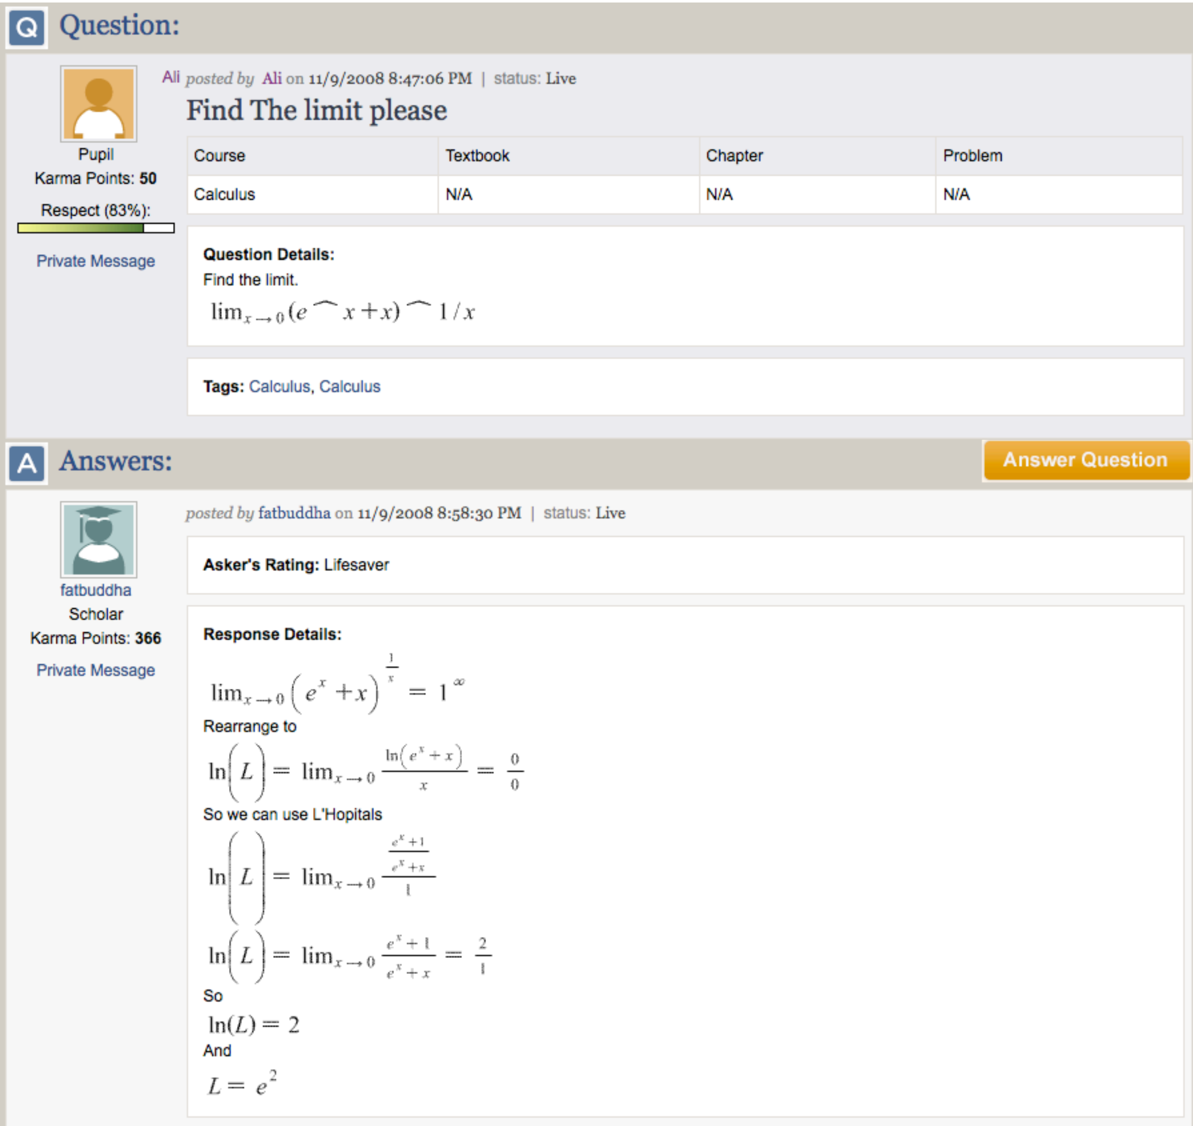

Figure 2. Cramster exchange showing absence of student activity and weak resolution.

### FreeMathHelp

Figure 3 contains an example of an exchange from FreeMathHelp. Although not prototypical in the sense that the student, **jerry**, contributes to the construction of the solution throughout the exchange ([1 1]), this example captures the flavor of many interactions that take place on this help forum. When **jerry** poses the query, he includes a suggestion, albeit hedged, for constructing the solution, namely substitution. **Jerry** suggests that the goal to the solution is finding the right substitution, but does not specify the substitutions that he has tried but which "didn't seem to lead anywhere." The first helper, **pastel**, provides the substitution, requisite trigonometric identities and outlines the rest of the solution, but stops shy of providing a worked solution. Shortly after this help is received, **jerry**, returns to the exchange, comments on the insight he has gained because **pastel** showed him the rearrangement of terms, and contributes the rest of the solution. Although **jerry** has indicated that the issue has been resolved from his perspective, a second helper, **skooter**, comes on the scene and suggests through hinting that the limit can also be framed alternatively as the definition of a derivative. In response, **jerry**, returns once again, expresses appreciation, and comments on how he has gained new insight on this problem, thanks to **skooter**. The exchange gives a definite sense that **jerry** has experienced "Aha!" moment(s) and an almost tangible feeling of excitement that is expressed through **jerry's** use of [very happy] emoticons.

[SPLIT] lim x->a (sinx - sina)/(x - a)
by jerry on Sat Nov 10, 2007 2:29 pm

We should do this without L'Hopital's rule.

The limit is:

$$\lim_{x \to a} \frac{\sin x - \sin a}{x - a}$$

Again the hardest part is probably figuring out the "right" substitution, anything I tried didn't seem to lead anywhere...

Since the majority of the proofs that this limit is the cosine, and since they all use the "x + h" form, you might want to substitute "a + y" for "x", so you have:

lim[y->0] [(sin(a + y) - sin(a)] / [y]

Then use trig identities:

sin(a + y) = sin(a)cos(y) + cos(a)sin(y) - sin(a)

= sin(a)[cos(y) - 1] + cos(a)sin(y)

Split the limit into two pieces. As y -> 0, you have the sin(y)/y going to 1, and the [cos(y) - 1]/y going to zero. See if that helps.

Thanks, Alex!

I actually tried that, but silly me didn't see that I could split it at the end.

So I get:

$$\lim_{y \to 0} \frac{\sin a \cdot (\cos y - 1)}{y} + \lim_{y \to 0} \frac{\sin y \cdot \cos a}{y} = 0 + \lim_{y \to 0} \cos a = \cos a$$

Yay.

maybe this is simply a problem of "recognition" ... ?

$$\lim_{x \to a} \frac{f(x) - f(a)}{x - a} = f'(a)$$

... just an illegitimate tutor paddin' the post count.

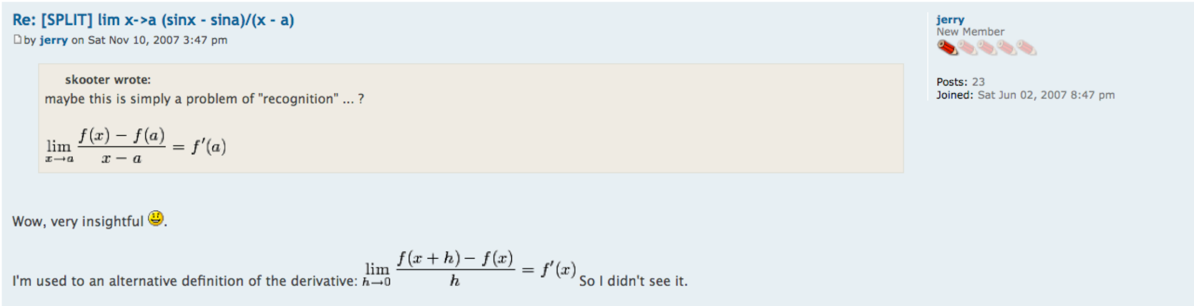

Figure 3. FreeMathHelp exchange showing student activity and strong resolution.

## Discussion

The message of this paper is that student activity looks dramatically different on two open, online, calculus, help forums. On Cramster, the forum in which CLT is the modus operandi, students do not contribute to the construction of the solutions, and favor weak over strong expressions of resolution. A typical dialogue frame (Graesser, Person, & Magliano, 1995) for interaction on Cramster consists of a student presenting a problem statement, a helper contributing a worked solution, and, perhaps, the student rating the help received. In fact, the primary instructional sequence is the traditional IR/E pattern from classroom discourse (Mehan, 1982), but with an monumental twist – the role of instructor and student is reversed. It is the student who initiates the interaction by asking a question (I), the helper who replies with the answer (R), and the student who evaluates the response (E). In contrast, on FreeMathHelp, the forum in which helpers to not adhere to any particular learning theory, students often initiate or follow-up on the construction of the solutions and favor strong over weak resolution by sharing how the interaction was helpful. Here, there is evidence of extended dialogue frames that include student contributions and reflections. Evidence for computer-supported collaborative learning (such as the joint construction of solutions) can be seen in interactions in FreeMathHelp.

However, the observational methodology employed by this project prohibits making stronger claims than the existence of these differences. First, only published contributions were part of the analysis. Private messaging is a feature of both forums, and may be more frequently used in Cramster since helpers can only receive karma for their initial response to a student. This policy may well encourage students and helpers to communicate off-line. Anonymity adds another layer of complexity to interpreting results, since participants could have multiple usernames linked to different accounts. Fortunately, however, multiple participants cannot have the same username. Finally and more importantly, the measures cannot speak to the effect of forum participation on student performance in the classroom. The dramatic difference in the nature of student activity across the two forums raises the question whether student learning also dramatically differs. This is a question that must be answered in the context of an experimental study.

Open, online, help forums are being used by students throughout the world and have become part of their learning experience. As an emergent resource, we must determine their potential for instruction and learning. In particular, there is a pressing need to delve into what constitutes the good, the bad, and the ugly for this resource that students and helpers are frequenting. Returning to the title of this paper, what can we say at this point?

- The Good: Open, online forums are a means of connecting students seeking help with those who can provide it in an efficient, cost-effective manner. Students who might not otherwise have access to help are able to ask for help in a non-threatening environment. The forums also present an opportunity for educators and researchers to reach students beyond the walls of the classroom.
- The Bad: What counts as "bad" depends on the epistemological stance of the reader. Different forums offer different definitions for what it means to help students. From the perspective of a cognitive load theorist, providing worked examples is not bad. However, a constructivist would rather have students construct their own solutions and would probably consider Cramster to be an anathema.
- The Ugly: Given the open nature of the forums, official forum policies and educational philosophies can be abused or ignored. Things can get "ugly" in any forum, regardless of its ideals. Students can abuse the forums by asking for too much help, by mindlessly copying solutions, and by trying to use the forum to replace instruction.

John Sweller's recent endorsement of Cramster is evidence that education researchers are becoming aware of (even associated with) open, online, homework help forums. This paper intends to start a discussion on the design, use, and analysis of these learning activities that are happening "in the wild." One of the most important questions that this exploration has raised but admittedly danced around is whether worked solutions are an effective choice for helping students in the forums, and, if they are, then why forums, such as FreeMathHelp, that offer alternative approaches thrive. I will say that Cramster paints a picture of mathematics as an activity in which the goal is to reach answers, and the faster this is accomplished, the better. Even if students are using the solutions they get on Cramster as worked examples to help them complete additional exercises on their own, these students are still being sent a message about the nature of mathematics that seems problematic for those who love the subject and want students to share this passion.

# Activity-Theoretical Research on Science Teachers' Expertise and Learning

Cory T. Forbes, University of Iowa, N252 Lindquist Center, Iowa City, IA, 52242, cory-forbes@uiowa.edu
Cheryl Ann Madeira, University of Toronto, 252 Bloor St. W., Toronto, ON, M5S 2V6, cmadeira@oise.utoronto.ca
James D. Slotta, University of Toronto, 252 Bloor St. W., Toronto, ON, M5S 2V6, jslotta@oise.utoronto.ca

**Abstract:** Teachers serve as critical mediators of student learning. As such, teachers' expertise and learning remain important foci for theoretical development and empirical research. Cultural-historical activity theory (CHAT) has been forwarded as an underutilized but potentially powerful tool for educational research, including teachers' expertise, practice, and learning. However, as yet, little CHAT-based research has been undertaken focused on science teachers and teaching. In this paper, we draw upon two such empirical studies in which CHAT was used as an explicit theoretical and analytical framework to explore CHAT-based perspectives on science teacher learning. We present findings from these studies to highlight important themes in CHAT-based research on science teachers' learning in and from practice. These findings can not only inform programmatic efforts to better promote teachers' learning, but also theoretical perspectives on science teachers' expertise, practice, and learning across the science education and learning sciences communities.

## Background and Theoretical Framework

In this paper, we present results from two CHAT-based studies of science teacher learning and practice to discuss theoretical contributions of CHAT to perspectives on science teacher learning and practice. In Study A, Forbes uses CHAT to investigate preservice elementary teachers' curriculum design and development of pedagogical design capacity for inquiry during the final year of their formal teacher education. In Study B, Madeira and Slotta use CHAT to investigate how lesson planning, enactment, reflection and peer exchange influence experienced secondary science teachers' development of pedagogical content knowledge (PCK) in a professional development context. Full findings from each of these studies have been presented previously. We therefore summarize here the study populations and designs, their explicit theoretical and analytical grounding in CHAT, the CHAT-based models we employed, methods of data collection and analyses, and main findings from each study. The primary purpose of this paper is to instead synthesize findings across these two studies to highlight and explore implications they hold for CHAT-based perspectives on teachers' learning and practice. These new theoretical insights can inform future research on science teachers and teaching.

### Situated Perspectives on Teachers' Knowledge and Expertise

Teaching is a complex and dynamic activity that requires teachers to develop robust expertise in order to best promote and facilitate student learning of science through inquiry. Teachers' expertise, and the manner in which it develops over time (i.e., learning), is fundamentally situated and embedded in contexts of practice. Participation in these communities of practice (Wenger, 1998), activity systems (Engeström, 1987), or ecosocial systems (Lemke, 2000) is one characterized by the process of semiosis, or meaning-making. Regular patterns of semiotic activity within such contexts, which develop over time and therefore have histories of their own, are characterized as practices. Through participation in existing practices, participants become more established participants and practitioners by aligning their own skill sets to conditions afforded in the setting where the activity occurs (Barab & Roth, 2006). However, by working to reconfigure constituent elements of existing practices, individuals can also fundamentally alter them. Learning, then, is defined as engaging in fundamentally new forms of practice (Engeström, 1987; Lemke, 2000).

This perspective has important implications for understanding teacher learning. Teachers derive socially-constructed and culturally-mediated principles of teaching from practice and reinstantiate these principles in future practice. Teachers first reify their past experiences as principles of practice that take the form of knowledge, beliefs, identities, and general orientations. These constructs do not exist as extant entities – rather, they are constructed and negotiated through activity and mobilized as tools in activity in light of norms and conditions of the contexts in which activities occur. Over time, their practice becomes more routinized. In teaching, it is routinized action that characterizes teachers' knowledge, demarcating the transitions from novice to expert teachers along the teacher professional continuum. This routinization is evidenced in a developed alignment between teachers' personal characteristics and features of their contexts, both material and symbolic (Barab & Roth, 2006; Brown, 2009). This developed alignment represents teaching expertise.

Questions surrounding teachers' knowledge, expertise, and learning have held a prominent role in education scholarship for many years (e.g., Putnam & Borko, 2000; Shulman, 1986). While such research has made invaluable contributions our understanding of teachers' knowledge, beliefs, identities, and orientations, a great deal remains uncertain about the nature of teachers' expertise and learning. Like many practitioners, teachers often struggle to articulate and represent the principles and rationales underlying their professional practice. There remains little to no consensus as to what exactly constitutes teacher expertise and how to differentiate between expert and novice teachers. We suggest that there exists a strong rationale for exploring the utility of novel theoretical and analytical perspectives in subsequent research on teachers' expertise and learning.

## Cultural-Historical Activity Theory (CHAT)

To better operationalize, capture, and describe expertise for teaching, cultural-historical activity theory (CHAT - Engeström, 1987) has been forwarded as a potentially useful tool for educational researchers (Grossman, Smagorinsky, & Valencia, 1999; Roth & Lee, 2007). Cultural-historical activity theory is a psychological, activity-based perspective on human activity and development. Consistent with situated perspectives on knowing and learning, CHAT affords a perspective on consciousness as an emergent property of interactions between groups of people in certain cultural contexts rather than an entity 'in the head'. As Engeström (1987) notes, it is a "concept of activity based on material production, mediated by technical and psychological tools as well as by other human beings" (pg. 25). In this way, CHAT is fundamentally concerned with socially- and culturally-mediated, as well as object-oriented, activity and the evolution of established practices over time.

The fundamental unit of analysis in activity theory is human social activity itself, driven by a goal-orientation relevant to a particular need or motive as defined by members of the community. Activity undertaken by an individual (subject) whose particular motive or need impels action oriented toward a particular problem or purpose (object). Consistent with the foundations of cognitive science laid by Vygotsky, such activity is also mediated by tools and artifacts (instruments) and by other human beings (community) within the activity system. The nature of activity as it develops is also structured and shaped by norms of the community (rules) and specialization or social stratification (division of labor). These complex relationships are embodied in the CHAT activity triangle, a generalized model for analyzing social activity, which is shown in Figure 1.

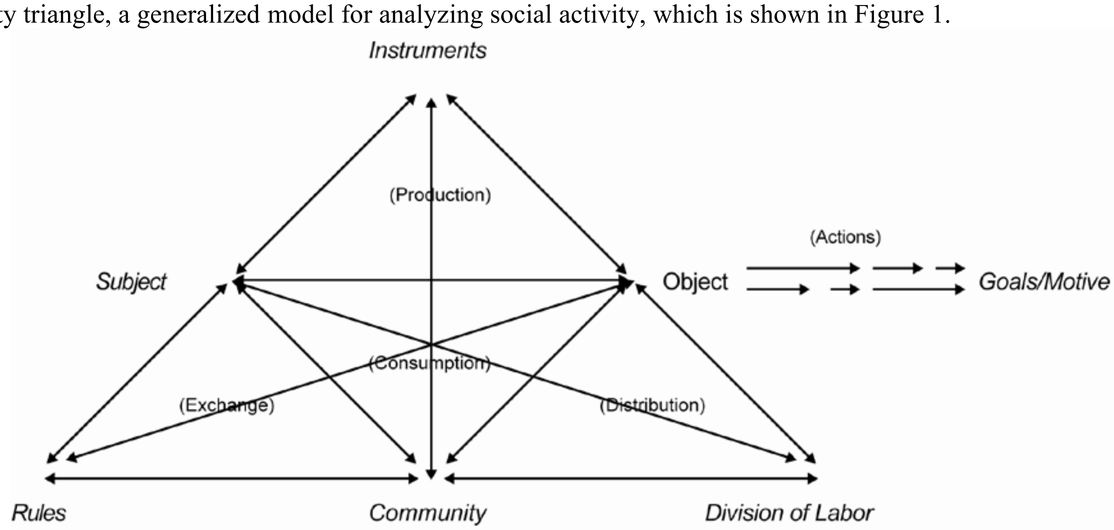

Figure 1. Cultural-historical Activity Theory Model of Human Activity (Engeström, 1987)

Activities are driven by their objects and motives. Activities are, however, also composed of composite actions which, in turn, are constituted by conditioned operations. Operations are best characterized as the kinesthetic foundation upon which sets of actions and, ultimately, activities, are based. These operations are the product of direct response to environmental stimuli, typically unconscious, routinized behaviors. In contrast, actions are consciously-driven by goals. Both actions and the goals toward which they are oriented are given meaning by the activities in which they are situated while, at the same time, constitute the achievement of the collective motive of activity.

The mediating influence of tools is a key assumption of activity theory. Vygotsky (1978) noted the importance of tools in transforming human activity from a direct to an indirect, or mediated, relationship to the environment. This is shown in the 'production' triangle in Figure 1, which illustrates the iconic triadic relationship between the individual, the environment, and mediating influence of available tools. Production processes, however, do not occur in the abstract. Rather, they are embedded in particular social and cultural contexts that serve to mediate and shape the relationships between individuals, their tools, and the particular focus of their efforts. Cultural and social influences on activity include three elements: rules, community, and divisions of labor.

The CHAT model in Figure 1 provides a complete account for the structure of a given activity system, or the central activity. However, third-generation activity theory assumes that the constitutive elements of a given central activity (i.e., nodes of the triangle) are themselves the products of related, interconnected activities. As such, a particular activity system is itself embedded in networks of activity systems. While these activities may appear stable, there exist ever-present tensions within and between nodes of activity systems and neighboring activity systems. These contradictions arise as "the clash between individual actions and the total activity system" (Engeström, 1987, pg. 30) and are the motor for and harbinger of change in activity. Contradictions are important because they lie at the heart of learning in practice. These contradictions, which develop within and between bounded activity systems or practices, like at the heart of learning in practice in that they must be negotiated and addressed to engage in culturally-more advanced forms of an existing practice. The goal of such learning is expansive development of new, more culturally-advanced and articulated forms of activity.

CHAT can serve as a useful tool to study teachers, teaching, and teacher learning (Grossman, Smagorinsky, & Valencia, 1999). CHAT centralizes activity itself as the fundamental unit of analysis, emphasizing goal- and object-oriented material production, the cultural mediation of these processes, and how a particular activity is nested within broader networks of systems. As such, it highlights the importance of learning in context (Putnam & Borko, 2000). Teachers learn from classroom practice but these are not the only settings in which they go about their work Especially in respect to preservice teachers, who traverse multiple activity settings on their way to becoming full-time, practicing teachers, accounting for these unique settings in which learning occurs is essential. Such a perspective also prioritizes the importance of tools, whether curriculum materials or others, that teachers use to structure and guide classroom practice. In this way, the CHAT model provides a mechanism through which to attend to both individuals and the worlds in which they learn and develop.

However, CHAT-based research on science teachers, teaching, and teacher learning is limited. In this paper, we present methods and findings from two parallel CHAT-based studies on science teachers (elementary and secondary) in professional learning contexts (formal teacher education and professional development). The specific purpose of this paper is twofold. First, we describe two studies that use CHAT to investigate science teacher learning through iterative cycles of instructional planning, lesson enactment, and reflection on practice. Second, we identify and discuss important theoretical contributions to perspectives on teacher learning and expertise that have emerged from these studies. Research methods, findings, and research-related issues discussed in this paper will not only help other researchers employ CHAT in research on science teachers, teaching, and teacher learning, but also inform theoretical discussions of the nature of teachers' expertise and learning.

## Methods and Main Findings

### Study A –Preservice Elementary Teachers' Development of Pedagogical Design Capacity for Inquiry-Based Science Teaching and Learning

Science curriculum materials remain one of the most widespread and important tools for teachers. However, rather than enacting them 'as-is', teachers actively mobilize, evaluate, critique, and adapt curriculum materials (Remillard, 2005). The curriculum design process is a function of teachers' personal characteristics (knowledge, beliefs, and identity, etc.), features of the curriculum materials, and features of their professional contexts (e.g., Roehrig, Kruse, & Kern, 2007). Together, these three factors, as well as the goals toward which classroom activity is oriented, constitute the pedagogical design capacity a classroom activity system affords a particular teacher (Brown, 2009). In order to leverage and maximize the capacity for pedagogical design afforded them, teachers need to learn to use curriculum materials effectively (Remillard, 2005). This is particularly important for preservice teachers who tend to rely heavily on curriculum materials as beginning teachers and who struggle to translate their reified understandings of inquiry-oriented teaching and learning into classroom practice. This study extends recent research on the use of curriculum materials in science teacher education (e.g., Forbes & Davis, 2008; Schwarz et al., 2008) by focusing on how preservice elementary teachers translate their espoused inquiry frameworks into planned and enacted science lessons, as well as how the curriculum design process is socially- and culturally-mediated across contexts.

This mixed-methods study involves 46 preservice elementary teachers in an elementary science teaching methods course and in-depth case studies of four elementary preservice teachers during the final year of their teacher education program. The focal point for data collection and analyses were science lessons the preservice teachers planned and enacted in elementary classrooms during the methods and student teaching semesters. Drawing on activity-theoretical frameworks, two interacting activity systems are articulated that are relevant to this study. Curriculum planning (central activity) and curriculum enactment (object-activity) are foregrounded as constituting curriculum design for inquiry, consistent with existing descriptions of teachers' practice (e.g., Remillard, 2005). This model provides a number of specific affordances. First, it highlights the use of both symbolic and material tools (preservice teachers' espoused inquiry frameworks and science curriculum materials), what Engeström (2007) refers to as 'tool constellations', with which they engage in curriculum design. Second, the model affords the ability to map the construction of science lesson plans as boundary objects between curriculum planning and enactment domains. Third, by identifying contradictions that the preservice teachers articulate within and across settings, it is possible to link their curriculum design decisions to underlying contradiction-specific rationales. Ultimately, this model, in addition to other representational tools described in the next section, affords the ability to trace the emergence and resolution of contradictions in curriculum design activity over time.

Data were collected throughout the academic year and included interviews, lesson plans, instructional artifacts, reflective journals, and observations of enacted science lessons. To code this data, a series of coding keys were developed that are explicitly aligned with the CHAT-based model used in this study. These coding keys afforded the ability to identify the preservice teachers' curriculum design decisions, assess the inquiry-orientations of their planned and enacted science lessons, and identify contradictions that emerged in their curriculum design activity. Using coded data from the total population of preservice teachers in the methods semester (n=46), quantitative analyses were performed to describe patterns in their curriculum design decision-making and to assess how inquiry-based their planned science lessons were. A regression model was also constructed to provide causal explanations for why their lessons were or were not highly inquiry-based. Qualitative methods were used to analyze data from the four preservice teachers studied over the year. These analyses were characterized by an iterative process of coding, reduction, displaying, and verification of data (Miles & Huberman, 1994) that were directed towards the development of case studies. The primary goal of these analyses was to identify contradictions within and across curriculum design contexts that explained the preservice teachers' curriculum design decisions. Multiple coding matrices were used to display these relationships, one that was lesson-specific and one that was contradiction-specific. The latter was necessary to trace the resolution of particular, pervasive contradictions over time and characterize preservice teachers' evolving inquiry frameworks and curriculum design practices.

Results from Study A illustrate how extant, reified models of classroom inquiry served as crucial instruments in the preservice teachers' curriculum design for inquiry. They developed their capacities to transform their professed models of inquiry into classroom practice by delimiting particular aspects of inquiry as the object of their curriculum planning activity. However, their curriculum design efforts led to emergent contradictions within their placement classrooms. The preservice teachers worked to resolve these contradictions in various ways, including constructing specialized, interim instructional plans; restructuring and reordering time; and reprioritizing particular facets of inquiry in ways that reflected these constraints. While the curriculum materials they used largely defined the material and conceptual space in which their curriculum design efforts occurred, it was the influence of their placement classroom contexts that ultimately determined how they were able to translate the abstract into the concrete. The preservice teachers ultimately represented the challenges they experienced enacting their science lessons as a fundamental contradiction between two object-motives of curriculum enactment focused on student learning. All were still struggling to reconcile this contradiction at the end of the study.

## Study B – How Pedagogical Content Knowledge Develops: The Impact of Reflection and Community

While many researchers have advanced the notion of pedagogical content knowledge (e.g., Shulman, 1986; Loughran et al., 2001), there remains a gap in our understanding of how this knowledge develops over the course of a teacher's career. There are many factors that likely influence the development of PCK, including the teacher's content knowledge within a subject domain, the students' prior knowledge, the pedagogical approaches employed, interactions between students and teacher, student assessments, and how the teacher reflects on these experiences before, during, and after the instruction (Morine-Dershimer & Kent, 1999; Magnusson, Krajcik, & Borko, 1999). Many scholars comment on the complex and cognitive nature of teacher planning and the influence of the teaching of any subject area on teacher knowledge (Magnusson, Krajcik, & Borko, 1999; Leinhardt & Greeno, 1986).

Teachers' knowledge growth can occur through professional development, which can "help teachers develop cohesive understanding about inquiry instruction by building on their existing ideas about student learning, technology and the role of the instructor" (Slotta, 2004, pg. 203). However, most teacher professional development is decontextualized. This study examines the role of reflection and peer-exchange in helping science teachers develop PCK though their design, enactment, and revision of a technology-enhanced, project-based lesson. An intervention is introduced where teachers reflect on their planning, enactment, and revisions, as well as with their peers in a community. CHAT is employed to analyze the connections among the activities in which teachers are engaged, the context in which these interactions are occurring, and the teachers' development of PCK.

This three-year longitudinal study uses an iterative design-based methodology to investigate the development of pedagogical content knowledge of nine science teachers (*n*=9) in relation to their instructional practices (e.g., lesson design, preparations, classroom interactions, assessment and feedback), and student understanding. The focus is on two specific interventions that serve to promote professional development: reflection, and peer-exchange. Teachers co-design and then enact a project-based, technology-enriched science lesson. Four main phases of teacher activities were captured by this study: (1) Prior teacher knowledge and experience; (2) Lesson design; (3) Classroom enactment; (4) Revision of lesson design.

Data sources include teacher surveys, interview questions, lesson plans, reflections (captured in a wiki), videotaped classroom enactments, field notes, student artifacts and responses, and peer exchanges (on wiki, and in group meetings). Following Koehler and Mishura (2005), all wiki documentation, interviews and field notes were coded for different categories of teacher knowledge, including pedagogical content knowledge. For each coded knowledge element, a qualitative score of 0-3 was assigned. For PCK, 0 represented the absence of that knowledge, while 3 represented a very clear understanding of students' prior knowledge and appropriate teaching strategies. These coded knowledge elements when combined with other enactment coding measures were used as data for subsequent CHAT analysis.

The activity and action patterns from the teachers' classroom enactments were identified from video documentation and field notes, and these were coded for types of action: Small group interactions (SGI); Large group interactions (LGI); Logistic actions (Log); and Isolated actions (Iso). Both SGI and LGI were subdivided into management (M) and pedagogical actions (Ped). Each type of action became its own segment. A qualitative score of 1-3 was assigned for the content of interaction. A score of 3 represented strong engagement and strongly addressing student learning needs. A score of 1 represented poor engagement or poor interaction. Students' activities were coded as either SGI or LGI and given a qualitative score of 1-3 based on the engagement, either with student peers or with teacher. A score of 3 represented high quality of engagement such as being on task and asking relevant questions. A score of 1 represents a weaker level of engagement. The SGI and LGI qualitative score was multiplied by the time frame of that segment and this value was then graphically represented. These codes were then cross-referenced to the nodes on an activity triangle for teacher enactment of project-based lessons, providing an iterative activity-based analysis. A within case and cross-case analysis of actions and operations (Miles & Huberman, 1994) provided evidence of challenges, contradictions and tensions that resulted in emerging knowledge or new learning opportunities for teachers.

Results in this study indicate that tools such as scaffolded wiki-reflections and lesson designs offered a mechanism for participants to make their actions visible to themselves and to their peers. The CHAT-based framework used in Study B helped expose tensions between subject-tool-object and community-tool-object relationships, which in turn affected the next iteration of the lesson design and teacher knowledge development, while also identifying the tensions within activity systems and the emergence of new rules. For example, during the lesson revision phase of the teachers' activities, participants were able to see specific flaws in the lesson design. All teachers had a pattern of lesson revision, which identified the student wiki-templates in the project-based lesson as underutilized. Through the reflective practices, teachers (subject) acted differently in their lesson design incorporating more scaffolding (rules) within the re-design of the lesson and, subsequently, enacted the lesson differently. In addition, teachers participating in the peer-exchange activities began to emphasize the structured use of wiki-templates as part of their lesson design. Tensions in the community-tool-object relationship caused dynamic shifts in the activity systems from one iteration to the next. Thus, the generative knowledge construction was not limited to self-reflections but also occurred through community exchanges and community reflections.

## Implications for Perspectives on Science Teachers' Expertise and Learning

There have been recent calls for increased use of CHAT in education research (Roth & Lee, 2007), including research on teachers' practice, expertise, and learning (Grossman, Smagorinsky, & Valencia, 1999). However, there remains little CHAT-based research focused on teachers and teachers' learning, particularly in science. The two parallel studies presented in previous sections are unique in that they draw explicitly upon CHAT as both theoretical and analytical frameworks to investigate science teacher learning. Findings from these studies reinforce the context-dependent nature of teachers' learning and expertise assumed in sociocultural theory (Putman & Borko, 2000). However, they also advance the field's theoretical understanding of how and why teachers' learning is situated by illustrating underlying contradictions that explain change over time in particular cultural contexts. In this section, we highlight important theoretical and practical implications for CHAT-based perspectives on teachers' expertise and learning that have emerged from these two studies.

A crucial element of CHAT is the break it makes with cognitivist psychology. Rather than characterizing learning as an internalization of mental schema or concepts, it assumes instead that learning is evidenced in changes in activity, emerging from the synergistic interaction between the symbolic (cognitive and cultural) and physical environment. CHAT foregrounds the translation of the abstract to the concrete, or realization of the symbolic in action through activity. However, the origins of expansive learning lie in the initial recognition of emergent contradictions and questions about the object and motive of a given activity. So, in effect, the beginning of the process of moving from the abstract to the concrete is spurred by the objectification of activity, or the articulation of ideas, principles, and truths from experience. Because activity also involves deriving the abstract from the concrete, they are therefore temporal, and the symbolic is already a product of the history of the activity in which it is mobilized and used. Ultimately, then, networked practices, as illustrated here in both studies with curriculum planning and curriculum enactment, rely not just on moving from the abstract to the concrete, but also from the concrete to the abstract through a cyclical process of internalization and externalization (Engeström, 2008), participation and reification (Wenger, 1998), and circulating reference between form and matter (Latour, 1999). What this suggests is that while practice-specific representations take many forms, they are both used *in* activity and developed *through* activity.

As a process of internalization and externalization (Engeström, 2008), activity systems appear twice to the subject, in this case the teacher; once in material form and once in symbolic form. Semiosis is an emergent property of both. For teachers, this highlights the dialectic by which they have, through activity, arrived at a particular point in their own learning, and has clear implications for perspectives on teacher learning. Most clearly, it highlights the need for teachers' to be engaged in teaching practice and for that practice to be foregrounded in programs designed to promote teacher learning. This is crucial not only for teachers to identify the contradictions and tensions that pervade classroom activity systems, but also for them to attempt to resolve those contradictions through activity. In Study A, for example, the preservice teachers articulated a fundamental contradiction in curriculum enactment for inquiry between two objects and motives of curriculum enactment. This tertiary contradiction emerged between positioning students as objects of activity who appropriate predetermined learning goals and as community members and co-collaborators involved in the co-construction of both the object and explanations of phenomena. This contradiction only emerged after engaging in multiple iterations of curriculum design for inquiry and was thus derived and objectified from activity. In Study B, teacher tools (such as online reflection notes, and lesson designs), highlighted teacher actions in classroom activities, and identified critical moments (tensions) where teachers recognized that a change in patterns of practice were required. The object in this study, PCK development, is connected to these tensions and contradictions. Through iterative activity-based analysis, these actions and changes in actions allowed the object in this study, PCK development, to be traced. These findings reinforce the importance of teachers' engagement in rigorous processes of self-reflection and analysis of practice.

From CHAT-based perspective, learning is defined as the evolution of an existing activity or practice to more culturally-advanced form of that activity. However, in addition to emphasizing teachers' learning as changes in practice, CHAT foregrounds the fundamental motives that drive activity and the physical and symbolic objects through which they are pursued. All activity, including science teaching and learning in the classroom, is situated. However, when cultural layers are removed from activities, they are left composed of the essentials of collaborative work – groups of individuals working together on a particular task that possesses shared meaning (Engeström, 1987). As a result, it is impossible to understanding teachers' learning without accounting for object-motives of their professional practice. In Study A, the preservice teachers' curriculum design for inquiry was punctuated by episodes of lesson-specificity determined by the curriculum materials they employed. While the episodic nature of their curriculum planning and enactment cycles resulted in lesson-specific tools and physical objects, their symbolic objects and motives largely remained constant – to promote students' construction of explanations from evidence through collaborative classroom inquiry. In Study B, the activity system occurs embedded in authentic teacher practice. The teachers design, enact and revise an innovative science lesson as part of their normal activity. However, active teacher learning requires collaboration with peers, as teacher knowledge development is demarked as a social process. The development of community and the role of reflection within the community are powerful elements for "expansive knowledge" (Engeström, 2007). Emerging teacher knowledge (object in Study B) is amplified through community exchange and community activity. As evidenced in both studies, to understand teachers' learning, it is critical to identify the object-motives that orient the activities through which their learning is manifested.

CHAT also emphasizes the material basis of activity, meaning that the products of activity are not just abstract concepts or ideas, but physical, tangible objects. Here, in both studies, the teachers' learning was made manifest in the curriculum materials they produced through iterative cycles of curriculum design. As boundary objects (Wenger, 1998) between curriculum planning and curriculum enactment, the teachers' lesson plans and other curricular artifacts served a dual purpose as a working problem space for curriculum planning and an instrument to support curriculum enactment. As such, they were representations of their learning, as others have argued before (Ball & Lampert, 1999; Loughran et al., 2001; Shulman, 1986). However, they also served as vehicles and conduits for the transport and application of expertise in novel contexts. For the preservice teachers in Study A, they were not only crucial instruments for translating inquiry frameworks into classroom practice, but also the contextualization and specification of those inquiry frameworks over time. In Study B, teacher lesson designs and student artifacts, manifested as evidence for teachers and for the peer-community. The teacher could comment on their learning in practice with these artifacts, and were able to articulate their meaning and their understanding of project-based learning. Given the challenges of promoting transfer, or learning across contexts, the focus on the physical and material basis of transfer inherent to CHAT is an important element of perspectives on teacher learning.

Finally, rather than emphasizing institutional stability, CHAT assumes that activity systems are inherently contradictory, full of tensions, and always subject to change. If such dynamicism exists as an integral feature of activity systems, including science classrooms, and it demands changes in practice to respond to emergent contradictions, then teacher learning from a CHAT-based perspective is a foregone conclusion. But this does, perhaps, speak more specifically to perspectives on teachers' expertise. Teachers' expertise must not only be marked by their ability to operate within particular activity systems, but also to effectively respond to changes to those activity systems and emergent contradictions. For the preservice teachers in Study A, the introduction of inquiry as an extant framework necessitated changes in their teaching practice, though likely made less contradictory by their lack of experience and participation in a mature, preexisting form of teaching practice. What came to define their expertise for inquiry-based science, however, was the ability to respond to unpredictable schedules (rules) and curricular resources (instruments) to engage students in inquiry practices. In Study B, teachers activity systems are dynamic, fluid and in constant flux as they are dependant on the enactment of the lesson. This enactment addressed school schedules, student learning and content-discipline. The revision in lesson design (artifacts) and rules that were set up for the next iteration of enactment occurred as a response to the tensions within the original activity system. Often these shifts or changes were first recognized within the classroom (or on the fly), prompting a quick adjust during the enactment which became more formalized in the revision of lesson design for the next iteration.

## Conclusion

The two studies presented here contribute to a limited but growing body of CHAT-based education research. Specifically, the two studies described in this paper illustrate how CHAT can be employed in research on science teachers' expertise, practice, and learning. As shown in the discussion of these two studies, such research can and, we believe, will continue to yield novel insights into science teachers and teaching, both empirical and theoretical, which possess the capacity to inform a multitude of design efforts focused on supporting science teachers' practice and development of expertise. However, the fusion of the CHAT framework with the material and conceptual spaces in which teacher learning and practice takes place is not without its struggles. As an emergent research domain, it presents many questions to yet be addressed, particularly methodological ones. We believe that these are important issues that should be further explored for the promise of CHAT to be more fully realized in educational research.

# Using conceptual blending to describe emergent meaning in wave propagation

Michael C. Wittmann, University of Maine, 5709 Bennett Hall University of Maine, Orono ME 04469-5709, wittmann@umit.maine.edu

**Abstract:** Students in interviews on a wave physics topic give answers through embodied actions which connect their understanding of the physics to other common experiences. When answering a question about wavepulses propagating along a long taut spring, students' gestures help them recruit information about balls thrown the air. I analyze gestural, perceptual, and verbal information gathered using videotaped interviews and classroom interactions. I use conceptual blending to describe how different elements combine to create new, emergent meaning for the students and compare this to a knowledge-in-pieces approach.

## Introduction

In several strands of research into student understanding of specific science content, one research assumption is that ideas (be they large scale (Wandersee, 1994; Carey, 1985) or small scale (diSessa, 1993; Hammer, 2000)) already exist and are triggered in a given context, ready to be used, fully formed. The ideas are given various names within physics education research, either misconceptions such as "impulse theory" (McCloskey, 1983a,b), phenomenological primitives (p-prims) such as "force as mover" (diSessa, 1993), or reasoning resources such as "actuating agency" (Hammer, 1996). Across all these different traditions, the research involves modeling which pre-existing ideas are activated and how they are used with each other in a context.

Ideas are not only activated. New ideas must come into existence, else learning would not occur and our toolbox of useful ideas would never increase. This prompts the need for explanations of the development of ideas, be they thought of as conceptions, p-prims, or resources. One could assume a long-term development of an idea through many processes. A rich literature on the development of misconceptions (see Wandersee, 1994, for a review) suggests that misconceptions are formed through inappropriate teaching, misinterpretation of observations of the world around us, or describing situations using inappropriate models. Primitives, on the other hand, might develop very early in life (Mandler, 1992), suggesting that some kinds of p-prims are nearly hard-wired into our thinking. We might reify the several processes we use to solve a problem into a single new cognitive object (Dreyfus 2002; Sfard, 1991; Tsamir, 2004). We can also think of connecting many different resources into a consistently activated network appropriate for a given setting (Hammer et al., 2004) or we can discuss ways in which networks of resources rearrange so as to describe different types of conceptual change (Wittmann, 2006). The plasticity of such networks can be defined, as well (Sayre, 2008). In summary, one can consider many pathways to the development of robust ideas which are later able to be activated.

Not all ideas need be developed in a robust fashion and for long times. Indeed, it is clear that new ideas must arise in new and novel situations. Such ideas might develop on the time scale of seconds and last for only as long as a problem needs solving. Thus, it is appropriate to ask if we can observe such events occurring: do we see students using an idea on very short time scales, and, if so, what observations allow us to conclude so?

In this paper, I suggest one approach to modeling emergent meaning in students who are solving physics problems. I look at common students' responses to a typical physics question about wave motion on a long, taut spring. Students were asked to describe how one creates a single wavepulse on the spring, and then predict how one might change the speed of the wavepulse. I show how students commonly use similar language and gestures as they give their answers. In summary, their answers are similar to descriptions given to describe how a ball is thrown through the air. To model the details of their answer, I use a certain level of formalism that is borrowed from the field of language development and linguistics.

I use the mechanisms of mental space integration, also called conceptual blending (Fauconnier and Turner, 2002), in particular the ideas of composition, completion, and elaboration. In this analysis, I consider two different mental spaces, one being the observed event of a wavepulse being created by a wrist flick and traveling along a long, taut spring, the other being the imagined space of a ball thrown in the air. These two spaces are connected by similar elements, forming a blend composed of elements of both spaces. New information is recruited from the different mental spaces, but only some information from each space is used. The idea represented in the blend is then elaborated upon, leading to emergent meaning. Specifically, students predict that flicking one's wrist harder leads to a faster wavepulse (as if throwing a ball harder). This response seems obvious within a simple metaphor (a wavepulse is like a ball) but gives us insight into ways in which student responses emerge rather than are activated. In particular, one well-documented idea, the Ohm's p-prim (diSessa, 1983, 1993) can be thought of as emerging from the blend rather than being a pre-existing idea that is activated in a new setting. This result is consistent with observations of students engaged in a time-consuming construction of new meaning as they explain their thinking.

## Student responses to a wave propagation problem

The data analyzed in this paper come from interviews where students make predictions about a basic physics problem that is commonly taught and studied in a high school or college survey physics course. Data presented in this section are taken from the author's 1998 Ph.D. dissertation, and have previously been analyzed in several ways (Wittmann 1999, 2002). Data on the question discussed here were gathered from hundreds of students in written questions (free response, multiple choice, and multiple-choice multiple-response questions on ungraded quizzes and specially designed, ungraded pre- and post-instruction surveys, as well as graded tests), tens of interviews, and hours of informal classroom observations. Rather than analyze all students, I am interested in a class of common responses for which I will give a few brief examples. The examples below illustrate the most typical response given by students. Data come from transcripts from interviews carried out with students who were made aware of the Think Aloud protocol (Someron, 1994). The role of the interviewer was to elicit responses about hypothetical situations and explore the reasoning students gave for their responses. Though the original intent of the interviews was not to explore the development of ideas, the data lend themselves to a re-analysis in terms of emergent meaning arising in new and novel situations.

The physics problem concerns wavepulse propagation along a long, taut spring. In a typical form of the interview question, students were given an image of an already propagating wavepulse (see Figure 1). They were asked to describe how such a wavepulse could be created. Then, they were asked how they might change the amount of time it took for the wavepulse to reach the wall; some students were asked to increase the time, some to decrease it. A correct response to such questions would have been to consider the tension in the spring (changing how tightly the spring is pulled) or changing the mass density of the spring (by replacing the spring with a different one, basically). The hand motion used to create the wave does not affect the speed of propagation. (A complete analysis of this situation is found in typical introductory physics textbooks and was part of instruction that all students had completed by the time of these interviews.)

Figure 1. Propagating Wavepulse. A hand moves up and down and creates a pulse which moves toward a distant wall.

Three examples illustrate common features of many student responses. "Ford" (all names are aliases) had already demonstrated how to create the wavepulse, making a brief up-and-down motion with his hand to show how the shape came to be. The following dialogue occurred shortly after, with information about his drawings and gestures included parenthetically:

IVW: Let's say that you are standing over there, you create it, and it takes a certain amount of time for it to reach the wall. Let's say you want to shorten the amount of time that it takes. What would you have to do?

Ford: One -- I could probably -- there are two scenarios that I have to think about, and since you want me to say right now -- I'd send a quicker one (he draws a pulse smaller than the original in both width and amplitude and makes an up-and-down hand motion in less time and with lower amplitude than the original)

I: Wait, let me stop you right here, by quicker you mean, you did your hand motion like this (copies Ford's small-amplitude motion) --

F: Shorter, I wouldn't go (repeats original large-amplitude hand motion) I'd try to make a shorter hand motion (repeats small-amplitude hand motion), I wouldn't want to like this (repeats original large-amplitude hand motion). It would get there faster.

Notably, Ford's explanation of "I wouldn't go" involved a grammatical pointer to his hand motion, the gesture acting as the predicate to the sentence. This first explanation was immediately followed by a second scenario in which Ford described a larger and therefore faster pulse instead, again with associated hand motion. This dialogue was long and is left out because essential features of the explanation have already been presented – the differences in hand motion and language pointing to them.

"Adam," when asked a similar set of questions, had given the same kind of explanation for wavepulse creation, a flick of the wrist up and down. His explanation used slightly different physics terminology, but involved the same sense of a change to how the wavepulse is created:

IVW: Imagine that we can measure, just clock the time it takes the pulse to go all the way down to that wall. How could you shorten the amount of time that it takes for it to reach that wall, what could you do to make the time less?

Adam: If we could make the initial pulse fast, if you flick it, you flick it faster.

I: ...And why would flicking it faster make it go faster?

A: That would make it, I don't know, it's kind of hard to explain
I: Do the best you can
A: It would put more energy in or something.

Like Ford, Adam emphasized the connection between the hand motion and the speed of the wave. Another student, "David," gave a similar response to Adam and Ford's when he said "I think possibly, you see a slower pulse … if the force applied to the spring is reduced ... that is: the time through which the hand moves up and down [is reduced]." Again, the "force applied to the spring" describes how the hand moves up and down and affects the subsequent speed of the wave.

Many students' explanations were strongly connected to the hand motions they made to indicate the creation of the original wavepulse. The "faster flick" or the "greater effort" or the "smaller wave" were all shown through gesture, typically a harder hand jerk, a quicker flick of the wrist, a more vigorous and robust arm movement, and so on. Their motions and words were consistent with the idea that they were thinking as if the wavepulse were like a ball. Formalizing this intuitive sense of their responses is the purpose of the next section.

## Summary of Conceptual Blending

My goal is to account for the ways in which students used hand and arm gestures and a specific language to arrive at a certain kind of prediction about how to change the speed of the wave (involving changes in effort in creating a wave). It would be facile to claim that they activated the idea that more effort leads to more speed in the face of resistance of the string to being moved (an application of the Ohm's p-prim (diSessa, 1983, 1993) in the context of wavepulse propagation). But, the data suggest that one can think of the idea not being activated (as Ohm's p-prim) but as emerging in this context. To describe emergent ideas, I will use the formalism of mental space integration (commonly called conceptual blending), a framework developed by Fauconnier and Turner (2002) to account for meaning generation in language. Briefly, mental space integration assumes that there are different mental spaces (ideas associated with a given situation) that can combine in specific ways to create new meaning. Distinct mental spaces are combined due to some shared content or structure. The two spaces are brought together ("blended"), with selective projection taking some information from each input to compose a blend. New structure and new information is recruited (perhaps from long term memory) to complete the blend. One can let the blend "run", i.e., let the newly developed idea be elaborated upon. Emergent meaning arises as the results of this elaboration are connected by backwards projection from the blend back into at least one input space, perhaps both. We observe all these elements in student responses to the wave physics question.

I should be clear that I do not consider the analysis of student responses to be a linguistic problem, but instead am using representations and mechanisms from mental space integration to analyze reasoning in physics. I present applications and explanations in the wave physics context below; more detail can be found in books (Fauconnier and Turner, 2002) and in special issues of the journals of Cognitive Linguistics (as summarized in Coulson and Oakley, 2000) and the Journal of Pragmatics (as summarized in Coulson, 2005). The discussion that follows is particularly indebted to Bache (2005) and Hougaard (2005). I introduce the idea of blending with an example that summarizes many of the ideas used later in this paper to describe reasoning about wavepulses. It is adapted from Fauconnier and Turner (2002).

Consider a situation in a lab where you and a careless colleague are setting up an instrument. Your careless colleague is across the room, and about to attach one piece of equipment to another in a way that will cause trouble. You blurt out, "If I were you, I wouldn't do that!" Your colleague stops. What's going on here?

We can imagine two input spaces. You (and what you would do) exist in one space, your colleague in the other. In the blended space, the two of you are fused into a single, unique person ("if I were you" turns into "I am you"). This process of creating a new entity (of you and colleague as one person) is a "composition," in that it is composed of elements from both inputs. This new individual has an agency that is not yours (it is your colleague's) but makes a decision that is not your colleague's (it is, instead, yours). You have knowledge of the system that your colleague does not (which guides your statement "I wouldn't do that!"). This information "completes" the blend. The projection of information from each input space is selective, in that the judgment from your space is used for the decision in your colleague's space. In the blend, your knowledge is applied to you-and-colleague-as-one. You "elaborate" on the knowledge by implying that something should not be done. New meaning emerges – there is danger here. From here, there is back projection, from the blend back into your colleague's mental space: your actual colleague (thankfully) acts differently than originally intended.

To summarize important terms from this example, there are three major aspects that drive blending:

- Composition: creating relations that are not necessarily obvious, but allow the blend to occur
- Completion: recruitment from long term memory, for example in pattern completion or assigning properties to blends based on knowledge from one input
- Elaboration: "running the blend;" imaginative mental simulation that leads to emergent meaning that was not necessarily part of either input

Further terms of importance are selective projection (not all elements of each input space go into the blend, since often there are contradictory elements in the input spaces) and backward projection (information going back from the blended space to at least one input space). The full formalism of mental space integration is much larger than these five elements and includes heuristics for how distinct mental spaces are connected. That formalism is helpful in modeling student reasoning and provides additional details (such as the concept of the compression of cross-space connections), but is outside the scope of this paper. In the next section, I apply the formalism to the data presented above.

## Conceptual Blending of Wavepulses

The formalism of conceptual blending allows us to take student responses (including language and gesture) and make sense of their responses as emergent meaning, without activation of pre-existing ideas. I describe two individual inputs, show how they blend into a single space, and describe the emergent meaning that arises in the blend. I give two examples, the first based on the data that we have of student responses to the interview question, the second a hypothetical discussion which shows that a different set of inputs might lead students to create a blend in which the correct answer emerges. In the following section, I compare this analysis to past analyses (including my own) using another model of student reasoning.

### Seeing waves as balls

One can describe two mental spaces in use when predicting how to change the speed of a wavepulse translating down the spring. First is the simple perceptual observation of the wavepulse, a bump on a spring created by a vigorous hand motion and moving down the spring. Second is one of balls or other finite sized things that can be thrown through space. An understanding of object motion happens extremely early in life (Mandler, 1992) and ideas about thrown balls are readily available to most children (and university students). How these ideas get connected to the wavepulse is described by mental space integration. The result is a blended space with emergent meaning: wavepulses “as” balls, with certain properties that are not there in the observation itself but play out in predictions, when the blend is “run.”

A blend is typically described by a diagram such as shown in Figure 2. In the upper left, there is an input related to the observed wave on the spring. As shown by the students, there is a kinesthetic (proprioceptive) element of the wrist flick. One observes a pulse, as well as its motion (translation) down the spring. In the upper right, there is an input that contains typical properties of thrown balls. The representation takes into account issues of selected projection from each input into the blend. The Observed Wave input contains only a selective set of the observed phenomena, while the Ball input contains only a selective set of properties associated with balls. Only those elements of the Ball input which match to elements of the Observed Wave input are shown.

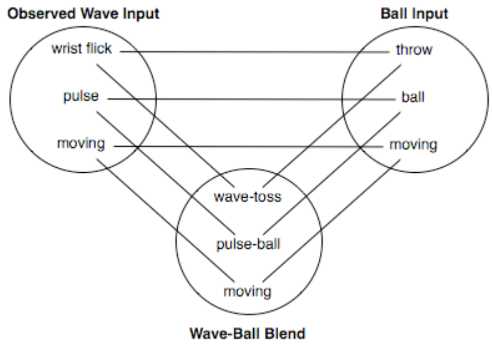

Figure 2. Wave-Ball blend. Two inputs (of the observed wavepulse and of thrown balls) are integrated to create a blend that leads to emergent meaning.

The Observed Wave and Ball input spaces are connected by like elements and integrated to create the Wave-Ball blend. There is selective projection, implied already because of the presentation of only selected pieces of information in each input. The wrist flick (perpendicular to the direction of motion) and a throw (in the direction of motion) are connected because they are both motions that initiate movement. The observation of a finite size pulse is connected to that of finite size objects, perhaps through a perceptual process of *binding*, a psychological term that describes how objects are seen as a whole. The act of binding is impossible for the (healthy) mind to stop. The motion of the pulse down the spring and a thrown ball through the air are connected because they are both propagation in a specific direction. Certain information is ignored: the perpendicular motion of pieces of the spring, for example, and information about the parabolic path of a thrown ball. It is probably unavoidable, based on the creation (by hand flick), shape (finite size), and directed movement of the wavepulse, to *not* think of the wavepulse as a finite-sized object like a ball.

In the blend, one can recruit information from the Ball input, namely that the speed with which you move your hand affects how fast a ball moves through the air. Furthermore, student predictions about how to change the speed of the wavepulse require that they "run" the blend. This leads to emergent meaning that was not present in the Observed Wave input. Notably, the hand motion perpendicular to the direction of wavepulse motion is taken as analogous to the throw of a ball in the direction of motion – obviously, they are not the same, but they are treated as such in the blend. So, in the blended space, the speed with which you move your hand affects the speed of the wavepulse along the spring; students like Ford, Adam, and David either describe a "quicker, faster hand motion" or that you "put more force in your hand" (with an accompanying larger/harder/faster wrist flick) when giving this answer. In the blend, the idea emerges that greater effort leads to greater speed. The Ohm's p-prim is not activated, it emerges.

## Seeing waves as events

One instructional goal of teaching students about waves has been suggested as helping students see the wave as a propagating event rather than an object translating down the spring (Hammer, 2000). For mental space integration to be useful, it must also describe what we believe expert physicists are doing when they think about waves. In Figure 3, we propose a blending diagram to describe how a physicist might model this situation.

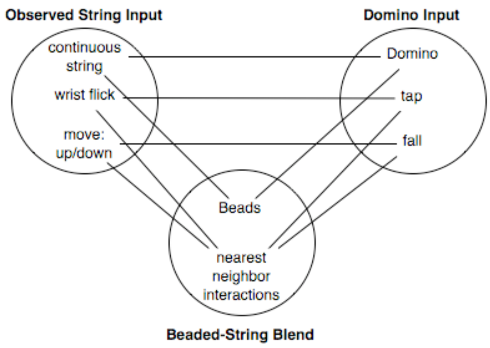

Figure 3. Wave-as-Event blend. In the blended space, the propagation of a wavepulse along a beaded string is an emergent phenomenon.

The blending diagram for this situation again contains two input spaces and a blend. The scale of observation is changed – rather than an Observed Wave (where one focuses on the propagating bump on a long, taut spring), one looks at the spring and has an Observed Spring Input. Three observations can be made. First there, is a long, continuous (taut) spring. Second, there is a flick of the wrist that is holding the end of the spring. Finally, one observes that the spring moves up and down (assuming, as always in this paper, a transverse wavepulse as shown in Figure 1) first at the end, and then consecutively at locations further down the spring. In the upper right of the figure, I suggest a second input: Falling Dominoes. It is important to note that any input containing effects spreading from discrete points to discrete points is sufficient. Examples include news spreading through gossip or a pile-up in a car crash during a traffic jam. The Dominoes example has the benefit that it is part of most people's everyday experience, is easily imagined, and is linear. In the Dominoes input space, there are individual dominoes, lined up in rows. One is tipped over, hitting the next. They fall down sequentially, each being knocked down by the one before it.

The blend is created through several connections. The spring and the Dominoes are both in a long line, so are visually similar. The motion of the wrist up and down at a single point (the end) of the spring is connected to the motion of the first Domino as it is tipped over. Just as each piece of spring goes up and down as it is pulled by the piece of spring next to it, the Dominoes keep falling over and hitting the next Domino in line. We have three elements: the long line, the repeated motions, and propagation of these events along the line.

The blend is composed of elements from each input. In the blend, the continuous spring is re-interpreted as being made up of discrete elements – the structure of the line of Dominoes is applied to the spring. Such a description was already implicitly used in the preceding paragraph, where "each piece of spring" acts on the next (this is not actually true in a continuous system). So, we have a Beaded-Spring in the blend. It moves according to the rules of the Observed Spring, where pieces of the spring go both up and down rather than simply falling over like Dominoes do. The blend, then, is a way of imagining the continuous spring as a set of discrete points that interact with each other through nearest neighbor interactions (like the discrete Dominoes) and move like the observed spring (rather than the discrete Dominoes).

The wavepulse is a global, emergent phenomenon of the blend. It arises because of elaboration, in which one "runs" the blend and plays out the consequences of the wrist flick and nearest neighbor interactions. The up motion of the wrist creates a signal down the spring; nearest neighbor interactions create the leading edge of the wave. The wrist changes direction; the peak of the pulse is created and propagates through the system as each bit of spring recapitulates the motion of the wrist. The signal ends when the wrist returns to its starting position; the wavepulse is completed and propagates through the system. The actual rules of propagation are not observed and only emerge in the blend. The speed of wave propagation depends on the nearest neighbor interactions due to tension and the mass of each individual “piece” of spring. We note that a typical textbook derivation of the wave equation describing wave propagation shows exactly this decomposition of a continuous spring into discrete segments and interactions among the nearest neighbors as the mechanism for propagation

What separates the Beaded-Spring blend from the Wave-Ball blend is the selective attention to the physical system being observed. It should come as no surprise that one reasons differently when attending to different details of a situation. Hougaard (2005) and Bache (2005) describe the choice of what to attend to as a process of disintegration, as one determines which parts of a system to use in the process of selective projection into the blend. In both cases, a motion acting on a system is connected to a different motion acting on a different system. One’s choice of system, balls or Dominoes, suggests different ideas of how to make sense of an observation. I do not pursue the analysis further in this paper, except to point out that choosing to observe either the “wave on a spring” or the “spring in motion” allows for different ways for dis-integrating the observation into blendable pieces.

## A knowledge-in-pieces analysis, instead

The analysis given above is not the only analysis possible with the simple interview data presented earlier. In this section, I review a previous analysis of wave propagation on a long, taut spring (Wittmann, 2002). Another possible analysis might be to use elements of the resources framework, a knowledge-in-pieces schema model of reasoning that builds off of diSessa's work (1983, 1988, 1993) on phenomenological primitives and is described more generally by Hammer (1996, 2000, 2004). Many of the ideas of the resources framework are consistent with Marvin Minsky's descriptions of frame systems (1975) and agents (1985). A more general review of the resources framework as used in this section is provided elsewhere (Wittmann, 2006).

### Resources as knowledge pieces

Resources are ideas that are useful and productive when solving some problem (Hammer, 2000). They are basic ideas one has that apply to a situation; they can be thought of as individual, nestable bits of knowledge.

As an example, “closer means stronger” (Hammer, 1996) implies that if you sit closer to a loudspeaker, the sound is louder; if you sit closer to your loved ones, you love them more; if you are closer to the sun, the heat is greater and it's summer. The first is typically true, the second of indeterminate veracity, and the last is false. The resource “closer means stronger” has no inherent rightness or wrongness. It's simply an idea, a knowledge bit, applicable (or not) in a given setting, and useful (or not) when engaged in problem solving. The term “resource” was originally meant to be very general, in the sense of computing, where a resource can be a printer (a tool outside the computer but useful for a program inside the printer), an API (in the software), or a re-usable object (in the code). One thinks of resources as activated or not. Typically, authors have been unclear about the origin of resources (whether they are built on the fly or exist as pre-compiled pieces ready to be activated), suggesting that both may be the case. In this section, for the sake of comparison with the previous discussion of blending diagrams and emergent ideas, we assume that they are pre-compiled and activated.

Few problems are solvable using a single resource; typically, many are necessary. Resources might coordinate with each other, as described by coordination classes (diSessa and Sherin, 1998). Furthermore, resources are useful at different scales - some very complicated concepts can act as resources in a problem solution (e.g., “force” as a primitive in the sense of “force as mover” (diSessa, 1993)) but can also be thought of as being made up of many individual resources (e.g., the coordination of resources and readout strategies about when to use them, described by the coordination class “force” (diSessa, 1998)).

### Resource graphs of wave physics reasoning

I rarely think of students (in interviews or classroom discussions) as thinking in terms of large-scale concepts (Wittmann, 2006). Instead, a simple model of students assumes that they activate only those parts of a concept that are relevant to the situation they are discussing. Similarly, I rarely expect that they use only one resource in a context, since a problem typically requires linking together more than one resource. I refer to the in-between level of description, neither primitive nor concept, as a mesoscopic description and use resource graphs (Wittmann, 2006) to represent this space of student thinking. A resource graph (see Figure 4) is a simple graphical representation of the resources activated by an individual in a particular setting.

Three resources, two previously described in the literature, can be used to account for student responses. First, and simplest of all (but important for later analysis) is Motion, specifically the translation of a bump along a long, taut string. This translation is caused by some startup effect, an Actuating Agency (Hammer, 1996), which diSessa has called Force as Mover (diSessa, 1993). Finally, increased effort in the face of resistance of the spring to being moved leads to greater speed, an example of the Ohm's p-prim (diSessa, 1983, 1993). These three resources are represented in Figure 4.

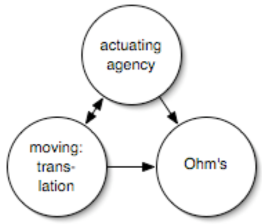

Figure 4. Resource graph to describe the typical response of thinking of wavepulses like balls.

Much as both the common student response and a hypothetical correct response could be modeled through a blending diagram, one can represent a hypothetical correct response using a resource graph, as well. As with the resource graph of waves-as-objects, the resource graph of waves-as-events contains only three elements (see Figure 5). There is an Actuating Agency that is, this time, carried out specifically on the spring. There is a displacement away from and back toward equilibrium for the end of the spring. Through Nearest Neighbor interactions, each element of the spring acts on its neighbor as it was acted upon. Finally, there is Motion, namely the propagation of the up-and-down motion of the hand.

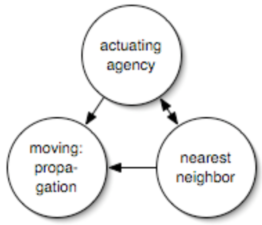

Figure 5. Resource graph for waves seen as events.

## Comparing Blending Diagrams to Resource Graphs

Mental space integration provides a more complete description of student thinking than does the resources framework because it makes fewer assumptions and has greater explanatory power.

There are fewer assumptions made about the nature of pre-existing ideas such as the Actuating Agency resource and how it is applied to different systems. In the blends, the connection between hand motion and the creation of the wavepulse or the motion of the spring is clear. In the resource description (as summarized in the graphs in Figures 4 and 5), one must make more assumptions about how the idea is applied – why was Actuating Agency connected to the wavepulse or to the spring? The use of the resource in its specific context is underdefined within the resources framework, while mental space integration shows directly how an idea is used in a setting.

Mental space integration also gives added explanatory power, indicating how the Ohm's p-prim emerges in a situation that is novel to students (as shown by their seeking many different explanations for their predictions). We need not assume that the Ohm's p-prim already exists and is activated in this setting. Instead, we can describe that the idea emerges, without assumptions of its pre-existence, and can be specific about what aspects of the blend led to its emergence. I do not doubt that there are cases where the Ohm's p-prim is activated as a pre-existing idea, but suggest that in this situation, it emerges. I generally believe that students have a self-checking mechanism ("does this idea make sense?"), and believe that they apply this and find some consistency between the Ohm's p-prim and their emergent idea. There is no evidence of such self-checking, though. It may be that the Ohm's p-prim acts as a "primary metaphor" to guide student thinking about a problem (Grady, 2005) and requires no self-checking mechanism. This suggests a way to combine the resources and blending analyses.

The idea of emergence within a specific context helps clarify some ambiguity in the resource graphs shown in Figures 4 and 5. Motion as a resource was related either to the translation of an object-like wavepulse or the propagation of a wavepulse; the blending description gives greater detail. In the Wave-Ball blend, the wavepulse moves like a ball, and a greater hand motion causes a greater wave speed. In the Beaded-String blend, the wavepulse emerges from elaboration of the blend. These are two very different descriptions.

Finally, modeling student responses with mental space integration provides a predictive power that is not possible in the resources framework. For example, if one throws a rock in a pond, water waves travel outward. An actuating agency caused a motion – but would one predict that a larger rock would cause a faster motion? Yes, the splash is larger; no, the speed is not. The resource graph in Figure 4 does not account for such detail, while the blending diagram in Figure 2 helps us recognize that the two situations might not be connected at all. Without a hand motion, the ball-space ideas simply won't be connected to the water-wave situation and it seems reasonable to predict that students would not think that a larger splash leads to a faster wave in the pond. Similarly, even though a hand is needed create a sinusoidal wave, its motion is not the same wrist-flick as when creating a wavepulse, and the idea of a throw might not exist to connect the one space to the other. Indeed, we find that few students talk about flicking the wrist harder when predicting how to increase the speed of sinusoidal waves.

Modeling student reasoning using mental space integration does have inherent problems. The description is more difficult, including issues of composition, completion, and elaboration (as well as details only alluded to in this paper, such as the compression of cross-space connections). In its favor, the assumptions about students' pre-existing knowledge are fewer, the explanatory power is greater, and the approach allows for a finer grain analysis of what is, and is not, affecting student reasoning in a given context.

# Adapting Workflow Technology to Design-Based Research: Development of a Method for Organizing the "Messiness" of Research in Technology-Rich Online Learning Environments

Alan J. Hackbarth, Sharon J. Derry, Brendan R. Eagan, Julia Gressick, University of Wisconsin – Madison, Educational Sciences Building, 1025 W. Johnson St., Madison, WI 53706
E-mail: ajhackbarth@wisc.edu, derry@education.wisc.edu, beagan@wisc.edu, gressick@wisc.edu

**Abstract**: A fundamental challenge of design-based research is that there are many variables that affect success of a design. Designers collect large amounts of data, but limited time and resources make analysis difficult and conclusions uncertain. Workflow technology is utilized in business and applied science environments to automate work processes and reveal "know-how," often tacit in scientific processes, which facilitate multiple levels of reuse. We developed a method for representing activity in an experimental online course as workflow expressions. Bielaczyc's (2006) Social Infrastructure Framework (SIF) is utilized to identify important variables, and *comprehensive data mining* (CDM) techniques are used to recover data from course session modules and activity logs. In this paper we review the literature related to our theoretical framework, describe the CDM-based methodology, and give an example of how we are using it to support design-based research within an online college course.

## Introduction

This contribution reports a new design research methodology based on workflow technology (Georgakopoulos, Hornick, and Sheth, 1995; Ludäscher et al., 2005) and the Social Infrastructure Framework (SIF) (Bielaczyc, 2006) that is especially appropriate for online learning environments. The context for our work is HAL Online, an innovative experimental section of "Human Abilities and Learning," a required course for teacher education and other education-oriented majors offered through the Educational Psychology Department at the University of Wisconsin-Madison. HAL Online includes reading assignments, online exams, and meets in person occasionally, but the primary instructional method is online argumentative discourse in small group discussion forums. Small groups comprise 5-7 students who are grouped by the instructional staff based on their similar majors and career interests and who work as a team throughout the semester. There are about 5 groups and 30 students in each course offering. The broad goal for HAL Online students is to acquire foundational understanding of human learning and thinking that is grounded in current research and theory from cognitive science, socio-cultural theory, and neuroscience. Students must demonstrate such understanding by using course ideas to: A. construct and justify well-formed arguments about a range of important topics; B. articulate and evaluate the reasoning and arguments of others, including peers and school children; C. participate effectively in argumentative small-group discourse online; and D. work collaboratively to design, justify, and critique instruction that aims to promote good thinking in areas related to their disciplinary majors.

The course is divided into 4 units: Language and Reasoning; Brain-Based Education; The Mathematical Basis of Reasoning; and Instructional Design (a small-group project). Each unit comprises 3 or 4 interrelated modules, each lasting one week. There is a required face-to-face (FTF) class for each unit. In FTF classes students hear lectures, discuss readings, solve and discuss reasoning tasks with their group, and build community and rapport with their peers. In a typical week students are given a reading assignment from a text that they complete over a 2-day period. During this period they may also participate in a warmup activity online which often involves viewing a video. Following this individual preparation they are required to go online and participate with their small groups in a discussion activity. A typical discussion activity is "Brain Gym," part of the Brain-Based Education unit, in which students are asked to play the roles of parents and educators trying to decide whether either of two brain-based curriculum proposals should be offered by their school. Another is "Math Wars" in the mathematical reasoning unit, a discussion of whether a school should adopt a progressive mathematics curriculum and approach exemplified in videos viewed online.

In this paper we illustrate our proposed workflow methodology with "Adventures in Argument," a one-week module within the Language and Reasoning unit. In this activity students are required to observe and evaluate arguments made in the popular media about current issues in the news. For example, in one semester students evaluated arguments made in political debates. In a recent semester students evaluated arguments about different health reform bills. Students' participation in small-group discussions is graded in accordance with a rubric (see Table 1).

Table 1. Criteria for evaluating students' forum contributions

1. Do you make a sufficient number of contributions? There is no set limit or number required, but a good rule of thumb is *at least* 4 thoughtful posts per forum (not per discussion topic).
2. Are your arguments thoughtful, intelligent, mature, and justified with reasons and evidence (rather than just expressing personal opinion)?
3. Do your posts specifically connect the forum discussion topics to the readings, providing evidence that you are thoughtfully connecting ideas from the course to the forum issues?
4. Do you participate in a discourse (versus post at the last minute)? Forum discussions usually start on a day a little before the previous topic closes and they wrap up before the beginning of the next topic. Engaging in the forum discourse *throughout* the period rather than just throwing up a few posts at the end will improve your grade.
5. Have you been a good group citizen, taken on some leadership -- starting discussions, serving as chair or summarizer, helping keep the group on task, contributing positive and encouraging words to others?

At the end of each unit each student is required to submit a reflection on what they have experienced and learned in that unit. These submissions are "published" through the blog facility provided in the Moodle course management system (CMS) through which we offer the course online. At the end of each unit students individually complete an online quiz assessing their mastery of the material in the unit. A typical quiz question provides students with a link to a video and asks the students to analyze the video in some way. For example, in the mathematical reasoning unit, a video of a child solving a mathematical task is provided and students are asked to use course ideas to describe and analyze the child's reasoning and problem solving strategies.

## Design-Based Research (DBR)

Design-based research is grounded in the systematic design and study of instructional strategies and tools in authentic contexts (Barab and Squire, 2004); as such, there is no one accepted definition or methodology. The Design-Based Research Group (2003, p. 5) identifies characteristics of "good" design-based research. The critical characteristic is that the central goals of designing learning environments and developing theories or "proto-theories" of learning are intertwined. Development and research takes place through continuous cycles of design, enactment, analysis, and redesign, and research must account for how designs function in authentic settings – not only in terms of success or failure, but also in terms of understanding the learning issues involved.

One purpose of our research is to improve the effectiveness of our course through an iterative process in which we make deliberate design changes. Another purpose is to assess the effects of design changes that are made out of necessity, often due to constraints over which the instructional staff has little control. For example, when the course is taught in summer it must be squeezed into a four-week intensive time period, which is very different from the full semester course that is stretched out over a 16-week period. Because the primary instructional method is online argumentative discourse in small groups, a third purpose of our research is to propose, test, and develop "proto-theories" about how small groups in online environments collaborate to produce successful outcomes.

Collins, Joseph, and Bielaczyc (2004) describe challenges that a design-research team faces when implementing design experiments. Foremost is that research is usually conducted in the "blooming, buzzing confusion" of classroom learning environments (Brown, 1992). There are many variables that influence the success of a design, and many of those variables cannot be controlled (Collins, Joseph, & Bielaczyc, 2004, p. 19). Furthermore, each variable is part of a systemic whole; it is impossible to change one aspect of the system without creating perturbations in others (Brown, 1992). Yet it is important to identify the critical variables of a design and how they fit and work together in practice (Collins, Joseph, & Bielaczyc, 2004, p. 34). One needs a well developed profile of an implementation in order to analyze a design in terms of its key elements and their interactions, and to determine how exactly one design differs from another in ways that might impact outcome. Because of the number of variables to account for, design researchers usually end up collecting large amounts of data, more data than they have time or resources to analyze (Brown, 1992; Collins, Joseph, & Bielaczyc, 2004, p. 19). To ensure that design researchers maximize their use of the collected data, analytical procedures that organize and document data in an easily accessible format that facilitates more efficient, deeper analyses are needed.

Barron (2007, p. 178) discusses the emergence and value of *intermediate representations* as a response to this need. Focusing her discussion on video research, she argues that intermediate representations are important for identifying *what to analyze* and for *understanding patterns within and across* segments of video. Macro-level intermediate representations may also be the appropriate level for sharing the details of a successful designed intervention with practitioners. This would satisfy a core characteristic of DBR; that the goal of developing sharable, adaptable learning interventions of practical use to practitioners is intertwined with the goal of developing theories or "proto-theories" of learning (Collins, 1992). Inspired by a suggestion from Rutgers colleague Grace Agnew (personal communication, 2007), we explored the potential of workflow technology to provide such representations.

### Workflow Technology

The core features of workflow technology – organizing the data, tools, participants, activities, and flow of a system – are well suited to the challenges of design-based-research (DBR). DBR researchers must attend to a large number and range of variables and their interrelationships, and they must control or at least be aware of the variable manipulations that occur either intentionally or unintentionally, during each iteration of the design research process. Workflow technology is especially useful in online learning environments such as ours because many variable values and their relationships *can be recovered post hoc* from activity logs and other data created in the online course management system (CMS). Workflow expressions derived from such data can provide diagrammatic, annotated representations of a targeted part of a course as a system. Strauss

In the following sections we will review the literature that contributed to the theoretical framework for our workflow expressions approach and provide an example of how the visual models are used to support analysis in design-based research.

## Theoretical Framework

Core concepts of our workflow expressions model come from the Social Infrastructure Framework (Bielaczyc, 2006), the literature on business and applied science workflows (Georgakopoulos, Hornick, and Sheth, 1995; Ludäscher et al., 2005), and adaptation of a comprehensive data mining (CDM) model developed by the Collaborative Technology Research Group (CTRG) at the University of Colorado-Boulder (Rembert, 2006).

### The Social Infrastructure Framework (SIF)

The SIF identifies critical design elements to be aware of and accounted for when designing socio-techno learning environments, and articulates them in terms of four dimensions (Bielaczyc, 2006). These are summarized in Table 2:

Table 2. Critical design elements of socio-techno learning environments.

| Dimension | Characteristics |
|---|---|
| Cultural beliefs | Cultural beliefs are not *designed* per se but cultivated over time, and influence such things as: how learning and knowledge are conceptualized, goals, how identities of students are shaped, how the identity of the teacher is understood, and how technology use is viewed. |
| Practices | Concerns the ways in which teachers and students engage in activities with tools, how students work on activities, how groupings of students are organized, what roles students play within groups, modes of interaction supported or constrained within and between groupings, and the role the teacher plays. |
| Socio-techno-spatial relations | Concerns the organization of physical space and technology workspaces as they relate to teacher and student interactions. Considerations include the physical organization of classrooms, how groups incorporate technology, the affordances and constraints of the technology, how pervasive technology use is in the intervention, how access is provided |
| Interactions with the "outside world" | Refers to the online and offline ways students are able to interact with people and be influenced by their engagement in events outside their immediate classroom environment. Aspects to consider include issues of authenticity: How is knowledge brought in from and extended to the outside world? |

Consideration of what variables can capture the characteristics of these dimensions informs the design of data collection from online modules, highlights what should be mined from available activity logs, and influences the look of a resulting workflow expression by identifying what information needs to be represented

## Workflows in Business and Science

*Workflow* is a concept closely related to the design, or reengineering, of business and information processes (Ludäscher et al., 2005). In a broad and multi-leveled sense a workflow expression is the diagrammatic result of "capturing" the workings of a system from beginning to end.

Within the literature two broad versions of a standard definition of workflow emerge: business and scientific. Georgakopoulos, Hornick, and Sheth, (1995) describe a *business-oriented* workflow as a collection of tasks organized to accomplish some business process, performed by one or more software systems, one or a team of humans, or a combination of these. A workflow defines the order of task invocation, task synchronization, and dataflow. S*cientific workflows* are valuable knowledge assets in their own right because they are graphical representations of scientific "know-how" that is often tacit. A key feature in the development of scientific workflows is the notion of reuse (De Roure, Goble, and Stevens, 2008). Reuse can occur at multiple levels. With different parameters and data, fragments and patterns of workflows can be reused to support science outside their initial application, or they can provide a means of codifying, sharing, and spreading the workflow designer's practice.

Both business and scientific workflow expressions attempt to define processes of a system in terms of the tasks performed, order, resources consumed and produced, and relationships between person and machine. Both account for control of events and flow of data. However, when analyzing the underlying principles of the approaches, Ludäscher et al. (2005) found a focus on *control flow patterns* and *events* – what was done, and in what order – in business-oriented systems, while scientific workflow systems tended to have execution models that were more *dataflow-oriented* – interest in how data gets passed through, transformed, and used by the system (p. 1046).

The concepts of reuse, control flow, and data flow are all important to account for in an educational workflow model; they facilitate sharing and analysis of adaptable interventions. However, the unpredictability of educational interventions noted by Brown (1992) suggests that educational workflows cannot be preprogrammed in the way that many business or scientific-oriented workflows are (e.g., loan applications or mineral identification systems). The important functions of educational workflows, then, include capturing and representing: 1) the intended, adaptable aspects of interventions that can be shared and reused across diverse educational and research settings; and 2) the actual and detailed data flow within interventions, which supports scientific analysis. This suggests two kinds of educational workflows; the former, which we will call *macro-flows*, may be roughly equated with educational *macro-scripts*– general pedagogical models, often representing intentions, that aim to create learning situations in which productive interactions and outcomes will hopefully occur (Dillenbourg and Hong, 2008). The latter are *micro-flows*, which are like "micro-scripts," although they may emerge during practice and are determined post-hoc. Micro-flows represent more detailed models of actual individual and group activity. In online environments, data for both types of workflow representations can be mined post hoc from activity logs and other data found in the course management system (CMS). We hypothesized that both would be useful in design-based research.

## Comprehensive Workflow Mining

Much of the literature on workflow modeling focuses on the use of Petri-Nets to automate and analyze business processes (e.g. van der Aalst, and van Hee, 2004), a highly structured, mathematics-based methodology that describes processes in terms of weighted nodal relationships among places and transitions. This workflow method's focus on control flow makes it too narrow to describe the relevant dimensions of a learning environment. However, the Collaboration Technology Research Group (CTRG) at the University of Colorado-Boulder has developed a comprehensive workflow modeling language called Information Control Nets (ICN) that is graphical and intuitive and broadens the scope of workflow mining to include a wider range of perspectives (Rembert, 2006). Briefly, the primary perspectives focused on by this modeling methodology include: the **functional** – *what* tasks or activity takes place; the **control flow** – *when* tasks are done; the **informational** – *which* data are processed and the *data flow* of the process; the **resource** or **organizational** – *who* or *what* performs a task; and the **operational** or **application** perspective – *how* a task gets done.

The ICN workflow modeling language has a mathematical and graphical representation; for the purpose of the present paper we focus only on the graphical elements of representation. These elements are shown and described in Table 3:

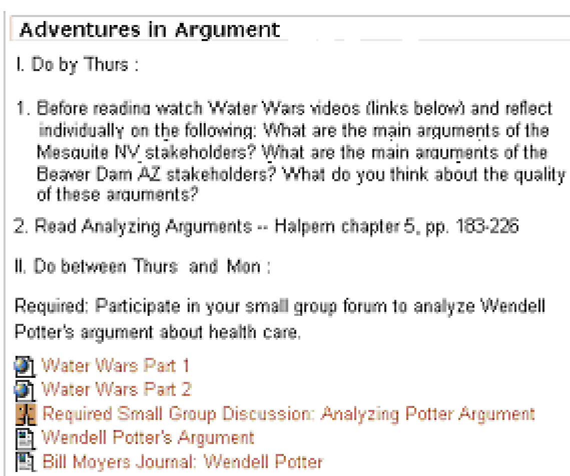
Table 3. Graphical elements of the ICN workflow modeling language.

| | | | |
|---|---|---|---|
| | *Tasks* (represented by labeled circles) are a unit of work carried out by one or more people. | | *Data repositories* (represented by labeled squares) have production/consumption relationships with tasks - they provide data that is consumed by a task or collect and hold data produced by a task. |
| | *Roles* (rounded rectangles) can represent individuals or groups, specified in terms of features such as responsibilities, authority, and availability. | | *Participants* are represented as labeled stick figures. An organizational population specifies which participants belong to which role/group, as well as relationships amongst participants. |
| | If a task requires a certain *application type* (hexagon), to be completed, then that task might be accomplished by any *application instance* (monitor). | | There are four *control tasks*; two branch tasks – parallel (closed circle) and conditional (open), and two join tasks – synchronization (closed circle) and merge (open). |

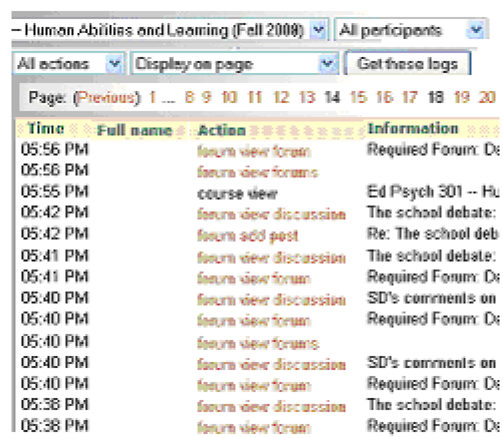
## Example of Analysis using CDM-based Workflow Expressions

### Mining Data and Constructing Workflow Expressions from Adventures in Argument

The Moodle session module shown in Figure 1(a) provides information to students about what activities to do, in what order, and provides links to online resources and tools that are needed for activities. (The link to the discussion provides further instructions to students, and hence workflow information, that is not shown here).



(a)



(b)

Figure 1. HAL Online module seen by students (left) and partial activity log (right).

Such information is used to construct the *macro-workflow* expression shown in Figure 2. Each activity is represented in a circle and the flow from one activity to the next is shown with arrows. Closed dots before the 'View Video' activities indicate that both activities must be done, but order doesn't matter. Open dots after indicate that activity can proceed even if a student only views, for example, one of the two videos. Percentages by each circle indicate the level of compliance for two groups that were examined in this example. These data were "discovered" by mining the activity logs (see Figure 1(b)). Information about tools, roles and data repositories are represented using ICN graphical elements (Table 3). We added new icons for special data repositories unique to educational work: a book for textbook-type information, and a silhouette for representing students' activated prior knowledge.

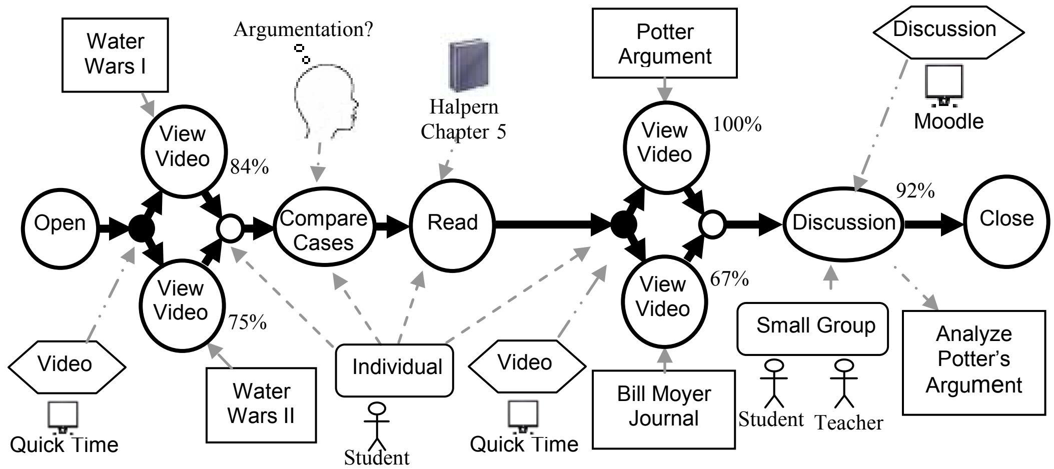


Figure 2. Macro-workflow expression for "Adventures in Argument".

Figure 3 illustrates how logs specific to Moodle tools (i.e., the discussion tool) and resources (i.e., videos) were used to construct *micro-workflows* for the discussion activity (part of the macro-flow) for students in two contrasting groups in our course. Micro-flows were organized in two musical-type "scores" above and below a master timeline that allowed us to see the flow of data for individual students in each group as they engaged in the discussion activity. In the diagrams, small open squares indicate when students viewed videos. The numbers inside the circles indicate thread number (left) and post-in-thread (right). Closed squares on the circles indicate that the post connects to a video or the assigned reading (which one can be seen specifically in the discussion log).

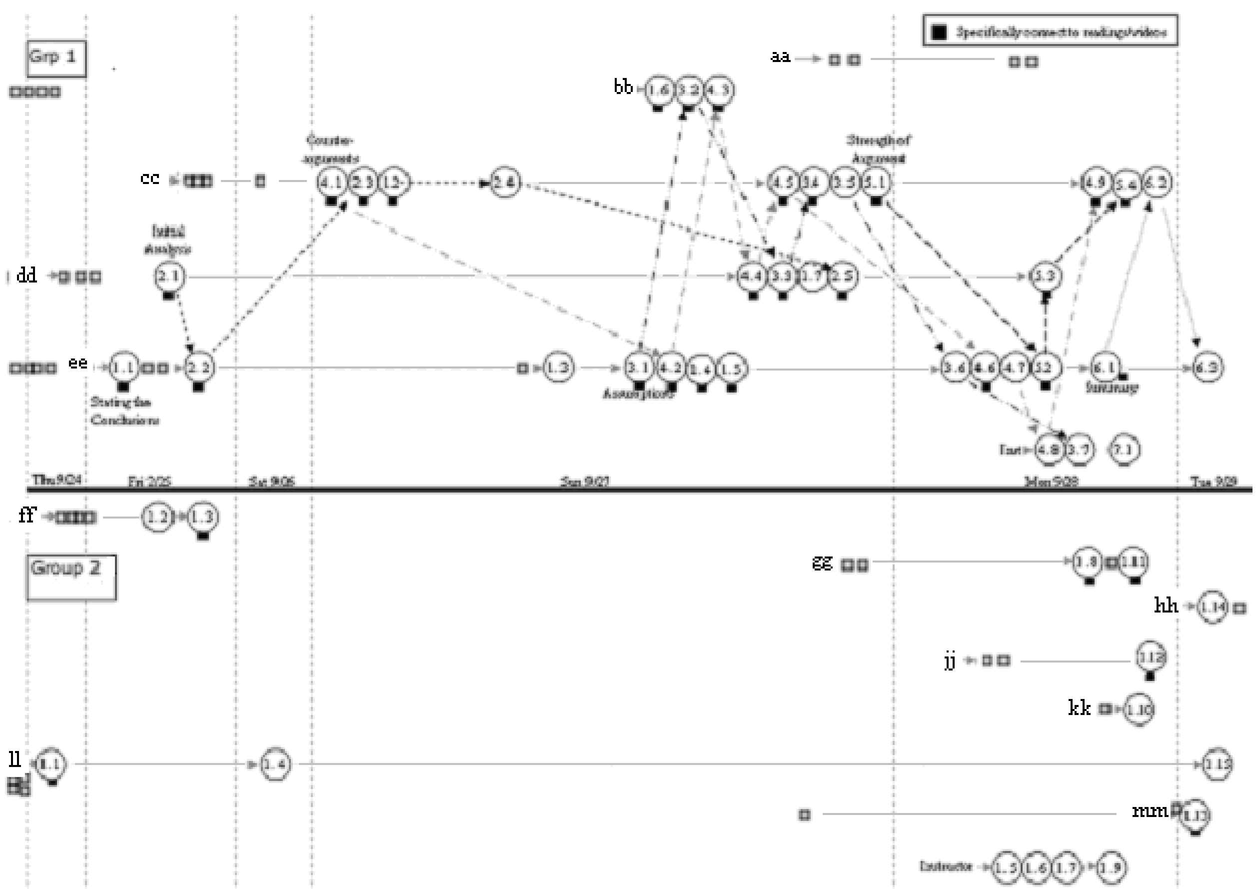

Figure 3. "Adventures in Arguments" micro-workflow expression for forum discussion of two groups.

## Analysis

When analyzed by the instructional development team, both the macro- and micro-flow representations helped the research team generate many ideas regarding how well the Adventures in Argument module worked and in suggesting design changes for the next iteration. Even a cursory glance at the micro-workflows for the two groups (Figure 3) revealed stark differences in two groups. Group 1 generated a greater number of threads, postings, made more references to course readings and videos, and referenced one another's postings. Three different members started threads over the course of the discussion. By comparison, Group 2's postings were contained in one thread, postings were disconnected, no student posted more than three times, and four members made only one post. A closer examination shows that most members of Group 1 accessed *all* of the supporting videos early and often and even re-viewed certain videos during the discussion forum. In contrast, only members of Group 2 viewed all four videos before beginning the forum discussion; the majority of members viewed *some* videos right before making their posting. (In light of this, the compliance statistics in the macro-workflow are a little misleading; Group 1 actually had 100% compliance viewing the videos where Group 2's overall compliance was less than average for the class.) As well as Group 1 appears to do in comparison to Group 2, there is room for improvement. One member (OB) viewed the videos very late in the work process and did not participate in the discussion. In her reflection on the experience with the unit she reported that she had trouble viewing the videos and felt she was too late to make a contribution to the discussion by the time she fixed the problem.

The interpretive power of workflows is illustrated in reflections by the professor-researcher in charge of the course, who made the following observation:

> "I noticed some things that are possibly important. One thing was the similarity of Group 1 to a strong group in a study of five online groups that Mary and I did awhile back. The strongest group in that study had a strong leader who organized the discussion space, breaking the discussion down into sub-topics, starting some topics in a certain direction, sometimes giving particular assignments. In Group 1, CC takes a leadership role and does something similar that turns out to be important: He wrote *'I would propose that we start a separate thread for each of the main areas of analyzing the argument, such as conclusion(s), premises and omitted premises, counterarguments, assumptions, etc. I have started one on Conclusions. This organization will help us get a lot of material in an organized way which will hopefully make it easier to summarize in a couple of days.'* Also, Group 1 was far from perfect; there were non-participants. Students who were left out expressed frustration in their blogs with their inability to interact with the technology. These "weaker" students seem intellectually capable, but the technology may be putting them on overload."

Additional analysis of the macro-workflow expression (Figure 2) revealed that there were two activities – comparing cases and reading the text chapter – for which we could not verify compliance. Both activities relied to some extent on data repositories that were located outside the Moodle logging system. Students' compliance with reading of the text could be inferred from a closer examination of the students' postings, but the comparing cases activity, which had a theoretical rationale, could not be evaluated due to insufficient data. One role of the workflow expressions in DBR is to focus attention on design flaws that exist because an activity fails to generate log data that can be mined.

## Conclusions

Our team was able to use the macro- and micro-flow expressions to guide us in making design changes to be implemented in the next iteration of our course. Examples under consideration include: 1) Create more explicit scaffolding on collaboration to be incorporated into the instructions for the discussion task – i.e., choose a leader, break discussion down into sub-topics, start discussion threads for each sub-topic, distribute tasks; 2) Emphasize in the discussion-task instructions that a post needs to include explicit references/connections to videos, readings, and/or other postings; 3) Mandate that students access resources early in the session (perhaps tying a grade to *when* they access or comment on resources). At the process level we decided to include logable tasks for all activities, e.g., write a brief summary of the case comparison in the warmup activity, or complete a short questionnaire about a reading.

## Discussion

The example above illustrates how workflow expressions derived from data mined from the online session modules and activity logs of an online course can help facilitate the analysis of a complex environment by presenting visual representations that incorporate design variables of interest.

Both workflow expressions served a valuable purpose. The micro-workflow expression allowed us to see when and how individual students engaged in activities – their *control flow* – and how group members interacted with one another during collaborative activities, how they used course resources, and how they took up and used data created by one another – their *data flow*. The micro-workflow expressions facilitated hypothesis generation about success in group argumentative activities – that students need to organize their discussion space by breaking down arguments into sub-topics, starting some topics in a certain direction, and distributing tasks. This hypothesis amounts to a proto-theory about successful online argument as pedagogy, supporting a dual focus on theory-building and instructional design. Finally, micro-workflow expressions help identify problems that may be related to course tools or processes, e.g., inability to access videos. These kinds of insights also lead to instructional design changes.

Macro-workflow expressions provide a means for researchers to see all design elements of an intervention and their relationships to one another. This is important because it allows researchers some sense of control as they contemplate design changes. As Ann Brown (1992) pointed out, it is impossible to change one aspect of the system without creating perturbations in others. Macro-workflow expressions allow the researcher to focus design changes on specific areas of macro-flow while striving to monitor activities and achieve some level of control within others. An important goal of design-based research is to continually adapt an instructional design given new insights about the design, but an equally important question to ask is, "How much adaptation is taking place?" We believe the workflow expressions derived from course session modules and activity logs has been a valuable asset as we strive to answer this question.

# Coordinating Collaborative Problem-solving Processes by Providing Part-task Congruent Representations

**Abstract:** This study investigated whether structuring an online collaborative problem-solving task into part-tasks and providing part-task congruent representations supports students establishing and maintaining a shared understanding of the concepts, principles and procedures in the knowledge domain and negotiating about them. This better coordination of students' discussions was, in turn, expected to lead to better problem-solving performance. In triads secondary education students worked on a case-based business-economics problem in four conditions. In one condition, groups received three representations, each congruent to one of the three part-tasks. In the other three conditions, groups received one of the representations for all three part-tasks, thus a representation congruent to one part-task, but incongruent to the other two. The results show that coordination processes were indeed more suited. That is, students where better able to establish and maintain a shared understanding and to negotiate about it and, therefore, led to better problem-solving performance.

## Introduction

Solving a complex problem is regarded as a sequenced phased process (i.e., problem orientation, problem solution, solution evaluation) in which each phase has its own specific purpose and where each phase requires a specific kind of interaction (Ploetzner, Fehse, Kneser, & Spada, 1999; Van Bruggen, Boshuizen, & Kirschner, 2003). Coping with the task demands of the different problem phases (i.e., part-tasks), requires students to actively engage in a process of sense-making of the knowledge domain by articulating and discussing multiple problem perspectives and problem-solving strategies. That is, students are required to carry out part-task related activities such as discussing the concepts, principles, and procedures of the domain (Barron, 2003; Hmelo-Silver, Duncan, & Chinn, 2007). Meaningful discussions about the domain can, however, hardly be achieved when students are not aware of each others' knowledge, ideas and do not negotiate about them with their peers. Students are required to activate their knowledge and skills and to establish and maintain a shared understanding of the domain; a common frame of reference where conflicting points of view be detected and negotiated. In this way collaborative learning situations require three main processes of coordination: (1) mutual activation and sharing of knowledge and skills, (2) grounding or creating a common frame of reference, and (3) negotiation or the process of coming to agreement (Erkens, Jaspers, Prangsma, & Kanselaar, 2005; Kirschner, Beers, Boshuizen, & Gijselaers, 2008). Research on Computer Supported Collaborative Learning (CSCL) has shown that representational tools can beneficially affect student interaction by providing external representations (see Fisher, Bruhn, Gräsel, & Mandl, 2002). First, an ER offers a restricted view of the knowledge domain, guiding the content-related interaction in a specific manner (Suthers, 2006). Second, in their discussions students can refer to the ER (i.e., deictic referencing), thereby supporting them to create a common frame of reference and facilitating a meaningful discussion (Suthers, Hundhausen, & Girardeau, 2003). These studies, though very valuable and informative, often neglect the fact that problem-solving tasks are usually composed of fundamentally different part-tasks that each require a different perspective on the knowledge domain. Therefore, multiple representational tools each containing a different external representation seem to be required. To be supportive for problem-solving, the external representation provided in the representational tool has to be matched to the part-task demands and activities of a specific problem phase. Otherwise, communication problems can occur and problem-solving performance might decrease (Van Bruggen, et al.).

The goal of the study presented in this paper is to twofold. On the one hand it is aimed at determining whether proper coordination processes can be evoked through providing part-task congruent guidance in the representational tools. On the other hand it is aimed at determining whether such an approach can lead to better problem-solving performance.

## Coordination Processes

For meaningful discussion to arise, students must properly coordinate their discussions of the concepts, principles and procedures by carrying out communicative activities such as making their own knowledge and ideas explicit to other group members, focusing, checking and argumentation (Andriessen, Baker, & Suthers, 2003; Erkens, et al., 2005; Weinberger Ertl, Fischer, & Mandl, 2005). When made explicit, students must try to maintain a shared topic of discourse and to repair a common focus if they notice a focus divergence. Students coordinate their topic of discourse by *focusing*. Also, not all concepts, principles, and procedures are relevant for carrying out a part-task, thus, students have to guard the coherence and consistency of their shared understanding of the knowledge domain. By *checking*, students ground their communication in a common understanding, which was found to be one of the major communicative activities in dialogues of collaborative problem-solving and related to the quality of the problem solving process (Van der Linden, Erkens, Schmidt, & Renshaw, 2000). Furthermore, students must come to agreement with respect to relevant concepts principles and procedures. By *argumentation* they will try to change their partners viewpoint to arrive at the best way to carry out a part-task or at a definition of concepts acceptable for all. In this argumentation process they try to convince the other(s) by elaborating on their point of view, giving explanations, justifications and accounts (Erkens, et al.; Kirschner, et al., 2008). Only when students carry out such communicative activities their interaction can be sufficiently coordinated and multiple perspectives on the problem and the problem-solving strategy can arise.

## Providing Part-task Congruent Representations

Due to its different part-tasks, problem-solving tasks require multiple representational tools providing different external representations. The specific ontology (i.e., objects, relations, rules for combining them) of each ER offers a restricted view of the knowledge domain (i.e., problem representations), guiding student interaction in a specific manner. To effectively do this, one must carefully match the external representation provided in a representational tool to the part-task demands and activities of a specific problem phase (Van Bruggen, et al., 2003). To ensure this alignment between tool, tool use and part-tasks scripting is employed (Dillenbourg, 2002; Weinberger, et al., 2005). According to Dillenbourg a script is “a set of instructions regarding to how the group members should interact, how they should collaborate and how they should solve the problem” (p. 64). Integrating scripting with the availability of representational tools sequences and makes the different part-task demands explicit so that they can be foreseen with part-task congruent guidance in the representational tools (see Table 1). By doing so, communicative activities beneficial for coordinating the collaborative problem-solving can be evoked.

Table 1: Congruence between external representation and part-task demands

| Problem phase | Part-task demands | ER | Representational guidance |
|---|---|---|---|
| Problem orientation | Determining core concepts and relating them to the problem | Conceptual (static) | Showing concepts and their interrelationship |
| Problem solution | Proposing multiple solutions to the problem | Causal (static) | Showing causal relation between the concepts and possible solutions |
| Solution evaluation | Determining suitability of the solutions and coming to a final solution to the problem | Simulation (dynamic) | Showing mathematical relation betweenthe concepts and enabling manipulation of their value |

## Design and Expectations

This study focuses on whether providing part-task congruent support in the representational tools affects both students’ communicative activities and problem-solving performance in a CSCL-environment. In four experimental conditions, student triads had to collaboratively solve a case-based problem in business-economics that was divided into three problem phases each coupled with a different ER. To study the effect of condition, ERs were either matched or mismatched to the different problem phases; in other words they were either congruent or incongruent to the required task activities. In three mismatch conditions, groups received either a static ER (i.e., conceptual or causal ER) or a dynamic ER (i.e., simulation) that matched only one of the part-tasks. The scripting structured the problem-solving process in three phases, but only one of the ERs is available to the students for solving the problem yielding a phase-match when the ER matched one of the three phases and a mismatch for the other two phases. In the fourth condition, groups received all three ERs in a phased order receiving the ER most suited to each problem phase. Here, thus, there was a match between all three ERs and all three part-tasks. Due to the presumed match between ERs and part-tasks, student understanding and communicative activities were expected to increase, allowing the students to reach better problem solutions. It was, therefore, hypothesized that students in the match condition *(H1)* carry out more communicative activities beneficial for coordinating their collaborative problem-solving and *(H2)* have better problem-solving performance. In this paper, the focus will be on guiding student interaction when collaboratively solving a complex business economics problem. One should, therefore, take into account that the congruency of the content-related guidance was tailored to the part-task demands of this problem. The premise behind the design of the representational scripting and its use, however, can be generalized to all situations where a problem-solving task has a part-task structure.

# Method

## Participants

Participants were students from a business-economics class in a secondary education school in the Netherlands. The total sample consisted of 39 students (24 male, 15 female). The mean age of the students was 16.74 years (*SD* = .83, Min = 15, Max = 18). The students were randomly assigned to 13 triads divided between the four conditions; four triads in the conceptual and three triads in each of the other conditions (i.e., causal, simulation and match).

## Problem-solving task and materials

### CSCL-environment: Virtual Collaborative Research Institute

Students worked in a CSCL-environment called Virtual Collaborative Research Institute (VCRI, see Figure 1), a groupware application for supporting the collaborative performance of problem-solving tasks and research projects (Broeken, Jaspers, & Erkens, 2006). For this study, five VCRI tools were augmented with representational scripting. All tools, except the Notes tool, were shared among group members.

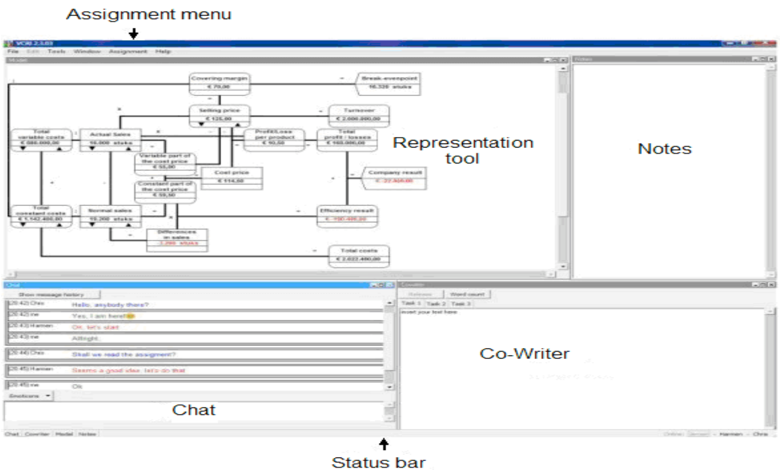

Figure 1. Screenshot of the VCRI-program.

The *chat tool* enables synchronous communication and supports students in externalizing and discussing their knowledge and ideas. The chat history is automatically stored and can be re-read by the students. In the *Assignment menu*, students can find the description of the problem-solving task / part-tasks. Besides this, additional information sources such as a definition list, formula list, and clues for solving the problem were also available here. The *Co-writer* is a shared text-processor where students can collaboratively formulate and revise their answers to the part-tasks. The *Notes tool* is an individual notepad that allows students to store information and structure their own knowledge and ideas before making them explicit. The *Status bar* is an awareness tool that displays which group members are logged into the system and which tool a group member is currently using. Students in all conditions had access to these tools and information sources. In other words, the different conditions were information equivalent and only differed in the way that the ERs are intended to guide the interaction.

### Problem-solving task and part-task congruent representations

All groups worked on a case-based problem in business-economics in which they had to advise an entrepreneur about changing the business strategy to increase profits (i.e., company result). To come up with an advice, students had to carry out three different part-tasks, namely (1) determine the main factors affecting the company's result and relate them to the problem, (2) determine how certain interventions affect company result, and (3) compare the effects of these interventions and formulate a final advice based on this comparison. Through scripting, the problem-solving process was structured into a problem orientation phase, problem solution phase, solution evaluation phase each focusing on one of the part-tasks. All groups were 'forced' to carry out the part-tasks in a predefined order; they could only start with a new part-task after finishing an earlier part-task. When group members agreed that a part-task was completed, they had to 'close' that phase in the assignment menu. This 'opened' a new phase, which had two consequences for all groups, namely they (1) received a new part-task, and (2) had to enter their new answers in a different window of the Co-writer. All conditions received the part-tasks in the same order, but only groups in the match condition received a new ER.

The *problem orientation phase* focused on creating a global qualitative problem-representation by asking students to explain what they thought the problem was and to describe what the most important factors were that influenced the problem. During this phase, students received the conceptual ER (i.e., a static content scheme; see Figure 2) that made two aspects salient, namely the core concepts needed to carry out this part-task and, how the core concepts are qualitatively interrelated. Students could see that 'company result' is affected by the 'total profit' and the 'efficiency result'. Such information should make it easier for them to create an overview of all relevant concepts, supporting them in finding multiple solutions to the problem in the following phase.

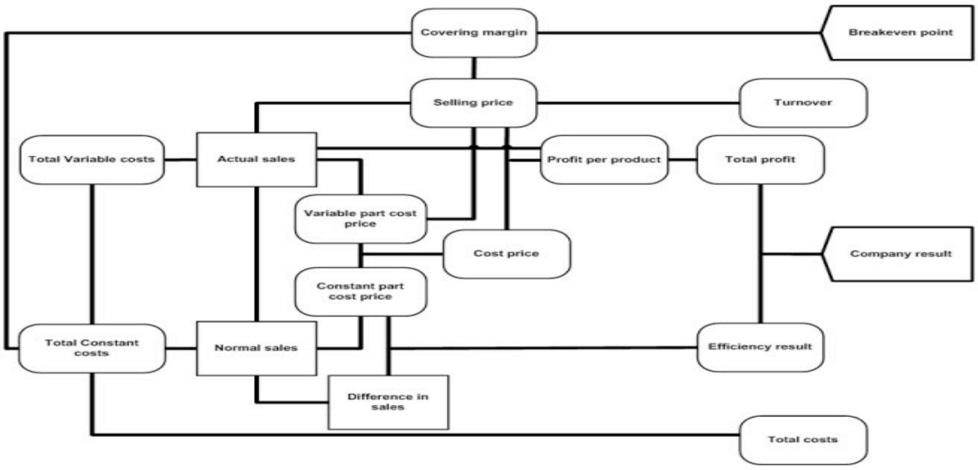

Figure 2. Conceptual ER.

The *problem solution* phase focused on creating a causal problem representation (i.e., making underlying business-economics principles explicit) by asking students to formulate several solutions to the problem. During this part-task, students received the causal ER (i.e., a static content scheme; see Figure 3), in which the causal relationships - visible through the arrows showing direction of the relationship between the concepts - were specified. The causal ER also contributed to increasing students' qualitative understanding by providing the students with possible interventions (i.e., changes in the business strategy), that each had a different effect on the company results. This should make it easier to effectively explore the solution space and should, in turn, support students in finding multiple solutions to the problem. Students could, for example, see that a PR-campaign affects 'actual sales that in turn affects 'total profit'.

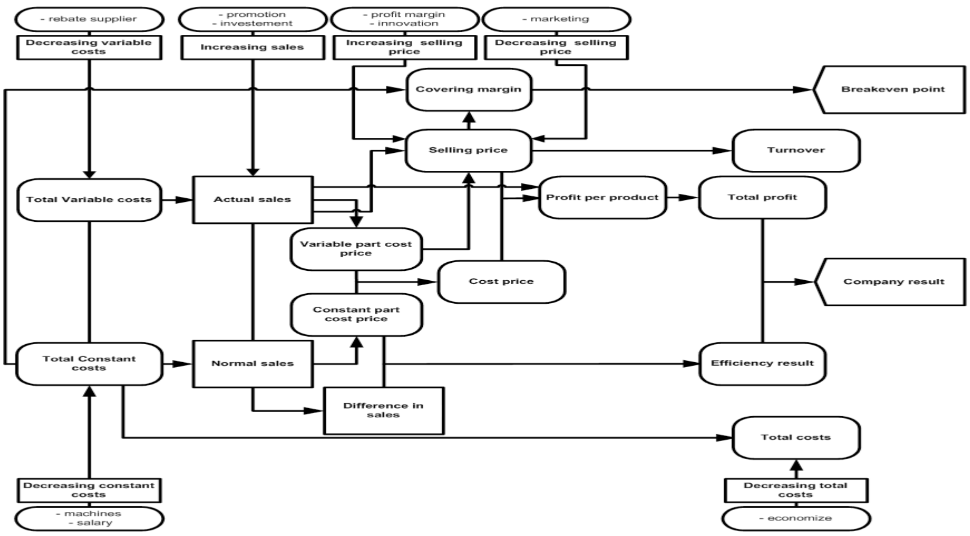

Figure 3. Causal ER.

Finally, the *solution evaluation phase* focused on increasing the students' understanding of the knowledge domain with the aid of a quantitative problem representation. Students were asked to determine the financial consequences of their proposed solutions and to formulate a final advice for the entrepreneur by negotiating the suitability of the different solutions with each other. During this phase, students received a simulation ER (i.e., a dynamic content scheme; see Figure 4) that enabled them to manipulate the values of the concepts by clicking on the arrows in the boxes. When the value of a certain concept was changed (i.e., increased or decreased), the simulation model automatically computed the values of all other concepts. This is meant to facilitate the determination and negotiation of the suitability of the different proposed solutions and reaching a final advice. Students could, for example, test how the PR-campaign affects the 'actual sales' and whether this in turn affects the 'total profit'. Only the simulation ER is capable of providing this kind of support, because the relationships between the concepts in this ER were specified as equations.

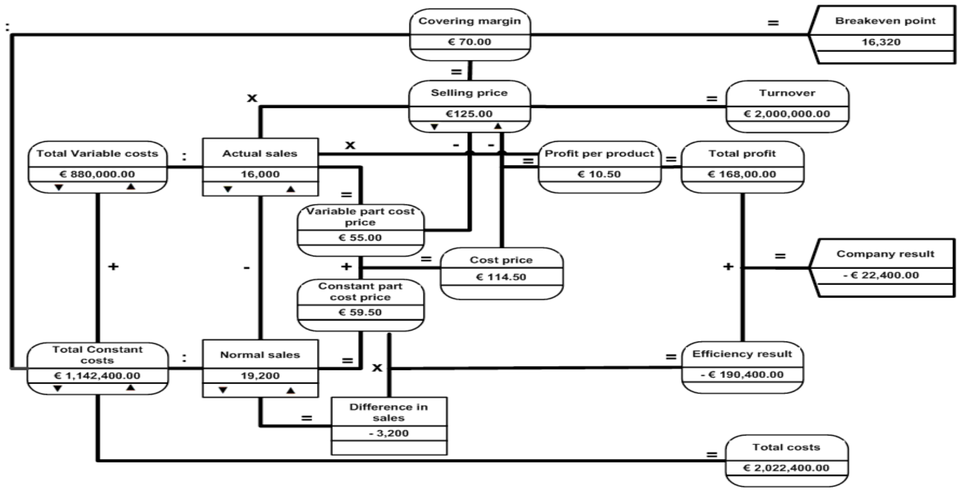

Figure 4. Simulation ER

## Procedure

All groups spent three, 70-minute, lessons solving the problem during which each student worked on a separate computer in a computer classroom. Before the first lesson, students received an instruction about the CSCL-environment, the group composition, and the problem-solving task. Students worked on the problem in the computer classroom, where all actions and answers to the part-tasks were logged.

## Measures

### Problem-solving performance

To measure the effect of condition on problem-solving performance an assessment form for all criteria of the problem-solving task was developed (see Table 2). All 41 items were coded as; 0, 1 or 2, whereby a '2' was coded when the answer given was of high quality (e.g., more suitable). Groups could, thus, achieve a maximum score of 82 points (41 * 2 points).

Table 2: Problem solving performance; items and reliability

| Criteria | Description | Items | α |
|---|---|---|---|
| Suitability | Whether the groups' answers were suited to the different part-tasks | 9 | .81 |
| Elaboration | Number of different business-economics concepts or financial consequences incorporated in the answers to the different part-tasks | 9 | .56 |
| Justification | Whether the groups justified their answers to the different part-tasks | 9 | .71 |
| Correctness | Whether the groups used the business-economics concepts and their interrelationships correctly in their answers to the different part-tasks | 9 | .68 |
| Continuity | Whether the groups made proper use of the answers from a prior problem phase | 2 | .67 |
| Quality advice | Whether the groups gave a proper final advice<br>- Number of business-economics concepts incorporated in the advice<br>- Number of financial consequences incorporated in the advice<br>- Whether the final answer conformed to the guidelines provided | 3 | .76 |
| Total score | Overall score on the problem-solving performance | 41 | .92 |

## Coordination processes

To examine the effect of condition data concerning students' coordination processes was collected by logging the chat-utterances of the group members. The content of these chat-protocols is assumed to represent what students know and consider important for carrying out their problem-solving task (Chi, 1997). A dialogue act is regarded as a communicative action that is elicited for a specific purpose representing a specific function in the dialogue (Erkens, et al., 2005), namely:

- argumentatives; indicating a line of reasoning,
- responsives; indicating responses to questions or proposals,
- informatives; indicating a transfer of information, often statements or evaluations,
- elicitatives; indicating questions or proposals requiring an answer,
- imperatives; indicating commands to take action or to draw attention.

Dialog-act coding was based on the occurrence of characteristic words or phrases (i.e., discourse markers) that indicated the communicative function of an utterance. The chat-protocols were searched for the occurrence of these discourse markers that led to the identification and coding of the dependent variables (see Table 2). This was automatically done with a MEPA-filter using 'if-then' decision rules that uses pattern matching to find typical words or phrases. Reliability of the dialogue act coding is 79% (Erkens & Janssen, 2008). After coding, score-frequencies for each dialogue act were computed and combined resulting in the measurement of the dependent variables.

Table 3: Coding of Students' Communicative Activities

| Activities | Dialogue Act | Description | Example discourse marker |
|---|---|---|---|
| Focusing | Elicitative proposal for action | Proposition for action | Shall we get started with the first part-task? |
| | Elicitative question open | Open question with a lot of alternatives | What do you think we should do next? |
| | Imperative action | Command to perform an action | Write the conclusion |
| | Imperative focus | Command for attention | Look at the representational tool |
| | Elicitative question verify | Question that can only be answered with yes or no | Do you refer to the company result? |
| Checking | Elicitative question set | Question where the alternatives are already given (set) | Are you for / against increasing sales? |
| | Responsive confirm | Confirming answer | Yes, sure |
| | Responsive deny | Denying answer | No, not |
| | Responsive accept | Accepting answer | Oh, Yes |
| Argumentation | Argumentative reason | Reason | Because…. |
| | Argumentative against | Objection | But … |
| | Argumentative conditional | Condition | If … (then …) |
| | Argumentative then | Consequence | Then … |
| | Argumentative disjunctive | Disjunctive | …or… or |
| | Argumentative conclusion | Conclusion | Thus… |

## *Data analyses*

In CSCL, group members influence each other (i.e., behave more or less similarly) causing non-independence of measurement (Kenny, Kashy, & Cook, 2006). This is problematic because many statistical techniques assume score independence and a violation compromises interpretation of the analyses (see Kenny, et al.). Non-independence was determined by computing the intraclass correlation coefficient and its significance (Kenny, et al.), for all dependent variables for student interaction. This resulted in non-independence ($\alpha < .05$) for all tests, justifying *Multilevel analysis* (MLA). MLA compares the deviance of an empty model and a model with one or more predictor variables to compute a possible decrease in deviance. The latter model is considered a better model when there is a significant decrease in deviance compared to the empty model (tested with a $\chi^2$-test). All reported $\chi^2$-values were significant ($\alpha < .05$) and, therefore, the estimated parameter of the predictor variables (i.e., effects of condition) were tested for significance. Due to the detection of outliers, the utterances of some students were deleted from the MLAs.

# Results

## Coordination processes

MLAs revealed that experimental condition significantly predicted the management of the interaction in the content space. The mean scores, standard deviations and the main effects (i.e., difference between match condition and non-matched conditions) for the communicative activities are listed in Table 4. A main effect for *coordination* was found, namely that students in the match condition, in total, exhibited more communicative activities compared to students in three non-matched conditions ($\beta = 37.36$, $p = .01$). For the specific communicative activities, the following results were obtained. First, a main effect was found for *focusing*; students in the match condition verified whether they were discussing the same topic and repaired the common focus more often than students in the non-matched conditions ($\beta = 8.48$, $p = .01$). When comparing the match condition to the other conditions separately, the effects were significant between all conditions. Second, a main effect for *checking* was found; students in the match condition devoted more attention to guarding the coherence and consistency of their shared understanding of the content space than students in the non-matched conditions ($\beta = 16.37$, $p = .02$). When comparing the match condition to the other conditions separately, this was the case for both the conceptual ($\beta = 16.02$, $p = .00$) and the simulation ($\beta = 23.20$, $p = .00$) conditions. Finally, a main effect was found for *argumentation*; students in the match condition exhibited more argumentative activities than students in the non-matched conditions ($\beta = 12.19$, $p = .00$). When comparing the match condition to the other conditions separately, this was the case for the causal (14.19, $p = .03$) and simulation ($\beta = 15.84$, $p = .04$) conditions.

As expected, students in the match condition were better able to establish and maintain shared understanding of the content space and negotiate about it better than students in the non-matched conditions. This enabled students in the match condition to acquire multiple perspectives on the problem and the problem-solving strategy, that are both seen as beneficial to problem-solving. Although more differences were expected, only one significant difference between the match and the causal condition was found.

Table 4: Multilevel Analyses concerning Students' Communicative Activities

| | Conceptual condition ($n = 10$) | Causal condition ($n = 10$) | Simulation condition ($n = 10$) | Match condition ($n = 6$) | Effects match condition ($N = 36$) | | |
|---|---|---|---|---|---|---|---|
| | *M (SD)* | *M (SD)* | *M (SD)* | *M (SD)* | $\chi^2(3)$ | $\beta$ | *SE* |
| Coordination | 76.50 (37.58) | 60.62 (44.41) | 46.40 (17.33) | 149.40 (39.33) | 33.42 | 37.36* | 11.57 |

## Problem-solving performance

One-way MANOVA on the total score of the problem-solving performance showed that groups in the match condition indeed scored significantly higher than groups in both the conceptual ($p = .02$; $d = 2.28$) and the simulation condition ($p = .05$; $d = 1.90$). Groups receiving a congruent ER for each part-task gave answers that (1) were more suited for a specific part-task, (2) contained more business-economics concepts and financial consequences, and (3) were more often correct. Although expected, no significant differences were found between the match and the causal condition.

# Discussion

Although based on 13 triads, the results of our study confirmed that providing part-task congruent guidance in the representational tools beneficially affects coordination processes and problem-solving performance. Groups receiving such support during their online collaborative problem-solving task were better able to coordinate their discussions about the concepts, principles and procedures of the knowledge domain than groups not receiving it. That is they more often (1) verified whether they are actually talking about the same discourse topic and, where necessary, repaired the common focus (i.e., focusing), (2) guarded the coherence and consistency of their shared understanding of the content space (i.e., checking), and (3) argued about their different points of view (i.e., argumentation). Those students were, therefore, better able to discus multiple perspectives on the problem and the problem-solving strategy (Hmelo-Silver, et al., 2007) and resulted in better answers to the part-tasks and better final solutions to the problem. Although the results seem very promising problem-solving performance of students in the causal condition was very similar to what was found in the match condition. Students in both conditions received the causal ER, that showed all relevant concepts, solutions and their causal interrelationships, providing the students multiple qualitative perspectives on the knowledge domain. It seems, therefore, important to support causal reasoning during collaborative problem-solving. Combining the causal ER with both other ERs might also hinder problem-solving when students experience difficulties integrating the different ERs. When students do not know how to combine multiple ERs, they might choose to stick with the familiar one and make no attempt to integrate the different ERs (Ainsworth, 2006). Additional research into the effects of representational scripting should be carried out to gain more insight into how students use and combine the concepts, solutions and relations within and between different ERs.

# Writing and commenting on professional procedures: In search of learning designs promoting articulation between school and workplace learning.

M. Gavota, M. Betrancourt, D. Schneider, University of Geneva, 1211 Genève 4, Switzerland
Email: Monica.Gavota@unige.ch, Mireille.Betrancourt@unige.ch, Daniel.Schneider@unige.ch

**Abstract:** The present study investigated the effect of scaffolding in a learning design in which apprentices were asked to reuse workplace experience to comment on peers' written productions. Apprentices were asked to perform an authentic workplace task, to explain how they got to the solution and then to comment on a peer's solution. Two conditions of scaffolding were compared: In the high scaffold condition, guiding questions were provided both for explanation and commenting, while in the low scaffold condition, a general instruction was given. The findings showed that, for the first tasks, the high scaffold group outperformed the low scaffold one with regard to the quality of the quotes and self explanations, but that the pattern reversed by the end of the activity. These results show that scaffolding is a useful tool for supporting reflection and learning, but that it should be adapted to the different steps of the activities.

## Theoretical background

According to Tynjala (2008), "the development of vocational and professional expertise requires the integration of different types of knowledge and interaction between theory and practice, and the development of the workplace as a learning environment both for employees and students is important to ensure the continuous development of competence. This requires close collaboration and partnership between education and work" (p.131).

In the case of vocational training, professional procedure acquisition represents a key issue in apprentices' professional development. Learning theories (e.g., Taatgen, Huss & Anderson 2008, Anderson, 1982) generally support the idea that direct teaching alone is not sufficient for the acquisition of procedural knowledge. Although largely untested, these theories suggest that teaching can only provide declarative knowledge, and that procedural knowledge should be acquired by the compilation of declarative knowledge through practice and feedback.

Nevertheless, learning theories focusing on procedure acquisition emphasize the role of direct instruction. Procedural knowledge development typically involves three steps (Weill-Fassina & Pastré, 2004). First, novices learn to apply a definite set of rules according to typical situations. In the second stage, workers learn to distinguish between classes of situations, particularly critical situations, and to behave accordingly. They form pragmatic "concepts", in the sense that they are oriented toward an improvement of the action performed, and not towards a better comprehension of the situation. Ochanine (1981) found that experts formed "operative images", which are simplified and biased representations of the objective situation, but are more relevant for the practice. For example, experts air traffic controllers typically under-estimate the distance between planes, which result in taking a larger security margin than strictly necessary (Bisseret, 1995). In the third stage, with the development of expertise, several operative concepts are formed and articulated, resulting in a more abstract representation of the task, which enables workers to handle efficiently a larger number of situations.

The main recent cognitive research in procedure acquisition still follows the central model ACT-R proposed and revised by Anderson (1993). In his revised model, ACT-R, Anderson (1993) focuses on the declarative memory of the examples demonstrating how the procedures should be performed. The first use of examples represents an analogy. Then, the production rules are compiled on the basis of this analogy. Moreover, it is assumed that the individual works on a declarative representation of the example. In other words, procedure acquisition would require a declarative representation of an example (but not necessarily in its long-term memory) because the procedure acquisition is done by learning from declarative traces of previous problem solving. This model emphasizes the importance of having a well developed declarative representation of the procedure in order to support the "compilation phase" meaning the passage from this declarative representation to the actual shortcut mastery of the procedure. In addition, according to Pirolli and Bielaczyc (1989), understanding the procedure's steps as well as the context to which the procedure is linked are essential elements for the procedure acquisition. It appears that the transferability of procedural knowledge is determined by a process of rules understanding (Kieras and Bovair, 1986). The initial acquisition of a procedure represents a process of understanding and not just a mimetic reproduction of the procedure's steps. The procedure acquisition is fostered by representing the procedure in its context, and understanding the different procedural steps in their own context (Broudy, 1977;

Bonner and Walker, 1994). Considering all those aspects of procedure acquisition, this study aims at finding means to support the construction of a strong declarative representation of a procedure as well as supporting the comprehension of its steps and the context in which it takes place.
Deeper processing of prior knowledge and examples represents a facilitating factor for supporting procedure comprehension and transfer (Chi, Bassok, Lewis, Reimann and Glaser, 1989). One effective way of avoiding superficial knowledge processing (King, 1992) and supporting deeper cognitive and metacognitive treatments - that students are likely to naturally avoid in the process of learning – is using external guiding under the form of prompts. These prompts are questions or hints supporting for efficient learning processes.
Metacognitive theories (e.g., Ge and Land, 2004) support the assumption hat becoming aware of oneself as a learner allows the student to reflect, monitor, and revise the process and products of his or her own learning. It was found that helping students develop abilities to monitor and revise their own strategies and to use resources may enable them to improve general learning expertise that can be used in a wide variety of settings (Kauffman, 2004). On the basis of this theoretical frame we designed and implemented learning tasks involving prompted self-explanations about the procedure, its steps and rationales.
Moreover, it has been shown (Hausmann and Chi, 2002; Chi, Bassok, Lewis, Reimann and Glaser, 1989) that both good students and prompted students tend to give more self explanations that refine and expand the conditions of an action, explain the consequences of an action, provide a goal for a set of actions, relate the consequences of one action to another and explain the meaning of actions.
Writing self-explanations about a procedure can thus be a suitable manner of supporting procedure comprehension as well as improving the organization of the declarative phase of procedure acquisition. In addition, the production of written text per se may be seen as a learning activity because it involves the production of a message based on domain knowledge and therefore domain knowledge should be "recovered", reorganized and incorporated into a linear form, a message understandable to someone else. Collaborative and peer writing/commenting activities represent an appropriate mean for reinforcing reflection and knowledge organization by the means of confrontation and hindsight taking in the reflection (Dillenbourg & Self 1994). Nevertheless, up to now, little research has investigated the effects of peer tutoring for "writing to learn" activities (Gielen, Dochy, Tops, Peeters, 2007). One critical issue is the level of scaffolding of such peer-commenting activity. As for self-explanation, it was assumed that peer commenting would benefit from guiding questions that orient towards argumentative and reflective writing, rather than on shallow and detail statements.

## The experiment

This paper reports a quasi-experimental study in which apprentices were asked to perform a task similar to a workplace situation (i.e. filling in a quote) and then describe how they got to the solution. Depending on the condition, self-explanation was either triggered by a general question (low scaffolding) or by guiding prompts (high scaffolding). They then were asked to comment on a peer's explanation, in the same scaffolding condition as their self explanation. Finally, they revised their quote taking into account the peer's comments.

We expected that prompted students would give more self-explanation statements (process measure) thus realizing deeper cognitive treatment than apprentices in low scaffolding condition, both for their own and for their peer's production. As a consequence, we expected that the "«high scaffold»" group would profit from deeper reflection activity and perform better in the two phases of the learning task (outcome measure).

## Methods

### Participants and context

This activity took place in Geneva dental care vocational training school. It was designed in collaboration with the dentistry course teacher and was implemented during the school hours. The topic "filling in an insurance quote" was part of the curricula. Participants were 3rd year apprentices from two classes of the dental care assistant school in Geneva, all women[1]. Overall 26 students aged of 18-23 years participated in the experiment and were randomly allocated in one of the two experimental conditions (low or high scaffolding) according to a one by 2 between-subject design. The activity took two consecutive school hours.

### Material and apparatus

A wiki-based environment was used in order to support the apprentices' writing activities. An electronic equivalent of the quote form containing 4 tables (below, referred to as "table 3", "table 5", "table 7" and "table 9", see Figure 1) was proposed, each one referring to different aspects of the patient's dental problems, the medical treatment and the financial dimension. The "table 3" had to be filled in with information about the

[1] There were no men in this dental care assistant school.

damages caused by the accident (type of damage, teeth involved), the "table 5" referred to the diagnostic and treatment measures to be taken, the "table 7" enumerated the measures to be taken as a definitive treatment and finally "table 9" concerned the financial aspects (medical treatment, points, price and some other specific details).

Figure 1. Screen capture of the wiki-based learning environment used in this study. From left to right: student A's answer, her self-explanation, student B's comment and A's final decision.

They were preceded by a yes/no question asking the apprentices about their previous familiarity at the workplace with this task.

Each table had two extra columns: one for students' explanations and the other one for the peers' comments. All apprentices were already familiarized with the use of the wiki tool since they already had used it for previous school activities. Depending on the condition, two versions of the material were designed, differing only on the content of the two extra columns of the quote: explanation and commenting. The "«high scaffold»" condition provided, for each of the tables, in the explanation column, a set of five questions guiding their answers. The questions were built on the 5W criteria (why, when, who, where, how) and used the Lin and Lehman's (1999) "reason justification", "rule based" types of prompts. In the «low scaffold» condition, there was only the general prompt: "Explain".

## Procedure

The apprentices were welcomed by the teacher, as for a normal class. In the first phase, starting from an authentic case study proposed by the teacher, the apprentices had to fill in an electronic quote and explain how they did it. In the high scaffolding condition, the apprentices had to explain why they had filled in that way, how they did to fill in, on which material/knowledge they based themselves and finally in which order they filled in the table and why. The «low scaffold» group had the same task but for the explanation column they didn't have any scaffolding questions, they only had the instruction to "Explain". In a second phase, a colleague had the task to correct a peer's quote and also comment about the changes she had done and explain, using the same level of scaffolding as for the first phase. The "high scaffold" group had a list of specific questions aiming to see if they agreed with the way the table had been filled in, if they had changed/corrected anything and why and if they considered the explanations given by the peer satisfying, while the "«low scaffold»«low scaffold»" group had only the instruction to "Comment".

### Data analysis

For each of the quote's tables we analyzed the percentage of filling in the quote, the explanations and the comments, as well as the quality for each of these three writing tasks.

For the percentage of filling in, we coded with 0 when there was nothing written, 1 when the table was filled in at 30%, 2 when it was at 50%, 3 at 75% and finally 4 representing a completely filled in table, by taking into account the number of fields to be filled in. These codes concerned only the fact of having filled in the table regardless of the entries' correctness.

When coding the quality of the quotes, we counted, in each table, the number of correct answers, the number of acceptable answers (representing neither correct nor incorrect answers) and the number of incorrect answers. We also calculated the sum of correct/acceptable/wrong answers for the entire quote, in its first and second version. With regard to the quality of the explanations, we counted the number of valid arguments, the number of details mentioned, as well as the number of incorrect explanations for each one of the four tables. Comments we classified into two categories, informative and non-informative. The comments classified as informative were those providing useful information to the author for improving the quote while the non-informative ones were the social ones (containing support, acknowledgement etc.)

## Results

In the first place, we checked out if there was any influence of the apprentices' declared familiarity with the task at the workplace and their performances at the quote activity in the classroom. We conducted an ANOVA, which showed no significant differences between the quality of the "familiarized" apprentices' quotes and the quotes of the ones declaring not being familiarized with this procedure ($F(1,23) = 4.85$, $MSE = 21.33$; $p < .05$).

Following our hypotheses, we looked for the differences between the two experimental groups with respect to 1) the proportion of filling in each of the quote's tables; 2) the quality of the entire quote as well as table by table; 3) the quality of the explanations; 4) the quality of the comments.

### Percentage of information entered in the quote

We looked at the number of information completed in the entire quote in its first and second version, as well as each of the four tables separately, regardless of their accuracy.

The proportion of completion of the entire quote was computed as the ratio of the number of information entered against the total number of answers required for each apprentice. An ANOVA analysis did not reveal any significant differences between the two experimental groups ($p > .05$), neither in the first, nor in the second versions.

Considering each table separately in the first and second version, the ANOVA analysis revealed one significant difference – the high scaffold group filled in more in the first version of Table 3 than the low scaffold group ($F(1,24) = 8$; $MSE = 22.15$; $p < .05$). Nevertheless, this difference faded away in the second version of the quote where no significant difference between the groups was found anymore.

### Correctness of the quotes

The quality of the quotes was evaluated through the number of correct answers to the first and second version of the quote for each apprentice. ANOVA test revealed that the low scaffold group produced better quality quotes than the high scaffold group in the first version ($F(1,24) = 4.82$; $MSE = 36.9$: $p < .05$) as well as in the second version of the quote ($F(1,19) = 5.82$; $MSE = 35.9$: $p < .05$).

A deeper analysis concerning the differences between the two groups with regard to the correct and wrong answers in each of the quote's four tables revealed interesting information.

In the first draft, the high scaffold group produced significantly better answers for the table 3 than the low scaffold group ($F(1,24) = 6.54$; $MSE = 0$; $p < .05$). Howver, we did not find any significant difference between

the groups in the second version of the table 3 – meaning that the «low scaffold» group compensated the difference after the revision of the quote.
Significant differences were also found in the quality of table 9. In the first as well as in the second version of this table, the low scaffold group gave significantly more correct answers than the high scaffold group (first version: $F(1,24) = 7.14$; $MSE = 30.15$; $p < .05$ second version: $F(1,19) = 4.58$; $MSE = 24.31$; $p < .05$). Moreover, the high scaffold group gave more incorrect answers in both versions of the table 9 (first version: $F(1,24) = 11.53$; $MSE = 3.84$; $p < .01$, second version: $F(1,19) = 7.13$; $MSE = 4.86$; $p < 0.5$). These results mean that participants in the high scaffold group did not take advantage of the comments on their first version to improve enough in the second draft in the extent that they would equalize or outperform the answers of the low scaffold group.

### Differences between the first and second versions of the quotes

To evaluate the evolution of the quotes from the first to the second version, the difference between the number of correct answers over the two versions of the quote was computed for each condition. Neither the high nor the low scaffold group significantly improved the quality of their quotes from their first to their second versions. Nevertheless, if we look at the observed results, both the low scaffold and the high scaffold group improved the quality of the quotes between the first and the second version (Low scaffold: $M_{first} = 9.08$, $M_{second} = 9.82$; High scaffold, $M_{first} = 6.69$, $M_{second} = 7.2$).

### Quality and quantity of the self-explanations

In terms of percentage of completing the explanations, ANOVA analysis did not reveal any significant difference between the two groups, meaning that the two groups produced more or less the same amount of explanations.
Nevertheless, there were significant differences between the two groups in the quality of the explanations. The high scaffold group gave significantly more arguments for the table 3 than the low scaffold group ($F(1,24) = 6$; $MSE = 6.5$; $p < .05$), but it also gave significantly more "details" ($F(1,24) = 7.38$; $MSE = 2.46$; $p < 0.5$). For the table 9, the situation was the exact opposite: the low scaffold group gave marginally significantly more arguments than the high scaffold group ($F(1,24) = 3.64$; $MSE = 26$; $p = .06$) but significantly less details ($F(1,24) = 4.52$; $MSE = 1.88$; $p < .05$).
Regression analysis performed on the entire data, without regard to the experimental condition, showed that more argumentative explanations given in table 3 ($Rsquare = .23$; $F(1,25) = 7.3$; $p < 0.5$) and table 9 ($Rsquare = .31$; $F(1,25) = 10.76$; $p < .01$), was related to better accuracy of these tables.

### Type of Comments

For each group, comments were simply classified into two categories, according whether they were superficial or essential. The number of comments in each category was used to evaluate the quality of the comments. On the entire quote, we found a marginal significant difference in the favor of the low scaffold group, who made more essential comments than the high scaffold group ($F(1,20) = 4.26$; $MSE = 10.8$; $p = .053$). Analyzing table by table, we notice that the low scaffold group systematically gave more essential and less superficial comments than the high scaffold group, but none of these differences was statistically significant. We can only consider them as tendencies.
Regression analyses did not reveal any statistical significant relations between the quality of the explanations and the quality of the comments or between the quality of the quote and the quality of the comments.

## Discussion

Apprentices' declared familiarity with the procedure did not seem to account for their actual performance, tested with the class activity. This might be explained by the apprentices' low self-evaluation competencies but also by the very heterogeneous workplace training they get. These conjectures reinforce the need to implement school activities based on apprentice's professional experience as well as supporting knowledge sharing and collaborative reflection.
With regard to the effect of the scaffolding, the results partly contradicted our hypothesis by showing that for some tasks, the group with low scaffolding outperformed the group with high scaffolding. Having a synthetic look at the results, we noticed that the high scaffold group outperformed the low scaffold group at all levels (quality of the table, percentage of filling in the table, quality of explanations) in the starting task (table 3). The two groups have similar performances on the middle tasks (table 5 and 7, not reported here). When analyzing the final task (table 9), the low scaffold group has significantly better results (at all levels) than the high scaffold group.
Considering the quality of the self-explanations proposed by the two groups, we notice that even though they seem to produce the same amount of information, the high scaffold group produced more valid arguments in the explanations in the first table but ended up by proposing more superficial ones in the final table. The low

scaffold group had exactly the opposite behavior. Statistical analysis also confirmed that the quality of the explanations was a predictor for the quality of the quote.

These results support the idea that high scaffolding may have helped in the beginning of the activity in order to support good explanations and reflection (King, 1992), generates more correct answers, and orients the apprentices towards appropriated task solving approaches. Nevertheless, by the end of the activity, the low scaffold group caught up with the high scaffold one and even outperformed it. One could argue that high scaffolds can be useful in the beginning of the task, in order to orient the apprentices' cognitive strategies and give indications about how the task should be dealt with, but, shortly after becomes superfluous or even too burdening. This study underlines the idea that scaffolding is a powerful tool for fostering deep cognitive treatment of knowledge in self-explanation task on procedures. Nevertheless, it identifies the need of conceiving and implementing adaptive designs in which these prompts fade out along the task in order to give place at the adaptive and learning skills of the student to take the place.

However, it should be noted that the low scaffold group started with better performance in terms of global accuracy of the first version of the quote. No data in our study can disentangle the effect of scaffolded self-explanation and initial level of each group.

Regarding the effect of peer commenting, the results could not confirm the positive effect of this instructional methods through statistical analysis, though the observed results showed an improvement in performance in both scaffolding condition. It may be that self-explanation in itself has such a great instructional effect that the effect of peer-commenting could not be easily demonstrated using few measures with few students.

Last but not least, we have to take into account that this study took place in real class settings, and that other factors may have interfered. Students were not very familiar with self-explaining activities nor commenting ones. They might not have fully benefited by the instructional device (e.g., Ainsworth & Burcham, 2007). It is nevertheless a real situation, valuable for conceiving and implementing these types of designs in real vocational training classes. Future long term studies will investigate further this issue as well as the relation between the computer support and the commenting instruction.

**Abstract:** This study explores the application of the complex systems lenses of robustness and trade-offs to evaluate the success of a STEM education program in terms of sustainability. A mixed methods approach is used to document contextual constraints, trade-offs considered such as modularity vs. one-size-fits-all, and actions taken by the project team to build toward adaptive capacities.

## Introduction

The issue of declining participation of America's youth in science, technology, engineering and math (STEM) education and careers has received a great deal of attention over the last few years from industry, government, and education sectors (Business Roundtable, 2005; Domestic Policy Council, 2006; U.S. Department of Education, 2007). As STEM jobs continue to grow, by 2012 the number of positions in science and engineering is estimated to outpace the number of qualified people to fill them by 26% and 15% respectively (NSF, 2006). From a citizenship science perspective, there is a broader issue of a general lack of STEM literacy in society associated with such declining participation. When fewer students are interested in and aware of emerging STEM research such as nanotechnology, the likelihood that they are able to contribute to intelligent decision making about applications that can affect their daily lives decreases (Yoon, 2008). Additional pressures on workforce development exist with the emphasis on developing 21st century and cyberinfrastructure-enabled scientific skills in which learning from and using digital technologies both for developing conceptual knowledge and process skills must now figure prominently in education (NSF, 2007; Partnership for 21st Century Skills, 2007). To respond to these needs researchers in the Learning Sciences and STEM education have focused attention on understanding how to develop, sustain and scale innovative science and technology reform-oriented programs. Investigation and discussion have centered on what mechanisms and variables are required to create the conditions for success and how success may be evaluated (Dede, Honan & Peters, 2005; Yoon & Klopfer, 2006; Yoon et al., 2009). One theme that resonates through much of this research is the challenge reformers face in adapting their programs to specific contexts (Datnow, 2005; Dede & Honan, 2005; Hargreaves & Fink, 2000). Elmore (1996) writes about the difficulties experienced by nested clusters of innovation in educational settings. He states that failures, historically, in generating successful large-scale reforms can be attributed to an "absence of practical theory that takes account of the institutional complexities that operate on changes in practice" (p. 21). Similarly, Goldman (2005) and Fishman et al. (2004) identify the need to account for multiple embedded levels of stakeholders when designing for improvement, who must actively support the reform if it is to succeed. Coburn (2003) reinforces the idea that educational reform and improvement are matters of complexity highlighting the inability of research to address the inherent multidimensionality between and within educational constituents. Building from this reform literature and the calls for research methods and practical theories that take a systems approach, in this paper we introduce the principle of robustness, both as a lens and a tool for understanding issues of sustainability and scale of innovative STEM education programs. We suggest that achieving a robust programmatic state is arguably the sine qua non of success with respect to sustainability, which in turn provides the rationale for going to scale. As we will argue, one of the core measurable mechanisms operating in the service of robustness is trade-offs. We present data, analyses, and results of the first year of a three-year STEM program in which we document the trade-offs experienced and then undertaken in the redesign process to create a more robust program.

## Theoretical Framework

### Complex Systems

Multidimensionality, nested clusters, and multiple constituents and levels are all characteristics of complex systems. The study of complexity has been a focus of research in many academic disciplines such as biology (Kaufmann, 1995), physical science (Bak, 1996; Prigogine & Stengers, 1984), psychology (Arrow et al., 2000), anthropology (Lansing, 2006), and economics (Stacey, 1996). The ubiquity of complex systems research appears to extend from the commonalities that exist between structures or contexts and behaviors in that they comprise multiple elements that adapt or react to patterns that they create (Arthur, 1999). By studying the patterns that emerge and the interactional dynamics that lead to these patterns, researchers can better understand among other things, how systems adapt, self-organize, fluctuate and either achieve or do not achieve steady states. For example, in the simple dilemma of the Tragedy of the Commons, one individual may choose to act selfishly and use up resources with no real impact on supplies. However, if many individuals decide to behave in the same way soon the resources will be depleted and the individuals along with the collective community will suffer. Thus the culture or the collective that exists must be considered. It requires one to know the limits of the culture and to adjust behaviors in order to sustain a robust system, which is also in the best interest of individual survival.

### Robustness in Complex Systems

Related to understanding the limits of the culture, robustness researchers study the contextual parameters that enable systems to persist or deteriorate in the face of negative often, unpredictable impacts such as the spread of viruses in an ecosystem, continual military conflict between countries, or the collapse of stock markets in economies. As a central complex systems mechanism, various problems across biological and social situations can be investigated through the lens of robustness which has led leading complex systems organizations like the Santa Fe Institute to devote whole research tracks to its study (http://www.santafe.edu/research/topics-innovation-evolutionary-systems.php#4). One of the unifying characteristics that enable its multidisciplinary application is that perturbations impact natural, cultural, and engineered systems. It is hypothesized that studying varying system's responses to these perturbations can provide general rules or principles that can be used to solve long-standing questions such as how evolution that requires variation supports the emergence of phenotypes from genotypes (Wagner, 2005). Others have used notions of robustness to understand how the structure of social networks enables information flow and resource management (Webb & Bodin, 2008). For example, as individual nodes, actors or elements are removed from the network key connections may be broken which may isolate subgroups and thus limit how information gets distributed. Elsewhere we have used social network theories, analyses, and tools to help students and teachers develop better information-seeking strategies to construct knowledge and to gain social capital (Yoon, accepted; Baker-Doyle & Yoon, 2009). In all these studies, creating robust systems requires ease of information flow in order to give and receive resources. Where constraints exist due to cultural or contextual barriers, trade-offs are needed to build adaptive capacities.

### Trade-Offs

Perhaps the most well known example of a general application of the idea of trade-offs is the situation of the Prisoner's Dilemma that falls under the general topic of Game Theory. This is a hypothetical case where two prisoners are interrogated separately for having together committed a crime. In the classic scenario, it is assumed that the base prison sentence is 5 years. The pay-offs or decrease of prison time will depend on whether the individuals choose to cooperate with each other or defect. In the context of the game, defecting (claiming innocence and implicating your partner), while your partner cooperates (confesses to the crime), will always provide the largest pay-off to the defector in that no prison time will be served. Similar to the Tragedy of the Commons example, using this simple algorithm, researchers have studied how it is possible that cooperation might have emerged as an evolutionarily adaptive strategy (Axelrod, 1984). While a full blown discussion of the mechanisms that lead to cooperation cannot be made here, one of the key ideas related to trade-offs for our research pertains to the fact that much of the study of strategies that allow populations rather than individuals within systems to benefit are underpinned by the fact that the success of someone or something that includes activities and resources may come at the expense or sacrifice of another person or another thing. For example, Janssen and Anderies (2007) write with respect to the trade-offs that organizations must make in choosing to satisfy short-term or long-term goals, "when all ‘low-hanging fruit’ is taken to increase robustness cheaply, [systems] will eventually reach a point at which it is no longer possible to generate additional robustness without a cost to performance and/or decreased robustness somewhere else in the system" (p. 44).

### Complexity, Robustness, and Trade-Offs in Evaluating STEM Education Programs

Understanding the educational system as a complex system is not new in educational research. In his *Change Forces* series focused on reform, Fullan (1993, 1999, 2003) uses complex systems theory as an organizing framework to reveal core concepts such as non-linearity, unpredictability and multi-level agency that are important issues to contend with in real-world educational systems. However, where states of existence like robustness become goals that drive the reform efforts rather than for description, and where mechanisms like trade-offs become actions, educational research takes a step closer to a "practical theory" that accounts for institutional complexities that Elmore (1996) searches for. The following study documents the multiple constituents, contextual limits, and important trade-offs made toward increasing robustness in a large-scale STEM education reform effort.

## Methodology

### Context

This work is funded under the National Science Foundation program "Innovative Technology Experiences for Students and Teachers (ITEST)". The ITEST program is designed to increase opportunities for students and teachers in underserved schools to learn and apply information technology concepts and skills in the STEM content areas. Our project is a school district-university partnership between one of the largest school districts in the U.S., a school of education and a leading university nanoscale research center. It aims to achieve the broader ITEST goals by updating standard high school science curricula and training teachers through a curriculum and instruction framework built on five component variables addressing content knowledge, pedagogical content knowledge, and workforce development goals. These variables are: 1) Real world science and engineering applications such as current nanotechnology research and ethical considerations of this research; 2) Educational Technologies to develop content knowledge such as NetLogo computer simulations; 3) Information Technologies for communication, community-building and dissemination such as Google Groups and wikis; 4) Cognitively-rich pedagogical approaches such as problem-based learning; and 5) Investigation and consideration of STEM education and careers.

There are two parts to the scope and sequence of project activities. The first part entails a three-week, 75-hour professional development summer workshop for science teachers, in which they learn to construct and pilot curricular units based on the five component variables. These curricular units are intended to be aligned with school district standards for high school biology and physical science. The summer workshop is followed by the school-year implementation of these units in teachers' classrooms and 5 follow-up Saturday professional development workshops. In addition to the central curriculum and instruction goals, another major goal of the project is to build teaching capacities and self-directed interests through communities of practice structures which include working with groups of teachers from the same school, implementing an online comprehensive professional development database for peer-to-peer interaction, and requiring teachers from different schools to construct units collaboratively. For this study, we focus on the activities and program developments of the first cohort of teachers who participated on the project between August 2008 and May 2009.

## Participants

Ten male and six female teachers participated in the workshop from 10 high schools and 1 middle school in the district. The group was racially/ethnically diverse: seven teachers were White, six were African American, and three were Asian. Courses taught ranged from grades 8 to 12 in the content areas of physical science, biology, chemistry, and physics. The average amount of teaching experience was 15.8 years, with a range of 1 to 39 years of experience. Data from 128 students taught by a sample of six teachers were collected with the following racial/ethnic breakdown: 23.4% White, 48.4% African American, 7.8% Hispanic, 14.1% Asian, and 3.9% other races. The study also investigated perceptions and actions of the project team, as the goal was to document and understand the kinds of trade-offs we experienced in the development and implementation of the program. Thus, we include the project team as participants who comprised: a professor, a post-doc and two doctoral students from the school of education; and a professor, two post-docs, and the educational outreach director from the nanoscale research center.

## Data Sources and Analyses

Eight data sources were collected for the study and analyzed through a mixed methods approach.

1. A 64-item 5-point Likert-scale survey administered to teachers to measure teacher's self-perceptions of pedagogical practices, beliefs, student participation, and teacher confidence levels with particular emphasis on the project's five variable curriculum and instruction framework. A pre-intervention survey was collected in August 2008 and a post-intervention survey was collected in May 2009. Complete data sets were obtained from 8 participating teachers due to various data collection challenges. A paired-samples t-test was conducted to determine if teachers had statistically significant change in their self-perceptions from the beginning to the end of the 2008-2009 academic year.
2. An 82-item 5-point Likert-scale survey administered to students to measure self-perceptions of attitudes toward science and use of classroom resources and strategies with particular emphasis on the project's five variable curriculum and instruction framework. Pre- and post-intervention surveys were collected from 5 participating teacher's classrooms immediately before and after the ITEST implementation. Times for survey collection were different due to the variability of implementation in the school-year curriculum. For example, some teachers chose to develop units in physical science on the topic of properties of matter, which corresponded with delivery of the standard curriculum at the beginning of the year. Others chose units that corresponded with latter times. A paired-samples t-test on 128 survey responses was conducted to determine if students had statistically significant change in their self-perceptions.
3. An 11-item open-ended research survey administered to teachers that probed in-depth understanding of nanoscale content and STEM education pedagogical beliefs related to the 5 variable project framework. A pre-intervention survey was collected in August 2008 and a post-intervention survey was collected in May 2009. Complete data sets were obtained from 8 participating teachers.

4. Qualitative case studies of 5 project teachers were conducted by the project's external evaluator. Case study classrooms were selected to obtain information from as diverse a sample as possible. The case-study implementation was guided by the following 4 questions: What does the ITEST curriculum look like as it is implemented in case-study classrooms?; To what extent do teachers implement the key elements of ITEST?; To what extent is each enacted unit similar or different from the intended unit?; What supports and challenges are observed and reported in the implementation of the ITEST curricular units? Data collection included: field notes from three classroom observations, informal conversations with teachers, informal conversations and/or focus groups with students, and a formal end-of-unit interview with each teacher.
5. Focus group interview for the entire cohort of teachers conducted during the Saturday workshop held at the end of February 2009. Focus group questions probed for details about affordances and constraints to implementation and suggestions for program redesign for the next cohort of teachers and schools. The cohort was divided into 3 smaller groups. Interviews were transcribed and compared by the external evaluator and the project team in order to identify common themes.
6. Weekly 1.5 hour project management meetings audio-recorded and transcribed.
7. Written and informal verbal reflections of the 4 scientists from the nanoscale science center after specific nano-content meetings and after content modules were implemented during the summer and Saturday professional development workshops.
8. Field notes and informal verbal reflections of the 4 school of education researchers documented throughout the year of implementation as facilitators in participant teachers' classrooms. There were 33 formal classroom observation field notes collected.

For data sources 3, 5-8, data were reviewed systematically by the 4 school of education researchers through a qualitative grounded theory approach (Strauss & Corbin, 1998) in which all open-ended surveys, transcribed meetings, observation notes, and reflections were mined for evidence illustrating various trade-offs that emerged throughout the project year.

## Results

With respect to increasing robustness and revealing and using trade-offs that are specific to our ITEST project, we were interested in documenting the emerging themes as they pertained to the 5 variable framework as well as impacts on the goal of building a practitioner community focused on the framework. In this paper, the results of two variables (i.e., real world science and engineering applications and educational technology) are presented and organized into the three sub-categories of: i) Contextual Constraints; ii) Trade-offs; and iii) Actions. We continue to work toward identifying more general categories of constraints and trade-offs that may be applied across similar STEM education programs, however, in this section we list them individually and attempt to apply a meta-level categorization later in the Discussion section.

### Real world science and engineering applications

Research in nanotechnology refers to the interdisciplinary study of physical, chemical, and biological phenomena in the 1 – 100 nanometer range. Manipulation of atoms and molecules at this scale have given scientists unprecedented abilities to engineer materials, products and processes in, medicine, the environment, cosmetics, clothing, and computer and automotive technologies (Roco, 2003). Nanotechnology research has undergone rapid growth over the past decade with an estimated annual global research expenditure of $13.9 billion (PCAST, 2008). The pervasiveness of these applications is also immense. The Woodrow Wilson *Project on Emerging Nanotechnologies* states that there are over 800 products currently on the market produced by over 400 companies in 21 countries. Therefore, in our project, incorporating current and cutting edge nanotechnology research and applications including nanoscale content and real world problem solving into the standard science curriculum was a central design element of the teacher constructed PBL units.

#### Contextual Constraints

Several contextual constraints limited the success of this variable. First from the case studies and focus group interviews, the most widely reported challenge teachers faced was the mismatch in PBL pedagogy and the school district's system of managed instruction, i.e., core curriculum and benchmarks. Due to time challenges, delivering a complete unit was not possible for some teachers choosing instead to deliver discrete lessons throughout the year. Despite significant increases in teacher confidence levels in their ability to use problem-based instructional practices ($t(7)=2.546$, $p=.038$), teacher effectiveness in helping students identify multiple solutions to a problem ($t(7)=2.121$, $p=.078$), and perceptions of increased use of real world applications in the curriculum ($t(7)=3.667$, $p=.008$), no significant differences were found in student perceptions of learning about real world issues, new science innovations or discoveries, teacher's demonstrations of science problems, and student problem-solving. Moreover, while teaching aspects of PBL units was found to occur in classroom observations, even in the best example of one of the case-studies, student final projects had low fidelity with the original curriculum, which included plans for students to gather, synthesize, and evaluate the various types of information used throughout the unit in order to assess the ethical issues related to their nano-application.

Difficulties also existed in aligning curricular content levels and school contexts with nanoscale applications. Despite significant increases in teacher's perceptions of their ability to incorporate nanoscale science content ($t(7)= 3.130$, $p=.017$), scientists frequently expressed concerns about finding the appropriate connections to the topics covered in the high school curriculum. Issues for the scientists also surfaced with respect to empowering teachers to "own" the presented concepts so that they felt compelled to shape it into instruction relevant for their classrooms. From a content knowledge perspective, responses from teachers that probed understanding of nanoscale concepts showed misconceptions at the fundamental level of size and scale as well as in their perceptions of nanoscale science requiring an entirely new understanding of canonical scientific domains. For example, the majority of teachers believed that nanotechnology is a distinctively new science (with its own set of laws), instead of an addition to existing sciences, like biology, chemistry, and physics.

## Trade-Offs

The trade-offs we would like to highlight here deal with structural and behavioral factors of social and human systems, which we have discussed elsewhere to be among the most difficult constraints to contend with in the educational system (Yoon & Klopfer, 2006; Yoon et al., 2009). In the first case regarding the implementation of PBL, the expectation was for teachers to develop a coherent unit with the higher-order inquiry skills of evaluation and synthesis however, given district testing pressures, the actualized curriculum looked much different. This is akin to the trade-off of robustness to performance. Essentially, the trade-off parameter can be described in terms of <u>some benefits are better than none</u> in the face of highly uncompromising intransigent constraints. In the second case in aligning curricular content and the existence of fundamental misconceptions, if we were to follow the research on how people learn or knowledge-building theory (Bransford et al. 2000; Scardamalia, 2002), providing scaffolds for teachers to construct their own knowledge would stand a better chance in helping them make curricular connections on their own, promote self-efficacy and self-regulation, and remediate misconceptions. However, the major constraints here are lack of time and resources to undertake the knowledge-building process. A logical trade-off parameter then, given that teachers felt positive about their ability to incorporate nanoscale content into their regular curricula, might be to <u>meet the teachers half-way</u>, i.e., providing instructional support and curricular resources to seed interest and a solid leverage point to explore research and application avenues other than the ones that are directly taught to them.

## Actions

Based on the trade-off parameters, a number of changes in project expectations and program delivery occurred for cohort 2 teacher professional development. Instead of mandating a coherent sequential unit, curricula could be constructed drawing on content connections in multiple topics throughout the school year. We identified a teacher from cohort 1 who developed particular expertise in working with project goals in this way and we enlisted her to teach a two-hour module on what we called semi-coherent curricular units where she modeled the process and provided to teachers her own tried and true unit with detailed explanation of the important modifications she made in practice. Actions spawned by the trade-off of meeting the teachers half-way, included constructing a comprehensive curriculum alignment inventory in which 11 nanotechnology and concepts/applications were identified in addition to how they interface with the State Standards and the School District's Core Curriculum for grade 9 Physical Science and grade 10 Biology. Table 1 depicts a sample of the inventory the project team developed. This was used in instruction for teachers when new content was introduced and given to them as a general heuristic to use when building their standards-aligned PBL units.

<u>Table 1: Sample of Curriculum Alignment Inventory.</u>

| Nano/Bio Concepts/Applications | Pennsylvania State Standards | | SDP Core Curriculum |
|---|---|---|---|
| | Physical Science | Biology | |
| 1. What is the nanoscale? How small is nano?<br><br>2. Unique properties at the nanoscale | 3.4A Explain concepts about the structure and properties of matter<br><br>3.1D. ## Educational Technologies to develop content knowledge

Educational technologies (ET) were presented to teachers as distinct in our framework from information technologies (IT) in that ET comprises imaging, simulations, and visualization tools that help scientists and students learn about science content and processes whereas IT is primarily used for communication and interaction. Teachers were instructed on the emerging importance of being able to navigate the cyberinfrastructure for STEM careers, which includes using computational tools for data collection, manipulation, visualization, and prediction. Several digital tools used with teachers included simulations found on the Internet such as The Nano Journey, http://www.nanoreisen.de/english/index.html and NetLogo (Wilensky & Reisman, 2008) software in which a drug delivery system for nanotechnology and cancer was constructed and used with teachers to learn about how to conduct scientific experiments with such simulations.

### Contextual Constraints

In comparison to using information technologies, this variable was much less prevalent in teacher's instructional practices. Classroom observation field notes indicated that only 2 out of the total cohort of 16 teachers used NetLogo in their instruction. Where as teachers surveys showed significant increases in the perception of their ability to incorporate IT into their lessons ($t(7)=2.198$, $p=.064$), no differences were found with ET. In student surveys, although the item investigating science or other ideas through simulations, images, or animations ($t(125)=2.594$, $p=.011$) was found to have positive gains, actual observed practice showed no use of these tools for higher order scientific inquiry skills. Rather, they were used mainly to illustrate or demonstrate a concept. In the case studies, similar results were found along with other contextual constraints. One major challenge was that the teachers did not have administrative privileges to download NetLogo onto their school computers. One teacher did download NetLogo onto his laptop and students individually came up to his computer and tried the simulation for short periods of time. Another teacher said that she was interested in NetLogo, but didn't have a laptop that she could load it onto. Of the other three, one said that he didn't have enough facility to use it, and the other two did not think it would have been feasible to use in their classes due to classroom management issues. All teachers did use other educational technology, the most common application being visualization software that allowed students to move between visualizations of the same item or location at different scales.

### Trade-offs

The lack of educational technology use triggered several in-depth discussions during project management meetings about how to facilitate greater applications as well as applications that resembled more closely how scientists really used such software for scientific discovery. NetLogo and similarly StarLogo were simulation tools used by the principal investigator in previous projects with some success in developing computational literacies and 21st century skills (Klopfer & Yoon, 2005; Klopfer et al., 2005). Particularly with respect to the potential for manipulating variables, changing initial conditions, and running multiple experiments, NetLogo/StarLogo modeling software could be extremely useful tools in the science classroom. However, given the difficulties in downloading the software, differences in teachers facility and comfort levels, and the fact that some ET was being used in instruction, the project team explored the trade-off of modularity vs. one size does not fit all. This trade-off is similar to the use and benefits of differentiated instruction. Although it was believed that more focused practice on a few ET applications for all teacher participants would work toward successful ET implementation, again, structural and behavioral realities posed seemingly insurmountable constraints and we needed to differentiate this component.

### Actions

Several actions were taken according to the identified trade-off. First, with the easily accessible Internet visualization programs, we developed exemplar lessons to show generically how experimentation could be done with any similar tool. Next, we devoted a good deal of time collecting and vetting ET sites on the Internet that would be appropriate for our project which culminated in a comprehensive Educational Technology Inventory with clickable links. We also planned to deliver parallel sessions that demonstrated different ET applications and associated pedagogies for which teachers could choose to sign up according to their interests and comfort levels. We would offer these iteratively so that when teachers felt that they had developed particular competencies, they could choose to attend increasingly more challenging ET modules to improve their skills.

We have documented and used several more trade-offs as a response to contextual constraints. For example, after realizing how little access we had to guidance counselors in schools and coming to the understanding that they were no longer assigned to just one school, plans to work on a comprehensive nanotechnology education and career package in which teachers and guidance counselors would collaborate to disseminate on a large scale needed to change. Instead we opted for different STEM education and career experiences, one of which was a short, real-world internship where teams of two high school students worked in a modestly paid after school job for two hours a week in the nanoscale professor's research lab. The trade-off and extensive project team discussions centered around project impact on individual vs. many students. With the variable of cognitively-rich pedagogies, a trade-off that we continually face is how much is enough theory vs. practice. In working toward our goal of building a community of practice one of the major trade-offs we grapple with is whether, how, and how much to build technological, human and/or social capital.

## Discussion

With all of these trade-offs, one common theme that organizes around building sustainable or robust programs appears to be negotiating the middle ground. When working with systems with high complexity, that is, many often competing factors that operate under unpredictable conditions, finding the compromise between ideal project fidelity and real-world constraints may be the key to ensuring that at least some parts of the vision survives. From this platform, we can create opportunities for continued growth of activities that have taken a hold in the education system to continue to grow. Another meta-level theme that clearly impacts the project team's decision-making practices is the disposition of flexibility. The adaptive process that these STEM education programs necessarily undergo can work if there is an expectation of flexibility and a willingness to carefully document and analyze the constraints in order to choose another path that may be more successful. Likewise, adopting an ideological stance of pragmatism may be a prudent choice. If we apply from the start, the expectation that ideas or theories such as how people learn best can only be measured or deemed successful in practice, we are forced to take account of the institutional complexities that can exert heavy influence on program success.

There are at least three potential contributions that this study can make. At the level of theory understanding sustainability of innovative STEM education programs through the lenses of complexity, robustness and trade-offs is a promising framework to evaluate the complexity of educational reform. The study also informs practice, operationalizing the framework in terms of documenting contextual constraints, trade-offs considered, and then actions taken. Finally, looking across the trade-offs and identifying the common themes of finding the middle ground, developing dispositions of flexibility, and adopting a pragmatic stance, can be used by other like-minded educational reformers in the design of future STEM education programs.

**Abstract:** This exploratory study examined how groups of sixth grade students worked together to create a collaborative concept map. We selected two contrasting cases based on their initial maps, one heterogeneous group with divergent maps and one homogeneous group with convergent maps. We analyzed group dialogue and collaborative and individual concept maps to understand: 1) if convergence of science ideas occurs during collaborative concept mapping and 2) how convergence or divergence during collaboration influences individual map construction. We found that collaborative concept maps facilitated greater convergence of ideas in groups with initially divergent pre individual maps. Further, the negotiation of divergent science ideas during collaboration led to gains in individual students' science understanding. Implications of findings and directions for future research are discussed.

Concept maps have been used in a variety of educational settings to support meaningful learning (e.g., Daley, et al. 2008) in contexts such as reading (e.g., Nesbit & Adesope, 2006), writing (Sharples, 1994), and measuring conceptual change (e.g., Edmondson, 2000). Concept maps represent knowledge by focusing on relationships between ideas. They consist of concepts delimited by circles and arrows linking two concepts (Novak & Cañas, 2008). Words placed on the arrow explain relationships between concepts.

The use of concept maps has been mainly informed by the cognitivist premise that learning occurs within the individual through the assimilation of new concepts and relationships within existing propositional frameworks. A concept map represents an individual's knowledge structure at a given point in time (Fisher, 2000). However, Roth and Roychoudhury (1994) point out that "the theoretical framework in which concept mapping is grounded is not much concerned with the social construction of knowledge" (p.438). They describe concept mapping as a conscriptional device for social thinking through engaging in discourse, and an inscriptional representation of the groups' shared understanding of concepts and their relations. Further, they assert that new knowledge is constructed in collaborative peer groups, and refer to prior research to claim that this knowledge is taken up by the individual participants through engagement in this social interaction.

Several other researchers have explored collaborative concept mapping activities from a socioconstructivist perspective, and have reported that collaborative concept mapping has potential to support student learning (see Basque & Lavoie, 2006, for a review). In particular, van Boxtel, van der Linden, Roelofs, and Erkens (2002) found in an experimental study that students involved in collaborative concept mapping engaged in elaborate conceptual discourse and co-constructed meaning. They also found that elaborate student discourse influenced individual learning outcomes. Although collaborative mapping research suggests learning benefits, Teasley and Fischer (2008) contend that collaborative activities do not always facilitate individual learning or ensure equivalent learning gains for all individuals. They further state that few studies have explored how collaborative convergence of ideas relates to individual learning outcomes. This issue of convergence and divergence in thinking is critical in collaborative learning. For instance, Stahl (2004) stresses the importance of initially divergent ideas during collaboration. Further, Schwartz (1999) argues that individuals create unique understandings as they attempt to co-construct shared meaning during collaboration.

There is limited research that has investigated what a group map as an inscription represents; that is, whether there is convergence (the construction of shared understanding) in ideas between students as they collaboratively construct a concept map in a classroom, and the effect of collaborative mapping on individual understanding of concepts. In this exploratory study, we examined the level of convergence during collaborative concept mapping. From a socioconstructivist perspective, we also explored if a concept map represents the ideas of an entire group and how collaborative concept mapping relates to individual student understanding. Our premise is that a movement from shared understanding to construction is seen when students generate their own understanding in a new individual context based on previous interactions with others. To document this premise, we employed individual and group concept maps as inscriptional products, and student audio during collaborative concept mapping as a conscriptional process. We first examined the group and individual concept mapping scores of five groups from one science class. We then selected two contrasting cases based on their initial maps, one heterogeneous group with divergent maps and one homogeneous group with similar maps, to explore how the two groups worked together to create a collaborative concept map. Our research questions were: 1) Is there convergence toward a shared understanding of science concepts during a collaborative concept map activity? 2) How does convergence or divergence during the collaborative concept map influence individual map construction?

# Methods

## Participants and Instructional Context

The study was conducted in a sixth grade science class in a private Midwestern school. Students engaged in a design-based science curriculum to learn about simple machines using the CoMPASS hypertext system to complete a set of design challenges (Puntambekar, Stylianou, & Goldstein, 2007). In this six week curriculum, students brainstormed predictions and questions, conducted research on the CoMPASS hypertext system, and conducted hands on investigations to test their ideas in the same small groups throughout the unit. Students completed five mini design challenges pertaining to simple machines. Students also engaged in several individual and collaborative concept map activities throughout the unit. Practice individual and collaborative maps were constructed during the first half of the unit followed by the pre map in the middle of the unit. Students then constructed post individual maps at the end of the unit. Collaborative concept maps were created at the end of each mini design challenge.

For this study, we used data from the pre and post individual concept maps and students' collaborative maps. Students worked for approximately 45 minutes to construct paper and pencil individual concept maps involving simple machines physics concepts. Students were instructed to draw a concept map with at least nine (on pre map) or 14 (on post map) physics concepts with a description of how the concepts were related. A focus on how the machines work was emphasized in these instructions. In contrast, the collaborative concept map served both as a conscriptional device to aid students in their physics learning and as a group product or inscription of their learning for assessment. For the collaborative concept map, constructed between the pre and post individual concept maps, students were instructed to create a paper and pencil concept map incorporating physics ideas related to pulleys. They worked face-to-face on these maps for approximately 15-20 minutes during their regular science class.

## Data Sources and Analysis

We calculated concept map depth ratios to capture the sophistication of science ideas of students in all five groups. Further, we examined the map layout and coded group dialogue captured while students generated their collaborative maps for two contrasting groups, selected on the basis of their initial individual maps.

### Individual and Group Concept Map Depth Ratios

For this part of the analysis, we focused on sophistication of concept map propositions. A proposition is two concepts connected by a linking word to form a semantic unit. Modified from prior work (Puntambekar, Stylianou, & Goldstein, 2007), we scored all concept maps based on 1) the number of accurately described concept propositions and 2) the sophistication of science ideas expressed in the propositions. We assigned proposition scores according to a five point scale. This scale ranged from: -1 to 3 (see Table 1). We then calculated a *depth ratio* for each concept map. The depth ratio was calculated by dividing the sum of the scores for each of the propositions on a map by the total number of propositions on the map. A higher depth ratio value signifies more sophisticated understanding of the relationships between concepts. We chose to use the depth ratio to measure student progress because it considers the depth of the propositions regardless of the number of propositions on the map, and gives an average score of the sophistication of all propositions. Two researchers coded 15% of all individual and group concept maps and achieved approximately 90% interrater reliability. One researcher scored the remaining maps.

Table 1: Concept Maps Scoring Rubric.

| Score | Description | Example |
|---|---|---|
| -1 | Incorrect | levers are inclined planes |
| 0 | Ambiguous language (has, gives, uses, needs) in reference to concepts (MA, force, friction, distance) | screw has effort force |
| 1 | Fact, type of, is a, example, overgeneralization | third class is one of three kinds of lever |
| 2 | Definition, affects, intuitive language, increases, decreases | friction reduces MA |
| 3 | Scientific language, elaborate explanations, specify conditions for increase or decrease | levers increase the MA when the fulcrum is closer to the load |

### Individual and Group Concept Map Layout

We compared the map layout of both individual and group maps. We examined the chosen root word and structural organization (relational vs. hierarchical) between individual pre and post maps, and group maps. The chosen root word, or most central concept on a map, could be a machine or a physics concept. A relational concept map differs from a hierarchical map because relationships could be vertical as well as lateral, whereas in a hierarchical map relationships are primarily vertical.

### Group Dialogue

We transcribed the audio of student dialogue that occurred during the collaborative concept mapping activity. Total audio data consisted of approximately 35 minutes of audio and seven pages of transcripts. We inductively developed a set of nine codes after a preliminary examination of transcripts to capture the convergent and divergent exchanges between group members as they talked about science to construct their group map (see Table 2). Our codes also align with the transactive knowledge convergence process described by Weinberger, Stegmann, and Fischer (2007). We coded the transcripts at the utterance level. Each utterance could be assigned multiple codes.

We examined percentages of group dialogue to understand both the patterns of overall interactions in each group and the contributions offered by individual students. We calculated percentages by dividing the number of utterances categorized into a particular code by the total number of utterances coded during the collaborative activity. Similarly, the percentages for types of individual talk were calculated by dividing the number of utterances coded into a category by the total number of coded utterances of a particular student. Two authors independently coded 70% of the transcripts and established an interrater reliability of approximately 83%. The first author subsequently coded the remaining transcripts.

Table 2: Coding Rubric for Examining Collaborative Concept Mapping Audio Data.

| Code: | Description |
|---|---|
| Initiation of Ideas (II) | bringing up a new science idea |
| Simple Sharing (SS) | stating a science idea not taken up by other group members |
| Agreement of Ideas (AI) | explicit agreement between at least two group members |
| Contention of Ideas (CI) | explicit disagreement between group members in the form of questions or statements |
| Resolution of Disagreement (RD) | explicit consensus after a disagreement |
| Raising Questions (RQ) | asking group members questions about science concepts |
| Extending Ideas (EI) | refining or elaborating upon other group member's ideas |
| Restating Ideas (RI) | student restates idea or summarizes many group exchanges |
| Negotiation of Map Construction (NMC) | dialogue pertaining to what ideas to include on the map and how to position and connect them |

## Results

We report our findings based on three types of data: 1) individual and group map depth ratios, 2) individual and group map layout, and 3) individual contributions and group interactions, to understand if convergence of ideas occurred and how convergence was related to students' performance on the post individual concept maps.

### Depth Ratio Comparisons between Individual and Group Concept Maps

In this section, we discuss concept map depth ratio scores on students' pre and post individual maps and group map scores. We also discuss learning gains made by students as seen in the difference between pre and post map depth ratio scores. We calculated learning gains by dividing the actual gain by the total possible gain from pre to post maps. As we discuss the depth ratio scores, it is important to understand what small differences in the ratios represent. The depth ratio gives an average score of all the propositions on a map. A depth ratio of 1.1 can be best understood as consisting of mostly propositions falling into a level one score (see Table 1). Since the depth ratio has a small range from negative one to three, small changes in scores are meaningful in terms of student learning gains and differences in scores.

In Group A, the pre individual map depth ratios suggested convergence in their, with a difference of only .09 between the highest and lowest scores in the group. Their collaborative map, with a depth ratio of 1.0, reflected a level of understanding similar to what students showed on their individual pre maps. We also found that Rose's depth ratio decreased on her post individual map and she exhibited no learning gain. Both Alex and Lincoln performed slightly better on their post individual maps, with learning gains of 21% and 13% respectively. Group A's average learning gain was 8.6%.

The difference in pre individual map scores in Group B was most divergent at 0.85. In contrast with Group A, their collaborative concept map showed a modest improvement in their depth of understanding (1.39) over their individual pre map scores. Unlike Group A, all students in Group B made substantial gains in their depth ratio scores on the post individual maps with learning gains ranging from 36% to 51%. The average learning gain for Group B at 41% was much higher than any other of the four groups.

The second most divergent group was Group C with a difference of .73 between students' pre individual depth ratio scores. Like Group B, Group C had a higher collaborative map depth ratio score at 1.4 than the other groups. Group C also had the second highest average learning gains at 16% out of all five groups, with all students in the group showing learning gains. Although their average learning gain is smaller than that of Group B's, it is twice the gain than that of Groups A, D, and E.

Overall, Group D and E had depth ratio differences and learning gains similar to those of Group A, including lower depth ratio scores on their collaborative concept maps (at .93 for Group D and .64 for Group E). Like Group A, Groups D and E were relatively more convergent on their pre individual map scores with a difference in scores of .32 and .28 respectively. The average learning gains of Group D at 6.6% and of Group E at 5.8% were slightly lower than that of Group A at 8.6%. Like Rose in Group A, Jesse in Group D exhibited no learning gain and Brian in Group E made a small learning gain.

Thus out of the five groups, Group A had the most convergent initial maps, and Group B had the most divergent map levels before the collaborative concept mapping activity. We therefore examined student dialogue in these two contrasting groups to better understand how students created a collaborative concept map, and how their collaboration affected their individual learning.

Table 3: Depth Ratio Scores and Percent Learning Gains of Students' Pre and Post Individual and Group Maps.

| Group | Student | Pre Individual Map | Difference on Pre | Group Map | Post Individual Map | Percent Learning Gain or Loss: Individual Maps | Average Group Percent Learning Gain: Individual Maps |
|---|---|---|---|---|---|---|---|
| A | Alex | 1.00 | .09 | 1.0 | 1.41 | 21% | 8.6% |
| | Rose | 1.09 | | | .94 | -8% | |
| | Lincoln | 1.06 | | | 1.35 | 13% | |
| B | Betty | 0.44 | .85 | 1.39 | 1.29 | 36% | 41% |
| | Keesha | 1.08 | | | 1.77 | 37% | |
| | Jake | 1.29 | | | 1.60 | 51% | |
| C | Kristen | 1.46 | .73 | 1.4 | 1.60 | 7% | 16% |
| | Jerry | 1.10 | | | 1.33 | 13% | |
| | Mary | 1.08 | | | 1.39 | 15% | |
| | Collin | .73 | | | 1.17 | 20% | |
| D | Naomi | 1.12 | .32 | .93 | 1.30 | 10.5% | 6.6% |
| | Jesse | 1.29 | | | 1.16 | -5.8% | |
| | Amy | 1.00 | | | 1.24 | 10% | |
| | Armando | 1.32 | | | 1.50 | 11.8% | |
| E | Allison | 1.22 | .28 | .64 | 1.32 | 5.6% | 5.8% |
| | Brian | 1.05 | | | 1.10 | 0.03% | |
| | Gage | 1.33 | | | 1.48 | 11.8% | |

## Map Layout Comparisons between Individual and Group Maps for Groups A and B

Examining contrasting cases shows potential for understanding how collaborative processes influence learning outcomes (Rummel & Hmelo-Silver, 2008). Alex, Rose and Lincoln were the students in the more convergent group, Group A. While Betty, Keesha, and Jake were the students in the more divergent group, Group B. In Group A, Alex drew the collaborative concept map and in Group B, Betty drew the group map.

Groups A and B present interesting contrasts in their group and individual map layouts (see Table 4). We first examined the root word choices on pre individual, collaborative, and post individual concept maps. We found that all students used a machine as a root word on their pre individual map. Group A chose a machine root word, whereas Group B used a physics concept. Rose and Lincoln in Group A continued to use a machine as a root word on their post individual map, but Alex chose a physics concept. In contrast, all students in Group B changed from using a machine root word to using a physics concept root word on their post map, consistent with what had taken place in the collaborative mapping activity.

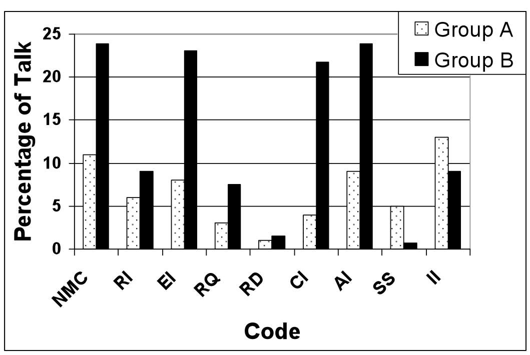
Second, we examined the structural organization of individual and group maps. Our analysis revealed that both groups drew relational group maps. Rose and Lincoln from Group A, and all students from Group B, had constructed hierarchical individual pre maps. Rose and Lincoln continued to draw a hierarchical map, but all students in Group B used a relational structure on the post individual map.

Table 4: Map Layout of Individual Students' in Group A and B's Pre and Post Individual and Group Maps.

| | | Root Word of Map: Machine (M) vs. Physics Concept (PC) | | | Map Structure: Hierarchical (H) vs. Relational (R) | | |
|---|---|---|---|---|---|---|---|
| Group | Student | Pre | Group Map | Post | Pre | Group Map | Post |
| A | Alex | M | | PC | R | | R |
| A | Rose | M | M | M | H | R | H |
| A | Lincoln | M | | M | H | | H |
| B | Betty | M | | PC | H | | R |
| B | Keesha | M | PC | PC | H | R | R |
| B | Jake | M | | PC | H | | R |

## Patterns of Group Dialogue and Individual Contributions in Groups A and B

We analyzed group dialogue to further understand the convergence or divergence that may have occurred when students engaged in collaborative concept mapping. This analysis was done to a) examine if students' ideas converged through engaging in collaborative interactions, and b) to see how convergence or divergence during the collaborative concept map activity related to individual map construction. These findings will enable us to understand how aspects of group dialogue may possibly explain the changes between students' pre and post individual concept maps. First, we will report on general discourse patterns for each group and compare the two groups (see Figure 1). Subsequently, we will present a more detailed analysis of each individual's major contribution to the group dialogue (see Figure 2).



| Code Legend | |
|---|---|
| NMC | Negotiation of Map construction |
| RI | Restating Ideas |
| EI | Extending Ideas |
| RQ | Raising Questions |
| RD | Resolution of Disagreements |
| CI | Contention of Ideas |
| AI | Agreement of Ideas |
| SS | Simple Sharing |
| II | Initiating Ideas |

Figure 1. Collaborative Concept Map Dialogue in Groups A and B.

In Group A, the most prominent pattern was initiating ideas (12.5%), agreement of ideas (8.75%), and extending ideas (7.5%). The percentage of talk related to the negotiation of map construction, was 11.25%. In looking at individual contributions to the collaboration, Alex's main contributions were agreement of ideas (20.69%) and extending ideas (13.79%). Rose's major contributions were initiating ideas (25%) and negotiating map construction and restating ideas (16.7%). Lincoln made a limited contribution to concept related talk (12.5%). Overall, the percentage of science related talk in this group during the collaborative concept mapping activity was relatively low, because a good portion of Group A's utterances were off task or not applicable to the study.

In contrast, Group B engaged in relatively more science talk during the collaborative concept mapping activity than Group A. Their dialogue mainly involved agreement of ideas (23.9%), extending ideas (23.1%), and the contention of ideas (21.7%). The percentage of talk related to negotiation of map construction was 23.9%. When examining individual contributions to the discourse, we find that Betty's talk focused on the contention of ideas (25.6%) and extending ideas (25.6%). Similarly, Keesha engaged in the group discourse through agreement of ideas (32.5%) and contending ideas (20%). Jake's principal involvement in the group process was mainly extending ideas (31%), but he also emphasized the negotiation of map construction (29.1%).

We found clear differences between the two groups' patterns of talk. Group A focused less on science, whereas Group B was focused on negotiating science ideas and negotiating map construction. Furthermore, the individual contributions from students in the two groups were also different. In Group A, students engaged less with the collaborative concept mapping and engaged in more talk unrelated to the activity and science. Students in Group B talked more about science concepts and contributed in diverse ways to their group map. Finally, a large proportion of talk in Group B was spent in contending ideas, unlike in Group A.

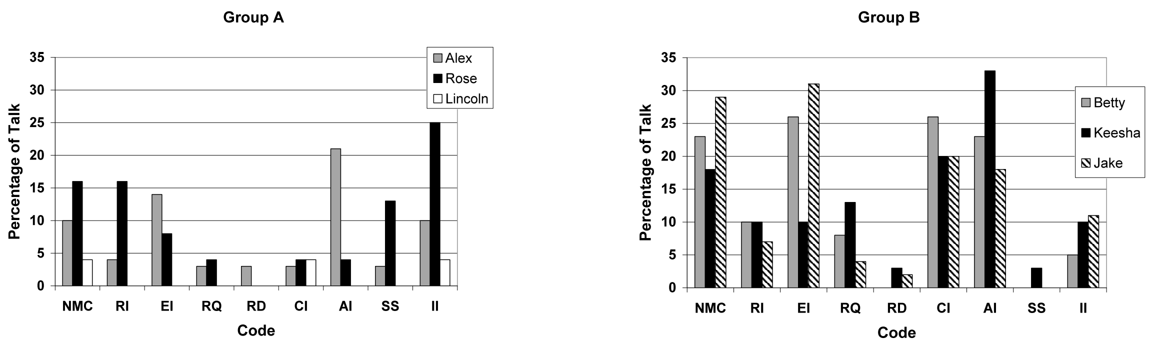


Figure 2. Individual Contribution to Collaborative Dialogue in Groups A and B.

## Discussion

Our exploratory study contributes to the literature on concept mapping and collaborative learning because it examines group maps both as conscriptional *processes* and inscriptional *products*. Our study is consistent with Daley et al's. (2008) call for research to understand how groups construct knowledge, and how this knowledge construction aids in group performance. It also aligns with Basque and Lavoie's (2006) emphasis for further investigation of the relationship between collaborative learning and concept mapping, particularly the types of interactions that promote learning.

In investigating whether a collaborative concept map serves as a conscriptional device in the classroom, we found differences between both the product and the process of collaborative concept mapping in the two contrasting groups. Our results indicate that there was less convergence between students in Group A than in Group B during the collaborative process. Roth and Roychoudhury (1994), as well as van Boxtel, van der Linden, Roelofs, and Erkens (2002), claim that collaborative concept mapping promotes shared understanding among students. However, our findings show that whereas a collaborative concept map may act as a conscriptional device to facilitate convergence of ideas, not all groups benefit equally from this activity when used in the classroom.

Students in Group A had pre individual maps that initially showed convergence. The negotiation and contention of science ideas and map construction between these students during collaborative concept mapping was relatively lower than Group B, resulting in a less sophisticated group concept map product, as evidenced by a lower depth ratio score and simple machines root word choice. Derbentseva, Safayeni, and Cañas (as cited in Novak & Cañas, 2008) found that root word choice affects the quality of a concept map. A physics concept root word may promote the creation of propositions focused on *relationships,* resulting in more sophisticated maps. Having a simple machine as a root word may lead to shallower, fact-based links. Further, Alex drew the map and was the only student in the group who made a relational map on the pre and post individual map. Despite having made a relational group map, Rose and Lincoln created hierarchical individual post maps. Ruiz-Primo and Shavelson (1996) have emphasized that relational maps provide a richer representation than a hierarchy, indicating more sophisticated maps. Group A's group map may reflect Alex's thinking more than that of the whole group, which could explain the low convergence in map layouts on the individual post maps.

The dialogue in Group A provides further evidence of a low level of convergence. We found that students in Group A did not participate equally in this process. Alex and Rose engaged in some negotiation of the science concepts, but there was little convergence on science ideas between group members. For example, of the ideas that Rose initiated many were also categorized as simple sharing, because they were not extended by the group, indicating limited mutual engagement as they discussed the science. Furthermore, Lincoln made little contribution to the science discourse. Thus, our findings suggest low convergence of science ideas in Group A.

Conversely, there was more convergence of science ideas among students in Group B. They created a more sophisticated group map than Group A, as measured by a higher depth ratio score, a physics concept root word and a relational organization. Students converged on their post individual map layouts, because all of them changed from using a machine-based root word to using a physics concept root word, and from a hierarchical to a relational structure, consistent with their group map.

Group B's dialogue provides further evidence for convergence. Group B had about twice as much dialogue about negotiation of map construction as Group A. These students contributed in diverse ways to the dialogue, which was more varied and involved more contention and negotiation of science concepts than Group A. Perhaps this dialogue contributed to both the changes and convergence of the map layout on individual post maps.

Our findings suggest that the level of convergence achieved during collaborative concept mapping could have influenced students' performance on the post individual maps. The students in Group A engaged less in constructing a shared understanding of the science ideas. Unlike van Boxtel et al. (2002), we found that students who actively contributed to the discourse did not always exhibit high learning gains. The post map depth ratios showed that Alex and Lincoln had greater learning gains than Rose's, whose depth ratio decreased. While Rose did engage in the science discourse, many of her contributions were not taken up, perhaps resulting in her less sophisticated post individual map and negative learning gain. Thus, the divergence in the level of engagement of ideas during the collaborative mapping activity in Group A could have played a role in their learning, resulting in differences in individual map layouts and learning gains on their post maps.

In Group B, the higher level of convergence during collaboration might have contributed to post map learning gains for all students and to more sophisticated map layouts by all three students in the group. For example, all of the students in Group B changed their root word to a physics concept and changed to creating a relational post individual map after having worked on a relational group map, suggesting greater convergence and sophistication. The higher level of convergence in Group B could explain the substantial learning gains of all individual students in the group. We contend that the remarkable growth of these students collectively and individually can be understood in light of Stahl (2004) and Schwartz's (1999) argument. First, Stahl (2004) suggests that divergent ideas between group members have a significant impact on collaboration. Because Group B started with more divergent individual maps, each student brought divergent ideas to the collaboration. The students also negotiated their diverse perspectives to construct a shared understanding. Individuals construct novel understandings as they attempt to create shared meaning during collaboration (Schwartz, 1999). Students in Group B constructed a sophisticated individual understanding after their collaboration, as seen in their substantial individual learning gains. This notion is further substantiated by examining data from the other three groups. Like Group A, Groups D and E, who were initially more convergent, made the least learning gains out of the five groups and created less sophisticated group maps. Alternately, like Group B, Group C, the second most initially divergent group, had twice as much average learning gain and made a more sophisticated group map than the three more convergent groups. These trends lend further credence to the notion that initial divergence between group members is important for productive collaborations and positive individual outcomes.

These results have important implications for the classroom, because the role that collaborative concept mapping plays as a conscriptional and inscriptional activity becomes complex in a classroom setting. For example, in this study, students did not contribute equally to the group activity, unlike in the experimental studies of van Boxtel et al. (2002). Also, students made unequal gains in their post depth ratio scores, a finding that is consistent with Teasley and Fischer's (2008) argument that collaborative activities do not ensure equal learning gains for all students. One area of concern is that the overall depth ratios are relatively low on individual post maps for students in all five groups. This indicates that there is room for improvement in the depth of science talk and learning gains. Further, our results question the validity of using collaborative concept maps to assess group understanding, because they may not reflect the ideas of the whole group. Specifically, these findings speak to the importance of the teacher carefully structuring and facilitating students' collaborative concept mapping. For example, our examination of transcripts revealed that the teacher focused more on the procedural aspects of map construction, than on emphasizing deep conceptual connections. This may have affected students' engagement with their map construction. Perhaps map quality might improve if teachers explicitly emphasize the importance of making deep conceptual connections in student discourse related to their maps, help students to establish group collaboration norms, and promote metacognitive reflection. Finally, our study sheds light on forming groups for classroom collaborative activities. Our findings lend support for the effectiveness of heterogeneous group composition to promote negotiation of divergent perspectives towards a shared understanding.

## Directions for Future Research

Future research could systematically investigate collaborative concept mapping with more groups in the classroom. Utilizing both audio and video to match student dialogue to the shared map referent may assist in this kind of analysis. Novak & Cañas, (2008) argue for presenting a *focus question* to facilitate richer map construction. Future research could explore both the effectiveness of focus questions in generating student negotiation towards shared knowledge construction and their impact during collaborative concept mapping. The growing interest in collaborative concept mapping and other collaborative activities in the classroom emphasizes the need for more research to understand the interactions occurring during collaboration and how these impact student learning.

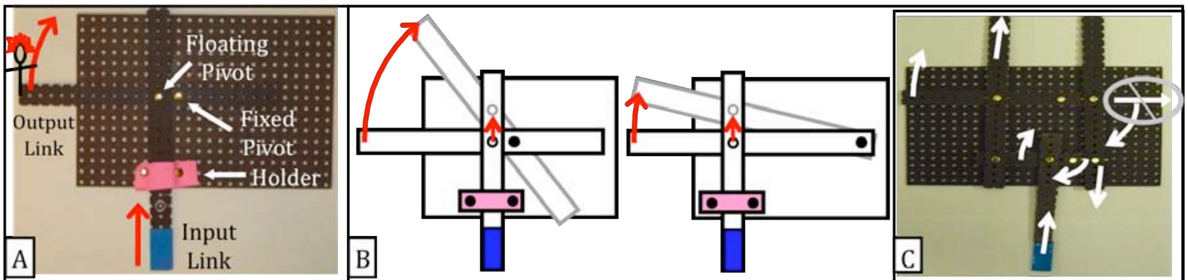
**Abstract:** Although simple mechanisms are commonplace, reasoning about how they work—mechanistic reasoning—is often challenging. To foster mechanistic reasoning, we engaged students in the third- and sixth-grades in the design of kinetic toys that consisted of systems of linked levers. To make the workings of these systems more visible, students participated in forms of activity that we conjectured would afford bodily experience of some of the properties of these mechanisms: constraint and rotary motion. Students progressively re-described and inscribed these embodied experiences as mathematical systems. We report a microgenetic study of one case study student, tracing how embodying and mathematizing motion supported the development of reasoning about how levered systems work.

## Introduction

Reasoning about mechanisms (i.e., mechanistic reasoning) is a key to understanding the designed world. Yet, despite the ubiquity of machines in our culture, and concerted efforts to support mechanistic reasoning in schooling (e.g., simple machine curricula in elementary grades), most students continue to find this form of explanation challenging (Lehrer & Schauble, 1998; Metz, 1991). To support the growth of mechanistic reasoning, we engaged elementary students in the design and construction of kinetic toys. However, our approach to learning by design included efforts to embody and mathematize (Kline, 1980) mechanical systems, such as the simple levered machines depicted in Figure 1. Though mathematical ideas are an intricate part of explanations for mechanical systems, engineering curricula for children often neglect mathematics as a resource (Prevost & Nathan, 2009). Our guiding conjecture was that mathematical description of levered systems would help children reason causally about objects and relations within the system. Our approach was anchored in a body-syntonic (Papert, 1980) wherein initial mathematization emerged from bodily activity, which was then re-expressed with the operation of the simple machine. The instructional design was informed by a prior study of children's naïve reasoning about these simple machines, in which children predicted and explained the direction and amount of output motion.



A: Levered machines are constructed from pegboard and links. Floating pivots are formed by connecting two links and fixed pivots by connecting a link to the pegboard. Holders restricted a link's sideways motion. Outputs were marked with stick figurines.

B: Key: Floating Pivot ○ Fixed Pivot ● Amount of Input Push ↑

Contrasting machines A1 and A3 were used to elicit children's reasoning about relative amounts of motion for input and output. Given the same input push, the output for Machine A1 will move much further than that for Machine A3.

C: Arrows show motions that could be visualized when reasoning about motion of this machine. The circled and crossed out arrow shows impossible motion that preserves the static shape of the machine.

Figure 1. Pegboard machines explained by children.

## Children's naïve mechanistic reasoning

Children in our previous study (Bolger, Kobiela, Weinberg, & Lehrer, 2009) exhibited a wide range of ability in predicting and explaining machine motion. Mechanistic explanations existed, but more commonly children explained machine motion by describing pattern regularities that they noticed (ie they related a cause and effect without explaining the mechanism for the relationship) or they provided fragmented explanations with some of the elements necessary for a mechanistic explanation. Some aspects of levered machine's mechanisms seemed particularly problematic for most children. First, most did not seem to "see" rotation in ways consistent with the operation of the machines. For example, children's gestures often indicated impossible motions that preserved the shape of the machines (Figure 1C). Talk or gesture to indicate rotation of links was not common in most children's explanations. Among the 9 children interviewed, 3 never indicated rotation and 4 did so only in one or two instances. In 22 instances where children drew paths with their fingers to predict output motion that should have been arced, 17 drew straight lines. Even after children moved a machine, they infrequently described rotary paths, seemingly focusing on starting and ending points rather than intermediate motion, as described by Piaget, Inhelder & Szeminska (1960). Second, most children rarely if ever suggested that fixing a link to the board would constrain its motion (4 children never did so and 3 did so on one occasion). Out of 72 total machines explained, there were only 6 instances in which a child recognized *both* constraint of the fixed pivot and rotation, emphasizing the difficulty of *coordinating* these two ideas. Third, children also had difficulty reasoning about relative amounts of input and output motion (which is important to understanding the concept of leverage). Children rarely paid attention to how far links moved, even when a paired contrast was used to draw their attention to this feature.

## Theoretical framework for designing instructional supports

In summary, students had difficulties with: 1) Recognizing an output link's rotation and causally ascribing that rotation to the constraint of the fixed pivot; and 2) Noticing and reasoning about the amount of motion traveled by an output link. In an effort to support these foundations of mechanistic reasoning we designed instruction to support development of reasoning about constraint, rotation and amount of relative motion of inputs and outputs.

Our instructional design is centered on embodied experiences that support student understandings of the mechanisms of the physical system and that provide a prospective pathway for mathematization of the system. Figure 2 suggests that mechanistic reasoning emerges from coordination of embodied experience and mathematization, a perspective consistent with Papert's (1980) conjecture about the role of embodied experience in mathematical development and the more recent work of Lakoff and Nunez (2001) and Barsalou (2008).

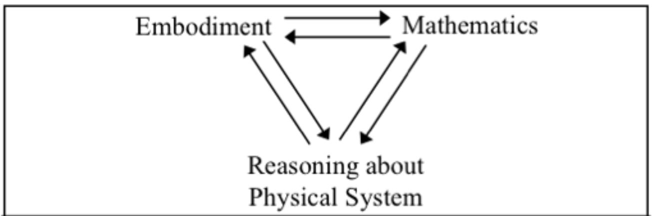


Figure 2. Supporting Learning.

Coordination between embodied experiences and mathematics is consistent with Freudenthal's (1973) notion of "progressive mathematization." Freudenthal states that to implement a program of progressive mathematization successfully, students have to use their experience (e.g., embodied experiences) and invent mathematics through well-developed instructional activities. We drew upon several decades of work leveraging experiences of walking (e.g., a path perspective) as grounds for developing a mathematics of space (e.g., Jordan & Henderson, 1995; Lehrer, Randle, & Sancilio, 1989). In this study, we capitalized on the students' embodied experiences through instruction that supported incorporation of experiential relations into more formal mathematics. These experiences allowed for students to take a path perspective of a moving part within the levered system. Further, we sought to help students integrate these mathematical ideas into their developing explanations for the function of the levered machines.

## Disruption of "Straight": The Embodiment of Rotation

This section describes one embodied task designed to take advantage of the relations in our theoretical model (another task was also designed, but we do not describe it here). We unpack task features that could directly contribute to multi-modal conceptual development (Barsalou, 2008) and highlight the relevant mathematical features of the system as potentially experienced by a student. This task was framed around an apparent tension or disruption, thereby problematizing the construction of an explanation for the experienced phenomenon.

The embodied task (illustrated in Figure 3A) was designed to address two qualities of the mechanisms: 1) fixing a link in one place generates a circular path and 2) the length of this circular path is related to the distance from the pivot to the output. We first engaged students in a conception of "straight" from a path perspective as no turns—a constant heading while walking. We then paired students - one held one end of the rope and remained in place (acting as the fixed pivot) while the other held the other end of the rope and attempted to walk in a straight path perpendicular to the rope's orientation (See Figure 3A). The student walking literally experienced the effect of constraint on path, while the student in the "center" experienced the force required to accelerate (constantly changing direction) the walker. The task was experienced twice with different lengths of rope. The constraint disrupted straightness and produced a circular (i.e., rotary) path, turning a constant amount as the student continued to walk at about the same rate. Ideally, this disrupted straight path, and its description as a mathematical object, could serve as a resource for explaining the operation of a system of levers.

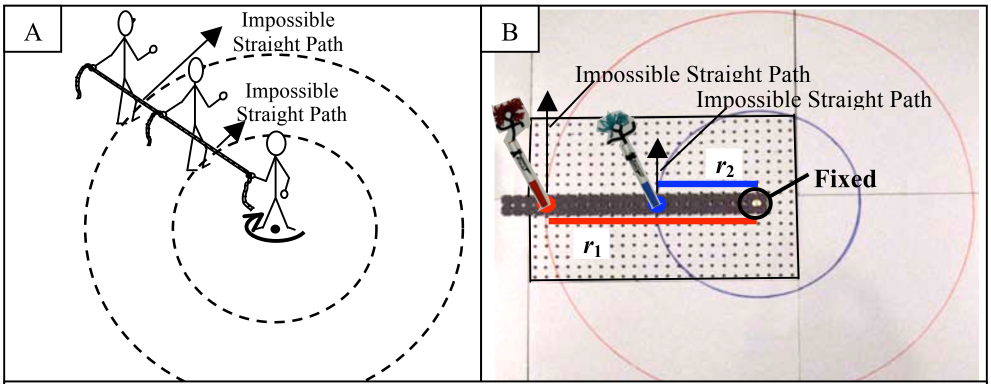

Figure 3. Disrupting "Straight" through Embodied Circular Walks with Rope.

Table 1 elaborates the task's embodied experiences, the mathematics involved in those experiences, and their relations to the physical levered system. During the embodied task, the student walking experienced the disrupted straight path: as he tried to walk straight, the constraint of the rope forced him to turn. Later when the student would be asked to reason about actual levered machines, the system's constraints would be made real by the experience of feeling the rope's pull. To help bridge between the embodied experiences and the physical system "little men" figurines were placed on the links to resemble walkers within the system (Figure 3B). The student who stood in the center, holding the rope, experienced standing in place, feeling "stuck," while pulling the other student toward a circular path. For her, the role of the fixed pivot was magnified as important in resisting the other student's pull to move straight, a resource as she later reasoned about the role of the fixed pivot in the physical system. The different perspectives taken by the two students could influence how the experience served as a resource for reasoning about the physical system. The perspective of the first student was that of a circular path, seeing himself move *around* the student holding the other end of the rope. As he walked, he may have also felt his body constantly turning. When the rope was shortened, this turning accelerated and he may have felt himself going around faster (that is greater angular rotation in the same amount of time) because of the decreased path length. The perspective of the second student did not include a circular walk, but seeing the walker move around her, furthered her experience as "center." When the rope was shortened, the she may have seen the other student moving around her at a faster rate. We conjecture these perspectives are significant in helping students mentally animate the operation of the pegboard machine.

The mathematization of the embodied experience is intended to help highlight relevant features of the experience and the relations between those features that can then be used to reason about the physical system. The stationary student may be thought of as a center of a circle, where the circle is created by the person walking along the constrained path caused by the fixed length of the rope. The rope gives significance to the (otherwise invisible) constant radius of the circle. In this sense, the mathematical features of the experience map directly onto the physical system: the person in center of the circle becomes the fixed pivot, the walking student becomes an output on a link traveling in a circular path. Additionally, the mathematical features can be used to help explain the "unable to walk straight" phenomenon (the path *must* be circular *because* there is a constant radius, - $r_1$ and $r_2$ in Figure 3B). Because a radius exists between the fixed pivot and the output, this mathematical relationship causally connects the constraint of the fixed pivot with the rotary motion of the link. The shorter rope may be then thought of as a shorter radius ($r_2$). In this sense, the path walked is shorter because the circle created is smaller. Mathematically, this occurs because of the proportional relation between the radius and the circumference. Later, when students are asked to reason about the *amount* of motion of an output as it relates to the distance between output and fixed pivot (i.e., radius), they can take the perspective of walking a smaller or larger circle using the longer or shorter rope.

Table 1: Embodied Experiences, Mathematics and the Physical System Related to the Rope Walk.

| Embodied Experience | Mathematics | Physical System |
|---|---|---|
| A ***person*** holds one end of a ***rope***. Another ***person*** holds the other end. | A point (***center***) is drawn with a line (***radius***) ($r_1$) extending out from it. Another ***point*** is drawn at the other end. | A ***link*** is attached to a pegboard at the end with a ***fixed pivot***. The other end is marked as the ***output*** (with a figurine). |
| One person tries to walk straight while the other rotates in place. His straight path is quickly disrupted by the constraining force of the rope held by the other person. | One end of the radius cannot be swept in a straight path without moving *both* ends of the line. | The output cannot be moved in a straight line without removing the fixed pivot. |
| The person walking is forced by the rope onto a ***path going around the person*** rotating in place. The walker is always the ***same distance*** from the center person. | A ***circle*** is created by sweeping the radius (***constant length***) ***around the center point***. | The output ***rotates around the fixed pivot***. At any point in the rotation, the output always remains the ***same distance*** from the fixed pivot. |
| The rope is now exchanged for a ***shorter rope*** and the person walking again attempts to walk straight. | The new, ***shorter, radius*** ($r_2$) is created. Again, the radius cannot be swept in a straight path without moving both ends of the line. | The output (figurine) is now moved in ***closer to the fixed pivot***. Again, the output cannot be moved in a straight line without removing the fixed pivot. |
| The walker is again forced onto a path going around the person rotating in place. This time, the path is ***shorter*** and the walker goes around ***faster***. | A new ***smaller circle*** (with smaller circumference) is created when the shorter radius is swept around the center point. | The output again rotates around the fixed pivot. This time, the path looks ***smaller***. |

## Methods

A microgenetic method was employed, featuring one child and one teacher, lasting an average of approximately 7.2 hours over 8 days. The rope embodiment activity, described above, took place on the first day of instruction. Around the fourth day of instruction, most students participated in a second embodiment activity designed to highlight relative input and output motions. Most instruction was centered around simple design challenges (for example, 'Can you make something that moves using these 3 links?' or 'Can you change this machine so that the output moves in the opposite direction?'). Students also designed and constructed a MechAnimation (a decorated toy driven by levers). Participants (n=11, 5 male) (5 third graders, 6 sixth graders) attended two urban schools in the southeastern United States. Sixty-percent of students at the middle school and ninety-percent at the elementary qualified for free or reduced lunch. The children were ethnically diverse and represented a wide spectrum of achievement in school. To assess gains in predicting and explaining machine motion, children were interviewed before and after instruction.

We chose to carefully study the learning of one child, Sarah. We chose Sarah primarily because of her willingness to express her thinking to us. Though she was a fairly successful student in school, she did not demonstrate a strong naïve ability to predict or explain levered machines in her pre-interview. Analysis of Sarah's learning included coding of her interviews (using the framework from our first study), group video noticings (Jordan & Henderson, 1995) of each day of instruction, and microgenetic analysis of the transcript and video to trace prospective relations between embodiment experiences and other instructional activities.

## One Student's Use of Embodied Activity in Reasoning about Pegboard Machines

We follow Sarah as she engaged in the embodiment task, represented her experience through drawing, and considered the operation of a single link connected to a pegboard. We highlight ways that the experience seemed to be a resource for reasoning about difficult concepts—that is, how constraint of the fixed pivot necessitates rotary motion, mental animation of the system and relations influencing amount of lever motion.

### Sarah's Embodied Experience

As Sarah performed the embodiment task, described earlier, the teacher took hold of one end of the rope and asked Sarah to hold another part of the rope several feet away. The teacher then asked Sarah to "try walking in a straight line that way" (pointing to indicate direction) while keeping the rope taut. Sarah immediately sensed difficulty, at first hesitating ("but uh") and then asked whether she should "turn." The teacher repeated the request to "try to walk in a straight line." As Sarah walked, she described feeling constrained and then *having* to turn. Note that italics in transcript represent ideas that we wish to emphasize; student's or teacher's emphasis is denoted by all caps.

> S: The um-*I can't move any more*…Like the rope can't (?) you *have to turn*.
> T: And then if you kept on just moving (Sarah continues the rotary walk)…what would start to happen?
> S: I would go in like (gestures in a circle with her arm) a *circle*.

Feeling the force of the rope constraining her, Sarah acknowledged that her path was circular. By taking this perspective, she seemed to experience a causal relation between the constraint of the rope and the rotary path. The teacher then highlighted the constant rope length of the walk. She asked Sarah to approximate the amount of rope between them, first standing at one position ("a fourth of the rope") and then standing at another position ("*still* a fourth"). The teacher asked about *all* possible positions: "And then so *anywhere* we turn?" Sarah completed the generalization by concluding that "it's *still* a fourth," By highlighting this feature of their experience, the teacher attempted to help Sarah relate the circular path of her walk to the unchanging distance between her and the teacher.

Finally, Sarah was asked to walk the circular path again, but with a shorter rope length. This time, Sarah was not directed to walk straight but instead immediately asked to "turn." While walking, Sarah initially observed that the path was again a circle and when the teacher asked her for more details, she noticed that "it'd be smaller." The teacher again scaffolded a generalization of the experience, this time emphasizing the relation between rope length and circle size. Moving her hand along the rope, she asked, "so when this becomes smaller?" Sarah completed the generalization, "the circle gets smaller." Thus, through the contrasting walks, a sense of magnitude as "smaller circle" emerged, as well as a relation between the rope length and the distance of the circular path.

## Inscribing the Embodied Experience: Moving towards Mathematization

Immediately following the embodied activity, the teacher requested that the student draw two pictures to show the two different rotations: with the long and the short rope. Her drawing (see top of Figure 4A) showed two circles, one smaller than the other, each with a line extending from it with a point at each end. As Sarah began to explain the drawing, it was evident that she had mathematized all of the relevant *components* of the experience (that is, the people as points, the rope as a line and the walk as a circle), but not all of the *relations* between them. Although her drawing accurately depicted relative differences in circle size and radius (smaller rope, smaller circle), it did not represent radius as moving *around* a center and the circular path as emerging from that interaction. However, Sarah realized this problem when attempting to reenact the experience within the drawing.

> S: I drew me (points to top dot in her drawing) and then you (points to bottom dot in her drawing) and then (moves finger back to top dot) I was holding the rope and (moves finger back to the bottom dot) then *when*, no but that's wrong.

Sarah's inability to animate her drawing motivated a new one (see bottom of Figure 4A). This time, she animated the static representation as she drew and explained. As the static components of the drawing were made dynamic, relations among them emerged. While explaining her drawing, she not only imparted agency within it, but also re-enacted the experience (via gesture) through it: "This one (points to the dot inside the rightmost circle) would be you. And me (points to the dot on the circle) holding the rope *going around* (moving her finger around the circle)."

Sarah's first drawing suggests that while she related "rope length" to circle circumference, this length had not yet been fully mapped to "radius". As she reasoned about the embodied experience and the representation together, her mathematization of the system showed structural relations of the circle—the rope became radius and the teacher (precursor for the fixed pivot) moved *inside* the circle. Her final drawing also symbolized three ideas that became important later in the session – fixed pivot as the center of the circle, the constant radius of the circle, and the relationship between radius and circumference.

## Reasoning about Rotation around a Pivot: Mapping to the Physical System

Within the pegboard system, Sarah's notion of "center" began to take on functional significance. After inscribing the embodied experience, the teacher gave Sarah a pegboard, a link, and a brad fastener and asked her to attach the link to the pegboard any way she wanted. Sarah placed the pivot at the very end of the link, a structure resembling the teacher standing and holding the end of the rope. Interestingly, when asked to describe her machine, Sarah spontaneously mapped the link's movement to this experience: "it [the link] can move around but, yeah like it can move around like rotating *how we did*." Moreover, as she continued describing the machine, she noted new relations among the parts of the system. We suspect that the literal resemblance of the machine's structure to the embodied experience perhaps afforded a "bird's eye" perspective of her previous experience that made these relations salient.

> S: …it *can only rotate* in like this spot (points to the fixed pivot) and no other (waves hand over the mechanism) spot…Like the starting point (touches fixed pivot) you can only start here (touches pivot again) and not start (points to the left of the fixed pivot) somewhere else because this (points to the fixed pivot multiple times) is *stuck* to THAT (points to pivot again) place.

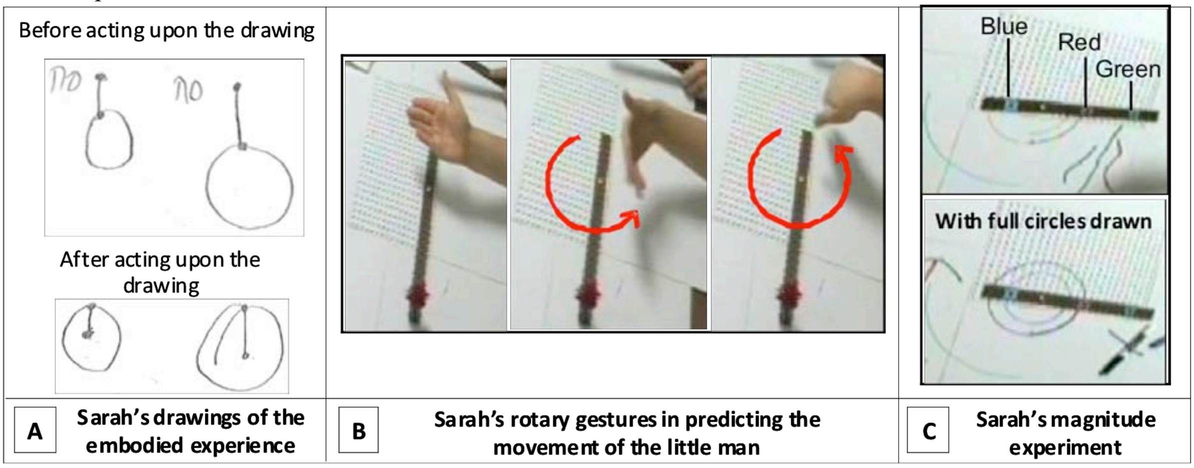

Figure 4. Sarah's use of her embodied experience.

Sarah's notion of "stuckness" attributed to the fixed pivot illustrates an important notion of constraint: that it is unable to move. Furthermore, by describing the rotation as only occurring "in like this spot," she indicated some sense of the source of rotation originating from the fixed pivot.

These ideas of coordinating the rotation of the link to the constraint of the fixed pivot resurfaced again a little later in the session. The teacher had moved the fixed pivot in towards the center of the link and had placed a little man figurine on the left end. She asked Sarah to predict the motion of the little man supposing they were to push the link, pointing to a particular place to the right of the fixed pivot. Sarah correctly predicted the direction of the man, invoking her knowledge of the link's rotary motion. She explained that, "this [the link] will *spin*," gesturing with her hand in a circular motion (Figure 4B). During her pre-interview, Sarah didn't talk about turning or spinning and didn't make rotary hand gestures (with the exception of her noticing the rotary motion of a round-shaped piece of pegboard), suggesting a different way of thinking that may have been supported by the tasks that proceeded this episode.

After testing Sarah's prediction, the teacher asked her how she had known that the path would be curved. In her explanation, Sarah again invoked the importance of the fixed pivot's immobility, but this time indirectly referencing the experience of trying to walk straight: "…it's not going up, it's just … on one brad and when you hit it (gestures pushing link), it will go, that way (gestures rotation) cause it (points near the fixed pivot) *can't always go straight*. Yeah cause it can't move up. It's *in its place*." Here, unlike in her earlier talk, the rotation of the link and the "stuckness" of the fixed pivot are more than simply related. Rather, Sarah now attributes the rotation to the constraint of the fixed pivot, giving it functional significance.

## Using Mathematics of the Circle to Reason about Magnitude of Link Motion

The final task undertaken on the first day of instruction was to focus on the relationship between two distances - the distance from a point on the link to the fixed pivot (radius) and the distance traveled by that point (arc length or circumference). This relationship forms the precursor for understanding the relationship between the magnitude of input and output motions. For this task, the teacher stipulated that the link would be rotated ¼ turn, marking the starting and stopping points. She then asked Sarah to choose 3 places on the link to put colored stickers to correspond with where the "little men" would be placed (Figure 4C, top image).When asked to predict how each sticker would move, Sarah understood that all stickers would rotate, but their paths would have different lengths: "I think that. They will move different-No they won't move differently but they're um (points to the board and then moves finger in a circle) lengths I think will be different." When the teacher talked further to Sarah about her prediction, Sarah spontaneously referred to her embodied experience "So they'll like (gestures finger in circles again) turn the same way but like our *rope* was different lengths and their shape is going to be smaller or bigger." Hence, Sarah seemed to use her experiences to reason that the rope length (radius) would affect the size of path walked (circumference) in this simple physical system. However, her specific mapping of the "rope length" onto the link was less clear as she went on to incorrectly predict the relative distances that each sticker would travel.

Sarah was guided by her teacher to find a generalization that would allow her to accurately predict the relative amounts of motion for points along the link, but she eventually came to an impasse. She explained her first prediction (blue>green>red) this way: "So yeah like the outer it is the bigger it's gonna be so this (points to blue sticker) is outer". Here, Sarah would be correct, if the link rotated around its center rather than the fixed pivot. After measuring the relative amounts traveled by the stickers (green>red>blue), Sarah created a new incorrect explanation to fit the observations at hand, "I think that the closer it is to (points to green sticker) this end, it will go the most and the farthest it is to that end (points to the right end of the link), it will go the least." When the teacher offered a counter example to disprove this new theory (the distance traveled by a point at the far left end is greater than the distance traveled by the blue sticker), Sarah was unable to pose a new explanation. At this point, it seemed that the fixed pivot was invisible when Sarah reasoned about these relative distances.

Finally, the teacher helped Sarah draw the full circles traveled by the stickers and by the point at the far left end of the link (Figure 4C, bottom image). This far left point, which began as an unexplainable counter example, was repurposed to provoke an explanation that involved the radius and the fixed pivot as center of the circle:

> T: So why do you think the [point at the left end] and the red went the same? Are on the same *circle*?...
> S: (gasps) Oh:: Maybe because like uh this one is (points to the far left end) one two three four (counting the holes) five six and that one's (points to the red sticker) one two three four five six. It's the same distance close to the brad.

The relevant mathematical relationship seemed to appear when the circles were drawn. This teacher move served a dual purpose – drawing the visual focus to the fixed pivot as center and bringing the task closer to the embodied experience. In the preceding section, we saw that Sarah seemed to draw from her embodied experience as she reasoned about the direction of turn for this same machine. However, when she moved to a slightly more complex task, seemingly small details (i.e. locating the pivot away from the end of the link and drawing arcs instead of complete circles) may have been enough to disrupt a literal mapping to the embodied experience. This speaks to the importance of teacher sensitivity about appropriate scaffolds that will allow for best use of embodied experiences. Interestingly, on later days of instruction, Sarah spontaneously invoked the embodied experience when asked to reason again about the radius-circumference relationship, suggesting that the experience was a useful support beyond its immediate context. For example, in the third day of instruction, when Sarah was asked again to explain the same phenomenon (also with a single link mechanism), she provided the following explanation.

> T: Why is it when it's really far it's making a big circle, like what MAKES the circle?
> S: Cause us like when we were doing the *rope*. There is only like, pretend this is me (points to green sticker) and that was you (points to pivot). There was only like this much *distance* between us.
> T: You can only like (turns her body in constrained manner)
> S: Yeah, like move that much.

Sarah's difficulty with reasoning about magnitude of link motion prompted the development of another embodied experience used later in instruction.

## Conclusion

We designed embodied experiences (Papert, 1980; Abelson & diSessa, 1980) to support "mathematization" (Kline, 1980) of mechanical systems, namely those containing simple levered machines. Drawing from our previous studies, we targeted particular naïve student conceptual difficulties that were seen in most students, even when working with the machines. These were: viewing rotary motion in the machines, attending to the amount of output link motion, and reasoning about the constraint resultant from fixing a link to the pegboard. Embodied experiences served as a resource for progressive mathematization of the system (Kline, 1980; Freudenthal, 1973), aided by strategic teaching supports, such as: asking the student to represent the literal embodied experience on paper, asking the student to reason about a physical system that closely resembled the embodied experience and frequently revisiting how relevant features of the embodied experience mapped to the physical system.

With our case study student, Sarah, the embodied rope experience and subsequent teaching supports seemed to help her reason about each of our target concepts. Though Sarah did not address the rotation of links in her pre-interview, this idea flowed readily from the embodiment experience. Within the experience, she noticed herself going "around," an idea later resurfacing in her drawings, talk and gesture. Though this experience helped Sarah readily see circular paths, she required additional supports to see other mathematical features of circles. Reasoning around her representation seemed to help Sarah map the "rope" to radius. As Sarah revised her drawing, she appeared to reenact the experience, imparting agency and replaying motion through gesture. Further, the relationship between radius and circumference, a necessary precursor to understanding the *amount* of output motion, was not obvious to Sarah. By helping Sarah work with the physical system (and adjusting it to visually cue the embodied experience), the teacher was able to guide her to discover this relationship and map it in a lasting way to the embodied experience.

Sarah's process of reasoning about how the fixed pivot served to constrain motion was refined throughout the first day of instruction. During the embodied experience, she talked about how her walk was constrained to a circular path, but the source of this constraint was not evident. As she refined her representation, the fixed pivot (teacher) was moved *inside* the circle. When she built the simple physical system and mapped it back to the embodied rope experience, she noted for the first time that the fixed pivot was "stuck" and assigned it significance as the source of rotation. When directed to reason about the path of a "little man" on the link she causally connected his circular motion with the fixed pivot as constraint. However, as instruction continued Sarah had difficulty locating the fixed pivot as the circles' center as well as maintaining a notion of fixed pivot as the source of the disruption of straight. We conjecture that Sarah's lack of experience acting as the fixed pivot in the embodied experience may have made her less aware of its role as a constraint.

Our results suggest that integrating mathematics into an engineering curriculum can support students as they begin to construct explanations for simple machines. However, many questions remain as to how best integrate mathematics in ways that will be accessible and meaningful to students and that will best support mechanistic reasoning. Current research is focused on answering these questions through further microgenetic analysis as well as analysis of data from intact classrooms. Classroom instruction used similar embodied activities, but was able to capitalize on the variety of student ideas. Comparison of ideas was used to motivate student reasoning.

# "Romantic" beats "classic": New insights on the effects of self-regulation on learning by writing

**Abstract:** For several decades writing has been advocated as an academic activity that can facilitate knowledge acquisition. Theories of writing and models of writing development that researchers draw on to explain the positive effects of writing to learn emphasize the importance of self-regulation, particularly, planning, monitoring and revision. Yet, there is some empirical evidence indicating that the self-regulation of writing may be detrimental to learning. To analyze systematically the effects of self-regulation on learning by writing we conducted an empirical study. Participants (*n*=87) read an instruction that induced (1) self-regulated writing, (2) spontaneous writing or (3) self-regulated and spontaneous writing. Under the control condition, participants did not receive instruction in writing to learn. All participants then wrote an entry to a learning journal. Results showed that self-regulated writing exerted a negative influence on knowledge construction during writing and on post-test performance. In light of these findings, the emphasis on self-regulation strategies in writing-to-learn instruction should be reconsidered.

## Introduction

As they move through high school and college, students engage in a variety of writing activities. They write to improve their writing and argumentation skills, to document academic work or to demonstrate what they have learned in a class. Teachers also assign writing-to-learn tasks which aim at supporting students in acquiring or deepening their knowledge of subject matter. One of the tenets of research-based writing instruction (e.g., Graham, 2006; Harris & Graham, 1992) is that learners should be taught to self-regulate their writing, i.e. to plan, monitor and revise the rhetoric, structure and content of their texts. However, the rhetorical and structural quality of the written product is not the main target outcome of writing to learn, in contrast to other academic writing activities such as writing a term paper or completing an essay exam. Hence, learners may not benefit from self-regulating their writing when engaging in a writing-to-learn activity. There is some empirical evidence suggesting that adopting a self-regulated stance toward writing, which Galbraith (1992) referred to as "classic", may indeed be detrimental to learning. Galbraith (1992) found that learners who adopted a "romantic" stance toward writing, treating writing as a spontaneous, creative process not involving the planning and monitoring of text characteristics, showed higher gains on measures of knowledge construction than those who adopted a "classic" stance toward writing. However, empirical studies involving a typical writing-to-learn task (such as journal writing) and comparing the effects of the self-regulated ("classic") stance and the spontaneous ("romantic") stance toward writing are missing. Therefore, we conducted an empirical study in which we instructed students to adopt different stances toward writing and had them write an entry to a learning journal. Our aim was to advance research on self-regulation and learning by writing and to contribute to the improvement of writing-to-learn instruction. Before reporting on the study we sketch the theoretical and empirical background relevant to our research.

## Self-regulation in cognitive theories of writing

Despite empirical evidence of the positive effects of writing on learning there are few models of processes of writing to learn. Therefore, researchers draw on cognitive theories of writing to explain the knowledge and achievement effects of academic writing activities. Klein (1999) subsumed research on learning by writing under four sets of theories: Shaping at the point of utterance, forward search, backward search and genre. The perspective on the self-regulation of writing offered by the "shaping at the point of utterance" and "forward search" models differs widely from that of the "backward search" and genre models. As a consequence, they also differ in their implications for writing-to-learn instruction.

The "shaping at the point of utterance" theory was proposed by Britton (1982). The central assumption of Britton's model is that knowledge emerges as ideas are expressed in writing. Therefore, writers should engage in spontaneous writing and not focus on the linguistic and rhetorical characteristics of the written product. That is, they should not self-regulate their writing. The assumption underlying Britton's model forms the backbone of the "forward search" models of writing-to-learn: Producing text in a spontaneous fashion allows the writer to reread and reflect on his ideas which triggers further idea generation, setting of rhetorical goals and text revisions. What Klein has termed forward search is strongly advocated by Galbraith (e.g., 1992). He argues that writing does not yield learning through a sequence of self-regulatory processes (planning, translating, monitoring and revising). Instead, he proposes that ideas are generated as the writer's implicit knowledge and the emerging text interact. Hence, when the goal of writing is knowledge acquisition writing should take the form of "spontaneous spelling-out of ideas in continuous prose" (Galbraith, 1992, p. 45) with subsequent linguistic and rhetorical revisions to the text. Rhetorical goals are not set prior to writing but emerge during writing. Galbraith refers to this stance toward writing as "romantic" – an allusion to romanticist writers' departure from adherence to prescribed rhetorical formats.

Empirical studies on the effects of writing-to-learn instruction that is based on "shaping at the point of utterance" and "forward search" models are scarce. There is some evidence of the benefits of revising notes taken during lectures (Benton, Kiewra, Whitfill & Dennison, 1993) and of rereading and revising entries to a learning journal (Hübner, Nückles & Renkl, 2006). Moreover, studies from writing research indicate that expert writers revise their texts several times to increase the global coherence of their output whereas novice writers make mostly linguistic and rhetorical revisions at the sentence level (Klein, 1999). Theoretical considerations speak in favor of and against instructing writers to adopt a "romantic" stance when engaging in writing-to-learn activities. On the one hand, externalizing ideas in writing may free working memory capacity for deeper processing and the external representation may facilitate the drawing of inferences. On the other hand, the continuous text that is written spontaneously has to be processed in order to trigger idea generation and revisions which may actually increase working memory load (Torrance & Galbraith, 2006).

The "backward search" and genre models provide a different perspective on the self-regulation of writing than the models just described. Among the theories described as "backward search" models by Klein (1999), the Bereiter and Scardamalia (1987) model has been the most influential in writing-to-learn research. According to Bereiter and Scardamalia's *knowledge transforming* model, expert writers move between the content space, which represents their knowledge and beliefs about the topic they intend to write about, and the rhetorical space, which contains their knowledge and beliefs about the context of the writing activity and the rhetorical goals they intend to direct their writing at. As they move continuously between the two spaces, expert writers solve the "problems" of what to say and how to say it by setting rhetorical goals, breaking them down into subgoals, translating knowledge into text to satisfy the goals, checking whether the goals were met and revising the text accordingly. Moving between the two spaces is supposed to yield learning as writers transform, i.e. restructure, their knowledge as they do so. The Bereiter and Scardamalia model is similar to genre models of writing (Klein, 1999) in that self-regulatory processes directed at the production of high-quality text are considered essential to learning. The core assumption of the genre models (e.g., Langer & Applebee, 1987) is that writing genres impose specific structural, linguistic and rhetorical constraints. In order to meet the requirements of the respective writing genre, learners have to self-regulate their writing which in turn induces deep-level cognitive processes, for example, identification of links between arguments and critical evaluation of counterarguments in the case of a compare-and-contrast essay.

Most of the evidence presented in support of the Bereiter and Scardamalia (1987) model stems from studies comparing expert writers' strategies and novice writers' strategies. The studies converge on the finding that expert writers plan and revise their texts more often and at a deeper level than novice writers. And the extent of their planning and revision activities is related to the quality of the texts they produce (for a review, see Klein, 1999). Kirkpatrick and Klein (2009) recently demonstrated that training secondary students to use planning strategies when writing analytic essays increases the quality of the texts written by the students. As with most studies on writing, however, Kirkpatrick and Klein did not include outcome measures of knowledge in their study. There are studies which provide support to the assumption of the genre models. Langer and Applebee (1987), for example, reported on the positive effects of analytic writing on comprehension with secondary students. However, the link between the characteristics of writing genres and the cognitive processes supposed to be triggered by them has not been established.

As pointed out at the beginning of this section, the "shaping at the point of utterance" and "forward search" models and the "backward search" and genre models imply different approaches to learning by writing. Galbraith (1992) contrasted the "romantic" stance toward writing with that of Bereiter and Scardamalia (1987) and termed the latter the "classic" stance toward writing, referring to the strict adherence of the old Greek writers to stylistic conventions. The writer adopting a "classic" stance carefully plans what to write in which way and engages in self-monitoring during writing. In his study, Galbraith provided participants either with a "classic" writing instruction (writers were supposed to plan a text) or with a "romantic" writing instruction (writers were asked to write a text without focusing on its structure and rhetoric). Galbraith found support for the "romantic" approach. Writers who adopted this stance toward writing outperformed those who adopted a "classic" stance on measures of idea generation and knowledge acquisition. However, the participants in his study were not instructed to write in order to learn but to produce a piece of text about a topic of their choice. A controlled experiment including a typical writing-to-learn task is still missing.

Before we report on our study we now turn to research on learning by writing and its implications for writing-to-learn instruction.

## Research on learning by writing

In the 1970s, researchers and educators began to advocate the inclusion of writing activities not only in language classrooms but also in mathematics and science classrooms in high school as well as at the post-secondary level (e.g., Fulwiler & Young, 1982). Although the voices of the *writing-across-the-curriculum* advocates have somewhat faded off their arguments stand strong. Writing has been shown to contribute to knowledge acquisition in a range of academic disciplines (e.g., Applebee, 1984; Connor-Greene, 2000; McCrindle & Christensen, 1995; Rivard, 1994) and to produce positive effects on academic achievement (Bangert-Drowns, Hurley & Wilkinson, 2004). However, the effects identified in writing-to-learn studies are typically small and found under certain conditions only. Nückles, Schwonke, Berthold and Renkl (2004), for example, showed that graduate students who engaged in journal writing over the course of a semester but were not instructed in writing to learn did not demonstrate use of deep-level cognitive strategies in their writing.

Studies such as that by Nückles et al. (2004) indicate that learners have to be provided with instructional support either before or while they engage in writing to learn. Writing research has converged on the findings that self-regulation characterizes skilled writing and determines students' written outcomes (for a review, see Graham & Harris, 2000). Therefore, instructional models of writing development, for example, the *self-regulated strategy development model* by Harris and Graham (1992) put strong emphasis on the teaching of self-regulation strategies, particularly planning, self-monitoring and revision strategies. However, self-regulation may not play the same role in learning by writing and may even be detrimental to learning (cf. Galbraith, 1992). With most academic writing activities (e.g., lab report, term paper, thesis) the texts produced by the students are judged against the standard or conventional characteristics of the respective writing genre. For information on the characteristics of well-written texts, students are expected to draw on the guidelines provided along with the writing task and on the knowledge of text genres which they have acquired through formal instruction and literary socialization. Students' success on a writing-to-learn task, however, is not evaluated based on the rhetorical and structural quality of the written product but based on their achievement on measures of knowledge, performance and academic achievement. Therefore, learners who invest limited cognitive resources (cf. Torrance & Galbraith, 2006) in self-regulating their writing so as to produce texts with certain rhetorical and structural characteristics may not succeed on writing-to-learn tasks.

The assumption that adopting a self-regulated stance toward writing can be detrimental to learning is refuted by the results of Bangert-Drowns et al. (2004). Based on their meta-analysis of school-based writing-to-learn interventions, Bangert-Drowns et al. concluded that metacognitive prompts were among the predictors of learning by writing. However, studies conducted in years following the Bangert-Drowns et al. meta-analysis have shown that facilitating metacognitive self-regulation via prompts may not be sufficient to secure the positive effects of writing to learn. In a study by Berthold, Nückles and Renkl (2007), for example, students were prompted to use cognitive strategies, metacognitive strategies, cognitive and metacognitive strategies or no strategies during writing. It turned out that metacognitive prompts per se did not have a positive effect on learning outcomes. The difference between the studies included in the Bangert-Drowns et al. (2004) meta-analysis and the Berthold et al. (2007) study was the nature of the writing-to-learn task. Berthold et al. had their participants write entries to a learning journal, a writing genre employed for the purpose of learning by writing only and characterized by few rhetorical and structural constraints (Nückles et al., 2004). Bangert-Drowns et al. (2004), however, meta-analyzed studies that included a range of writing assignments. With some writing genres (e.g., analytic essays) the aim of writing to learn - as opposed to learning to write or demonstrating knowledge - may not be salient (cf. Klein, 1999). Metacognitive prompts might take effect with such writing assignments because they direct the writer's attention to learning processes and away from the constraints implied by the writing genre.

Altogether, we argue that instructing students to adopt a self-regulated stance toward writing may not be effective with regard to learning by writing.

## Research questions

As shown in the background sections, cognitive theories of writing and research on learning by writing do not allow firm conclusions as to the effects of self-regulation on learning by writing. As a consequence, it is still unclear which model of the writing process writing-to-learn instruction should be based on – should students be instructed to adopt a "romantic" or a "classic" stance toward writing when asked to engage in a writing-to-learn activity? We addressed this gap in research by conducting an empirical study. In particular, we were interested in the following questions: How do writing-to-learn instructions that differ with regard to the stance toward writing they induce impact on (1) the number and adequacy of ideas generated while writing an entry to a learning journal, (2) the acquisition of content knowledge, and (3) the quality of the written product?

## Method

### Participants and design

The study was advertised through flyers and posters on the campus of a medium-sized research university and involved a sample ($n$=87) of college students ($n$=79) and professionals holding a college degree ($n$=8). With the exception of age, the subsample of professionals did not differ significantly from the subsample of college students on any of the control variables we assessed. The mean age of the total sample was 24.16 (*SD*=4.91). The mean age of the professionals was 27.38 (*SD*=2.87). Females (*n*=59) and males were evenly distributed among the conditions.

A 2x2 experimental design was used with participants randomly assigned to one condition: (1) self-regulated writing (*n*=23), (2) spontaneous writing (*n*=22), (3) self-regulated and spontaneous writing (combined instruction condition, *n*=21), (4) writing without instruction in writing to learn (control condition, *n*=21).

### Procedure and writing-to-learn instructions (experimental variation)

All participants attended a 30-minute video-taped presentation on a topic from the field of educational psychology (cognitive architecture, cognitive load theory and worked-examples effect). They were not allowed to take notes while watching the presentation. Then they were informed about the general aim of writing learning journals (attaining deep-level comprehension and improving strategic learning) and received the writing-to-learn instruction of the respective condition. The spontaneous writing instruction contained three metaphors: Participants were instructed to engage in self-talk, to approach the task with a creative mindset and to treat writing as discovery. Thus, the instruction induced a "romantic" stance toward writing (Galbraith, 1992). In the self-regulated writing condition, the instruction centered on three metaphors. The metaphors were supposed to induce a "classic" stance toward writing (Galbraith, 1992): Participants were instructed to think of writing as rhetorical problem solving, to approach the task with an analytic mindset and to treat writing as a process of continuous reflection and revision. For the combined instruction, we integrated the spontaneous and the goal directed writing instruction. Hence, it contained six metaphors that instigated participants to set and monitor rhetorical goals, write down their ideas as they occurred to them and revise the text if necessary, thus treating writing as a self-regulatory activity and a process of self-talk and discovery at the same time. In the control condition, participants did not receive any instructions beyond the information about the general aim of writing learning journals.

We decided to use metaphors to induce specific stances toward writing for the two reasons. First, persons bound for or holding a college degree can be expected to have at least some experience in writing at an academic level and to have acquired strategies for writing over the course of their academic and professional careers. Therefore, a flow chart or other representation of a writing scheme (as often used in writing instruction) was likely not to be considered by the participants during the actual writing activity because of low perceived usefulness. Second, metaphors are well suited to assist learners in forming a conceptual model of a task as they illustrate complex concepts and trigger associations. Metaphors were successfully used as vehicles for instruction, for example, by Bromme & Stahl (2005) in a study on learning from hypertexts.

### Measures and rating

Participants' knowledge of the presentation topic at post-test (after they had completed the writing-to-learn task) was assessed by means of six free-response items. Three items tested participants' understanding of the concepts directly addressed in the presentation (e.g., "Explain the types of cognitive load and how they interact."). The remaining three items required deep understanding of the presentation topic. Hence, these items addressed transfer of knowledge. One of the items described, for example, a classroom scenario in which students were unable to solve math problems on their own after having been presented one example. Participants were asked to explain the scenario from the perspective of cognitive load theory. We also administered a knowledge pre-test to assess participants' prior knowledge of the presentation topic. The knowledge pre-test consisted of four free-response items: One question on cognitive architecture, two on cognitive load theory and one on worked-out examples. The knowledge tests were graded for the overall quality of the answers on a six-point scale (following Biggs & Collis, 1982) and for the number of correct answers (post-test only). In order to be able to control statistically for other potential confounding variables, participants were asked to provide socio-demographic information and information on their prior experience in writing learning journals. They were also asked to rate the perceived helpfulness of the writing-to-learn instruction.

The texts produced by the participants were analyzed for the number of new ideas, correct statements and incorrect statements they contained. With regard to the quality of the written products, two independent raters assessed the structure and coherence of the texts and the degree to which deep-level cognitive (elaboration) and metacognitive (reflection) learning strategies were evidenced in the texts. Inter-rater reliabilities for these ratings were satisfactory ($ICC_{unjust}$=.71 to $ICC_{unjust}$=.76).

## Results

The participants of the four conditions did not differ significantly with regard to any of the socio-demographic variables, their prior experience in writing learning journals, their performance on the knowledge pre-test and the amount of text they produced. Hence, the subsamples constituting the four conditions were comparable. Across conditions, participants reported low experience in journal writing (number of entries to learning journals written prior to participation in the study: *M*=3.47, *SD*=11.28).

A two-way univariate analysis of variance (ANOVA) with overall quality of the answers on the knowledge posttest as the dependent variable and $\alpha=.05$ revealed a significant main effect for self-regulated writing, $F(1,83)=5.74$, $p=.019$, $\eta^2=.07$ (Figure 1). Further ANOVA analyses also yielded a significant main effect of self-regulated writing on quantitative performance at post-test (number of correct answers on the knowledge post-test), $F(1,83)=7.35$, $p=.008$, $\eta^2=.08$ (Figure 2). Hence, the participants in the self-regulated writing condition and those in the combined instruction condition learned less from writing the entry to the learning journal and acquired a more shallow understanding of the presentation topic than those who received the spontaneous writing instruction or no instruction in writing to learn (control condition).

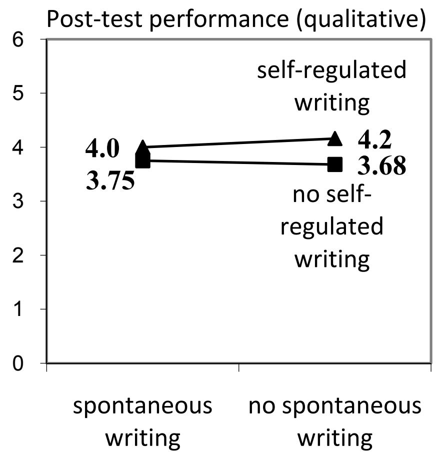

Figure 1. Main effect of self-regulated writing on overall quality of answers on the knowledge post-test (rated on a six-point scale with higher numbers indicating lower quality).

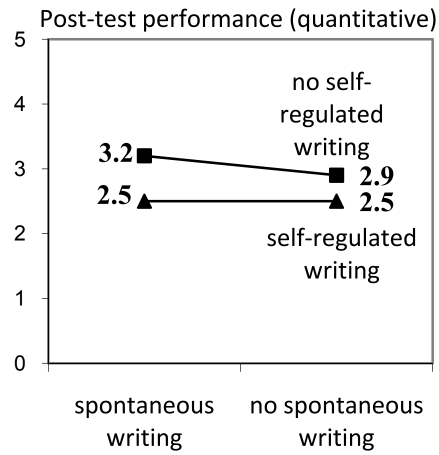

Figure 2. Main effect of self-regulated writing on number of correct answers on the knowledge post-test.

Similar findings emerged from the separate ANOVA analyses we conducted with the number of new ideas and the number of correct statements identified in the learning journals as the dependent variables: The participants who had been instructed to self-regulate their writing produced significantly fewer new ideas ($F[1,83]=4.37$, $p=.040$, $\eta^2=.05$) and fewer correct statements ($F[1,83]=7.41$, $p=.008$, $\eta^2=.08$) than those who had not been instructed to do so (Figures 3 and 4). In all of the four conditions, the average number of incorrect statements made in the learning journals was low. The highest number of incorrect statements was found in the combined instruction condition, followed by the self-regulated writing condition.

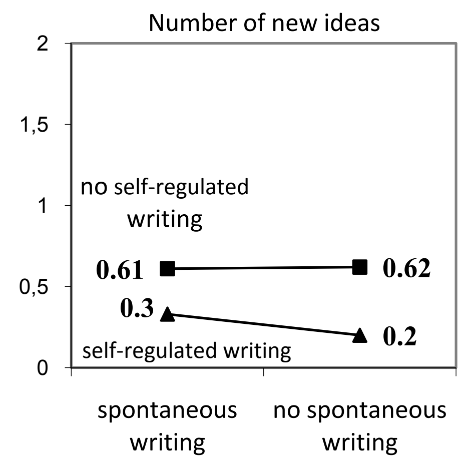

Figure 3. Main effect of self-regulated writing on number of new ideas in the journal entry.

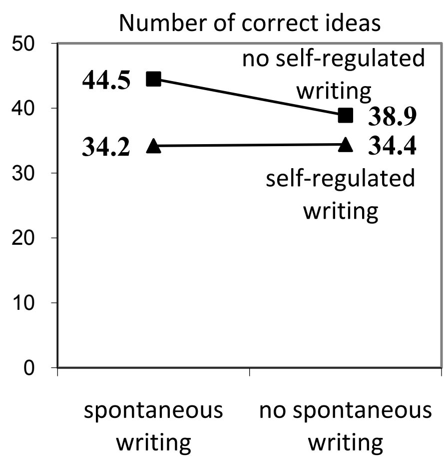

Figure 4. Main effect of self-regulated writing on number of correct ideas documented in the journal entry.

There were no significant differences between the conditions with regard to the quality of the written product (see Table 1 for means and standard deviations). Descriptively, however, participants who had been instructed to adopt a "classic" stance toward writing (self-regulated writing, combined instruction) received lower structure and elaboration ratings than those who wrote spontaneously or without prior instruction.

Table 1: Ratings of the quality of the journal entries written by condition

| | Spontaneous writing condition | Self-regulated writing condition | Combined instruction condition | Control condition |
|---|---|---|---|---|
| Structure *M (SD)* | 3.57 (1.50) | 3.50 (1.53) | 3.33 (1.27) | 3.52 (1.53) |
| Coherence *M (SD)* | 4.04 (1.58) | 4.55 (.96) | 4.00 (1.41) | 4.00 (1.51) |
| Elaboration *M (SD)* | 3.96 (1.49) | 3.82 (1.22) | 3.62 (1.49) | 3.81 (1.25) |
| Metacognition *M (SD)* | 2.04 (1.52) | 2.50 (1.37) | 2.24 (1.64) | 1.48 (1.25) |

*Note.* The journal entries were rated (separately on each dimension) on a six-point scale ranging from 1 (no evidence in the journal entry) to 6 (strong evidence in the journal entry).

Despite the differences in learning processes and outcomes between the four conditions, participants did not perceive the helpfulness of the writing-to-learn instructions to be different. An ANOVA with perceived helpfulness as the dependent variable did not yield a significant result, $F(3,83)=2.37$, $p=.077$.

Altogether, the following picture emerges from the analyses of the knowledge post-test and the journal entries written by the participants: Adopting a self-regulated ("classic") stance toward writing impeded learning (as evidenced by participants' quantitative and qualitative performance on the knowledge post-test). At the process levels of writing and learning, the results are somewhat inconsistent but also point toward negative effects of self-regulation on learning by writing.

## Discussion and future work

The results of our study support the notion that learners should not be instructed to self-regulate their writing when they engage in a writing-to-learn activity. Not only did those writers whom learning by writing had been presented to as a self-regulated activity fare worse with regard to knowledge acquisition. There also was some indication that setting rhetorical goals, followed by planning, monitoring and revision of the emerging text exerted a negative influence on writing and learning processes: Writers who had been instructed to adopt a self-regulated stance toward writing were less successful at demonstrating idea generation, correct knowledge and high-quality writing than those who wrote spontaneously, in a "romantic" fashion.

Our findings corroborate the results of the study by Galbraith (1992) who found that writing spontaneously was superior to careful planning with regard to idea generation and knowledge acquisition. The results of the present study are also in line with recent studies on learning by writing which have called into question the sole effectiveness of metacognitive prompting (e.g., Berthold et al., 2007). Furthermore, the outcomes of the self-regulated writing condition and the combined instruction condition challenge the assumption that findings from research on writing and writing development can be generalized to learning by writing. The fact that the participants in our study were adults whereas those in most studies on writing development were children and adolescents might have played a role. But it is much more reasonable to assume that there are fundamental differences between the processes of writing to learn (and learning how to do so most effectively) and learning to write (cf. Klein, 1999). When designing writing-to-learn instruction this has to be taken into account. An interesting question would be whether changing the focus of the self-regulated writing instruction would have affected the outcomes of our study. In the self-regulated writing condition and in the combined instruction condition, participants were asked to monitor their understanding of the presentation topic but also to set and monitor rhetorical goals. This might have decreased the salience of the actual aim of the writing-to-learn task, i.e. knowledge acquisition. In the future, we plan to conduct a study involving two self-regulated writing conditions: In both conditions writers will be instructed to adopt a self-regulated stance toward writing - but the focus will be rhetoric and structure in one condition and on comprehension in the other. To our knowledge such a design has not been realized with a writing-to-learn task.

At first glance, the outcomes of the control condition do not seem to fit into the general picture that emerged from our study. The participants of the control condition showed strong performance on the knowledge posttest and the quality of their journal entries was almost as high as in the spontaneous writing condition. The apparent contradiction between these findings and studies pointing toward the ineffectiveness of unguided journal writing (e.g., Nückles et al., 2004) may be explained by the very nature of the writing-to-learn instructions. The instruction of the control condition asked participants to write in such a way as to obtain deep understanding but did not refer to any characteristics of the writing genre. This may have lifted the rhetorical and structural constraints off the writing-to-learn task that operated in the self-regulated writing condition and in the combined instruction condition but not in the spontaneous writing condition. Hence, participants in the control condition may have engaged in the same writing behavior and cognitive processes as those in the spontaneous writing condition. This explanation is somewhat speculative though as our design did not include a manipulation check on the experimental variation. Hence, we do not know how the participants processed and implemented the writing-to-learn instructions of the experimental and control conditions. Future studies should consider analyzing the writing process itself (in addition to its product and outcomes) both at the level of writing behavior (e.g., via log-file analysis) and cognitive processes (employing a think-aloud methodology).

Another surprising finding is that we were unable to identify significant differences between conditions regarding the quality of the texts written by the participants. The descriptive differences, however, largely reflect the instructions the participants received in the respective condition. Participants who were instructed to adopt a "classic" stance toward writing demonstrated low cognitive-elaborative strategy use but relatively high metacognitive strategy use. Despite being instructed to self-regulate their writing they received lower ratings for the structure of their texts than the participants who had been instructed to adopt a "romantic" stance toward writing. In the present study, the lack of significant differences and the partially inconsistent results may be explained by the fact that the participants were inexperienced in writing learning journals and wrote a single journal entry only. Studies are needed in which participants write several entries to a learning journal over an extended period of time.

In conclusion, additional studies are required to further clarify the effects of self-regulation on the outcomes (and processes) of writing to learn. In addition to comparing writing-to-learn instructions which direct self-regulation either at text characteristics or at comprehension we suggest that process analyses and long-term interventions be carried out. Along the lines of Klein (1999), we hope to have reopened inquiry into metacognitive processes in writing to learn and sparked further discussion on effective writing-to-learn instruction.

# Teacher Learning about Teacher-Parent Engagement: Shifting Narratives and a Proposed Trajectory

Corey Drake, Iowa State University, E115 Lagomarcino Hall, Ames, IA, 50011, cdrake@iastate.edu
Angela Calabrese Barton, Michigan State University, Erickson Hall, East Lansing, MI, 48824, acb@msu.edu

**Abstract:** In this paper, we examine teacher learning about teacher-parent engagement in mathematics and science education. Using data from three different schools participating in TE-PAC$^2$ (Teacher-Parent Collaborative Communities), we find evidence of teacher learning in the stories teachers tell about the meanings of – and possibilities for - teacher-parent engagement in the context of broader cultural narratives about the teaching and learning of mathematics and science in their schools and districts. In particular, teacher learning was reflected in *changes* in teacher narratives over time and in the new understandings of parent resources incorporated into these shifting narratives. We conclude with a proposed trajectory of teacher learning about teacher-parent engagement.

## Introduction

National policies (e.g., No Child Left Behind) emphasize parental involvement in schooling, but little research has been done to establish *how* teachers might engage with parents in content-based instruction, particularly in ways that acknowledge the diversity of backgrounds and resources parents bring to the classroom. This is the issue we investigated through our work in three schools with teachers and parents engaging together in science and mathematics education. As part of this effort, our research questions included:

> How and what do teachers learn about teacher-parent engagement in support of mathematics and science instruction when engaged with parents in the collaborative study of science and mathematics education reform policies, documents, and curriculum materials? How is teacher learning reflected in teachers' narratives about parent engagement in their particular schools and districts?

We investigated this question through the design and implementation of a teacher-parent collaborative experience, TE-PAC$^2$ (Teacher-Parent Collaborative Communities). At each of the three schools, this experience took on a different structure and focus, but common elements included multiple sessions of teachers and parents (along with a researcher/facilitator) working together to discuss goals for mathematics and/or science education, investigate mathematics and/or science curriculum, and jointly planning classroom or school events that engaged parents, teachers, and children together in learning and teaching mathematics and/or science.

## Theoretical Framing

In our own work, we, like others, have observed that while the rhetoric of reform—especially from multicultural perspectives—suggests that parents should be closely involved in the reform process, the reality is that parents and teachers alike struggle with how best to bring parents into reform-based instructional practices (Peressini, 1998; Remillard & Jackson, 2006). We believe that if teachers are to be successful in engaging parents in support of student learning, then it must happen within the framework of—not peripheral to—content-based instruction. In other words, teacher-parent engagement must occur not only in the context of helping with bus lines, lunch or recess duty, and field trips, but also around issues central to the teaching and learning of mathematics and science.

Our view of teacher learning is grounded in sociocultural perspectives on learning, where learning is framed as changing participation within communities of practice (Lave & Wenger, 1991). We concur with Peressini, Borko, Romagnano, Knuth and Willis (2004) that "teachers' knowledge and beliefs interact with historical, social and political contexts to create the situations in which learning to teach occurs" (p. 68). We assert that these interactions can be particularly powerful when parents are co-participants with teachers, especially when teachers and parents reflect different cultural and social backgrounds. This view of teacher learning re-situates how we think about teacher–parent engagement and how teachers learn by engaging parents. In contrast to traditional understandings of parent involvement, which include parents volunteering in a range of school-defined ways, we define engagement as an interactive process in which teachers and parents draw on multiple experiences and resources to define their interactions with one another. In prior research, we developed a model of parental engagement in urban elementary schools, specifically in relation to "what" parents engage in and "how" they do so

(Calabrese Barton et al., 2004). Parents' effectiveness in schools is related to where engagement in the curriculum occurs, as well as to the resources parents activate to support their children's schooling. This understanding of parental engagement differs from traditional models because it highlights the importance of space and capital as mediators of parental engagement and positions parents as authors and agents within schools. This last distinction is particularly important in low-income urban schools, where parents tend to feel more alienated and with little power (Harvard Family Research Project, 2002).

One area of capital exchange that has proven critical is the exchange of resources and understandings related to subject matter knowledge, pedagogy, and goals. Studies of learning in mathematics professional development indicate that teachers increased their communication skills and content understanding when engaged in content learning activities with parents (Civil & Quintos, 2002). Likewise, parents who participated in their children's elementary classrooms reported that talking about teaching, learning, and personal experiences, listening to different perspectives and opinions, and teaching mathematics to other parents were rewarding aspects of working in schools (e.g., Jackson & Remillard, 2005).

Lee and Bowen (2006) suggest that the link between parental involvement and increases in student achievement might be explained by the capital gained by parents through school involvement. However, little work has explored gains in *teachers*' capital that might also contribute to this link, especially when parental engagement is deeply situated in instructional content. It makes sense that we extend current research to include not just the nature of resources gained by parents but also those resources gained by teachers, and how the deployment of these resources frames their changing participation with parents. Thus, an integral part of our investigation is understanding teacher learning with respect to the resources that parents and families offer for a particular content area, the potential spaces within mathematics and science curricula and curriculum materials for accessing and building on these resources, and the relationship between these resources and school-based knowledge and practice.

## Data Sources and Methods

### Contexts

Our work has taken place across three distinct schools and districts, all of which are faced with intense pressures for testing in mathematics and literacy, and all of which have significant percentages of students living in poverty. The overall study took place over two years, though we spent one year in each school.

Palmer School is a fairly small school in Granite School District, with about 420 students, K-6. The school had recently taken in students from a neighboring school that closed due to lower enrollments and test scores. The principal of Palmer is highly active in recruiting novel programs to her school, such as linking her school with a fine arts center in the city, allowing the students and teachers multiple opportunities to integrate the arts across instruction. Palmer Elementary School is located in a mid-sized US city confronted with issues of changing demographics, limited resources, and testing mandates. The school district is an urban school system with approximately 20,000 students, of whom 78% are African American, 19% white and 3% Latino/a. 70% of the students are eligible to receive free lunch.

Washington Elementary, in the River City School District, is a mid-sized elementary school with three or four classrooms per grade (K-5) and approximately 550 students total. Washington Elementary was created through the merger of two schools two years prior to this study and is housed in a modern building built at that time. The building also houses a large Boys' and Girls' Club as well as a thrift store. The two schools that were merged to create Washington School were among the district's lowest achieving in terms of standardized test scores. Part of the Washington's vision is to engage parents, families, and the community in their children's education. To support this vision, Washington Elementary has a dedicated space in the school for parents and also offers several adult education opportunities. However, there is little parent involvement in classrooms or in the content of children's schooling. The student population at Washington is racially and ethnically diverse, with significant numbers of African-American, Latino/a, and Asian students, as well as students from a variety of European and African countries.

Beacon Academy is a free k-8 public charter school in Middleton. It sits on the west side of town, on the edge of two transitional neighborhoods. The school focuses overtly in its mission statement on "character" and "special" education, marketing itself to families whose children have not fared well in the regular school district. While the city of Middleton serves as home to 22% African American, 10% Hispanic, 3% Native American, and the remaining 64% White, Asian, or Pacific Islander and 23.2% children in poverty, Beacon Academy serves >95% African American or Hispanic students, and 100% in poverty. The school promotes itself on brochures and its website as a high quality school that teaches all core subjects and also offers "instruction in computers and technology, art, music, drama and Spanish.". However, due to low test scores, the school administration mandated in mid-April that no science or social studies be taught, causing some tension with our own project. Finally, Beacon

Academy's administrative staff is proud of its level of parental involvement. They hold an annual parental involvement celebration day, and the very first bulletin board one sees upon entering the school is one that welcomes parents and contains information and notices to help them navigate the school. Parents are employed on the staff to work in the office and to help out in the lunchroom. However, most parents have not been involved in the academic side of the school.

## Data Generation

We have utilized a narrative-driven ethnographic approach to investigating how learning with and about curricular materials, reform-driven documents, and academic content in collaboration with parents impacts the ways in which teachers engage parents in the design and enactment of school-based instructional practices. We utilized a range of primary methods in crafting our case studies (See Table 1).

Table 1: Overview of data generation strategies across sites

| | **Palmer** | **Washington** | **Beacon** |
|---|---|---|---|
| Teacher Interviews | 3 teachers, each interviewed twice (student artifact think aloud, interview on T-P engagement) | 5 teachers interviewed twice (beginning and end of experience), 1 interviewed once (end of TE-PAC$^2$ experience) | 4 teachers interviewed once (end of experience) |
| Parent Interviews | 4 parents, each interviewed once on T-P engagement | 2 parents, each interviewed once (Several other parents participated in TE-PAC$^2$ activities, but were not interviewed) | 2 parents interviewed once (end of experience) |
| TE-PAC$^2$ sessions | Audio and fieldnotes | Fieldnotes | Fieldnotes |
| Classroom observations | 3 teachers, science classrooms observed 6 times each, 30-60 minutes per observation, fieldnotes | Observations and field notes for Family Math Night | Observations and Fieldnotes for 7 science lessons (in science, computer, and ELA classrooms) |
| Teacher and Parent-related Artifact Collection | Lesson plans; home extension lessons; student life cycle stories | Planning sheets from TE-PAC$^2$ workshops, activities created for Family Night | Lesson plans<br>Extension activities<br>Pictures of materials for walls |
| Student Interviews and Artifacts | Student lifecycle stories<br>Fieldnotes on student participation | Artifacts<br>Fieldnotes related to student participation | 6 student interviews<br>Student storyboards<br>Student movies<br>Fieldnotes on student participation |

## Data Analysis

In analyzing and discussing these data, we utilized the Ecologies of Parental Engagement (EPE) framework we developed in a previous study (Calabrese Barton et al., 2004) and focused on the importance of space and capital. In particular, to make sense of teacher learning, we examined how participation within certain communities frames issue of space and capital. Given our work with parents in low-income urban schools, we were particularly concerned with how parents are often positioned within and against the communities of practices that make up urban schooling. This led us to a key analytic idea, which emerges from cultural-historical and hybridity theories - namely, that acts of creating hybrid spaces, discourses and identities are always political and of the highest risk for those whose knowledge, discourse, and identities are positioned as lesser. Individuals in any given community of practice engage in acts of hybridity all of the time when confronted with differences. They draw upon multiple resources or funds to make sense of the world. Yet, being "in-between" several different funds of knowledge and Discourses can be either productive or constraining, and even marginalizing, depending upon how they are recognized by those in power (Moje et al., 2004).

Case study data analysis involved multiple stages and levels of coding, all of which were based on Strauss & Corbin's (1998) procedures for open coding and method of constant comparison. In analyzing case study data, we have begun to develop coding schemes on those aspects of teaching which seem to be particularly relevant to teacher-parent engagement in urban settings, including the kinds of curricular spaces teachers create for parental engagement, the forms of capital teachers activate in support of engaging parents in content-based instruction, the roles/identities teachers take on in relation to parents, and the ways in which scientific and mathematical ways of thinking are linked to families' interests, experiences, and everyday understandings of the world (Perez Carreon, Drake, & Calabrese Barton, 2005).

In this paper, we focus in particular on the stories and counter-stories teachers tell about parent engagement in their schools. We claim that changes in these stories over time provide evidence of teacher learning related to teacher-parent engagement in mathematics and science content – including the goals, purposes, and practices that support this kind of content-related engagement. We define teacher stories, or narratives, as socially shared accounts of human intention and action (Bruner, 1990). For stories to have meaning in teaching and educational research, they must report more than a listing of dates, places and events. They must also speak to the meaning of those events in an individual's life. In the tradition developed and expanded by Clandinin and Connelly (2000) and others, we use teacher stories to develop rich, contextual, accounts of their learning. Drawing from place-based sociocultural theory, we argue that personal stories, such as teacher stories, always exist in interaction with narratives at other levels, including social and cultural (Tzou, Scalone & Bell, in press). As teachers, for example, interact with each other they do so in spaces that are shaped by cultural narratives and resources available in those places, such as a school climate deeply shaped by NCLB, curricular policies, and other boundaries and supports related to the teaching and learning of mathematics and science.

## Findings

Our findings are grounded in teacher stories and teacher practices with respect to mathematics and science instruction and parent engagement. These stories consist of the narratives that teachers craft about their teaching alongside the artifacts from practice they use as evidence for their claims. We begin with cases from two of the participating schools. (Due to space limitations, we do not present a detailed case from the third school, Beacon Academy, here, though we incorporate findings from that case in the discussion section below.) These cases provide a sense of the kinds of activities involved in the TE-PAC$^2$ experience, as well as the supports and constraints available in the different school and district contexts for this kind of work. We then describe findings related to teacher narratives – and changes in those narratives – across the three sites.

### Case 1: Palmer School

This group began meeting in February and involved three 3rd and 4th grade teachers who attended all six of our after school study group sessions, except one week when one of the teachers was absent due to a technology conference. The teachers were supported by their principal who would often stop in for a brief moment with a big smile and ask how everyone was going. They were also supported by the district curriculum coordinator for science who came to the fifth of our six sessions to ask the teachers and parents to discuss their work with her. Four parents attended fairly regularly, with one missing occasionally, and one additional parent showing up at science class because she could not make the after school sessions. One of the parents was a grandmother who had extensive parenting responsibilities for her grandchildren. Sometimes her granddaughters would come to our sessions but they mainly played with each other and tended to "ignore" what the adults were doing.

The structure of the meetings was to first to talk about "science experiences" of the week, then to "do science" together and then to discuss ways to increase parent-teacher engagement using two strategies that we proposed: Lesson Extension Ideas and Lesson Integration Ideas. Playing with science often involved taking one aspect of the mandated curriculum and doing the activities together, often in ways not prescribed in the text. The early work of the group tended to focus more on designing and implementing "extension lessons for the home" and then shifted to lessons that integrated activity in the home with activity in the classroom. The focus of these latter discussions sat within a tension of "what would parents know about science" and "what will kids do in the classroom who don't do the home component." These discussions tended to focus on the deficiencies of some of the parents within the school community, but the group decided to move forward with the belief that these activities might "bring parents in."

The major barrier that the participants seemed to face related to instructional mandates that involved science. The Granite City School District, like many around the nation, had been undergoing a series of reforms meant to help boost test scores. A recent reform initiated by the superintendent's office had been the discontinuation of any interdisciplinary teaching to ensure that each subject area was taught for the required amount of time each day. All three participating teachers were vocally opposed to the new mandate and felt "harassed" by the district official who roamed the building making unannounced visits to "check up" on instruction. This topic came up each week as teachers met to explore life cycles together – and, through these discussions, teachers and parents were able to expand their knowledge related to one another's perspective and to the broader policy and instructional contexts of school science.

What seemed particularly salient was *how* discussions of these new mandates emerged within the group and the barriers these mandates imposed for teachers and parents in their efforts to support student science learning. In particular, we noted that the teachers, from our very first TE-PAC$^2$ session onward, spoke critically of the new regulations for scripted "page a day" curricula and on the emphasis on basic skills or what the teachers referred to as "kill and drill." We also noted that the teachers contrasted these mandates with their desire to use more "hands-on" and "inquiry-based" learning in support of student motivation to learn science and making science more authentic. As Beth reminded us, students need a reason to want to understand science. Parents were less critical of the new mandates primarily because they seemed to not be as aware of the specific mandates. However, in support of the teachers' desires to use more hands-on learning, the three parents harshly criticized the culture of accountability and test scores as making it more abstract and difficult for them to understand what their students were learning and how they might better support them in learning.

## Case 2: Washington School

This group began meeting in November, 2008. Five teachers (1$^{st}$, 2$^{nd}$, 2 4$^{th}$, and 5$^{th}$ grades) showed up very regularly for all meetings, except for occasional family/child care conflicts. They had significant support from one of the Title I math teachers, who serves as a mathematics leader within the school. He worked a second job, so typically could not come to the meetings. Two out of the first three meetings were cancelled because of weather, so the facilitator and teachers decided to re-group in January.

Each meeting was attended by 2-6 parents, often with their children. The structure of the meetings was to first "do math" together (teachers, parents, and children) and then to discuss ways to increase parent-teacher engagement. Keeping in mind the "playing with science" theme from the Palmer case, most of the math provided by the facilitator for participants to do together was in the form of math activities that are not traditionally done in school – puzzles, games, tangrams, etc. There were a number of positive results and stories that emerged from this aspect of the meetings. For instance, one father was very good at a particular kind of spatial puzzle and, after observing his success with these puzzles, both the teacher and his own children began to position him as having increased expertise in mathematics. Children from the 2$^{nd}$-grade class began taking the puzzles back and forth between home and school and other children in the 2$^{nd}$-grade classroom (whose parents were not involved in the initial teacher-parent meetings) began asking for copies to take home. One family, in which the parents spoke only Spanish, worked back and forth with their child and one another to complete a Magic Square, with the child and one of the facilitators translating the "rules" of the activity while the parents provided the mathematical knowledge.

The teacher-parent-child groups generated several interesting and ambitious ideas for increasing teacher-parent engagement, including developing a school store to work on money concepts and a school garden to draw on parents' expertise in carpentry and gardening with a focus on the mathematics involved in these activities. There were frequent discussions within the groups about designing artifacts that could move between home and school in order to increase parent engagement and connections between home and school. There was considerable concern about sending things home that would not be used and ideas were generated for addressing this concern. Out of these discussions, the plans for the Family Math Nights were developed. Ultimately, the group enlisted the Title I teacher's help in putting together two Math Nights – one for 1$^{st}$/2$^{nd}$ grade and one for 4$^{th}$/5$^{th}$ grade (reflecting the grade levels of the participating teachers and parents). They, along with the Title I teacher, designed the Nights to have parents and children rotate through 4 classrooms – each with a laminated game or activity that the parents and children would play in the classroom and could then take home with them (along with the necessary dice, counters, etc.). Ultimately, these Nights were very well-attended (particularly the 1$^{st}$/2$^{nd}$-grade night) by more than 200 children and family members and teachers were very positive about this outcome.

As researchers and facilitators, this case leaves us with several conjectures and questions. In particular, Family Math Nights were not the initially-intended outcome of the project and, in that sense, the outcome is a disappointment. On the other hand, having observed the Nights and the preparation that went into them and having interviewed the teachers afterwards, the Family Nights seem to have served several positive functions related to teacher-parent engagement. Specifically, the teachers had clear ownership of this project and they continued to hold Family Math Nights during the next school year without the formal support of the TE-PAC$^2$ project.

## Teacher Stories about Teacher-Parent Engagement and Content

Initially, teachers' narratives about teacher-parent engagement were grounded in or mirrored the broader and more dominant cultural narratives of their schools. Teacher narratives, for example, focused on what it meant to teach mathematics or science in their particular school (and district) to their particular students, and what forms of parental engagement were appropriate or necessary. These cultural narratives organized teachers' discourse and practices related to what students (and parents) in their schools could accomplish, what good teaching was for their school's population, and who had the power and the right to make instructional decisions.

For example, at Washington School, teachers and parents all initially shared narratives of a general lack of parental involvement in the school, despite the school's clear mission and formal policies to engage parents and families. Some of the group's more ambitious ideas for teacher-parent engagement were rejected because of a conviction that parents at "this school" would not participate. Related to this narrative was an on-going discussion that the parents who "need" to be here (i.e., the ones whose children are struggling) were the not the ones who were participating.

This narrative at Washington School was situated in a broader cultural narrative related to the district's somewhat unique approach to mathematics teaching and curriculum. Although there was a set of standards and objectives for the district, there was no district-adopted textbook or set of curriculum materials. Instead, there was a strong and consistent narrative across the district related to teacher control over instructional and curricular choices in mathematics. This narrative was told in contrast to the district approach to literacy – a subject in which a scripted curriculum series had recently been adopted. Having an artifact in the form of common curriculum materials or even common activities/practices across classrooms might have helped focus the TE-PAC$^2$ group on examining these artifacts in order to identify "spaces" for teacher-parent engagement. The set of standards and objectives used in the district was somewhat too broad and abstract to serve this purpose.

As we can see with the teachers at Washington School, it was within these broader cultural narratives that teachers revealed how much their views of teaching and subsequent parental engagement in that teaching were framed by No Child Left Behind legislation and its extant policies and practices for mathematics and science teaching in their schools and districts. A school's status as failing or near failing and the supports and constraints this status imposed upon teachers were central to teacher narratives.

We noticed similar constraints at Beacon School. Interestingly, even when teachers had expressed views of learning that ran counter to cultural norms or formed fairly robust relationships with parents, who were highly active in the school, their more personal ideas about how teachers and parents might collaborate on instructional decisions were trumped by their perceptions of acceptable institutional practices and needs. For example, while the lead fifth grade teacher at Beacon held an expansive view of learning, which included views on how she might integrate youth interest in social networking technologies, she also spoke openly about not being able to trump the institutional narrative at her school due to the students' low test scores and school expectations for what classroom teaching ought to look like. At the same time, she had a fairly robust relationship with the one of the parents involved in TE-PAC$^2$, and yet while both she and the parent had ideas for ways to incorporate local cultural knowledge into the curriculum (i.e., incorporating oral histories or folklore into a lesson on predicting weather), they deprioritized these ideas to take on more traditional tasks supported by the broader cultural narrative. The day the lesson plan involved the students interviewing the parent on her "rules of thumb" for weather, the parent ended up not coming to science class because she felt it was more important for her to help oversee the lunch period in the cafeteria. The teacher felt she could not ask the parent to leave the cafeteria because that was the parent's "real" role in the school.

## Changes in Teachers' Narratives: Counter-Stories

We found that having opportunities to study science and mathematics together (through curriculum materials and reform documents) provided a space in which teachers began to try out narratives regarding mathematics and science instruction and parental engagement that ran counter to the broader institutional and cultural narratives. These counter-narratives were deeply grounded in the instructional content - either in how the goals for teaching content were framed, what the content of the lessons looked like, or how school and home could connect content. These counter-narratives were strikingly different from the original narratives teachers told. The original narratives focused on the spaces – or lack thereof – for parent engagement in mathematics and science instruction. As part of the TE-PAC$^2$ experience, teachers began to see new roles and identities for parents. This allowed the teachers to then imagine new narratives for teaching and learning mathematics and science. These counter-stories were supported by non-routine resources made available within these communities (e.g, family stories) and/or new meanings given to traditional resources (e.g., Family Math Nights). Finally, these counter narratives were co-authored and constructed/re-constructed over time as parents and teachers took greater risks in sharing ideas and perspectives (e.g., building an understanding of and then an opposition to district policies over several weeks as parents and teachers realized they shared similar concerns).

Engaging in the study of science and mathematic curriculum and reform materials supported opportunities for teacher learning by shifting the spaces in which teachers and parents typically engage each other. Instead of interacting over individual student issues or becoming involved in the management of the classroom, studying science and mathematics curriculum and reform materials together provided opportunities for sustained dialogue on science and mathematics in everyday lives and shifted discourse from expert/novice to co-learners. In other words, these shifts in spaces altered the resources and roles available to parents and teachers allowing them to take up alternative narratives that countered the cultural norm. Teachers' views on resources for learning shifted as they began to view parents in a more collaborative way. Some of the teachers expanded their repertoire of resources to support their teaching and student learning when they began to understand that parents were more than recipients of information or experts only on their own kids.

At all of our sites, parents and teachers' collaboration eventually served as a somewhat safe space for critical discourse on school policies, and in two cases such discussions led to opportunities for teachers and parents to subvert aspects of school policy that they collectively agreed worked against children's learning. In both cases the policy subverted related to the allocation of instructional time: In one case (Palmer) ignoring the superintendent's call for no interdisciplinary teaching, and in a second case (Beacon) ignoring the school mandate to eliminate all instructional time for science. At the third site (Washington), these discussions led teachers and parents to carve out a space for parent engagement in mathematics that was notably and explicitly resistant to the dominant curricular and parent engagement policies that had been created with respect to literacy. Also at Washington, the high attendance at the Nights provides a "counter-story" to the clear belief and expectation of both teachers and parents that parents at this school do not participate in school events, particularly those related to content.

## A Cycle of Teacher Narratives

If we think about teacher learning about teacher-parent engagement as a trajectory, we conjecture teachers made important movement along the trajectory, but that movement was mediated by the social context (i.e., school level support for science, teaching morale) along with teachers' personal resources for learning (i.e., teaching identity and knowledge of content). Teachers in all three schools experienced a culture of regulation and disempowerment and/or exhaustion among teachers. In fact, this trajectory cannot be understood separate from trajectories related to teachers' understandings of what it means to teach mathematics and science in their particular school and district. In proposing a trajectory of teacher learning about teacher-parent engagement, we claim that the center of this trajectory is defined by a cycle of teacher narratives (Figure 1) in which narratives of teacher-parent engagement are initially situated in broader cultural narratives about mathematics and science education and the role of parents. However, as teachers exchange resources with parents in the spaces defined by the TE-PAC$^2$ experience, they begin to tell counter-narratives not only about teacher-parent engagement, but also about the teaching of mathematics and science more broadly. In other words, teachers' narratives shift from questions of where parents might "fit" within the traditional teaching of mathematics and science to how new understandings of parent engagement might transform the teaching and learning of mathematics and science.

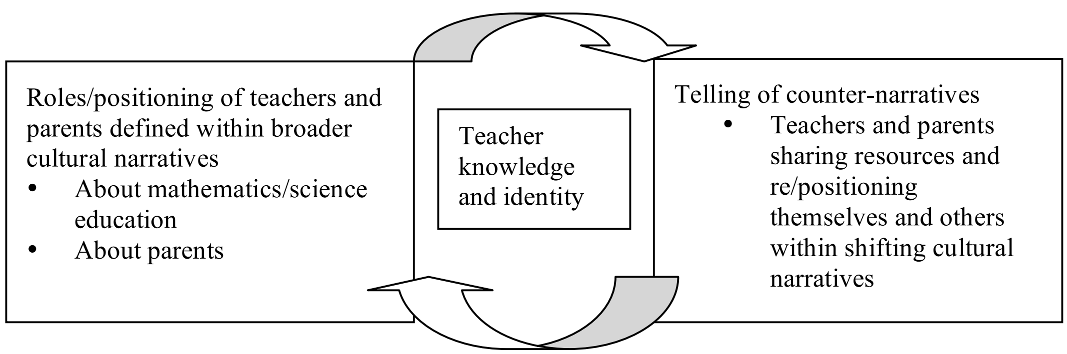

Figure 1. Cycle of Teacher Narratives.

At Beacon, we see the teachers as positioned at an early point along this trajectory. The teachers at Beacon were less familiar with the new science standards and also had no school-purchased resources for science. They tended to use the environment as a shield to prevent further engagement with parents. The initial narrative that emerged among teachers and parents in the context of *content* explorations focused on the "troubles of the school" that positioned teachers and parents differently and sometimes in opposition rather than the content of instruction.

Teachers at Washington and Palmer appeared to be positioned further along the trajectory as they were better able to take advantage of opportunities to learn with and through parental engagement and engage in the iterative cycle of narratives depicted in Figure 1. For example, at Palmer, teachers used the TE-PAC$^2$ experience as an opportunity to cultivate allies to work against policies that they felt worked against meaningful student learning. They used the TE-PAC$^2$ space to share complaints and to strategize on how to work against the negative environment. At both Washington and Palmer, teachers' relationships with parents as people with experiences that matter in science and mathematics developed dialectically with their views on the kinds of resources that support student learning. Consequently, teachers shifted classroom practice to reposition parents with more authorship in the classroom and/or curricular space. Parents helped to design extension lessons and served as content experts. They also provided feedback on their children's responses to the classroom. However, in this hybrid community, teachers still maintained overt control over when and how parents' shifting roles became public, even though many of the teachers expanded their views on what was possible in their school or classroom. Going forward, we hope to continue to understand, both theoretically and practically, the nature of this trajectory and ways to support teachers and parents in moving along this trajectory towards creating broader spaces and capital exchanges for engagement in the teaching and learning of mathematics and science.

# Effects of Instructional Design Integrated With Ethnomathematics: Attitudes And Achievement

Melike Kara, Illinois State University, Cardinal Court, B21, 61761, Normal, IL, mkara@ilstu.edu

**Abstract:** Development of an instruction integrated with ethnomathematics and its effects on 7th grade students' attitudes towards mathematics& achievement levels are the main concerns of this paper. Participants were selected from the 7th grade students. Six hours of instruction consisting of transformational, reflectional and rotational symmetry, patterns and ornaments based on the mathematics used in Topkapı Palace were presented to treatment group. An attitude scale, two achievement tests were administered as pre and post tests. Repeated measures two way ANOVA was used in order to test the hypothesis.

## Introduction

Schools tend to ignore the ethnomathematical knowledge that the children themselves can bring into the classroom from their homes and communities although math is not a culture-free discipline (Zaslavsky, 1998), therefore mathematical concepts and ethnomathematical perspectives should be synthesized in the curriculum in a way which is sensitive to all cultures. Development of an instruction integrated with ethnomathematics for 7$^{th}$ grade math lessons and its effects on students' attitudes towards mathematics and achievement levels are the main concerns of this paper. Practical mathematics and scholarly mathematics are tried to be narrowed with the instruction developed in the study.

D'Ambrosio (2001) states that ethnomathematics encourages us to witness and struggle to understand how mathematics continues to be culturally adapted and used by people around the planet and throughout time. In traditional math classes there exists no connection between culture and mathematic. As a result of this practice students believe that there is no connection between them and math is "acultural" which means that a discipline without cultural significance. Researches show that achievement level in math is highly correlated with students' attitude towards math. Butty (2001) noted that students with better attitudes towards math had a significantly higher achievement scores than those with poorer attitudes toward mathematics. Schultes and Shannon (1997) found that many students gained greater appreciation for math after learning the subject matter from a cultural perspective since it made students more comfortable and confident about discussing mathematical concepts such as infinity with their peers. (Cited in Arishmendi-Pardi, 2001).

## Literature Review

All of the definitions of ethnomathematics consider the points such as the culture in which mathematics arise, mathematics that is implicit in cultural in cultural practices, the use of anthropological principals to investigate mathematical practices, relation and implications for mathematics education. The definition of D'Ambrosio, which is the mathematics practiced among identifiable cultural groups, such as national-tribal societies, labor groups, children of a certain age bracket, professional classes (D'Ambrosio, 1985; cited in 1997, p. 16) is used as the main focus of the instruction integrated with ethnomathematics. Besides Zaslavsky (1998) stated that ethnomathematics includes mathematics of people's ethnic and racial group's, various classes in the society and practices of students' own communities.

The researches on ethnomathematics attempts to supplement the existing curriculum through the cultural practices and or/and examine the outcomes of integrating ethnomathematics into classroom instruction. There are many studies that seek to supplement the curriculum and their focus is usually on indigenous cultures (e.g. Barta, Abeyta, Gould, Galindo, Matt, and Seaman, 2001; Gerdes 1988; Lipka, Hogan, Webster, Yanez, Adams, Clark, and Lacy, 2005; Morales 1993). Studies that focused on outcomes did this through an examination of cultural practices and or artifacts, students' home/everyday experience or students' cultural practices. In general related research studies reach to similar conclusions that integrating ethnomathematics into mathematics instruction has positive effect on students performances (Arishmendi Pardi, 2001; Lipka et. al, 2005; Brenner, 1998).

The literature review showed that people use the mathematical activities in their real life with cultural practices, artifacts (Morales, 1993). In everyday activities, people involve a substantial amount of mathematical applications, which are universal behaviors such as counting, measuring, designing, locating, explaining, playing and for example, when designing tools, patterns are used especially for clothing, weapons (Bishop, 1991 as cited in Barta et. al, 2001). Moreover Moses (2005) noted that students' achievement levels in mathematics increased as they learn about African culture. The grades of algebra course of students taught ethnomathematical pedagogy were higher than the students' who took without the ethnomathematical pedagogy (Arishmendi-Pardi, 2001). The connection between mathematical ideas and lived experience of individual students, were emphasized in the study of Presmeg (1998) which argues that the ethnicity of students is a resource for mathematics. Powell and Temple (2001) say that Oware which is a board game played in Africa can help children understand that humans encode their mathematical ideas in diverse cultural products, including architecture, art games, music and written texts. Gerdes (1998) argued to develop an awareness of the social and cultural bases of mathematics, which contributes both to enhance self-confidence, capacity, readiness and openness to work in a multicultural environment among future math teachers. Teachers can make students see that in their activities, there are mathematics engaged in and they know math (Gerdes 1998). Barkley and Cruz (2001) noted that Native American beadwork incorporated in daily lives shows a high degree of sophistication in terms of specific symmetrical patterns which are used to symbolize the balance and communicate people's feeling of harmony with the natural world in which they lived. Gerdes (2001) suggested that teachers may look for suitable activities from diverse cultural contexts and analyze how these activities may be integrated into their teaching to create a truly simulating and enriching environment to help all students fully develop their potentials. Lipka and his colleagues (2005) found that the results of students' mathematics performance were in favor of the instruction which is math in a cultural context and based on two case studies of a successful culturally based math project.

In the light of the studies conducted on ethnomathematics, the purpose of this study is to investigate the effects of math instruction integrated with ethnomathematics. Specifically to find out if there will be any statistically significant difference between the level of attitude towards mathematics and mathematics achievement levels of seventh grade students who receive instruction integrated with ethnomathematics and regular instruction.

## Methodology

All of the definitions of ethnomathematics consider the points such as the culture in which mathematics arise, mathematics. In this section, the experiment set-ups and procedures will be described. These include the participants, the instruments, the data collection process, and the analytical procedure.

### Participants

Fifty students in seventh grade participated in this study. Due to practical reasons, convenient nonrandom sampling technique was used. The school is a state supported school, which has two seventh grade classes. One of the classes was control group (n=30) treated with the regular instruction and the other one was treatment group (n=20), treated with the instruction integrated with ethnomathematics.

### Design

In this quasi experimental study, since the participants were selected non-randomly except the random assignment of intact groups to treatments the design may be called as non-equivalent control group design (Gay, 2003). Before the treatment, Mathematics Achievement Scale1 (MAS1) and Mathematics Attitude Scale (MATT) were administered as pretest to all control and treatment groups. After the treatment, in order to find out achievement and attitude differences MATT scale and Mathematics Achievement Scale2 (MAS2) were administered as post tests.

### Instruments

In order to determine students' attitude towards mathematics at the beginning and at the end of the study, students were given mathematics attitude scale (MATT) which was developed by Nazlıçiçek and Erktin (2002). The reliability of MATT was calculated with the Cronbach Alpha Coefficient which is .84 for the sample 234 students from 6th, 7th and 8th grades. For the content validity of the test, factorial analysis of variances was conducted and in three subscales -which are mathematics achievement level perceived by the students, the benefits of mathematics perceived by the students and interest toward math lessons- 52 percent of the variance explained. For construct validity of the scale, the correlation coefficient between students' attitudes towards mathematics and their math achievement is found as .36 which is statistically meaningful for .01 significance level. According to Nazlıçiçek and Erktin (2002) this value was consistent with the previous studies Minato and Yanese, (1984); Ethington and Wolfle, (1986); Cheung (1988); Erktin, (1993).

In order to measure students' knowledge on the prerequisite topics for the symmetry and patterns (angle, line and plane using protractor to measure angles, basic characteristics of polygons), Math Achievement Scale 1(MAS1) was developed and used as a pre-test. Mathematics Achievement Scale 2 (MAS2) was developed for the line symmetry, rotational symmetry and patterns topics and used as a posttest. Both of instruments were developed by the researchers. The questions were adapted or directly taken from nationwide Teacher Guide Book of 7th Grade (Aygün, S.Ç., Aynur, N., Çuha, S.S., Karaman, U., Özçelik, U., Ulubay, M., Ünsal, N., 2007). For content validity of the instruments two mathematics teacher with master degree judged whether they evaluate students' knowledge on the prerequisites of symmetry and patterns topics for MAS1 and all subtopics of the symmetry and patterns topics for MAS2.

## Procedure

This section includes the description of the treatments, which are instruction integrated with ethnomathematics and regular instruction in "Mathematics in Our Daily Life" chapter. Both experimental and control treatments lasted in six-lesson hours. All of the instructions were implemented by the same mathematics teacher who is one of the researchers.

Instructions were prepared for the symmetry and patterns topics of the $7^{th}$ grade math lessons. Both of them are developed according to the objectives of $7^{th}$ grade mathematics curriculum of National Education of Turkey, as stated in Teacher Guide Book of $7^{th}$ Grade (Aygün, et al., 2007).

The regular instruction was based on the activities stated in the text-book. The instruction integrated with ethnomathematics for the $7^{th}$ grade symmetry and patterns topics aimed to enrich the existing curriculum with the cultural artifacts and ornaments. This type of instruction was based on the second strand of ethnomathematics defined as the analysis of the mathematics of the traditional cultures and of indigenous people and the fourth strand which focuses the relationship of ethnomathematics with the formal education system (Vithal and Skovsmose, 1997). It was designed according to mathematics of the tilling and patterns of the rooms called as Murat III Private Room, Mother of Sultan Flat in Topkapı Palace, practiced by the carpenters and tilling experts and the reasons behind the usage of the mathematics in those rooms by integrating to the instruction stated Teacher Guide Book of $7^{th}$ Grade Chapter 5, prepared according to mathematics curriculum of National Education of Turkey. Students discoverd the use of symmetry and patterns Turkish ornaments and Topkapı Palace which has an important role in Turkish History and full of symmetric ornaments. After a PowerPoint and a video show with photographs was shown, the selected rooms in the Harem section of Topkapı Palace, were examined with a simulation named as "360 degree" which makes use to see all the room within different perspectives. The motifs and ornaments are examined one by one with their photographs in the presentation and in the worksheets. Students made activities to define pattern types in the ornaments of to answer the questions: *Does the shape have rotational symmetry? If yes, what is the minimum angle that we should rotate to have the shape in the same posisiton? Does the shape have reflectional symmetry? Does the shape have reflectional symmentry more than one axis? Is there any translation of the main motif?* Then social and architectural properties of Harem Section was explained to students. Some of the properties are as follows:

*This is the house of the Ottoman emperor where his family lives so reflects the family life of the emperor. It was forbidden to enter the foreigners to enter Harem Section. Harem section was dark and cold since there were very few windows because of its secrecy. There was a hierarchical placement in the rooms and the most important people rooms' ornaments had higher complexity that the less important ones. The ornaments do not include animated figures because of religious reasons. Geometrical figures and flowers are used in tilling, cushions and carpets. The pools and taps were to cool off in the summer, and also for hygienic reasons. Another usage was not to make others listen outside of the room. When somebody is talking, another person outside of the room cannot hear anything if the tap was opened. The basic living problems were secrecy, light and heating. To make the rooms hotter there were fireplaces. The walls were full of tilling with symmetrical figures to reflect the heat and to foreclose humidity. There were candle places in the walls and they were also full of those figures. The carpets on the ground and hang in front of doors and windows were also to avoid cold weather. In the rooms, there were three types of ornaments which are calligraphy, flower deigns and patterns with repeated polygons-tessellations. The third type was related with the instruction integrated with ethnomathematics. Their basic characteristics is having infinitely continued, symmetrical and n-sided.*

The main difference between the instruction integrated with ethnomathematics and the regular instruction is the shapes used in the activities. The regular instruction activities, as stated below consist of the shapes and examples in the geometry. On the other hand in the activities of the instruction integrated with ethnomathematics, the shapes are chosen from The Flat of Valide Sultan and Room of Murat III. The other difference is that students in the experimental treatment also learn about Turkish history and lifestyles of the people who were living in the palace in the past centuries. The worksheets which were implemented as class exercises during experimental treatment are parallel to the students' practice and activity parts stated in the Teacher Guide Book of 7th Grade Chapter 5. However the shapes were selected from the patterns and ornaments of Room of Murat III and The Flat of Valide Sultan. In addition, they were prepared in the ethnomathematical perspective.

Both of the instructions include the use of the symmetry and patterns in daily life. In regular instruction it is presented with only examples, without any explanation or reason about the usage of them. The instruction integrated with ethnomathematics on the other hand includes the use of symmetry and patterns with reasons in a cultural context.

## Data Analysis and Results

Firstly, the distribution of the a) MATT as a pretest and b) MATT as a posttest c) MAS1 and d) MAS2 scores of the students in the treatment and control group were determined. Normality tests of Kolmogorov-Smirnov and Shapiro-Wilk showed that these scores are not significantly different than the scores which have normal distributions.

Since two dependent variables are measured repeatedly on independent groups where each group is exposed to a different condition Repeated Measures Analysis of Variance (ANOVA) was conducted for control and treatment groups. In order to determine whether control and treatment groups are significantly different or not in terms of their attitudes towards mathematics (MATT test scores) and mathematics achievement levels (MAS1 scores and MAS2 scores) at the end of the treatments, Repeated Measures Two Way ANOVA were carried on the pretest and posttest scores of two groups for both of the variable. Descriptive statistics are presented in Table 1.

Table 1: Descriptive Statistics for Attitude towards Mathematics and Mathematics Achievement.

| | Control Group | | Treatment Group | | TOTAL | |
|---|---|---|---|---|---|---|
| | Mean | SD | Mean | SD | Mean | SD |
| N | 30 | | 20 | | 50 | |
| **Pretest** | | | | | | |
| MATT | 41,97 | 12,694 | 55,50 | 20,433 | 47,38 | 17,382 |
| MAS1 | 66,83 | 14,130 | 66,00 | 16,746 | 66,50 | 15,069 |
| **Posttest** | | | | | | |
| MATT | 33,32 | 10,346 | 58,42 | 15,812 | 43,36 | 17,739 |
| MAS2 | 64,43 | 13,756 | 67,05 | 13,193 | 65,48 | 13,459 |

First hypothesis of the study was; *there will be statistically significant difference between the mathematics achievement levels of seventh grade students who receive instruction integrated with ethnomathematics and regular instruction* was not supported. Repeated Measures Two way ANOVA for control and treatment groups' scores on MAS scores revealed that ($F=1.812$, $p=.185$) the difference between the groups in terms of mathematics achievement was not statistically significant.

Second hypothesis of the study; *There will be statistically significant difference between the attitude levels of seventh grade students who receive instruction integrated with ethnomathematics and regular instruction* was supported by the results of the statistical analysis. Repeated Measures Two way ANOVA for control and treatment groups' scores on MATT indicated that $F=8.295$ with $p=.006$. The difference between the groups is statistically significant ($p=.006$) in favor of treatment group.

## Conclusion and Implications

The study showed that there were no significant effects of instruction integrated with ethnomathematics on mathematics achievement. This finding of the study contradicted with the report of Moses (2005) that African-American students' achievement scores in mathematics increased as they learn about African culture. Also the grades of algebra course of students taught ethnomathematical pedagogy were higher than the students' who receive instruction without the ethnomathematical pedagogy (Arishmendi-Pardi, 2001). Moreover, many researchers reported the superiority of integrating ethnomathematics into mathematics instruction on students' mathematics performance (e.g. Arishmendi Pardi, 2001; Lipka et. al, 2005; Brenner, 1998,). Another contradiction was found with Lipka and his colleagues (2005) findings that the results of students' mathematics performance were in favor of the instruction which is math in a cultural context and based on two case studies of a successful culturally based math project. So results of the current study about achievement levels may be questioned in terms of the time/length of the treatments or about the differentiation of the treatments.

Second finding of the study showed that instructional practices which was enriched by ethnomathematical examples effected students' attitudes towards mathematics positively in treatment group.
This study provides an argument for a teaching technique, instruction integrated with ethnomathematics to improve math education. The findings suggested that, integrating ethnomathematics is an effective strategy to promote students' attitudes towards mathematics. In order to enhance self-confidence, capacity, readiness and openness to work in a multicultural environment among future math teachers Gerdes (1998) argued to develop an awareness of the social and cultural bases of mathematics.

Additionally, this study provides helpful findings on integrating ethnomathematics to mathematics lessons within a mathematics learning setting. The connection between mathematical ideas and lived experience of individual students, were emphasized in the study of Presmeg (1998) which argues that the ethnicity of students is a resource for mathematics. As Gerdes (2001) suggested teachers may look for suitable activities to create a truly simulating and enriching environment to help all students fully develop their potentials.

The ornaments in Topkapı Palace prompted students to look at the colors, shapes, and patterns in the culture and reinforced the idea that ornaments can be a means of expressing one's cultural heritage, living style, psychology and status. The exploration of different ornaments, ethnomathematical practices, tilling and patterns allows students to begin to see how cultures express themselves and realize how the mathematics that they use in school is connected with things that they see in the world. This presentation offers a few ideas for using ornaments to help students explore various cultures and mathematical concepts. These activities can be modified for use with students in other grades. As students arrange and learn the characteristics of the shapes to form the tilling, they can explore the importance of the number of sides, angles, and so forth. Teachers might also modify the lessons by searching other ethnomathematical practices.

Finally in this paper, although the influence of instruction integrated with ethnomathematics was not statistically significant, in general a potential trend showing the higher mathematics performance was observed in other researches investigating the effects of instruction integrated with ethnomathematics. This is an interesting trend deserving further research.

**Abstract:** Current educational practice in higher education shows a growing use of CSCL-environments. In secondary education, however, we only see the first signs of transformation in the age of technology and the Internet, and many of these signs are particularly at the administrative level rather than in the classroom. Nevertheless, research, as well as national standards, support collaborative learning and the integration of ICT as an answer to the decreased interest and motivation in science learning and the growing importance that is attached to inquiry skills. This research project deals with the use of web-based collaborative inquiry as a promising approach for secondary science education. In particular, this study investigated the impact of the implementation of a Web-based Inquiry Science Environment (WISE) on students' content knowledge, their inquiry skills and their attitude and engagement towards science. An empirical study in 19 secondary science classes was conducted and 375 students were involved. Additionally, this study focused on gender differences and highlighted the transformation of the teachers' role in web-based teaching. The present study demonstrates the effectiveness of this innovative instructional approach in the attempt of making science accessible and interesting to all and to rectify the gender imbalance in science education.

## Introduction

The latest Eurobarometer on "Young People and Science" (2008), investigating the public's opinion, revealed that young Europeans (aged between 15 and 25) have a positive view about science and technology. However, when presented with several choices of scientific study, only a minority of these young people said they were considering them. These findings are in line with the first results of PISA 2006. The PISA results reveal that Flanders belongs to the group of OECD countries which achieved very high results for scientific literacy. On the other hand, in comparison with the 15-year-old students in the average OECD country, fewer Flemish students reported that they are motivated to learn science, and only an absolute minority thought that they will work with science later on (De Meyer, 2008). The number of students who consider taking up studies and careers in science is at a low level. This is especially true for female students. Recent research findings emanating from a range of countries demonstrate that gender equity in science education is still a cause for concern. One of the reasons for this gender differentiation in science interest is the perception shared by many girls that only boys or men are good in science and technology (Sedeno, Balmaseda, Suarez, & Dauder, 2008). Nevertheless, different research findings demonstrate that during elementary education girls' scientific achievement is equal to boys' achievement. However, in secondary education, boys significantly outperform girls with respect to science (TIMMS, 2003; PISA, 2006). The number of girls that graduate in a scientific, mathematic or technical master is lower than the number of boys. Moreover, according to the Flemish board for scientific policy (2008), this number is still decreasing.

Concerns are raised about this lack of interest in science, and the resulting reduction in the numbers of young people who opt to study science subjects at an advanced level. These concerns seem justified, especially in an industrialized society. In addition to potential economic and labor market consequences of this disinterest, there are also social and cultural consequences, since science represents an important part of the culture in which an understanding of scientific phenomena is required to participate fully in many topical debates (Woodgate & Stanton Fraser, 2007). One of the reasons for young people's lack of interest in science is that much of what goes on in science classrooms is not particularly attractive to students (Stark and Gray, 1999; Flemish governmental enquiry, 2005).

Next to that, National standards stress the growing importance that is attached to inquiry skills. More particularly, enhancing student's understanding of science concepts and process skills rather than merely teaching the lower textual-level scientific knowledge is a major goal for science educators (Galili, 1996).

These findings stress the review, rethink, and reform of science education to make science accessible and interesting to all and to rectify the gender imbalance in science education. In this respect, we investigated the impact of web-based collaborative inquiry as an innovative instructional approach for science learning in Flemish secondary education.

## Theoretical and Empirical Framework

Inquiry-oriented science instruction has been characterized in a variety of ways over the years (Collins, 1986; DeBoer, 1991; Rakow, 1986) and promoted from a variety of perspectives. Inquiry based learning is a student-centered, active learning approach which stimulates students to get involved in a social, active, engaged, and constructive learning process, as opposed to more traditional approaches which tend to emphasize the memorizing of factual information. According to constructivist models, learning is the result of ongoing changes in our mental frameworks as we attempt to make meaning out of our experiences (Osborne & Freyberg, 1985).

Inquiry-based programs have been found to generally enhance student performance related to scientific literacy and understanding of science processes (Lindberg, 1990), conceptual understanding (Slotta & Linn, 2009) and positive attitudes toward science (Kyle et al., 1985; Rakow, 1986). Moreover, research shows clearly that by reflecting, applying ideas, and collaborating with peers, students develop a sense of the relevance of science (Bransford, Brown, & Cocking, 1999). Research confirms the commonly held view that collaborative learning motivates students (Gillies, 2003) and there is evidence for the fact that students develop a positive attitude towards the course in which collaborative learning is applied (Stevens & Slavin, 1995; Nichols & Miller, 1994; Nichols, 1996; Springer, Stanne & Donovan, 1999).

With the growing importance of the World Wide Web, this information resource can serve as a means for collaborative inquiry that opens the boundaries of the classroom and creates the possibility for students to pursue questions of personal interest (Wallace, Kupperman, Krajcik, & Soloway, 2000). Research on Computer Supported Collaborative Learning (CSCL) has contributed to the claim that collaborative activity among students can effectively be supported with computer technology (Lou, Abrami, & d'Apollonia, 2001). In this respect, web-based collaborative inquiry is a promising approach. National standards and policy advisors confirm this and call for inquiry learning and the integration of technology into science classes.

In higher education, we are now witnessing a slow but steady growth in the use of CSCL, where student activities and student-teacher exchanges are coordinated through online environments. In primary and secondary education, however, we only see the first signs of transformation in the age of the Internet, and many of these signs are particularly at the administrative level rather than in the classroom (Cox, Abbott, Webb, Blakeley, Beauchamp, & Rhodes, 2004; Tondeur, van Braak, & Valcke, 2007). Apparently, teachers prefer conservative, rather than revolutionary applications of technology. Teachers remain predominantly focused on lectures and textbooks, using the Internet primarily as a supplemental resource for Web searches or multimedia materials (Slotta, 2004). Nevertheless, in research institutions technology-based environments for (collaborative) inquiry learning have been developed, such as WISE (Slotta, 2004) , Co-LAB (van Joolingen, de Jong, Lazonder, Savelsbergh, & Manlove, 2005) or BGuILE (Reiser, Tabak, Sandoval, Smith, Steinmuller, & Leone, 2001) as an arguably, more interesting and motivational approach to secondary science education.

Although different technology-based environments for collaborative inquiry learning have been developed, little large-scale research has been conducted with regard to the benefits of this approach. Through an intervention study we investigated the impact of a web-based collaborative inquiry project on content knowledge, inquiry skills and attitude and engagement towards science.

## Research questions

Four major research questions drove this study:

1. What is the impact of the web-based collaborative inquiry project on students' understanding of scientific phenomena?
2. What is the impact of web-based collaborative inquiry on students' inquiry skills, particularly hypothesis generation?
3. What is the impact of web-based collaborative inquiry on students' attitude and engagement towards science?
4. Is there a differential impact for gender?

Additionally, this study wanted to investigate web-based collaborative inquiry from the teachers' point of view with the aim of exploring how the changed classroom activity created by being online and involved in an inquiry project affected the work of teaching.

## Research design and Method

### Participants

The participants in this study were 375 students from 19 secondary school classes (grade 9, 10, and 11, the average age of these students was 16 years). The ratio of males to females in the participants was 54% girls to

46% boys. The classes were selected from 15 Flemish secondary schools and a group of 17 science teachers were involved in the research project. Teacher participation in the intervention was voluntary and teachers agreed to dedicate 4 lessons of 50 minutes to implement the CSCL-project.

## Procedure and design

Forty-six master students Educational Sciences were involved in this study to support the implementation of the project and to conduct the questionnaires and tests. For these students, this assignment was a formal part of the 7-credit course Educational Technology at Ghent University. The 46 master students were divided over the 19 classes participating in this study. There were several reasons for designing the study in this way. First, the classroom teachers did not have the time to go through a training period and the interventions had to be carried out according to a set of instructional principles. Second, the master students had more expertise in the theoretical backgrounds of CSCL and were more prepared and familiar with the inquiry-based learning environment. Third, master students acted as a researcher as well. After a specific training, master students were responsible for data collection through a semi-structured interview, pre- and posttests, and observations during the sessions.

The inquiry-based learning environment used in this study was the Web-Based Inquiry Science Environment (WISE). WISE is developed to provide a solid technology platform that allows teachers to adopt new forms of inquiry-based instruction (Slotta & Linn, 2009). Based on Peters & Slotta (2009) a Flemish WISE-curriculum project was co-designed in partnership with science teachers and technology specialists. The project addressed global warming and climate change and was connected to the standards-based curricula in secondary education. The intervention was developed taking into account research-based design principles promoting knowledge integration and scientific inquiry.

During the first session, secondary students completed the individual pretest and were introduced to WISE. Depending on the time left, they also started in dyads the first activity of the project. The total project consisted of four main activities. Students worked in the same dyads during the whole intervention and navigated through the sequence of inquiry activities using the inquiry map in the WISE environment. During the project, students were asked to write their answers down in reflection notes. Consequently, all of their project work was stored in a database, which was accessible to teachers and researchers for purposes of assessment. Finally, all students completed the individual posttest.

During the sessions, master students were asked to act as a “leader from the within” instead of a “guide on the side”. A “leader from the within” does not only monitor students but actively engage the students, helps them to synthesize their views, and maintains a dynamic process of exchange within the classroom (Slotta & Linn, 2009). After each session master students provided electronic, both positive and critical, feedback through the feedback tool of WISE.

## Data Collection, Instruments and Analysis

In this study data was collected using a mixed method approach.

First, a pretest-posttest design was used to assess the impact of the intervention. The test consisted of three main parts which assessed content knowledge, the ability to do scientific inquiry, and the attitude and engagement towards science. In the first part, thirteen assessment items were developed to measure content knowledge, eight of them were knowledge/multiple-choice items and five of them were explanation items that went beyond reproducing knowledge and asked students to connect ideas in arguments. The latter items were scored using the knowledge integration rubric that rewards both accurate and connected ideas, created by TELS. This rubric contains a number of proficiency levels. The higher the proficiency level, the more complex the skills that the students have to master to tackle the scientific problems. In the second part, students were asked to read a research article and to generate the underlying hypotheses and research questions. In order to assess students’ attitude and engagement towards science, in the third part, three scales of the international PISA (2006) questionnaire were used: support for science, interest in science and responsibility towards resources and environments. Response options consisted of a 5-point Likert scale.

Second, data was obtained through content analysis of all students’ reflection notes during the four successive science lessons and the additional observation reports made by the master students.

Finally, after completing the project, semi-structured interviews of the classrooms teachers were conducted to assess their acceptance and attitude towards the innovative environment and approach. Furthermore, focus groups were organized twice with the master students to reflect on their experiences with the organization and implementation of the web-based sessions. Special emphasis was put on their role as a teacher in a web-based collaborative project.

Data analyses were conducted using the software program SPSS, version 15.0. Paired sample t-tests, independent sample t-tests and analysis of variances were conducted to determine the impact of the intervention.

# Results

## General results

Based on the observations and focus groups, we found that master students had difficulties to perform as a "leader from the within". Most of the time they monitored the way students were progressing and mainly responded to any confusion, in this way they acted generally as a "guide on the side". They were quite occupied managing the technology and monitoring students. Secondary school students who did not ask for help or did not have obvious technical problems that required help, were not stimulated to do more. Master students asked on a regular base how students were doing but when these students responded positive, no follow up questions were asked.

Regarding the classroom teachers, all of them were positive about this experience. They were especially pleased to have their students learn in a web-based collaborative inquiry environment and are willing to participate in future research.

## Content knowledge, inquiry skill and attitude and engagement towards science

Based on the pre- and posttest items we can determine that, overall, there is significant improvement in terms of knowledge and explanation. As shown in Table 1, students made progress in connecting ideas in arguments (explanation items) and their active knowledge (content knowledge items) about climate change has increased. In the pretest the numbers of incorrect and irrelevant answers were significant higher and knowledge about the topic was rather isolated.

Table 1: Average item mean, average item standard deviation, and differences (effect size and t-test for paired samples) between pretest and posttest using the individual as the unit of analysis

| | Pretest | | Posttest | | Difference | |
|---|---|---|---|---|---|---|
| Different scales | M | SD | M | SD | ES | T (df) |
| Content knowledge items | 1.38 | 0.57 | 2.23 | 0.44 | 1.6 | 27.97 (364)** |
| Explanation items | 1.70 | 0.68 | 2.62 | 0.66 | 1.36 | 23.93 (365)** |
| Inquiry skill | 1.8 | 1.03 | 2.17 | 0.82 | 0.41 | 6.49 (357)** |
| Support for science | 3.69 | 0.43 | 3.68 | 0.48 | | -0.237 (327) |
| Interest in science | 3.43 | 0.68 | 3.47 | 0.67 | 0.05 | 2.02 (314)* |
| Responsibility towards resources and environments | 4.07 | 0.48 | 4.13 | 0.49 | 0.12 | 2.95 (305)** |

* $p < 0.05$ ** $p < 0.01$
N=375

The results for the second part of the test where students were asked to deal with a research article are also significantly higher. Students became better in generating the underlying research questions and hypotheses in a research article. However, the qualitative data based on the reflection notes and observation reports force us to refine this result. We observed frequent use of the 'copy and paste' function, so that text fragments from the internet were directly included in their answers. Furthermore, students tend to reduce the whole task to finding an obvious answer on a particular website while less attention was paid to understanding the content and critical thinking.

With regard to the impact on attitude and engagement towards science, the results are less consistent. Concerning the support for science, we noticed that this is quite high at the pretest (3.6 on 5-point-likert), however no significant differences can be found compared to the posttest. However, the other two attitude scales (interest in science and responsibility towards resources and environments) do show significant differences between the pre- and the posttest although the effect sizes are low.

## Gender differences

Boys and girls do not score significantly different on the knowledge part of the pretest. In contrast, the scores on the posttest do significantly differ. Girls outperformed boys on knowledge items ($t$ = 3.09, $df$ = 367, $p$ < .01) as well as on explanation items ($t = 4.32$, $df = 368$, $p < .01$). In other words, girls benefited more than boys from the intervention. With respect to inquiry skills, no significant gender differences can be revealed.

With regard to the attitude towards science, no significant gender differences are found concerning the *support for science*, this in contrast to the *interest in science* and the *responsibility towards resources and environments* where significant gender differences are revealed. Girls had a significant lower interest in science on the pretest, but this difference disappeared after the intervention. Regarding the responsibility towards resources and environments, we can observe the same trend as in the knowledge part. Boys and girls do not score significantly different on the pretest, but in the posttest girls were more positive than boys on this attitude scale ($t = -2.36$, $df = 269$, $p = .02$).

## Discussion and conclusion

This study aimed to get students engaged with science content through inquiry and action. More specifically, this study dealt with the use and impact of web-based collaborative inquiry as a promising approach for secondary science education on students' understanding of scientific phenomena, their inquiry skills, and their attitude and engagement towards science. In addition, this study examined gender differences.

The present study demonstrated the effectiveness of web-based collaborative inquiry. This effectiveness is especially shown for girls. On the posttest, girls outperformed boys on knowledge items, explanation items, and responsibility towards resources and environments. This implies that this innovative instructional approach is an effective contribution in the attempt of making science accessible and interesting to all and to rectify the gender imbalance in science education (TIMMS, 2003; PISA, 2006). Overall, after the intervention, students made significant gains in understanding standards-based science concepts and improved on the inquiry test. Yet, we can conclude that information seeking as a part of an inquiry-based learning environment seems to be a complex and difficult progress for these students. During the web-based inquiry project students were faced with information problems, tasks that require them to identify information needs, locate corresponding information sources, extract and organize relevant information from each source, and synthesize information from a variety of sources (Brand-Gruwel, Wopereis, & Vermetten, 2005). It is often assumed that students naturally master this complex cognitive skill of information problem solving. According to this study, this assumption can be countered. According to previous research, we know that metacognitive knowledge and awareness is critical for students to be able to control and regulate their information problem-solving processes (Lazonder, 2003). However, little is known so far about effective instruction in information problem solving. Further research planned in March 2010 will provide insight into effective scaffolds to support student-directed inquiry. Furthermore, future research needs to focus on what teachers can do in an online classroom to effectively support student learning at more than a merely technical level, given that CSCL works best if the teacher interacts with the students and maintains a dynamic process of exchange within the classroom (Slotta & Linn, 2009). Unfortunately, our findings show that most of the time, the teachers acted mainly as a "guide on the side".

# Reconceptualizing Mathematical Learning Disabilities: A Diagnostic Case Study

Katherine E. Lewis, University of California, Berkeley, kelewis@berkeley.edu

**Abstract:** Mathematical learning disabilities (MLDs) research aims to define, diagnose, and remediate the cognitive impairments that characterize MLDs. Unfortunately little progress has been made towards these goals, because of unresolved methodological issues involved in distinguishing general low math achievement from low math achievement due to MLDs. To address these methodological issues, I conducted a small-scale exploratory study of MLD, which relied on several data sources to ensure that a student's low achievement was due to persistent and debilitating difficulties with mathematics that cannot be attributed to non-cognitive sources. I conducted four weekly video-taped one-on-one tutoring sessions with students focused on the topic of fractions. In this paper I present a case study of one student with MLD. Analysis indicated that the student understood mathematical representations of fractional quantity in atypical ways and this alternative understanding was problematic for the development of more advanced fraction concepts.

## Introduction

Lisa counts on her fingers to solve addition problems, cannot add fractions, and has just failed an arithmetic course. Lisa is a 19-year-old college student. Despite her best efforts and years of tutoring, she has not mastered elementary mathematics. Unfortunately, research on mathematical learning disabilities (MLDs) offers little insight to help understand why students, like Lisa, experience persistent, pervasive, and debilitating difficulties with mathematics. How are the difficulties experienced by students with MLD qualitatively different than those experienced by all students? What are the sources of the student's difficulties? How can researchers distinguish students with MLDs from students with low mathematics achievement? These difficult questions remain unanswered and are the focus of this exploratory study.

Research on MLD is in its infancy, as compared to research on more general learning disabilities (Fletcher, Lyon, Fuchs, & Barnes, 2008; Mazzocco 2007). Learning disability research has traditionally focused on language-based learning problems, which involve difficulties with processing phonemes (the smallest unit of sound), and therefore provides little insight into the cognitive difficulties students experience in mathematics (Fletcher et al., 2008). MLDs are typically understood as core cognitive deficits, which result in a student's failure to learn or remember mathematical procedures or concepts (Geary, 2004). However, there is currently no consensus operational definition of MLDs and no diagnostic instruments available to accurately identify students with MLDs (Murphy, Mazzocco, Hanich, & Early, 2007). Consequently, researchers rely on low math achievement test scores to classify students, which does not address the myriad reasons, besides MLDs, a student could have performed poorly on the test. Given the definitional and methodological issues hindering this field, I adopt an alternative theoretical and methodological approach to the study of MLDs.

In my research I adopt a *difference*, rather than *deficit*, understanding of disability and leverage advances made in language-based learning disability research for both subject identification and analytic foci. I ensure that the students, not only meet the low-achievement criteria established by other researchers, but that the student's low-achievement is likely due to a cognitive rather than environmental factor. I define MLD by building upon innovative subject classification methodologies used in learning disability research, which require that students demonstrate (1) low achievement (for my purposes, in mathematics), (2) no evidence of confounding factors explaining that low achievement, and (3) failure to respond to an instructional intervention (Fletcher et al., 2008). In this case study, I conducted a detailed qualitative analysis of one student as she engaged in the process of learning over several tutoring sessions with a particular focus on the student's ability to conceptualize, represent, and work with numbers, specifically fractions. Just as the capacity to process phonemes is fundamental to reading competency, numbers are the fundamental building block of mathematics (Dehaene 1997, Landerl, Bevan & Butterworth, 2004). Numbers, or quantities, get represented in a variety of modalities (e.g., orally: "three-fourths", numerically "3/4", and graphically: area model for 3/4, see Figure 1). Fluency with these representational systems is a crucial part of what it means to do and understand mathematics (Ball, 1993; Lesh, Post, & Behr, 1987; NCTM Principles and Standards, 2000). This suggests that students' fluency with number, quantity, and representations is a crucial component of mathematical development and a productive analytic lens through which to explore MLDs.

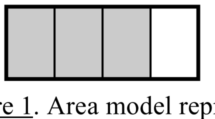

Figure 1. Area model representation of 3/4.

This exploratory case study focuses on identifying characteristics of MLDs. I conducted detailed diagnostic analyses of tutoring sessions focusing on the difficulties the student experienced, the kinds of atypical understandings she demonstrated, and her use of representations. This research addresses the following questions:

1) What is the nature of the student's difficulties during the tutoring sessions?
2) What are the characteristics of the student's atypical understanding of mathematical concepts over the course of the tutoring sessions?
3) How does the student use and understand mathematical representations?

Analysis indicated that the student experiences persistent difficulties with fraction equivalence and operations. Additionally, the student demonstrated atypical understandings of representations of fractional quantity, which hindered her ability to make sense of more complex fraction concepts.

## Prior Research on Mathematical Learning Disabilities

Prior research on MLDs has made limited progress towards understanding this complex phenomenon due to a lack of a consensus definition for what constitutes a MLD. Currently, it is a widely accepted practice to use achievement test scores below a given cut-off (typically the 25$^{th}$ percentile) to identify students with MLDs (Murphy et al., 2007; Geary, 2004). Various critiques of this approach have been identified. The cut-off score used is arbitrarily selected (Francis et al., 2005), and can range from the 8$^{th}$ percentile to the 46$^{th}$ percentile for studies of MLDs (Gersten, Clarke, & Mazzocco, 2007; Swanson & Jerman, 2006). This has led to variability in the profile of students classified as having MLDs, suggesting researchers are not all studying a common phenomenon (Murphy et al., 2007). In addition, researchers rarely attempt to control for factors that are well-established as correlated with low-achievement. Hanich, Jordan, Kaplan, and Dick (2001) report that studies of MLDs have an over-representation of minority, poor, and non-native English speaking students in the MLD group. This signifies that the proxy of low achievement does not adequately address the complex social components at play in the operational definition of MLDs. Given the lack of adequate subject identification methods, it can be argued that researchers are studying *general characteristics of low math achievement rather than MLDs*. To address this methodological hurdle, I propose adopting an alternative theoretical perspective and methodological approach.

## Theoretical Approach

Rather than adopting the traditional conceptualization of MLDs as cognitive *deficits* (Geary, 2004), I conceptualize MLDs in terms of cognitive *difference.* A deficit understanding of MLDs orients researchers to identifying the ways in which a group of students classified as having MLDs are in some way deficient when compared to a typically achieving group. Therefore, any statistically significant group difference is assumed to be consequential and indicative of the students' MLDs. In contrast, a *difference* understanding of MLDs orients researchers to identifying the nature of the individual student's qualitative differences. Instead of asking: "by how much is the MLD group deficient?" this approach asks: "what differences are consequential for an individual with a MLD and how are they consequential?" Recent MLD research supports the idea that qualitative differences exhibited by students with MLDs may ultimately be the key to differentiating these learning disabilities from low math achievement (Mazzocco, Devlin, & McKenney, 2008). Therefore, I adopt a difference model of MLDs, building on a Vygotskian perspective of disability, in which a student with a disability "is not simply a child less developed than his peers but is a child who has developed differently" (Vygotsky, Knox, Stevens, Rieber, & Carton, 1993 p. 30). I argue that the nature of a student's disability is revealed through an analysis of *qualitative* differences in how the student is reasoning over time, rather than in a quantification of deficits in knowledge measured at one point in time.

## Fractions

For a number of reasons, fractions provide a mathematically rich terrain to explore how students with MLDs make sense of mathematical concepts. First, MLDs research to date has focused almost exclusively on students' difficulties remembering math facts (e.g., 4+5=9; Gersten, Jordan, & Flojo, 2005; Swanson & Jerman, 2006). Equating MLDs with difficulty learning math facts reduces mathematical cognition to efficient and accurate production of an answer. This finding does little to explain the range of difficulties students may have across the variety of mathematical domains (Dowker, 2005; Geary, 2005). Second, the kinds of difficulties that typically achieving students experience when learning fraction concepts have been extensively documented in math cognition research (see Lamon, 2007 for a review). It is therefore possible to classify the difficulties demonstrated by students with MLDs as typical or atypical. Considering MLDs in the context of fractions allows for the exploration of procedural, conceptual, and representational difficulties that students with a MLD may experience in this more complex mathematical domain.

## Methods

This case study was drawn from a larger study that involved an extensive subject recruitment and classification process to ensure that each student's mathematical difficulties were due to an MLD and not other factors. Low achievement in math was considered a necessary but not a sufficient criterion for a MLD classification. In addition, subjects classified as having MLDs did not exhibit any evidence of other factors that could explain their low achievement and when given a sufficient instructional intervention, the student failed to show learning gains. Figure 2 provides an overview of each phase of this project including: initial recruitment, data collection, subject classification, and diagnostic analysis. Each will be discussed in turn.

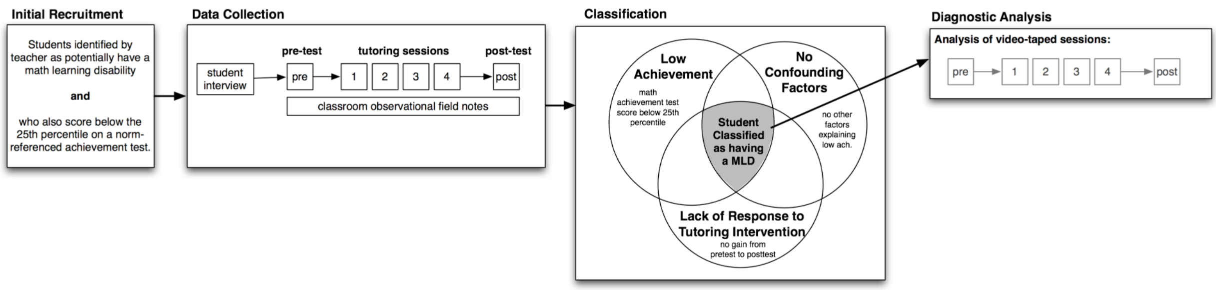

Figure 2. Overview of the design of the study.

### Initial Recruitment

Subjects were recruited from several school sites, including: a public middle school, a private high school, and a community college. Math teachers from these schools were asked to identify students who they believe may have a MLD. For those students identified, only students who met the canonical MLDs low-achievement qualification (scoring below the $25^{th}$ percentile on their most recent math achievement test) were invited to participate in the study.

### Data Collection

#### Student Interview

A 30-minute interview was conducted with the student before the administration of the pretest. The interview questions attempted to elicit the student's characterization of his/her difficulties (e.g., what about learning math is hard for you?), perceived level of effort (e.g., do you tend to complete all your math homework?) and available resources (e.g., what do you do when you don't know how to answer a math problem?)

#### Pretest / Posttest

A videotaped semi-structured clinical interview-style pretest and identical posttest was administered to all subjects. The assessment was designed to cover all fraction concepts targeted in the tutoring sequence (see Table 1 for exemplar problems). The pretest was administered the week before the commencement of tutoring sessions and the posttest was administered the week following the completion of the tutoring sessions. The student's answers and explanations were scored according to a rubric and total scores were calculated for each of the target concepts.

#### Tutoring Sessions

Four hour-long weekly videotaped tutoring sessions were conducted with the subjects focusing on fraction concepts. These sessions were designed based on prior research on the teaching and learning of fraction concepts and have been piloted and refined. In each session a sequence of problems was posed to the student, each problem was intended to build upon prior problems and provoke conversations about important math content. Table 1 provides details of the targeted concepts and exemplar problems from the pretest/posttest and tutoring session problems. Each of the problems had follow-up questions and/or counter suggestions. To refine the tutoring protocol (pretest, tutoring sequence, and posttest), it was administered to fifth-grade students with no learning difficulties. The fifth-grade students demonstrated substantial gains from pretest to posttest and therefore, this instructional tutoring sequence was considered to be an adequate learning environment.

Table 1: Target fraction concepts, exemplar problems from pretest/posttest and tutoring sessions, and references for related research.

| Concept | Details | Exemplar Pretest/Posttest Problem | Exemplar Tutoring Session Problem | Related Research |
|---|---|---|---|---|
| Fraction Representation and Interpretation | A fraction represents a single number rather than two independent numbers, which involves determining the number of equal parts of a unit out of the total number of equal parts. | Can you circle the pictures that you think are the same as 1/2? [*representations include number lines, discrete pieces, area models. Both 1/2 and equivalent fractions (e.g. 2/4) are included along with common student errors.]* | Without writing down any numbers can, you draw a picture of 3/4 so that other people would know that it's a picture of 3/4? | Ball (1993)<br>Lesh et al. (1987)<br>Mack (1990)<br>Post et al. (1985)<br>Behr et al. (1992)<br>Saxe et al. (2005) |
| Fraction Comparison | Fraction size depends on relationship between two numbers. | Which is bigger or are they equal?<br>[*2 area models are presented based on Armstrong & Larson*] | Put these cards in order from least to greatest. (Card values: 0, 1/1000, 1/2, 2/3, 8/12, 9/10, 7/7, 1, 1 2/5, 3/2) | Armstrong & Larson (1995)<br>Post et al., (1985) |
| Equivalent Fractions | Many different fraction names designate the same amount | Can you come up with a fraction equivalent to: ½, 1/3, 2/5, 8/12? | Using a whole sheet of paper, draw 2/3 of a cake. Figure out how you can cut the cake again so you still have even pieces. What has change and what has stayed the same? | Lamon (1996)<br>Lamon (2006)<br>Lamon (2007)<br>Post et al. (1985)<br>Ni (2001)<br>Kamii & Clark(1995) |

## Classroom Observations

Classroom observations were conducted concurrently with the tutoring sessions. Field notes documented any evidence of the student's attention or behavior issues, level of effort, and performance relative to peers. This was an exclusionary data source intended to capture evidence of students who have non-cognitive issues, which could explain their poor performance.

## Subject Classification

Several data sources were drawn upon to determine if the student's low achievement could be explained by other factors. Those factors highly correlated with low math achievement were considered confounding factors for the purposes of this study. These included: attention or behavior problems, lack of English fluency, insufficient resources, math anxiety (Ashcraft, Krause, & Hopko, 2007; Chatterji, 2005; Diversity in Mathematics Education, 2007; Zentall, 2007). Classroom observations, interviews, and the videotaped pretest, tutoring sessions, and posttest were used to determine if any students exhibited or reported potential confounding factors. I do not assume that MLD cannot co-occur with these factors, but that disentangling the effect of the confounding factor from the effect of MLD is beyond the scope of this study, and therefore any students demonstrating these factors were excluded. The goal was not to identify all students with MLDs, but to ensure that all students included in the larger study had an MLD. In addition, this tutoring protocol attempts to rule out the possibility that the student's history of low-achievement was simply due to poor instruction. If the student *did* show gains from pretest to posttest, it suggests that prior instruction may have been insufficient and an underlying cause of the student's low achievement. Conversely, if the student *did not* show gains from pretest to posttest, this suggests that poor instruction was not the primary cause of the student's low achievement and indicates that the student likely has an MLD. For example, Figure 3 displays a comparison of a fifth grade student's pretest-posttest change as compared to that of a community college case study student (Lisa), who I classify as having a MLD. The contrast between the student's scores (as measured by slope from pretest to posttest) is striking, providing strong substantiation of an MLD classification for Lisa.

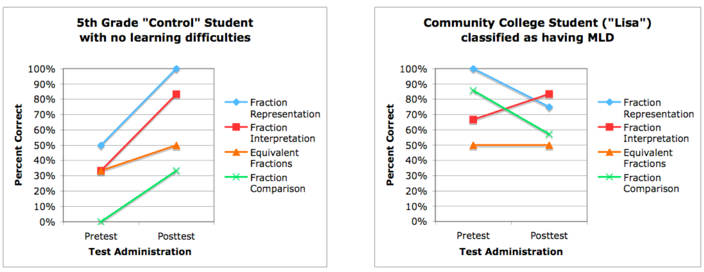

Figure 3. Comparison of a pretest/posttest scores for a typically-achieving fifth grade student and a community college student who is classified a having a MLD.

## Diagnostic Analytic Approach

All videotapes of the sessions (pretest, tutoring sequence, and posttest) were transcribed and all student work was scanned. A microgenetic bottom-up analysis of the whole data corpus for each student was conducted (see Schoenfeld, Smith, & Arcavi, 1993, for an example of this kind of analysis applied to graphing). This kind of analysis involved iterative passes through the data in an attempt to generate analytic categories that capture the nature of the student's understanding (including difficulties, atypical understandings, and uses of representations). The generation and refinement of the analytic categories involved a process of compiling the instances of a proposed kind of understanding, specifying inclusion and exclusion criteria, generating a hypothesis about the understanding, and returning to the entire data corpus (both transcripts and videos) to support or reject the hypothesis. Analysis focused on identifying the kinds of student understanding that resulted in difficulties or appeared to be consequential for how the student was making sense of the mathematics. Some of these student understandings were well documented as common problems in the math cognition literature (e.g., thinking that 1/100 is larger than 1/10 because 100 is larger than 10) and were therefore not the focus of my analysis. The rationale for focusing on these atypical understandings was an attempt to evaluate what, beyond the canonical difficulties, resulted in the student's failure to learn during the tutoring sessions.

## Results

The focal case study subject, Lisa, was considered to have a MLD because she exhibits low achievement, which was not attributable to other factors, and because she failed to respond to the tutoring instruction. Lisa had just completed her first year of community college, and her math achievement test score was in the lowest 25th percentile. Interviews and observations revealed that there were no identifiable confounding factors; Lisa was a white upper-middle class, native English speaker with no attention or behavior problems. Lisa's overall score did not improve from prettest to posttest, and for some fraction topics, her score was lower at the time of the posttest (see Figure 3).

### Diagnostic Analysis

Why does Lisa fail to learn from the tutoring sessions? A detailed analysis of all sessions (pretest, tutoring sessions, and posttest) indicates that Lisa experienced difficulties with comparing fractions, adding fractions, and generating equivalent fractions throughout all of the sessions including the posttest. Her understanding of fractional quantity appeared to be unstable, in that she operated on representations of fractions as if they represented a partitioning or removal activity as opposed to a fractional quantity. This alternative understanding of fraction representations appears to derail Lisa's ability to build an understanding of fraction equivalence, comparisons, and operations.

A detailed analysis of Lisa's use and understanding of area model representations was conducted. Area models are a common pedagogical representation for fractions, in which a shape is partitioned into evenly-sized pieces corresponding to the denominator, and then the number of pieces corresponding to the numerator is shaded. For example, an area model for 7/12 would be drawn by partitioning a shape into 12 even pieces and then shading 7 of those pieces. Lisa, however, understood area models as if they signified an *action* as opposed to a *quantity*. This understanding has two primary manifestations. First, the shading of area models was understood as the amount taken away, rather than indicative of the fractional quantity. Second, Lisa understood "one-half" as an *action* of halving rather than the quantity of 1/2. These understandings were considered atypical because they have not been documented in the math cognition literature, and were not experienced by any of the fifth-grade subjects used to validate the tutoring protocol. In addition, this alternative understanding proved to be highly consequential for the student's ability to make sense of more complex fraction concepts.

#### Understanding Area Models as Representing an Amount "Gone"

Lisa understood the shading of area models as the amount removed, rather than indicative of the fractional quantity. Lisa's focus on the removal action as opposed to quantity led to inconsistently between her construction and interpretation of area model representations. In the following example, she was asked to compare the fractions 7/12 and 1/2. She correctly constructed a drawing of 7/12 by partitioning the shape into 12 pieces and shading 7 of those pieces. However, she incorrectly determined that 7/12 is *smaller* than 1/2 and when I asked her to explain she referred to the shaded pieces as "gone" and began attending to the five pieces "left."

a)  b) 

Figure 4. Reproduction of the student's drawing of 7/12, in which she (a) partitioned a shape into 12 pieces, and then (b) colored 7 of the pieces.

L: I mean, ok, so let's say that this is the cake (gestures back and forth over entire shape– Figure 4b) and seven pieces are gone (makes sweeping motion over the shaded pieces of the shape).

…

K: Which one do I have more for?

L: Um. The half.

Although she drew a canonical area model (using shading to represent the numerator) she subsequently interpreted the shaded region of area models as being "gone". This disconnection between her correct construction and incorrect interpretation was not easily remediated and persisted throughout the tutoring sessions to the posttest. I argue that, for Lisa, the shading represented the *action* of removal rather than the fractional *quantity*. In this example, her ability to make sense of the fraction comparison task was compromised by her atypical conception of the mathematical representation. Throughout the tutoring sessions, this understanding of fractional representations in terms of action appeared to be highly consequential and detrimental to her ability to build a more complete understanding of fraction equivalence, fraction comparison, and fraction addition.

## Understanding "one-half" as Partitioning Rather Than a Quantity

Lisa often represented the fraction one-half as a partition rather than a quantity. For example, in the posttest she drew one-half by "halving" the shapes but not by designating a quantity of one-half (see Figure 5). When asked about what part of the drawing was one-half, she pointed to or redrew the line darker.

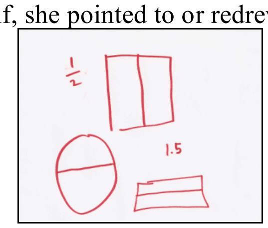

Figure 5. The written work of the student's answer to the posttest item "draw or write one-half".

This action orientation to area model representations of quantity appeared to be consequential to her inability to develop a robust understanding of equivalent fraction and fraction addition concepts. For example, at the end of one tutoring session she was attempting to write in her journal about what she had learned. During the tutoring session she had been correctly generating equivalent fractions by repartitioning area models (see Figure 6).

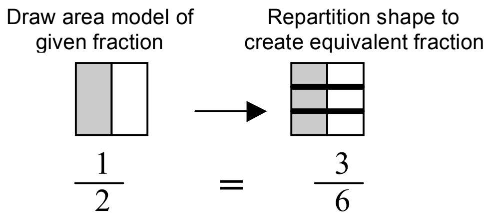

Figure 6. Illustration of the process used to create equivalent fractions during the tutoring session.

Although she had been successfully using area models to create equivalent fractions during this session, when she attempted to summarize what she had learned with an example, she incorrectly determined that 1/2 equaled 1/6. She began by drawing a square and partitioning it into two pieces (without shading). She then added two new horizontal partitions. However, because her drawing did not involve shading of 1/2, she incorrectly determined that 1/2 was equivalent to 1/6.

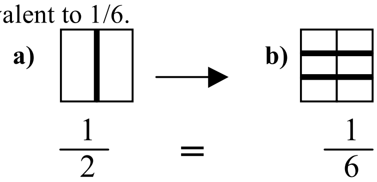

Figure 7. Recreation of Lisa's attempt to construct an equivalent fraction for 1/2 which omitted shading.

L: Ok, so like, what we were doing, if you have like one-half (draws shape and draws vertical line, see Figure 7a), and then like, cut it like that, (draws partitions, see figure 7b) it stll stays the same. It is just cut into different sections then.

K: So, how many sections is it cut into?

L: Six. So one-sixth?

After representing 1/2 as the partitioning line rather than by shading one-half of the shape, she produced a repartitioned area model with no shading. She correctly determined that the shape was divided into six pieces and guessed that the equivalent fraction for 1/2 was 1/6. This recording of an example, intended to be the culminating activity for this tutoring session, was undermined by her unconventional representation of one-half as a partition rather than a quantity. Lisa's answers and gestures throughout the tutoring sessions suggested that she understood one-half to be represented by the act of partitioning rather than a resulting quantity. Lisa's understanding of both the shaded region as signifying an amount taken away and her understanding of one-half as a partition, involved what proved to be a detrimental orientation to the area model representation as *action* rather than a *quantity*.

## Conclusion

Lisa's atypical understanding, representation, and manipulation of quantities appeared to be a fundamental source of her difficulties, which interfered with her ability to develop a foundational fraction concepts of equivalence and fraction operations. The two primary manifestations: understanding shading as taken away and understanding one-half as a partition as opposed to a quantity, have appeared in two other students in the larger study who are classified as having MLD. This suggests that the atypical understanding of representations of quantities may be a powerful finding and a productive avenue to consider in the design of diagnostic tools. Given this kind of diagnostic understanding of a student's difficulties, it is possible to begin designing and testing remediation tools, which help the student compensate for these difficulties. This case study explored the nature of MLDs, by identifying the kinds of problems a student with an MLD exhibits beyond the canonical problems typically experienced by students when learning mathematics. Future work should attempt to capitalize on the existence of these kinds of qualitative differences exhibited by students with MLD, rather than relying upon math achievement tests for classificatory purposes. Ultimately the goal of MLD research should not be to label students and classify their deficiencies, but to understand their differences and help them learn to compensate.

{wichmann, engler, hoppe}@collide.info

**Abstract:** The possibility of sharing results and ideas is an important benefit of networked communities. In educational design, practitioners (e.g. teachers) specify educational scenarios that can be (re-)used, exchanged and modified at a later stage. In addition to supporting educational scenario design as such, our graphical editor SCY-SE offers functions to retrieve scenarios created by others based on a similarity measure. To examine the validity of this similarity measure in terms of correspondence with pre-defined cases, 25 participants were asked to produce graphical scenarios from given textual descriptions. First results strongly indicate that the calculated similarity was much higher between corresponding scenarios (related to the same text, but by different modellers) than in non-corresponding cases. Also, scenarios created by the same person show high dissimilarity for different cases. These results suggest that similarity-based matching is an effective and acceptable method to support the exchange among educational designers.

## Introduction

Networked communities of practitioners have a great potential for accumulating ideas and artefacts that can be (re-)used, exchanged and modified at a later stage. This view is consistent with Wenger's notion of communities of practice (Wenger, 1998). The ability to share and exchange ideas and/or artefacts needs a certain degree of awareness on the part of the participants, which includes awareness of other active members in the community and their interests (social awareness) as well as awareness of the objects or artefacts produced in the community (content awareness). In small local communities, social awareness and social interaction often guide the identification of objects of common interest. Yet, in realistically sized networked communities, this will only work to a very limited extent. Alternatively, objects of common interest have to be identified on the content level. Technically, this identification can be achieved through providing a similarity measure for pairs of objects. Here, we assume that a community repository will accumulate objects produced by community members, and that these objects can be seen as indicators of the current interests of their authors (at creation time). So, for each new object that is uploaded to the community repository we can automatically search for similar objects that already exist. These existing objects may be brought to the awareness of the new author, which may result in revising the content in regard of existing material or even in contacting the creators of the existing objects to coordinate further elaboration and other actions.

A similar approach within a community of science learners has been suggested by Hoppe et al. (2005). Here, the objects of interest were so-called "emerging learning objects" created by members of different local teams in an international learning community that shared different scientific challenges without personally knowing each other between the different local teams. Objects of common interest between two partners were also identified by similarity, exploiting the internal structure of the objects. The similarity measure had to work in the absence of user-defined metadata since it was assumed that a sufficiently complete and consistent indexing of emerging objects by the creators (high schools students) could not be expected. A comparable mechanism to identify congruence of interests in a community of scientists has been suggested by Francq & Delchambre (2005) based on a publication database with a similarity definition using automatic indexing techniques. Generally, similarity measures can be used as a source of continuous information on themes of personal interest. Similar functions are served by *recommender systems* (cf. Konstan & Riedl, 2002), which usually rely on information about usage processes, namely by computing object-object associations through co-occurrences in user traces.

In our study, we target a community of educational designers who produce semi-formal designs of structured learning scenarios using a graphical editing tool. The potential benefit of automatically identifying objects of common interests (i.e. specific educational designs) as a content awareness function is evident: It will be possible to relate new suggestions to existing ones early at design time. Thus, unnecessary redundancies can be avoided and synergy between similar approaches can be exploited. The question, however, is if the underlying similarity measure does really capture those features that would be considered as relevant by human judgment. Suggestions based on irrelevant or artificial similarities would soon lead to rejection of the support mechanism. To validate the similarity mechanism in this sense, we provided users with a number of different textually defined learning scenarios that were to be represented (or modelled) graphically using our editing tool. To be “valid” and acceptable the mechanism should adequately reproduce the original differences irrespective of personal preferences and idiosyncrasies. This makes another assumption, which is that the modelling task with the given tool itself is well-defined in that a substantial amount of relevant information can be transferred from the textual description to the graphical model. A negative outcome would still not clarify if the problem was with the similarity calculation or with the coding task (or both). A positive outcome, however, would confirm both the task-tool fit and the adequacy of the similarity measure. In the sequel, we will first describe the scientific context of this study in a European research project, then elaborate on the technical ingredients (editor and similarity measure) and finally report our empirical findings.

## Educational design of inquiry-based learning scenarios

The requirements for the work presented in this paper stem from a new European research project called SCY[1]. In the SCY project (de Jong, Joolingen van, Weinberger, 2009), students engage in inquiry learning activities supported by computer tools such as simulations and modelling software. In SCY-Lab (the SCY learning environment), students work on missions and meet challenges collaboratively and individually supported by learning material, tools and scaffolds. To meet the challenges of inquiry learning, the configuration of SCY-Lab is adaptive to learners’ capabilities and progress. In order to support the cyclic nature on inquiry learning, SCY-Lab provides tools and scaffolds, which provide just-in time support (Anjewierden, Chen, Wichmann, & Borkulo van, 2009). Another characteristic of inquiry learning is learners’ rich interaction with learning material. In SCY missions, students not only receive learning material (e.g. in form of text), they also produce material (e.g. in form of data by running experiments). The construction of artefacts that emerge from the learning process has been articulated as one of the central ideas in SCY. These emerging learning objects (ELOs) are re-usable and sharable products of learning activities, which are created by learners. As part of SCY’s pedagogical approach, several so-called *learning activity spaces* (LASs) have been identified. These are characterised by specific combinations of tools, activities and types of input/output objects. *Learning scenarios* are defined on an upper level by a set of LASs with partial sequencing.

One goal of SCY is to support a community of practitioners (teachers and instructional designers) in creating and sharing educational scenarios. Existing languages and tools in the area of learning design such as LAMS (Dalziel, 2003) or IMS/LD[2] appeared to be not sufficient for our purposes for different reasons: LAMS is too coarse grained with respect to capturing object-tool-activity relationships and results in quite fixed sequential models with too little flexibility. IMS/LD is more expressive with regard to tools, activities and roles, yet it lacks a conceptual model and graphical representation that would be usable by non-technical experts (cf. Miao, Harrer, Hoeksema, & Hoppe, 2007). Both approaches lack possibilities to adequately represent input and output relations with ELOs.

As argued above, effective community support has to include the sharing and re-use of previously developed scenarios. For teachers who develop new scenarios for SCY missions it is important to be able to find scenarios with specific characteristics. For instance, several strategies exist to introduce scientific texts to learners. One teacher might favour a concept mapping activity to identify and integrate new concepts while another teacher would request the students to summarize the text using a note-taking tool. Different approaches to facilitate sharing and re-use have been suggested. One approach is to select and filter scenarios based on certain categories such as age and subject. However, single categories like these may not be sufficient to capture what is relevant for the teacher (cf. Ronen, Kohen-Vacs, & Raz-Fogel, 2006). Another method is to let users (here: teachers) freely tag their design objects. Tagging, however, bears several problems. First, it is an additional effort, which is often avoided. Second, the degree of freedom and subjectivity in free tagging may lead to inconsistencies of various types, which will lead to unreliable results when used for retrieval. Therefore, we propose a similarity measure that reflects the two-level structure of our learning design and uses several content categories (such as activities, tools and object types). For instance, a teacher may want to focus on argumentative activities and might thus be interested specifically in other scenarios involving argumentation tools and ELO types compatible with argumentation.

## The SCY- SE Scenario Editor and graphical language

The SCY Scenario Editor (SCY-SE) has been designed and implemented following the definition of pedagogical requirements and the ensuing specification of a graphical representation language (de Jong et al., 2009). SCY-SE has been implemented as a plug-in to the multi-functional graphical modelling environment FreeStyler (Hoppe & Gaßner, 2002). FreeStyler provides a uniform platform for various visual languages with free-hand annotation

[1] SCY – “Science created by You” is an EU project of the 7th Framework Programme. For more information, see http://www.scy-net.eu (last visited in October 2009).

[2] For the full specification and more information in IMS-LD, see http://www.imsglobal.org/learningdesign (last visited in October 2009).

facilities and shared workspace facilities. The graphical user interface of SCY-SE offers a two-level view reflecting the pedagogical design: the scenario view combines several LASs with input and output ELOs, whereas the lower-level LAS view specifies activities, tools, intermediate ELOs and other resources. SCY-SE provides a toolbox ("palette") from which objects can be dragged onto the workspace.

Table 1. Concepts in SCY-SE

| Concept | | Specified by the SCY-SE user |
|---|---|---|
| ELO (Emerging Learning Object) |  | ELO characteristics (functional role, technical format, logical representation, belonging activity) |
| LAS (Learning Activity Space) |  | - LAS type (e.g., conceptualization, build, debate, experiment)<br>- Location (at home, classroom, field)<br>- Setting (peer to peer, whole class, alone)<br>- Computer use (yes, no) |
| Tool |  | Tool type (e.g., simulation tool, modelling tool, note taking tool) |
| Activity |  | Activity type as suggested by the LAS type (e.g., build model, run experiment, define ) |
| Scaffolds |  | Scaffold that is connected to a tool or LAS that represents scaffolding mechanisms for the specific entity. |
| Resources |  | Resource that is used for an activity (e.g. video, audio, text) |

The table above (Table 1) shows the objects that are currently implemented in SCY-SE and part of the SCY language. In the study, SCY-SE was modified so that ELOs did not need to be specified with respect to format etc. and scaffolds were not available in the toolbox.

## Background: Blackboard architecture and ontology

The SCY environment relies on loosely coupled components with intelligent agent support. Agents communicate with other system components as well among themselves using a so-called *blackboard architecture*. The basic idea of the blackboard architecture is to provide interaction between components (such as agents) not by addressing other components directly, but by communicating only via writing and reading messages on the blackboard. The advantage of this paradigm is that every component is running autonomously and little knowledge about other components is necessary. This approach leads to a more robust system and provides an architecture that can be easily and flexibly extended or modified. A well-known technical approach to implementing a blackboard architecture is TupleSpaces (Gelernter, 1985). Here, a dedicated server acts as an operational centre for exchanging information. The information is stored on this server in form of tuples, which are ordered sequences of typed data. There are several implementations of TupleSpaces like JavaSpaces (Sun Microsystems) or TSpaces (IBM). We are using an implementation called SQLSpaces (Weinbrenner, Giemza, & Hoppe, 2007). SQLSpaces offer some extra features such as asynchronous call-backs, programmable expiration time of tuples, blocking and non-blocking operations, a web-based visualization, versioning and user management. Furthermore, SQLSpaces come client interfaces for several programming languages, including Java, C#, Ruby, Prolog and PHP. In the case of SCY-SE, the agent that calculates the similarity between scenarios is written in Prolog, a logic programming language.

SCY-SE also makes use of a pedagogical ontology, which captures the basic terms describing activities, tools, object types and their interrelationships. The checking mechanism, which is described later, utilizes these relations to check whether the relations between the concepts of the user are valid or not. Using the ontology for the concepts and relations results in a system, which is easily extend- and adaptable. New constraints or types of concepts can be inserted into the ontology using an editor like Protégé[3]. Using an ontology allows us not only to access concepts related to SCY, but also to specify relations between these concepts, which is useful for determining similarity between concepts.

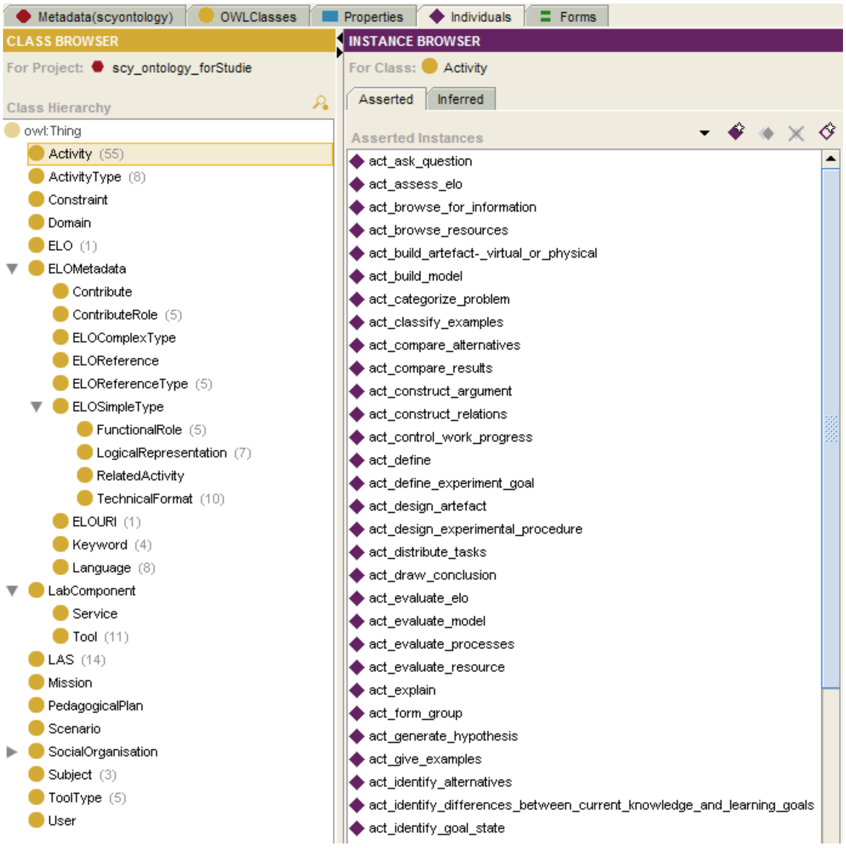

Figure 1: Protégé screenshot of the ontology and its concepts.

## Similarity algorithm

The overall process of calculating the similarity is shown in Figure 2. In the first step, SCY-SE constructs lists of the relevant entities of the scenarios to be compared. These relevant entities consist of the three components ELOs, tools and activities, which are grouped by the corresponding LASs of the two scenarios. These can again be divided into two categories: Activities and tools are atomic values, so that lists of them can be compared directly through the “weighted symmetric distance” of two sets. This distance is based on the cardinality of the symmetric difference, which is then divided by the cardinality of the union of the two sets A and B:

$$\Delta_{A,B} = \frac{\#((A \cup B) \setminus (A \cap B))}{\#(A \cup B)}$$

This distance calculation has been modified by component weights based on the ontological proximity between the single elements. The resulting similarity value ranges between 0 and 1.

ELOs, on the other hand, are not suited for a plain comparison as mentioned above. In fact, they are built up from four properties and therefore have an intrinsic complexity that requires a different approach for calculating the similarity. At first glance, it is possible to calculate the similarity of two ELOs A and B by comparing the four properties, so if two ELOs share three of their four properties, they would have a similarity of 0.75. Nevertheless, the comparison of A and C might result in an even higher similarity. So, each ELO of the first list needs to be compared with each of the second one. The outcome of this step is a matrix of similarity values. To condense this matrix to one single similarity value that expresses the similarity of these two lists, we decided to use the so-called “Hungarian method” for graph matching (Kuhn, 1955) to solve this assignment problem (to determine which ELO is identified with which other ELO).

[3] For a documentation and download location visit: http://protege.stanford.edu/doc/users.html (last visited in October 2009)

As shown in Figure 2, the calculation inside the Prolog agent is done in several steps. After the lists have been written to the SQLSpaces server, a "start comparing" tuple is written to inform the agent about a new query. Then the agent fetches the lists and calculates the weighted symmetric distance for each of the lists. At that point the matrix for the ELOs is already calculated by using the "Hungarian method". The next step uses the merged matrix of these three matrices. The Hungarian method is then used again to determine the best mapping between the LASs of the two scenarios with respect to the similarity encoded in the matrix. The method may take several iterations, but will eventually terminate and return the optimal solution. From the resulting mapping, a single value can be easily calculated by normalizing the selected matrix entries. The returned "similarity value" (Sim(A,B)) is transformed in such a way that Δ=0 corresponds to Sim=100% and Δ=1 corresponds to Sim=0%.

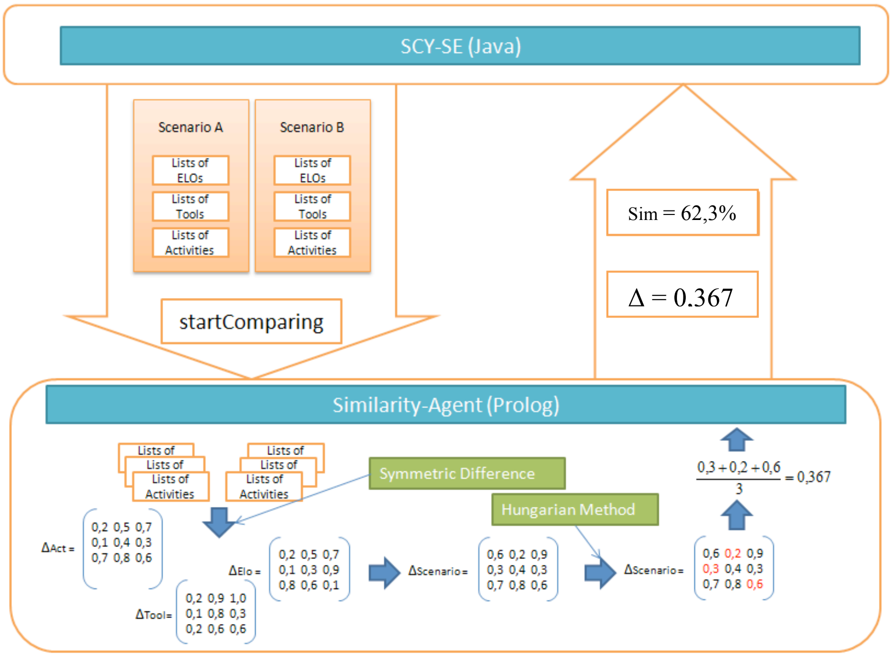

Figure 2: The overall process of the similarity measurement.

For the study, not all components of the similarity measure had an effect on the result because of the limited version of SCY-SE that participants were using. Since the limited version did not include options to specify ELOs with respect to technical format etc., all ELOs were similar. Therefore, the similarity measurement was based on other factors (e.g., number of LASs, number and type of tools and activities).

## Checking

SCY-SE allows for the automatic checking against several types of constraints and constraint violations (such as incompatibilities of object types) in given designs, some of which are ontology based. The more obvious ones apply to the way nodes are connected. To distinguish between ELOs that are emerging from a LAS and ELOs that work as starting material for a LAS, SCY uses the notion of input and output ELOs. An output ELO needs some activity that produces it and an input ELO needs some activity that consumes it. Moreover, ELOs can have more or less precisely defined types. These types also have a "compatibility" relation to tools (that support activities) based on the tool's potential output data formats. This compatibility relation is stored in the ontology. Violations of any rule are displayed next to each incorrect node with short information about the problem and possibly a hint for resolving this violation.

## Research goals and questions

The main goal of this study was to test the validity of the similarity algorithm. We prepared three textual descriptions of scenarios consisting of inquiry learning activities. Based on these textual scenarios, students created graphical scenarios using SCY-SE. In addition, expert solutions were created beforehand by researchers, to which the student scenarios were compared. To distinguish between student scenarios and expert solutions, scenarios created by students use a lower case letter (a, b, c) and expert solutions use an uppercase letter (A, B, C). The following questions were of interest:

1. a) Are SCY-SE scenarios created based on the textual scenario a, more similar to a corresponding expert solution A than to a non-corresponding expert solution B?
   Hypotheses: Sim(a, A) > Sim(a, B); Sim(a, A) > Sim(a, C); Sim(b,B) > Sim(b,A) etc.

b) Are the differences induced by the given textual scenarios still discernable in the graphical scenarios produced by the same subject?
Hypotheses: Sim(a, b) < Sim(a, A); Sim(a, c) < Sim(a, A); Sim(b, c) < Sim(b, B) etc.

Additionally, we were interested in the influence of checking and ensuing feedback:

2. a) Does the checking feature help to guide users during the process of creating a complete SCY-SE scenario?
   b) Does using the checking feature increase the similarity to the corresponding expert solution?

## Design of the Study

### Participants, procedure and instrument

Twenty-five students of media-technology or teaching were participating in the study, taking place at a university lab in Germany. Participants listened to a half hour introduction to the SCY-SE approach and to the language including a demo of how to use SCY-SE. After the introduction, everyone received a small manual and the task description. Every student worked individually on one computer. The task was to translate three textual scenarios into graphical scenarios using SCY-SE. Participants had to decide which LASs, activities, tools and ELOs need to be selected to represent the textual scenarios graphically. When a student was finished with the last scenario, she was requested to save the *SCY-SE scenario c* under a different name, to use the checking button, and to revise *SCY-SE scenario c-checked* accordingly. The participation time was two hours. A questionnaire including demographic questions and single-item questions with respect to perceived difficulty was administered right after the study.

### Material

Every textual scenario consisted of four paragraphs. Each paragraph represented one LAS. All textual scenarios described activities following an inquiry approach within the subject matter of photosynthesis. The textual scenarios differed from each other with respect to activities, tools and ELOs. The following paragraph is an example of how activities were described in the textual scenario:

> "Students work in groups to do their experiments using SCY Simulator. They define their experiment goals in SCY Simulator. Afterwards the students start doing their experiment runs. Then, the students compare the results with their hypothesis stated earlier. They make notes, which they upload together with their experiment data."

The translation of this paragraph into a SCY-SE scenario may look like this:

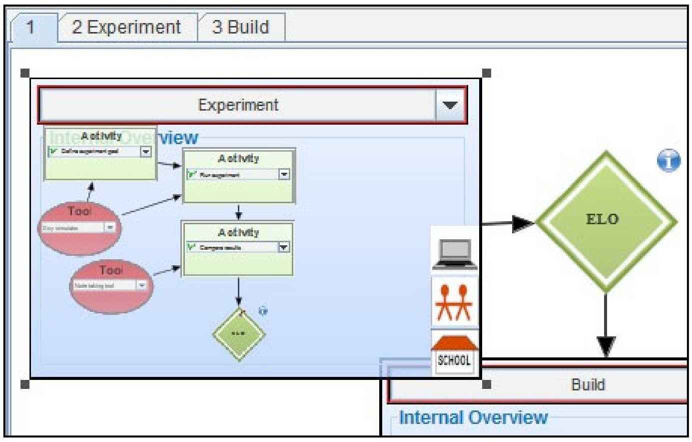

Figure 3. SCY-SE Scenario view

### Source of Analysis

Hundred SCY-SE scenario files (four – three unchecked and one checked- from each participant) were collected and analyzed. Similarities were calculated. For answering research question 1a, SCY-SE scenarios were compared with corresponding and non-corresponding SCY-SE scenario expert solutions. Concerning question 1b, SCY-SE scenarios were compared with SCY-SE scenarios by the same student. Answering research question

2a required logging the number of errors detected by the checking mechanism and question 2b required to compare SCY-SE scenario c with SCY-SE scenario c-checked.

## Results

Due to low sample size, descriptive statistics were favoured and non-parametric methods were used. From the questionnaire, we found that most participants (72%) reported that textual scenarios were of similar difficulty level. Some participants (24%) identified one of the three scenarios as most difficult. Most participants (76%) reported that it was most difficult to select the tools (besides LASs and Activities).

First, we compared every student's scenario a, b, c with the corresponding expert solution and with the non-corresponding expert solutions. As expected, if student scenarios were compared with the corresponding expert solution, the percentage with respect to similarity was higher (M=81, SD=07) than if student scenarios were compared with the non-corresponding expert solutions (M=55, SD=04). Wilcoxon's Signed-Rank test showed that this difference (Table 2 and Table 3) was statistically significant (z=-4.37, p=.000).

Table 2. Descriptives for similarity between student scenario and corresponding expert solution in %

| student scenario \| expert solution | N | Min | Max | Mean | Std. Dev. |
|---|---|---|---|---|---|
| a \| A | 25 | 25 | 85 | 74 | 12 |
| b \| B | 25 | 62 | 99 | 83 | 09 |
| c \| C | 25 | 62 | 96 | 86 | 08 |

Table 3. Descriptives for similarity between student scenario and non-corresponding expert solution in %

| student scenario \| expert solution | N | Min | Max | Mean | Std. Dev. |
|---|---|---|---|---|---|
| a \| C | 25 | 24 | 68 | 54 | 10 |
| a \| B | 25 | 19 | 69 | 55 | 10 |
| b \| C | 25 | 40 | 68 | 54 | 06 |
| b \| A | 25 | 44 | 69 | 56 | 05 |
| c \| A | 25 | 47 | 55 | 58 | 05 |
| c \| B | 25 | 41 | 67 | 48 | 04 |

Second, we compared student scenarios with student scenarios (Table 4) done by the same student (Sim(a,b); Sim(a,c), Sim(b,c)). As expected, similarity was low (M=53, SD=08) and comparative to similarity between expert solutions A, B, C (M=58, SD=49).

Table 4. Descriptives for similarity between (non-corresponding) scenarios for every student

| student scenario \| student scenario | N | Min | Max | Mean | Std. Dev. |
|---|---|---|---|---|---|
| a \| b | 25 | 14 | 68 | 55 | 10 |
| a \| c | 25 | 21 | 75 | 53 | 11 |
| b \| c | 25 | 39 | 65 | 51 | 06 |
| Valid N (listwise) | 25 | | | | |

### Checking

Results show, that the checking feature was necessary for most participants to create complete and correct SCY-SE scenarios. On average, participants made 4.7 (SD=3.3) errors that were detected by the checking mechanism. In order to find out whether the checking feature would increase similarity between student scenario and expert solution, we compared the last scenario (*SCY-SE scenario c*) that was developed with the corresponding expert solution (*SCY-SE Scenario expert solution C*). We found no significant difference with respect to similarity comparing unchecked and checked scenarios. On average, *SCY-SE scenario c* was 86% similar to the *SCY-SE scenario expert solution C*. After using the checking mechanism, average similarity was still 86%. In order to find out why the checking feature did not yield higher similarity, an in depth analysis with respect to the types of errors was done. The errors that were displayed while using the checking feature were mostly related to incorrect usage of links between objects or missing links. For example, many participants missed making links between tools and activities. Since the similarity algorithm did not take into account the number of links, the checking had no positive effect on the similarity measure.

## Conclusion and Implications

The results demonstrate that the similarity measure captures well the plausible similarity between graphical scenario designs originating from the same textual source across subjects (as “modellers”). We could also show that dissimilarities of scenarios developed by the same person but based on dissimilar textual scenarios were detected (and therefore discriminated). It was somewhat surprising that scenarios that were based on non-corresponding textual descriptions still resulted in a similarity of over 50%. One reason was that all three textual scenarios (which were the basis for the graphical representations in SCY-SE) had approximately the same length and the same number of LASs. Together with certain tool similarities suggested by the ontology this resulted in a quite high baseline. Yet, as the similarity of scenarios based on corresponding textual scenarios was over 80% (which results in a statistically significant difference), we were able to reliably discriminate similar scenarios from dissimilar scenarios. Another finding was that guiding a practitioner during the creation of a scenario using SCY-SE is beneficial. Using a checking mechanism helps to reduce the number of errors and to use the SCY graphical language consistently.

# Preparing for the Long Tail of Teaching and Learning Tools

Charles Severance and Stephanie D. Teasley, School of Information, University of Michigan,
1075 Beal Ave, Ann Arbor, MI, 48109-2112
Email: [csev, steasley]@umich.edu

**Abstract:** In this paper we apply the concept of "the long tail" (Anderson, 2006) to teaching and learning tools to discuss how the limitations of current Learning Management Systems (LMS) can be overcome to allow instructors to customize the technology they use to support their own classroom practices. Learning tools in the long tail are those that are widely used by a subset of instructors - tools specific to large courses or tools specific to a particular field, and tools that are only used in a few courses or a single course. Using several examples from courses taught on our campus, we show how to put extensibility in the hands of the instructors to create knowledge-age learning technologies that are customizable, interactive and controlled by users.

## Introduction

Increasingly, learning management systems (LMS) such as Blackboard or Sakai are seen as one of the most essential Enterprise Services in education. A recent survey of 115 American universities has shown that 89% of students reported that they had taken a course that used a LMS (Smith, Salaway, & Caruso, 2009). In addition, a 2009 survey of US school district administrators estimated that more than a million k-12 students took online courses in the school year 2007-2008 (Picciano & Seaman, 2009). That these systems are basic infrastructure for learning in higher education is already a fact; that they are as common in K-12 education may also soon be true (see Means, Toyama, Murphy, Bakai & Jones, 2009). Yet what do we know about using LMS well for teaching and learning? How can we help teachers to incorporate the promise of Web 2.0 technologies into their classrooms? In this paper, we examine the trends in the evolution of learning management systems and how those systems are currently being used in higher education. We then propose how learning management systems must change by leveraging the "the long tail" (Anderson, 2006) of teaching and learning tools. These suggestions apply to higher education specifically, but also provide guidelines for development and use that may ease the transition as LMS use permeates K-12 education.

## Background

Few other campus enterprise systems have the requirements of 24x7 availability, with the ability to scale to support over 10,000 simultaneous users during peak loads. On many campuses, learning management systems must run for months without allowing for an outage to perform major software upgrades. These requirements lead to a very careful and conservative approach to upgrading or changing the LMS software in the middle of a semester. This trend is coupled with increasing penetration of the LMS system as measured by the percentage of students and faculty who are using the LMS (Smith, Salaway, & Caruso, 2009). On our own campus, the annual IT survey shows that 99% of students and 81% of faculty have used our LMS for at least one course in the past year (Lonn & Teasley, 2009).

Because LMS use has become so pervasive in higher education, we have an opportunity to analyze how the average instructor uses these systems across many different subjects. Most analyses of LMS use (Hanson & Robson, 2004; West, Waddoups, & Graham, 2007) point to a distribution that follows the "long tail" typically found in analyses of most online systems (Anderson, 2004). Specifically, the long tail refers to the statistical phenomenon of a power law or Pareto distribution where few items comprise the most use but there is a long tail of many items used with a much lower frequency. This distribution is clearly seen with the use of tools available within LMS, where a few tools are heavily used then usage drops off dramatically after five or six core tools. Overall, document management and broadcast-oriented communication tools (Content Sharing, Assignments, Announcements, Schedule, and Syllabus) comprise 95% of all user actions (Lonn & Teasley, 2009; Hanson & Robson, 2004). By contrast, the tools that are more interactive (Chat, Discussion, and Wiki) are not used as much. While research coming from the Learning Sciences would have much add to the current literature addressing the relative value of teaching with one tool or another, in this paper we leave this to others and focus here on the fact of current LMS use and how to empower instructors improve their own use of these systems.

The two trends of "LMS as critical infrastructure" and "only a few of the tools are heavily used" leads to the inevitable conclusion that LMS development efforts need to focus on improving the core tools which make up the LMS and spend less effort on the long tail of tools. If the trend was extended to infinity, LMS systems of the future might have exactly seven tools which are never changed or upgraded. While this will insure that the core infrastructure is solid, consistent, and reliable, it will have a tremendous negative impact on the ability for instructors and learners to innovate and find new ways to use technology in education. One possible path forward is that learning management systems will go "underground" - where in order to experiment with innovative ideas, savvy faculty host their own learning management systems under their desks or perhaps run software on their own ISP account. The "Edupunk" movement (e.g., Kuntz, 2008; Young, 2008) expresses this sentiment in a call-to-arms to reject commercial LMS products. This approach does allow instructors to be innovative, but it adds the burden of maintaining a production infrastructure and saps precious energy away from their teaching efforts. Another extreme reaction to the perceived limitations of current LMS is a call to "teach naked" and reject the use of technology in the classroom altogether (Young, 2009). This, however, seems like a “baby with the bathwater” solution that is not likely to be realistic for today’s students who are considered to be the “net generation” and “tech-savvy Millennials” (Junco & Mastrodicasa, 2007).

Rather that going Edupunk or even teaching naked, we believe the solution to this problem is to add features to LMS systems that allow the core functionality to focus on scalability and stability while allowing innovation at the edges by encouraging more use in the long tail. The key to this approach is that we need to add features to LMS systems so that they can be extended without adding a new feature on to the LMS servers or needing to upgrade the LMS to a new version (Severance, Hardin, & Whyte, 2008). The extensibility needs to be placed in the hands of the instructors rather than only in the hands of the LMS system administrators. This DIY (Do It Yourself) attitude reflects the growing capacity of Web 2.0 applications to put users in control of the content and distribution of materials. In popular culture this DIY capability can be seen in zines, self-publishing, and music re-mixes. We believe this approach can be extended to educational tools as well and fulfill Collins & Halverson’s (2009) call for knowledge-age learning technologies to be customizable, interactive and controlled by users. Only then can we meet both the needs of enterprise production and innovative approaches to teaching and have the best of both worlds. The average instructor who only uses 5-6 core tools has access to a scalable and stable toolset, while the instructor with a new idea is allowed to bring that idea into their class in a few days or weeks of effort - all without destabilizing the LMS production system.

## Teaching Tools in the Long Tail

We see learning tools falling into three basic categories: (1) the core 5-10 tools used by nearly every teacher, (2) a set of tools that are widely used by some subset of the teachers - perhaps tools specific to large courses or tools specific to a particular fields like mathematics, and (3) tools that are only used by a few courses or even a tool purpose built for a single course. As we look at the nature of the tools in (1) and compare them to the tools in (3), we are likely to see a transition from tools that "manage" the learning process towards tools that support the learning process. The tools in category (2) are likely a mix of management and learning. This leads to a "long tail" effect where the more learning-oriented tools are in the long-tail. While each individual tool may have a very small "market share" when aggregated together, these long-tail tools may well represent a majority of the overall usage.

The nature of the content-oriented tools (category 1) that are used universally is that their features are likely to be useful to every single instructor, regardless of context or discipline. Hence Category 1 tools comprise the bulk of the distribution of use curve. By contrast, the tools in the second category tend to end up appealing to a smaller but identifiable population of instructors. For example, the CAPA testing system uses LaTeX as its question authoring language and as such naturally appeals fields such as mathematics, chemistry, and physics where most of the instructors with a Ph.D. in those fields learned LaTeX to write and publish papers. Furthermore, CAPA provides a very rich (albeit complex) mechanism for generating many equivalent variations of a problem by altering numeric values randomly. This functionality is very useful for courses where many of the problem sets assigned to students involve numeric calculations. While the CAPA system is very popular for use in first and second year physics, math, and chemistry classes with high-enrollment numbers, it is simply too difficult to learn to ever become widely used for fields like literature or the humanities. This naturally limits the *overall* number of courses and faculty who will use a CAPA-based system to a small fraction of the market – perhaps less than 2-3% of the overall courses taught. However, for those courses, CAPA is nearly the *perfect* solution particularly when coupled with the ability to collectively build large question pools across institutions and with some publishers providing CAPA question banks with physics and chemistry textbooks. Since CAPA reflects such a small market share overall, the testing systems provided in mainstream LMS products do not include CAPA-like features and so if you teach a course that needs CAPA – pretty much your *only* choice is CAPA. For tools in the third category, the potential market share is smaller yet and these tools may have very individualized use that can not necessarily be generalized across disciplines or teaching contexts.

In what follows below, we discuss several examples of category 2 & 3 tools in the long tail and provide detail about the ways in which these tools extend instructors’ use of the standard LMS toolset to meet their unique needs. These examples reflect current teaching practice at the University of Michigan where the enterprise LMS is based on the Sakai open-source LMS.

**Student Assessment Management System (SAMS)**

In our College of Literature, Science, and Arts (LSA), instructors have access to a CAPA-based system called SAMS (Student Assessment Management System) which is heavily used by the physics, mathematics, and chemistry departments. A requirement unique to SAMS is the need to do extensive data mining across the multiple sections of the same course. Since there are so many sections taught by graduate student instructors in introductory-level courses, SAMS must be able to provide regular reports to course coordinators so that problems encountered by individual student-instructors can be diagnosed and addressed as quickly as possible. In addition, error patterns in problem sets seen across sections provides the main instructor with feedback about which concepts and/or formulas need further elaboration in lecture or additional time in section. For these reasons, SAMS is considered to be a powerful tool in achieving consistently high quality in the teaching of these large-enrollment courses.

Despite its important role in the largest academic unit on campus, SAMS is not in the standard toolset provided by the LMS. Since SAMS is written in PERL and the underlying architecture of the LMS (Sakai) is written in Java and because the requirements for SAMS are so complex (e.g., including rules about to who can see which data and reports), it was never practical to re-write SAMS inside of Sakai. For many years students in classes that used SAMS visited two separate sites for their courses: one course site in the LMS and one course site in SAMS. This was confusing and inconvenient for students *and* instructors as the SAMS site had its own navigation, login process, and user interface conventions. After an early version of IMS Learning Tools Interoperability was installed in Sakai, we were able to integrate SAMS into Sakai to share identity and roster information with SAMS without any user intervention. We even created a virtual tool in Sakai that made it look like we have built SAMS into Sakai. Instructors can now simply add the SAMS tool to their course site like any built-in Sakai tool. Figure 1 displays the user's view of SAMS inside of a Sakai course site.

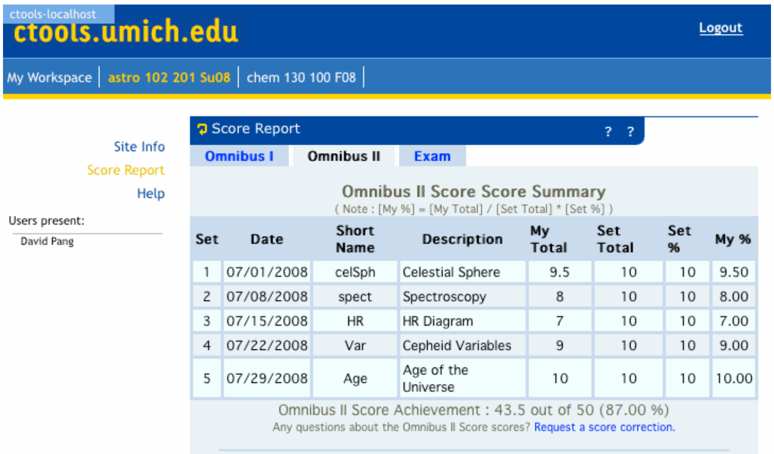

Figure 1. SAMS Running Within Sakai

Effectively the user experience for both the instructors and students is as if the SAMS tool had been ported into Sakai. There is no need to rewrite any software; we only had to add some integration in SAMS to receive and process the IMS Learning Tools Interoperability launch requests from Sakai. This approach also allows the College of LSA to maintain their strategic access to their data, and to independently upgrade and improve SAMS to meet their needs on their own schedule, unencumbered by the Sakai development or production priorities.

This is an excellent example of how we can develop category 2 tools to meet both the enterprise-wide needs in teaching and learning as well as the school-level needs for teaching and learning. The approach allows reuse of the common capabilities of the enterprise systems while allowing schools or departments to address their own unique needs in focused areas of teaching and learning. An enterprise LMS does not have to be a win-lose proposition across campus.

**LectureTools**

The LectureTools project provides free tools that support interactivity and enhanced modes of learning during lectures. Like CAPA, LectureTools is most useful for medium to large lecture courses where the teaching staff wants to use support interactions between the instructor and student, and between students as part of the lecture experience. Again we see a situation where the overall population of instructors for whom LectureTools is useful is a fraction of the entire set of courses that are taught at the university. And, here again, the functionality provided by Lecture Tools is not likely to be included into the core functionality of most LMS systems.

Like the SAMS project, we developed a similar virtual tool approach to integrate LectureTools into Sakai. Instructors can add the LectureTools tool to their course site like any other tool built into Sakai. Sakai uses IMS Learning Tools Interoperability to launch and provision course sites in LectureTools, giving students and instructors a seamless user experience from a single course site. Unlike SAMS, the LectureTools service is available to instructors at any university in the US and Canada. These additional schools may or may not use Sakai as their LMS. As IMS Learning Tools Interoperability support is added to all LMS, any school can integrate LectureTools into their campus-wise enterprise LMS systems.

We are currently in the middle of a project integrating LectureTools into Blackboard LMS running at a community college and one commuter campus of the large research university as shown in Figure 2. This project will not only demonstrate the ability of LectureTools to run regardless of which enterprise LMS is in use, but provide a model for allowing cross-campus collaboration in teaching specific courses.

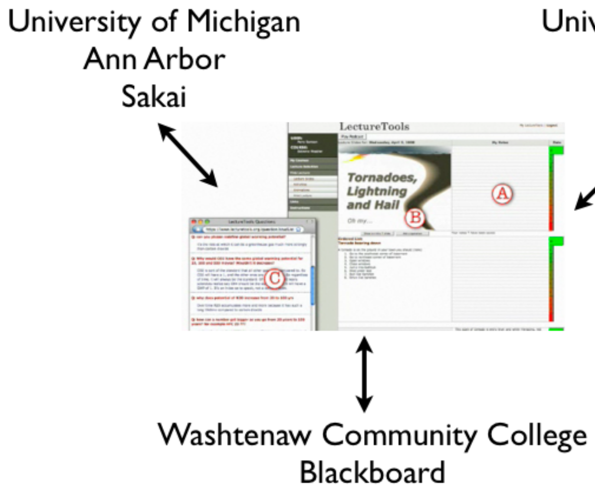

Figure 2. Using LectureTools in Sakai and Blackboard

We are using an open-source Blackboard Building Block that supports IMS Learning Tools Interoperability developed by Stephen Vickers of Edinburgh University [www.spvsoftwareproducts.com]. Once the IMS Tools Interoperability integration is completed, the same tool can be used across these three institutions with each set of users experiencing the tool seamlessly integrated into their local LMS user interface. As this pattern is extended, it allows a cross-institutional community to develop where the common thread is the use of the LectureTools platform to augment their lecture experiences. By combining small pools of interest across many campuses, is it possible to end up with a much larger overall demand for a tool or capability. By reducing the integration costs to nearly zero using IMS Learning Tools Interoperability, we increase the likelihood that these cross-institutional communities will form around particular pedagogy or domain specific tools.

In summary, the middle category of tools, Category 2, are those tools that appeal to some subset of the overall teaching space and are very valuable to that those teachers and learners. By allowing tools to be scoped at a college or department level or perhaps by bringing a cross-institutional community of interest together, we can match the tool with its level of demand. While the core tools are very focused on the management of learning, the tools in the middle category are generally some combination of "learning management" and content or context specific learning. That is, these more narrow tools will often focus on supporting a particular teaching pedagogy or objective rather than simply moving content around and facilitating students' access to that content.

## Wisdom of Crowds

In addition to Category 2 tools that have broad use with a small market segment, there are also tools that only appeal to a very tiny population – perhaps as small as a single instructor (Category 3). The exemplar for this category of tools comes from the book "Wisdom of Crowds" by James Surowiecki (2005). Surowiecki's book provides examples of how groups of people can have collective intelligence that surpasses the intelligence of any of its individual members. The author uses examples from social science, economics, and game theory to provide a basis to explain the mechanisms that make crowds wise. Often these concepts are explained in the form of a multi-player game where students play a game and then afterwards the class analyzes player behavior to illustrate the point of the exercise.

Often when teachers use the book "Wisdom of Crowds" they play the games with small scraps of paper and a designated student who "runs" the games. However it is also possible to write computer software that simulates the game and enforces its rules. When computer software is used to run the game, the educational advantage is we can retain the history of player interactions to facilitate a deeper insight into why a player made a move at a particular moment in time. For example, the simplest of the games proposed by Surowieki has a group guess a numeric value such as the number of jellybeans in a jar. First people independently guess the value and then an average the values is calculated.

This game can be played much more effectively on a computer using student laptops or PDA's rather than averaging numbers on slips of paper. Using technology, students experience first hand how their own guesses may be less accurate that the group mean and the visible display of individual guesses shows more clearly how the collective arrives at the correct answer. To implement the software for the game, we built a simple application that consisted of 118 lines of Python code hosted in the Google Application Engine cloud environment. The tool handled the IMS Basic LTI protocol and implemented the rules of the guessing game. The instructor could reset the game or view the results – the students could simply make a guess. The tool was then integrated into Sakai using IMS LTI and made available in the course site as shown in Figure 3.

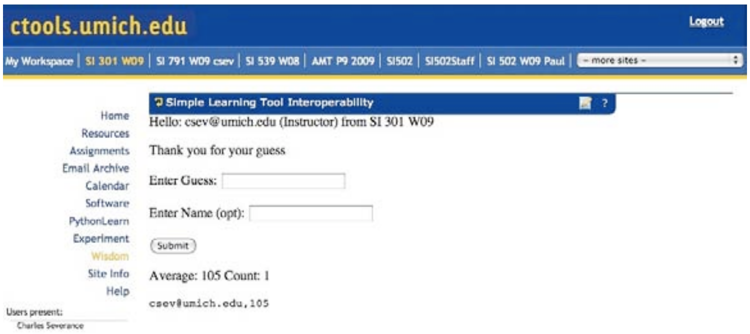

Figure 3. The Number Guessing Application Running in Sakai

The number guessing game was written in about two hours and used in lecture on the same day that it was written. After the game was used for one lecture, there were a few bugs that were found and fixed for use in later lectures. A tech-savvy instructor did the entire process with no impact on, nor involvement of, the enterprise Learning Management System. And since the tool was hosted for free on the Google Application Engine, the instructor did not even have to worry about the infrastructure needed to run the tool.

Another game was written to demonstrate the "Free Rider" problem which occurs when groups are sharing the costs of some shared common good and how people balance the overall group benefit against their own short-term potential for gain. The Free Rider Application had several features that made it very effective for in-class use. First, since the game enforced the rules, it was not necessary to teach anyone how to "run" the game. Also, the game picked five students to play the game automatically. Once the players were selected and the game started, the other students were given a display that updated dynamically as the game was played. So students could learn by playing the game and when they were not playing, they could watch as game masters. The students who were watching could see when players changed strategies and could see the game develop and see which strategies led to the largest payoff.

The games are very simple and easy to write – since they are embedded in a rich LMS, the tools only have to solve the very simple problem related to the lesson at hand. Once these tools are written and put up on Google Application Engine, they could be used by any instructor using the "Wisdom of Crowds" book in their classroom by simply exchanging the IMS Learning Tools Interoperability URL, Key, and Secret.

The number of teachers using "Wisdom of Crowds" in their classroom at any given moment or during any given semester is very small. But at the same time, the effort to develop and the tools is also very small. And the effort involved is small enough that a single teacher might do it simply for his or her own use. Following the example of free applications available in an "apps store" this instructor might also post it on a public site for any other instructor using Surowiecki’s book in their course. This example is toward the far end of the long tail of teaching applications. However, even if it only affects 25 courses across the country in any semester, these tools can be designed to be really helpful for helping students to understand more deeply this material. One could imagine a future where books like "Wisdom of Crowds" might come with already-built games developed and provided by the author or publishers. These games would be ready to plug into the local enterprise LMS using IMS Learning Tools Interoperability.

## Required LMS Features to Enable the Long Tail

If we are to address the need to build and use the long tail of learning tools, we must reduce the barriers to plugging new tools into Learning Management Systems. Opening up these system to outside applications ultimately puts the ability to "add a tool" in the hands of the instructors and allows them to add the new tools in a few clicks and with no intervention on the part of the technical support staff. Sakai is generally designed to give instructors a great deal of control of course content to the instructors. A Basic LTI tool has been developed for Sakai that allows the instructor to easily integrate externally provided tools into Sakai. The primary information needed for to integrate a tool using Basic LTI is a URL, Key, and Secret as shown in Figure 4.

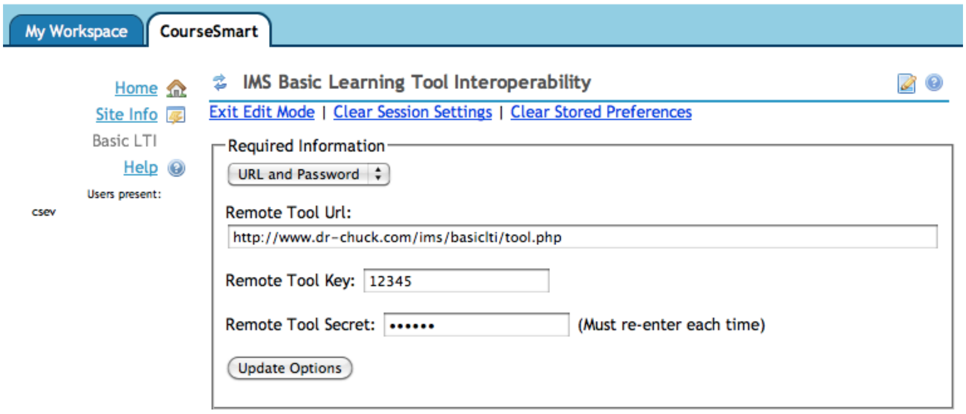

Figure 4. Setting the URL, Key, and Secret in the Sakai Basic LTI Tool

Since the IMS Basic LTI tool will send roster information to the externally provided tool, it is important to make sure that the instructor is aware that this is happening and approves the release of any identifying information using the configuration options shown in Figure 5.

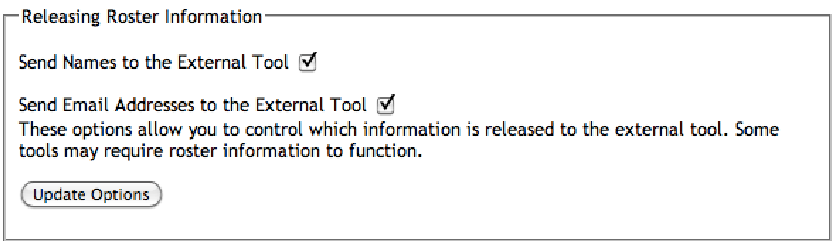

Figure 5. Privacy Controls in the Sakai Basic LTI Tool

The IMS Basic LTI specification makes any data that contains identifying information optional. The default in Sakai is not to send any identifying information so the teacher must explicitly agree to send the identifying information to the external tool.

The developers of each LMS will make their own choices about which aspects of LTI are placed in the hands of instructors and which aspects of configuration are only available to system administrators or technical support staff. The Sakai tool allows local customization of the configuration process for LTI, giving system administrators fine-grained access control over which features and capabilities are made available to the Instructors. This allows each institution to progress toward the model of many tools in the long tail at the pace that is comfortable and sustainable for their organization.

## Conclusion

We present the case for adding more flexibility to Learning Management Systems and putting that flexibility in the hands of instructors. By making it possible to easily integrate more narrow and learning-centered tools into the LMS without requiring a change in production software or server reboot, we make it far more practical for teachers and students to experiment with new tools and to find the right set of tools for their particular course, supporting a move from accidental to intentional pedagogy (McGee, Carmean & Jafari, 2005). Once the barriers are removed from within the LMS, a market for these externally hosted tools can develop– particularly in the "middle tail" category where tools have broad applications within a narrow segment of the population. We would hope that many commercial and free tools would be developed and made easily available – resulting in many innovative experiments that can lead to a greatly improved learning experience for students of any age.

Once the barriers for implementation are reduced even further, we envision that tools will be written by teachers or students to solve very focused learning needs. As LMS evolve and interoperability standards improve, many of these tools will be very simple to develop and use because they will be placed in the rich context of a mainstream LMS.

Perhaps the most exciting aspect of enabling teachers to build, exchange, and use thousands or even hundreds of thousands of new tools is how we enable the exploring of an increasingly wide range of new ways to teach. In addition, by opening the enterprise LMSs to virtually unlimited expansion, we have a place to explore emerging approaches such as social learning and the increased use and remixing of content from Open Educational Resources in new and novel ways. In a sense, while we can see an immediate exciting future that this approach enables, the truly exciting innovations are those that we can't even imagine because we are locked into the content-delivery patterns of the current crop of enterprise LMS. Finally, by opening up these opportunities to instructors we simultaneously open them up for students to build, organize, and use tools for their own collaboration and learning purposes.

# Students' Use of Multiple Strategies for Spatial Problem Solving

Mike Stieff, Minjung Ryu, Bonnie Dixon
University of Maryland-College Park, College Park, MD
mstieff@umd.edu, mryu@umd.edu, bdixon1@umd.edu

**Abstract:** In scientific problem solving, spatial thinking is critical for reasoning about spatial relationships in three-dimensions and representing spatial information in diagrams. Despite the importance of spatial thinking, little is known about the underlying cognitive components of spatial thinking and the strategies that students employ to solve spatial problems. Namely, it is unclear whether students employ imagistic reasoning strategies while engaged in spatial thinking. In the present study, we investigate which strategies students use to solve spatial chemistry problems and the relationships between strategy choice, achievement, spatial ability and sex. The results indicate that students employ multiple strategies that include the use of diagrams and heuristics rather than merely relying on imagistic reasoning. Moreover we observed women to employ strategies differently than men after extended instruction in the domain.

## Objectives & Theoretical Framework

A recent report from the National Research Council (2006) identifies spatial thinking as a critical component of scientific problem solving and reasoning and advocates for training spatial thinking in the science classroom. Such a call is consistent with the content of science instruction, which often requires students to reason about the three-dimensional relationships of objects and phenomena that are of interest to scientists. For example, chemistry students must learn about the three-dimensional structure of molecules, physics students must learn about the trajectory of projectiles and geology students must learn how geological structures transform over time. Given the prevalence of spatial thinking across the sciences, several researchers have suggested that student aptitude for spatial thinking, as measured by spatial ability psychometrics, predicts their success in science classrooms (Pallrand & Seeber, 1984; Wu & Shah, 2004) and careers (Shea, Lubinski, & Benbow, 2001). Indeed, a host of studies have shown positive correlations between visuo-spatial ability and achievement in several science domains (Carter, LaRussa, & Bodner, 1987; Hegarty & Sims, 1994; Keehner, Lippa, Montello, Tendick, & Hegarty, 2006). Consequently, these findings have led to claims that sex differences in spatial ability are responsible for sex differences in science achievement (cf. Fogg, 2005).

Despite the importance of visuo-spatial ability, questions remain about the cognitive components of spatial thinking. Typically, spatial thinking in science has referred to imagistic reasoning that includes mental imagery, mental rotation, spatial perspective taking and spatial visualization (Bodner & Guay, 1997). However, practicing scientists and novice students alike successfully solve spatial tasks through the use of external diagrams, models, and computer simulations that may or may not recruit these cognitive processes (Stieff, 2007; Stieff & Raje, 2010; Trafton, Trickett, & Mintz, 2005). Also, a variety of domain-specific analytic algorithms and heuristics have been reported that lead to solutions with little to no use of spatial information given in a spatial problem (Schwartz & Black, 1996; Stieff, 2007). The availability and utility of these alternative strategies raises several questions about the components of spatial thinking and their role in scientific problem solving at all levels.

The present paper aims to identify the underlying cognitive components that comprise spatial thinking in science. We address this aim with four questions: What strategies do problem solvers use to solve tasks that involve spatial thinking? Does strategy choice predict success on a variety of spatial tasks? Do spatial ability and sex predict strategy choice? How does instruction affect strategy choice? We address each of these questions by examining student problem solving in the domain of organic chemistry. Historically, this domain has privileged the role of visuo-spatial ability due to the content of organic chemistry which includes the analysis of three-dimensional relationships within and between molecular structures (Mathewson, 1999; Wu, Krajcik, & Soloway, 2001; Wu & Shah, 2004); yet, little is known about what strategies students employ when considering these relationships. Previously, Stieff and Raje (2010) have shown that expert chemists engage in spatial thinking using a variety of domain-specific diagrammatic and analytic strategies as opposed to mental imagery; however, strategy use among chemistry students remains unknown. Here, we build on the work of Stieff and Raje, by examining college students' choice of problem solving strategies for solving spatial organic chemistry problems to determine the extent to which chemistry students employ multiple strategies and how strategy choice changes with increasing domain knowledge.

## Study 1

In Study 1, we designed a strategy choice questionnaire that first asked students to solve 10 canonical organic chemistry assessment tasks. On each task, students were asked to indicate how they solved the problem using a list of known strategies applicable to the task. Previously, Stieff and Raje (2010) documented experts' use of specific imagistic and non-imagistic strategies for solving organic chemistry problems; the findings of that study were used to populate the list in the present work. The goal of Study 1 was to identify patterns of strategy use among students and any associations between strategy choice, achievement and sex.

## Method

Thirty-nine college students (20 males, 19 females) who had completed 6 months of instruction in organic chemistry were asked to complete a chemistry strategy choice questionnaire. The strategy questionnaire consisted of 10 organic chemistry problems that asked participants (1) to identify spatial relationships between molecules or substituents within a molecule and (2) to consider spatial transformations of molecular diagrams. All chemistry problems were scored for correctness using a binary rubric (1 = correct, 0 = incorrect). Participants were also asked to report the strategy they used to solve each chemistry problem by selecting from a list of possible strategies applicable to each problem. Participants were allowed to choose more than one strategy and to write in their own strategy if they believed that none of the choices matched their strategy. Each list of strategies for individual problems was developed in an earlier protocol study conducted by Stieff and Raje (2010); each strategy was coded according to a priori categories of strategy type listed in Table 1. Briefly, categories included those strategies that relied more extensively on reasoning via mental imagery (Spatial-Imagistic), diagrams (Spatial-Diagrammatic), rules and heuristics that operated on spatial information (Spatial-Analytic) and rules and heuristics that operated on non-spatial information (Algorithmic). Participants could also indicate if they knew the answer to a problem (Recall) or if they randomly guessed (Guessing). We note that the three categories that include the *spatial* prefix involve the direct consideration of spatial information while the algorithmic category does not. In cases where participants wrote in their own strategies, two researchers independently coded the free responses according to the four categories in Table 1. Comparison of the two raters' codes indicated an inter-rater reliability score above 85%.

Table 1: Strategy Categories.

| Strategy Type | Example Fixed-Choice Strategy Responses |
|---|---|
| Spatial-Imagistic | I tend to imagine the molecule in 3D and rotate it "in my head".<br>I tend to imagine myself moving into the paper or around the molecule. |
| Spatial-Diagrammatic | I tend to first draw a basic skeletal structure and then make changes as I go.<br>I tend to redraw the molecule using a different chemical representation to help me think about it. |
| Spatial-Analytic | I tend to assign R/S labels to each molecule. |
| Algorithmic | I just know that in stable molecules particular groups must be in a specific relationship.<br>I tend to use a specific formula to calculate the number of stereoisomers. |

## Results & Discussion

Figure 1 summarizes the frequency of each strategy choice across the 10 tasks. Among the 418 strategies reported, participants selected Spatial-Analytic strategies most frequently (36%) followed by Spatial-Diagrammatic strategies (26%), Spatial-Imagistic strategies (22%) and finally Algorithmic strategies (16%). Figure 2 shows a detail of strategy frequencies by task. The distribution of strategies differed dramatically among the ten tasks, which suggests that students freely switched between the different types of strategies depending on each task. For example, the majority of reported strategies applied to Tasks 1, 5, 6, and 8 were Spatial-Analytic strategies, but Spatial-Imagistic strategies were reported more often on Tasks 9 and 10. The dataset was further analyzed to determine whether participants used primarily one strategy for each task or applied multiple strategies. In total, we were able to identify the strategy used by participants in 326 (83.5%) of the 390 cases of problem solving. The remaining 64 cases either lacked strategy choice information or were solved via Guessing or Recall. As Table 2 illustrates, 240 tasks (73.6%) were solved with only one type of strategy, 80 tasks (24.5%) were solved with two types of strategies, and 6 tasks (1.8%) were solved with three or more types of strategies. In cases where participants used only one strategy, Spatial-Analytic strategies were reported most frequently. Interestingly, in cases where participants selected two types of strategies, the majority of reported strategies involved the use of a Spatial-Diagrammatic strategy and one other type of strategy. Notably, we observed a negative correlation between the number of participants who successfully completed a problem and the number of participants who used two or more strategies, ($r(10) = -0.654$, $p = 0.040$), which suggests that students tend to apply multiple types of strategies as questions become more difficult.

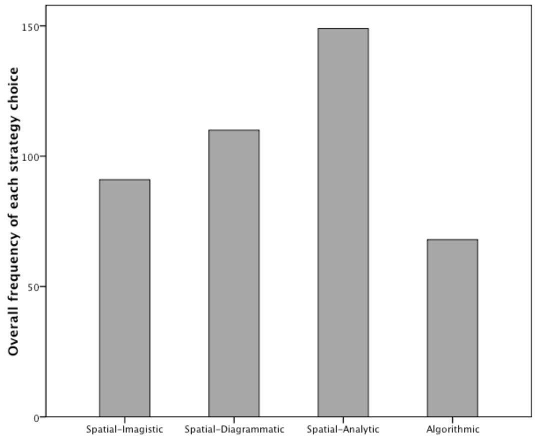

Figure 1. Overall frequency of strategies reported by category.

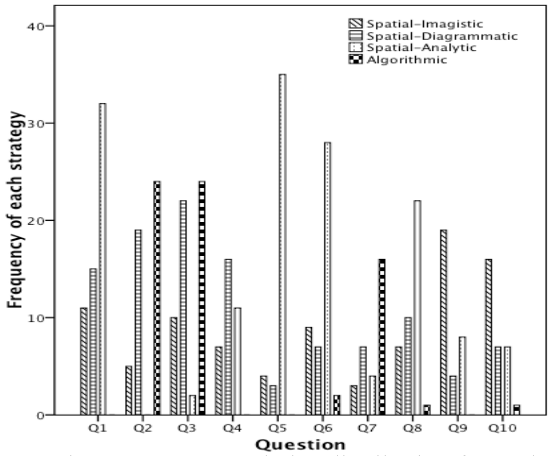

Figure 2. Strategy choice distribution for each task.

Table 2: Numbers and types of strategy used for each task.

| No. reported strategies used | Strategy type | Frequency | Total |
|---|---|---|---|
| 1 | Spatial-Imagistic | 49 | 240 (73.6%) |
| | Spatial-Diagrammatic | 47 | |
| | Spatial-Analytic | 107 | |
| | Algorithmic | 37 | |
| 2 | SI+SD | 16 | 80 (24.5%) |
| | SI+SA | 15 | |
| | SD+SA | 21 | |
| | SD+AL | 21 | |
| 3 or more | - | - | 6 (1.8%) |
| Total | | | 324 |

*Note.* Dashes indicate no further analysis was conducted. SI=spatial-imagistic, SD=spatial-diagrammatic, SA=spatial-analytic, AL=algorithmic. 64 tasks coded as recall/guessing/unknown are not included.

The relationship between correctness and type of strategy used was tested using a Pearson's $\chi^2$ test for 2 (use of each strategy) x 2 (correctness) contingency table. Using an alpha level of 0.05, no association between success and strategy use was found, indicating that strategy choice does not have an impact on whether a participant answer a task correctly. Sex differences in problem-solving success and strategy choice were tested using an independent two-sample $t$-test. The mean total correctness score of male participants ($M = 4.25$, $SD = 1.45$) was not found to differ from the mean total correctness score of female participants ($M = 4.15$, $SD = 1.12$), $t(37) = 0.22$, $p = 0.41$. Likewise, strategy choice did not differ significantly between female and male participants, as illustrated in Figure 3. Men and women displayed similar patterns of strategy choice: in order of reported strategy use, both groups employed Spatial-Analytic, Spatial-Diagrammatic, Spatial-Imagistic and Algorithmic strategies. In order to examine the relationship between sex and strategy choice, strategy scores of participants were calculated by counting the numbers of each strategy used across the ten survey items. $t$-tests to compare Spatial-Imagistic, Spatial-Diagrammatic, Spatial-Analytic and Algorithmic strategy scores between male and female were not found to be statistically significant at an alpha level of 0.05.

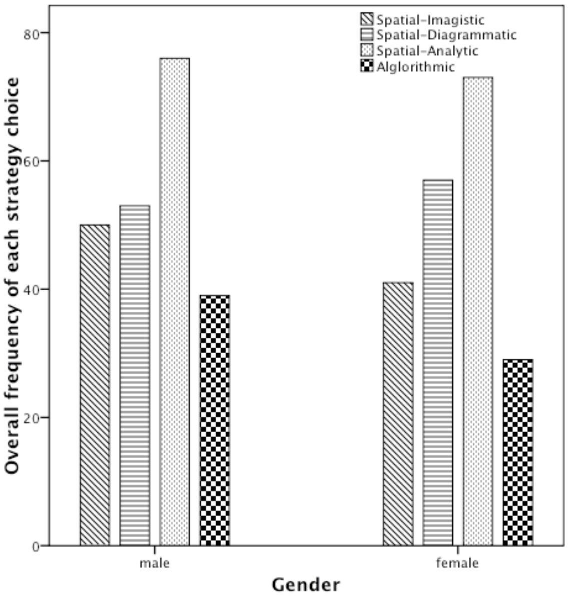

Figure 3. Overall frequency of strategy choice by males and females.

## Study 2

In Study 2, we adapted the strategy choice questionnaire for group administration via a remote personal response system (i.e., "clickers") in an organic chemistry classroom during instruction. Although Study 1 established that students primarily made use of spatial-analytic strategies for solving organic chemistry tasks, the participants in that studied had completed several months of instruction in the domain. Thus, Study 1 yielded no information about how student strategy choice changes with instruction. Therefore, we conducted Study 2 to determine whether students employed spatial-analytic strategies in the context of an organic chemistry course and whether students employed the same strategies uniformly over the course of instruction.

## Method

103 undergraduate students enrolled (sex was reported for 90 students: 33 males and 57 females) in a 6-week intensive organic chemistry course were assigned unique personal response devices to respond to adapted strategy choice questions administered during the course. Over the duration of the course, students were asked 10 unique organic chemistry questions and related strategy choices. Questions were administered approximately once each week of instruction. During the final meeting of the course, students were asked 8 organic chemistry questions and related strategy choices that included 6 of the 10 questions administered during earlier sessions of the course. All questions were presented on large LCD televisions at the front of the classroom and students answered questions by clicking a multiple-choice answer on their assigned device. The scoring rubric and strategy categories from Study 1 were used to analyze student responses. Notably, the adapted questions in Study 2 did not contain algorithmic strategies as the course instructor deemed that the strategy survey questions that included algorithms were beyond the scope of her course. In addition, unlike the strategy survey questionnaire, students were not able to choose more than one strategy per problem because the classroom clicker system could not capture multiple answers per student for a given question. Students were able to report their own strategies after each class if they employed a strategy not presented in the provided options.

Among the 103 students, 91 students volunteered to complete a spatial ability battery that included the Vandenberg Mental Rotation Test (Vandenberg & Kuse, 1978) and Guay's Visualization of Views (McDaniel & Guay, 1976). Descriptive statistics of strategy choice were generated for each task and strategy use on both administrations of the 6 questions was compared. Unlike Study 1, group administration of the questions permitted students to interact and discuss their responses prior to inputting an answer on their clicker devices and the course instructor assigned these questions for course credit; therefore, the independence of student answers to chemistry problems could not be guaranteed and reports of student achievement were not considered valid for analysis. In contrast, because students did not receive credit for strategy responses and the instructor emphasized that there was no correct answer to these questions, we considered student responses to these questions valid for analysis.

## Results & Discussion

The distribution of strategy choices at each administration time point in the classroom is presented in Table 3. As indicated, the students reported that they employed Spatial-Imagistic strategies more than any other strategies both during and after instruction. Excluding recall, guess, and unreported strategies, Spatial-Imagistic strategies were most frequently reported by students (947 times, 64.95%), followed by Spatial-Diagrammatic strategies (397 times, 27.23%) and Spatial-Analytic strategies (114 times, 7.82%). Although Spatial-Imagistic strategies dominated both during and after organic chemistry instruction, comparison between the two occasions suggests that fewer Spatial-Imagistic strategies were employed after instruction while Spatial-Diagrammatic and Spatial-Analytic strategies were reported more frequently.

Reports of strategy use on the six questions appearing both during and after instruction were examined further to clarify changes in strategy use after instruction. As indicated in Table 4, after instruction the average number of Spatial-Imagistic strategies across all tasks reported decreased ($t(102) = -3.98$, $p < .001$), and the average number of Alternative strategies increased ($t(102) = 4.95$, $p < .001$). Figure 4 illustrates the frequency of reported strategies for each of the six questions at each presentation. Examination of these items indicates that students do indeed employ Spatial-Imagistic strategies less frequently after instruction. Interestingly, distributions of strategy choice after instruction varied across the six question items. For questions 1 and 6, reports of using Spatial-Analytic strategies rose dramatically, while reports of using Spatial-Diagrammatic strategies rose relatively higher on questions 2 and 4. In contrast, no noticeable difference in the relative use of each strategy type was seen on questions 3 and 5. Examination of these six items revealed that students not only adopted strategies alternative to Spatial-Imagistic Strategies after instruction, but the choice of strategy after instruction was related to the task itself.

Table 3: Frequency of strategy use.

| | No. strategy choice | | |
|---|---|---|---|
| Types of strategy | During instruction [a] | After instruction [a] | Total |
| Spatial-Imagistic | 596 (73.22%) | 351 (54.50%) | 947 (64.95%) |
| Spatial-Diagrammatic | 172 (21.13%) | 225 (34.94%) | 397 (27.23%) |
| Spatial-Analytic | 46 (5.65%) | 68 (10.56%) | 114 (7.82%) |
| Total | 814 (100 %) | 644 (100%) | 1458 (100%) |

[a] 10 question items were administered during instruction and 8 items were administered after instruction.

Table 4: Mean number of Spatial-Imagistic and Alternative strategies reported during and after instruction.

| | During the instruction | | After the instruction | |
|---|---|---|---|---|
| Types of strategy | *M* | *SD* | *M* | *SD* |
| Spatial-Imagistic strategies | 3.56 | 1.48 | 2.63 | 1.91** |
| Alternative strategies | 0.99 | 1.09 | 1.83 | 1.79** |

*Note*. Scores for each category range from 0-6 excluding recall and guessing strategies.
** $p < 0.001$

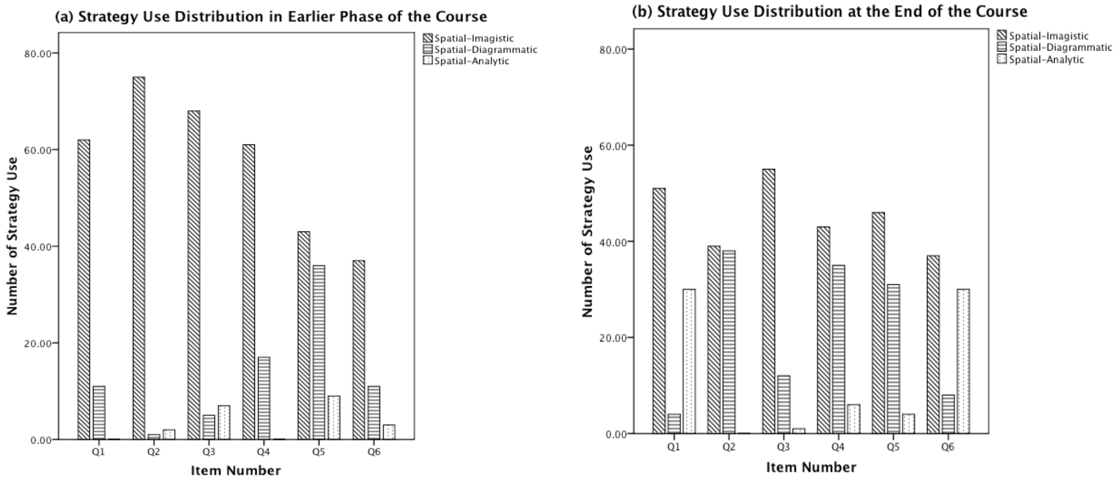

Figure 4. Frequency of strategy use reported by students (a) during and (b) after instruction.

Associations between spatial ability and strategy choices were analyzed via ANOVA. The 91 students who completed the spatial ability psychometrics were categorized into three groups based on their performance on the Mental Rotation Test (MRT) and Visualization of Views Test (VoV): High ($N$=31, $M$=51.94, $SD$=13.02 for MRT and $M$=17.74, $SD$=4.56 for VoV), Medium ($N$=30, $M$=34.20, $SD$=10.39 for MRT and $M$=8.71, $SD$=4.44 for VoV), and Low ($N$=30, $M$=15.40, $SD$=12.08 for MRT and $M$=4.21, $SD$=3.58 for VoV). Table 5 illustrates the results from the ANOVA. On the first presentation of each strategy question, the use of Alternative strategies did not vary with spatial ability ($F(2, 88)$=0.96, ns) at an alpha level of 0.05. After instruction, however, we observed a trend in the data that indicated students in the lower ability group employed Alternative strategies more frequently than higher spatial ability students ($F(2, 88)$=3.10, $p$=0.05). Associations between each student's strategy choice and spatial ability were analyzed via a Multivariate Analysis of Variance (MANOVA) test of Alternative strategy scores with within-subjects effect of administration time (i.e., during and after the instruction) and between-subjects effect of spatial ability group. The analysis failed to show a significant interaction between student strategy choice after instruction and spatial ability, *Wilk's* $\lambda$= 0.968, $F$ (2, 88)=1.43, ns. Thus, spatial ability was not found to predict the use of any particular strategy after instruction.

Table 5: Comparison of Alternative scores during and after the instruction in three spatial ability groups

| | High | | Medium | | Low | | |
|---|---|---|---|---|---|---|---|
| Occasions of the task | *M* | *SD* | *M* | *SD* | *M* | *SD* | $F$ (2,88) |
| During the instruction | 0.90 | 1.07 | 1.30 | 1.08 | 1.06 | 1.20 | 0.96 |
| After the instruction | 1.35 | 1.56 | 2.43 | 1.94 | 2.17 | 1.80 | 3.10 |

Finally, relationships among sex, spatial ability and strategy choice were investigated. Using an alpha level of 0.05, males were found to outperform females on the Mental Rotation Test ($M$ = 45.63, $SD$ = 16.07 for male, $M$ = 27.62, $SD$ = 17.63 for female, $t(83)$ < 0.001) and on the Visualization of Views ($M$ = 13.42, $SD$ = 8.27 for male, $M$ = 8.66, $SD$ = 5.94 for female, $t(83)$ = 0.003). During instruction, males and females did not differ in use of Spatial-Imagistic strategies ($M$ = 3.81, $SD$ = 1.36 for male, $M$ = 3.32, $SD$ = 1.40 for female, ns) or the use of Alternative strategies ($M$ = 1.00, $SD$ = 0.87 for male, $M$ = 1.07, $SD$ = 1.10 for female, ns). After instruction, however, females were observed to use Alternative strategies more frequently than males ($M$ = 1.24, $SD$ = 1.56 for male, $M$ = 2.47, $SD$ = 1.79 for female, $t(88)$ = 0.002); however, the difference between male and female use of Spatial-Imagistic strategies was marginal ($M$ = 3.21, $SD$ = 1.92 for male, $M$ = 2.53, $SD$ = 1.83 for female, $t(88)$ = 0.096). Repeated measures analysis of Alternative strategy scores involving within-subjects effect of administration time (i.e., during and after instruction) and between-subjects effect of sex resulted in significant interaction between sex and occasion of the tasks (MANOVA, *Wilk's* $\lambda$ = 0.892, $F(1, 88)$ = 21.31, $p$ = 0.002).

## Conclusions & Implications

The above results offer some tentative answers to the questions we posed initially. First, the findings clearly illustrate that students employ a variety of strategies to solve tasks that involve spatial thinking. In Study 1, we observed students to rely more consistently on Spatial-Analytic and Spatial-Diagrammatic strategies as opposed to Spatial-Imagistic strategies, as typically believed. Likewise, in Study 2, we observed students to employ Spatial-Imagistic strategies preferentially during instruction, yet adopt more alternative strategies by the end of the course. Moreover, we also observed students to fluidly switch between different types of strategies between tasks. The findings of the present work suggest that students choose task-dependent strategies in a manner similar to expert chemists and apply multiple strategies on problems of increased difficulty. These results indicate that students are aware of the availability of diverse strategies and are willing to employ alternative strategies. In other words, students are not limited to reasoning about spatial information in molecular structures via imagistic reasoning, but can reason about spatial information with a variety of strategies.

The results also indicate that strategy choice does not predict success on spatial tasks in chemistry. The findings in Study 1 suggest that students reach equivalent levels of achievement regardless of whether they employ strategies that involve reasoning via mental imagery or alternative strategies. Equally important, we did not observe significant differences in achievement between men and women on chemistry tasks. Despite these findings, we did observe that multiple strategies were applied on tasks that the majority of students failed to solve. This finding is consistent with the literature on flexible strategy choice that reports individuals employ multiple strategies on tasks of increased difficulty (cf. Siegler, 1996). The use of multiple strategies, however, did not lead to increased success on such tasks. Thus, it did not appear that the application of one or more strategy types (e.g., Spatial-Imagistic, Spatial-Analytic, Spatial-Diagrammatic, Algorithmic) predicts achievement. That is, each strategy is equally likely to result in success or failure on a given task.

Study 2 permitted us to examine the relationship between strategy choice and instruction in the context of an organic chemistry classroom. The results of that study clearly illustrate that instruction has a direct effect on strategy choice. In the beginning of the course, we observed students rely primarily on Spatial-Imagistic strategies to solve spatial tasks; by the end of the course, we observed a sharp increase in the use of strategies alternative to Spatial-Imagistic strategies. Interestingly, the participants in Study 2 reported greater use of Spatial-Imagistic strategies at the end of instruction while the participants in Study 1 reported greater use of Spatial-Analytic strategies. We believe the reason for this discrepancy is due to two important differences between the participants in each study. First, the students received instruction over different time periods. The students in Study 1 completed ~20 weeks of instruction during course of an academic year; however, the students in Study 2 learned less material in a 6 week summer course. It is possible that the longer duration of study in Study 1 resulted in better apprehension of and preference for alternative strategies. Similarly, the instructors for each course reported notable differences in their own emphasis on strategy use. The instructor in Study 1 reported she was 'bad at visualization' and emphasized diagrammatic and algorithmic heuristics, but the instructor in Study 2 reported she attempted to teach as many strategies as possible for the benefit of the students. Thus, instructional differences may have resulted in the observed differences in strategy preference. Nevertheless, although students in Study 2 reported using Spatial-Imagistic strategies as their primary strategy, the increased use of domain-specific alternative strategies suggests that as expertise develops, students may rely less on imagistic reasoning and more on heuristics to solve spatial tasks.

Study 2 also permitted us to examine the relationship between spatial ability, sex and strategy choice in the classroom. Although the results of that study do not indicate a direct relationship between spatial ability, sex and strategy choice, they do suggest a potential interaction may exist. First, our findings clearly show that over the course of instruction women reported a significant increase in the use of alternative strategies compared to men. Second, our findings tentatively suggest that low spatial students may preferentially switch from Spatial-Imagistic strategies to alternative strategies after instruction; high spatial students do appear to rely on Spatial-Imagistic strategies throughout instruction. Thus, the data suggests that low-spatial females preferentially switch to alternative strategies. Two major limitations of the Study limit the validity of these findings. First, our analysis relies solely on students' strategy reports on 6 questions. The results of Study 1 indicate that several strategies are task-specific and our reliance on so few tasks casts doubt on the interpretation of these findings. Second, students were asked to respond to the clicker questions in Study 2 under classroom time constraints and they were also permitted to collaborate on their responses. Thus, there was an increased risk in Study 2 of failing to detect changes in strategy choice and individual differences in spatial ability. Nevertheless, we believe the trends in the data suggest a potential interaction between spatial ability, sex and strategy choice does exist and warrants further investigation.

Taken together, the results of the present studies indicate that spatial thinking in advanced scientific problem solving, specifically organic chemistry, involves a range of strategies that vary significantly in the extent to which they rely on imagistic reasoning. Of particulate note, our findings suggest that students approach the study of organic chemistry using mental rotation and other spatial-imagistic strategies to reason about molecular structures, but quickly adopt a variety of algorithms and heuristics after instruction. This behavior leads us to question the utility of instructional methods that emphasize the exclusive focus on training students to use imagistic strategies (e.g., by improving students' visuo-spatial ability, Ferk, Vrtacnik, Blejec, & Gril, 2003). Rather, we suggest instead that students may benefit most from instruction that teaches the applicability of multiple strategies, as in Study 2. Moreover, the present study did not identify significant correlations between sex and chemistry problem solving success. This result contradicts previous claims that men outperform women in science due to their aptitude for spatial reasoning (Fogg, 2005). Rather, our findings suggest that female students apply the same strategies as male students with equal levels of success in chemistry and that they are likely to switch to alternative strategies when necessary in a course.

# What Are They Talking About? Findings from an Analysis ofthe Discourse in Peer-Led Team Learning In General Chemistry

Patrick Brown, Keith R. Sawyer, Regina Frey, Sarah Luesse, Daniel Gealy, Washington University in St. Louis, Campus Box 1022, One Brookings Drive, Eads Hall Rm. 105
Email: Pbrown23@wustl.edu, ksawyer@wustl.edu, gfrey@wuchem.wustl.edu

**Abstract:** Peer-Led Team Learning (PLTL) is a structured method for helping students engage actively in collaborative conversations. The method originated in undergraduate chemistry courses, but is now used in math and in other science classes as well. Previous studies have shown that PLTL results in improved student learning in undergraduate chemistry. However, researchers have not studied the group mechanisms and the discourse processes that lead to this improved outcome. This study is one of three inter-related studies that are the first to explore those mechanisms and processes. In this study, we observed videotapes of PLTL sessions and analyzed the discourse of peer leaders and of students. We found that the structure and nature of the problems influences student discourse.

## Introduction

There is now a consensus in science education research that the most effective learning environments are those in which students engage in productive, collaborative discourse to build knowledge (e.g., American Association for the Advancement of Science [AAAS], 1989; National Research Council [NRC], 1996). Knowledge building occurs when students engage in collaborative conversations intended to advance both individual understanding and the collective knowledge of the group in pursuit of a common goal (Bereiter, 2002; Engle & Conant, 2002; Rogoff, Matusov, & White, 1996). In response to this research, numerous institutions of higher education have introduced a form of collaborative learning into lower level science courses that is called peer-led team learning (PLTL) (Gafney & Varma-Nelson, 2008; Gosser et al., 2001; Gosser & Roth, 1998; Hockings, DeAngelis, & Frey, 2008; Sarquis et al., 2001). Although there are still large lectures each week, PLTL supplements the lecture with formalized study groups that are facilitated by a peer leader and provide opportunities for active and collaborative learning. A PLTL study group contains 6-8 students facilitated by a peer leader, a student who has previously received a high grade in the class, and who works under the close supervision of the instructor of the class. In each PLTL session, students work together to solve problems designed by the instructor of the class. Neither the peer leader nor the students are given the solutions to the problems, because the goal of the session is not to get the correct answer; instead, it is to provide opportunities for engaging in problem solving while discussing the concepts in the problem. The goals of PLTL are to: (i) teach undergraduates how to effectively study in a group; (ii) improve students' problem-solving skills; (iii) provide facilitated help for students; and (iv) provide an active- learning environment for students to engage in scientific discourse.

Although previous studies have shown that PLTL results in improved learning in undergraduate chemistry (Gafney & Varma-Nelson, 2008; Hockings, DeAngelis, & Frey, 2008; Tien, Roth, & Kampmeier, 2002), few researchers have studied the group mechanisms and discourse processes that lead to this improved outcome. In two inter-related studies, we found that peer leaders used two distinct interactional styles, which we call *instructional* and *facilitative*, that influence students' dialogue, participation, and knowledge building. In the first study, we found that peer leaders who use a high percentage of facilitative discourse was related to increased chains of student-to-student interactions and more equal student participation (Brown, Sawyer, & Frey, 2009b). Conversely, peer leaders who used equal amounts of facilitative and instructional discourse had shorter chains of interactions and unequal participation. In the second study, we observed that when a peer leader used primarily facilitative discourse and provided abundant managerial support, students displayed extended discussions that went beyond applying equations in a rote manner and began to develop an understanding of the concepts (Brown, Sawyer, & Frey, 2009a). This study is the third in a series of studies that examines the discourse practices used in PLTL. After observing the transcripts of the first two studies, we believed that the specific nature and framing of the problem presented to the students had an impact on their discourse, and we wanted to better understand the specific links between the posed problem and the resulting discourse. Thus, the research question we posed for this study is: How does the nature and structure of the problem influence how students talk about the underlying concepts?

# Research Design

## Participants

In fall 2006, during the 14-week semester, three PLTL sessions (# 4, #7, and #9) of each of 15 returning peer leaders were videotaped. For the project, all verbal interactions in 6 PLTL groups for two parts of session 7 were analyzed from these recordings. We used a purposeful sampling approach to identify cases and parts of problems that were "information-rich" (Beals & Tabors, 1995; Patton, 2002). The 6 groups were chosen based on observation of all the video data. Based on our experiences working with peer leaders, we purposefully selected: (1) 6 PLTL groups that represented a range of peer leader styles (instructional or facilitative) (see Brown, Sawyer, & Frey, 2009b); and (2) questions that represented typical PLTL activities (reviewing content, problem solving, and concept discussion).

## Data Analysis

We implemented multiple approaches to analyze the data. We identified, labeled, and time-stamped the amount of peer-leader talk, student talk, individual tasks, and off-task behaviors that occurred during the selected PLTL activities based on relevant, transcribed portions of the video data. Each transcription was divided into segments of talk, in which a segment of talk represented an individual's contribution to the discussion. An individual's talk could consist of multiple utterances depending on how many ideas were included in one segment of talk. Each utterance was assigned a code (Brown, Sawyer, & Frey, 2009b). The coding scheme involved two levels of coding: categories and codes. The categories we developed were consistent with the constant comparative method of qualitative data analysis (Glaser & Strauss, 1967). Categories are general types of speech observed and include 4 broad areas: (1) explanation, (2) content question, (3) facilitation, and (4) problem solving. Codes refer to specific types of identifiable speech within these 4 categories. For example, closed question and open question are both codes within the category "content question."

To calculate the reliability of the coding manual, two trained coders were used; one has a background in science education and qualitative research and the other was a co-instructor of the general chemistry series. The second coder was blind to the motivation and hypotheses of the study. When disagreements arose, the two coders discussed differences and either a rule for coding was decided upon or a revision was made to the coding manual. Cohen's Kappa is an inter-rater reliability measure for qualitative studies (Bakeman & Gottman, 1986; Lunn, 1998). Bakeman and Gottman (1986) characterized a Cohen's Kappa of greater than 0.75 as excellent. The Cohen's Kappa for the final stage of coding was 0.90; thus, meeting the criteria for excellent inter-rater reliability.

# Results

Our data at this stage of the project is preliminary. Thus, we chose relevant portions of the data from our qualitative analysis to highlight findings from our full data set. We focus on a specific trend in our data that we observed across our 6 PLTL groups.

To study whether the nature and structure of the problem influences knowledge-building discourse we examined a portion of the seventh PLTL session. During the session, students reviewed and solved problems associated with understanding the topic "periodic trends" — characteristics of elements as one moves across a period (row) and down a group (column) of the periodic table. This analysis focuses on the Review and Problem 1 portion of the session. During the review, students discussed the content covered in lecture and recitations. During Problem 1, students arrange each set of atoms (e.g., (a) Rb, Cs, Li; (b) B, Li, F; (c) Cl, F, Br; (d) Rb, Be, K) in order of increasing atomic radius.

## Review

The transcript that follows is an example of how Gillian's students began to talk about the periodic trends during the review.

[1] F1: So I have a bunch of periodic trends (inaudible). There's Z* (effective nuclear charge), one for electronegativity, and one for Atomic radius. Do you wanna draw all those?
M7: And electron affinity.
F1: Draw the, Draw the boxes [[2]*Student tells peer to draw a "box," in the shape of a rectangle, on the*
F4: *front board*]
F1: Why don't you just draw the boxes?
F4: I like the boxes. (laughs). Just write like, Z*, and then arrow, increasing (pointing). And then arrow down, decreasing (pointing). [*Student tells her peer who is at the front board to draw a box with a one-sided arrow pointing from left to right and another arrow pointing from the bottom to the top of the box*]

[1]Line number
[2]Relvant nonverbal interactions

In this excerpt, students drew a “box” to represent the periodic table and used arrows to indicate whether atoms increase or decrease across a period (row) and down a group (column) according to the different diagrams for the period trends that they covered in lecture (e.g., electronegativity, atomic radius, electron affinity, and Z*) (LN: 1-6). For example, students began talking about the periodic trends by focusing on the procedures for describing how Z* increases and decrease across and down the periodic table (LN: 7). When identifying important content to review from the lectures and recitations, and without prompting from the peer leaders, students used the diagrams they had learned in class as an algorithm (a set of finite rules) for solving problems (LN: 7). Without the peer leaders guidance, we found that students used the diagrams they had learned in class almost exclusively when reviewing the periodic trends.

## Problem 1

In problem 1, students arranged atoms in order of increasing atomic radius. The problem-solving discourse was characterized by students using the diagrams they discussed during the review to solve atomic radius problems. The transcript that follows illustrates how Rachael’s students focused on applying the diagram that was discussed during the review to arrange the atoms B, Li, and F in order of increasing atomic radius. Rachael’s students’ discourse was typical of how students talked about the atomic radius problem (Problem 1).

254 M1: Umm, Bi, Li, and F (reading the problem). So we’re going left to right, and the diagram says is
255 decreases (referring to the diagram on the board developed during the review), so, if I want it
256 from increasing, it’s Li, B, F. [*Student looks at the diagram on the board showing a one-sided*
257 *arrow pointing from right to left to answer the question*]
258 F3: No
259 M2: No, it goes the other way (inaudible).
260 PL: Increasing should start with the smallest, and then…
261 M1 Oh. So, F, B, Li.
262 PL: Don’t let it trip you up. Does everyone agree?
263 F3: Yeah.

In the excerpt above, M1 used the diagram on the board that they discussed during the review to solve the problem (LN: 254). In this example, M1 accidentally listed the elements from largest to smallest atomic radii (the directions in the problem asked students to list the elements from smallest to largest atomic radii). In line 259, the peer leader calls to attention that M1 has placed the elements in the reverse order. In line 260, M1 reacts by listing the elements in the correct order. In this excerpt, students discourse was entirely focused on the diagram discussed during the review and they did not discuss the underlying concepts associated with the trend.

Gillian’s students’ discourse was also focused on applying the diagram they had discussed during the review on problem 1. However, Gillian engaged students in the concepts by using probing questions (LN: 337).

337 PL: …So what's the, what's the idea with radius? What are you doing, to kind of put those(referring to
338 atoms) in order?
339 F1: We just compared it to the, the, drawing up there (referring to the front board), the table.
340 F5: The number of, like, protons, um, of each element and then the number of, I don’t know, I guess
341 electrons?...
342 F1: Well, one, we didn't have any ions, so that wasn't really important (laughs).
343 F5: Right. So if there was like, more protons, like, going down the periodic table, like down a column,
344 or whatever, um, they (referring to atomic radii) would be increasing because they would just be a
345 bigger
346 F1: Well, there's more elect...(referring to electrons)
347 F5: It would be more electrons...If we're going down, it's, it would be more electrons.
…[3] … …
420 PL: So you guys down there, what's the, what's kinda like the trend?
421 M7: Whichever one has the lower number of protons has a tighter pull on the electrons, so the radius
will be smaller (across a group)
… … …
425 PL: … (Does everyone) agree with that?
426 F1: And as you're adding elect..., it's like the same if you're adding electrons (down a period), then an
427 increased radius.

[3]Transcripts were omitted because student talk was off task.

Gillian's students' responses indicate that they focused on applying the diagram they had discussed for atomic radius during the review to the problem (see line 339). However, Gillian used probing questions to promote discussions, student interactions, and scientific explanations of the content (LN: 337 and 420). Students acknowledged, built upon, and elaborated on each other's ideas. Additionally, Gillian's students' explanations went beyond using the diagrams they learned in class to solve the problems and they began to address some of the underlying concepts (LN: 340-346, 421, and 426).

In summary, both the nature and structure of the problem influenced student discourse. We found that during the review students focused on describing the periodic trends according to diagrams that they learned about in class. Without prompting from the peer leader, students almost exclusively talked about the periodic trends according to a finite set of rules that they learned about in class. Students' discussion during the review had an influence on how they talked about the periodic trends problems. Students used the diagrams that they discussed during the review to solve the periodic trends problems. Thus, the nature and the structure of the PLTL problems influenced students discourse.

## Conclusion

There is a great deal of research evidence that students who participate in PLTL perform better than students who learn individually and alone. Our work begins to examine exactly how the discourse in PLTL groups contributes to improved chemistry understanding. From our analysis, it appears that not all peer-group experiences are equivalent in promoting chemistry understanding.

Based on previous research we found that peer leaders who used equal amounts of facilitative and instructional discourse had shorter chains of interactions and unequal participation. Conversely, the use of a high percentage of facilitative discourse was related to increased chains of student-to-student interactions and more equal student participation (Brown, Sawyer, & Frey, 2009b). Second, we observed that when a peer leader used primarily facilitative discourse and provided abundant managerial support, students displayed extended discussions that went beyond applying equations in a rote manner and began to develop an understanding of the concepts. Conversely, when a peer leader used more equal combinations of discourse coded as instructive and facilitative, students spent considerable time working individually and their discourse focused on the algebraic steps necessary to solve the problem (Brown, Sawyer, & Frey, 2009a). In this study, we observed that students' discourse was related to the nature and structure of the problem. Students mostly talked about the periodic trends using the diagrams they learned about in class. The discussions that occurred during the review influenced how the students solved periodic trends problems. Students focused on using the diagrams they discussed during the review to solve problems and rarely engaged with the underlying concepts associated with understanding the periodic trends. Thus, for some problems, students would benefit from explicit conceptual questions in order to engage in discussions of the underlying concepts.

The goal of PLTL is to engage students in building chemistry knowledge through a more open forum of collaborative discourse with greater student involvement. To provide quality PLTL sessions, Chemistry instructors must understand the discourse practices of peer leaders and students. Many education researchers have stressed that an effective student culture of collaboration requires close attention and scaffolding, and once a collaborative group culture has emerged, classroom conversations can lead to significant individual cognitive advancement and the development of deep conceptual understanding (Greeno, 2006; Sawyer, 2006; Scardamalia & Bereiter, 2006). This preliminary study suggests that the nature and structure of the problem influence student discourse. If problems include explicit conceptual questions then collaborative group cultures could emerge that encourages students to engage in deep knowledge building.

## Implications for Future Research

Examining student discourse during a content review and problem solving activity has implications for the redesign of PLTL problems and future research. We believed that students would discuss the underlying concepts associated with the review and the problem based on their experiences in lecture and recitation sessions. Based on the early stages of our third study, implications arise for the redesign of PLTL problem sets. Based on the findings of the third study we are redesigning PLTL problem-sets to begin with guiding questions that encourage students to discuss key concepts and experiments in addition to equations and variables. Altering existing problem sets to provide explicit questions that have students discuss phenomena before problem solving may engage students in higher-order thinking and alter students' interactions with each other and the peer leader. Future research is needed that investigates whether revising the way PLTL problems are written better fosters the type of conversations that lead to deep conceptual understanding. Restructuring the problems could favorably affect student's chemistry understanding, critical thinking, and knowledge building from collaborative discourse.

# A Web-based Reading Environment Designed to Fundamentally Extend Readers' Interaction with Informational Texts

**Abstract**: Given that text (the word "text" is used to refer to both verbal only and multimedia text) is a primary means of acquiring and communicating knowledge, development of effective reading skills is crucial to the success of any society in a global knowledge-based economy. The research being reported led to the design of a Web-based reading environment that fundamentally extends the ways in which readers interact with text. This research had two purposes: (a) to design and develop a Web-based reading environment that supports the use of a set of reading strategies, and (b) to investigate the impact of this Web-based reading environment on readers' memory and understanding of an instructional unit on the human heart.

## Introduction

Students, particularly those in Science, Technology, Engineering, and Mathematics (STEM) fields, are faced with a situation in which they are expected to develop mastery of substantial and ever-growing bodies of knowledge in a limited time (Yore, Bisanz, & Hand, 2003). This requires adeptness with text which unfortunately is lacking in many US students. A report by the RAND Reading Study Group (Snow, 2002) noted that US students' lack of proficiency in reading puts them at a clear disadvantage with regard to learning from informational texts when compared with their peers in other countries. In fact, 11th grade students in the US were placed close to the bottom of all industrialized countries in a comparison on reading achievement. This deficiency in reading skills leads many students to drop out of STEM fields. There is also substantial evidence of an achievement gap in reading between low-economic status, at-risk students and their more privileged peers (NCES, 2000). At the same time, the RAND Reading Study group (Snow, 2002) noted that our knowledge of cognitive processes and strategies related to reading comprehension is inadequate to sufficiently reform comprehension instruction. This state of affairs has motivated work on a Web-based reading environment that is designed to extend the ways in which readers engage with informational text (Kidwai, 2009).

### Reading Comprehension

Reading for understanding is a non-trivial task, particularly when the reader is unfamiliar with the material being read. Even if readers can understand individual words in a text, they may not be able to link meanings of these words so as to be able to derive an understanding of larger chunks of text (Kintsch, 1988; van Dijk & Kintsch, 1983). Comprehension, defined as the ability to understand the ideas conveyed in a text, involves the creation of a mental representation of the text being read. The representation that is generated is a function of the information contained in the text and the reader's prior knowledge, which includes the reader's knowledge of the subject matter as well as the strategies for comprehension that the reader applies on the text (Mannes & George, 1996).

The quality of the reader's memory and understanding of a text is a function of the quality of the mental knowledge representations that are generated upon reading the text (Kintsch, 1988; van Oostendorp & Goldman, 1999). Higher quality knowledge representations directly impact an individual's ability to apply knowledge in novel situations. For example, the quality of knowledge representations is a known indicator of the probability of success in problem-solving situations (McNamara, E. Kintsch, Songer, & W. Kintsch, 1996).

### The Technology of Text

Humankind has witnessed revolutionary advances in technologies in the past centuries, yet the "technology of text" (the form in which text is presented to readers) has remained more or less unchanged (with few exceptions such as hyperlinks and animation) since the time of the handwritten scrolls and the invention of the printing press. Research on comprehension processes demonstrates a dissonance between the form in which text is presented to readers and the cognitive processes that successful readers engage in when they read (DeStefano & LeFevre, 2007; Bannert, 2004; Gervais, 2007, Zumbach & Mohraz, 2008). For example, instead of attempting to understand a large amount of text all at once, skilled readers use a "divide and conquer" strategy which leads them to identify and tackle smaller sections of text. Only when they are comfortable with their understanding of smaller sections of the text do these readers begin to integrate their understanding of the smaller pieces into a larger whole. Even though successful readers routinely engage in such bottom-up processes, the current technology of text does not allow readers to "manipulate" text in ways that support such processing. That is, even though readers mentally break up, reorganize, and reassemble sections of text that they read, they are not able to manipulate printed text, on paper or online, in ways that reflect these operations.

## Design of Web-based Reading Environment

The research being reported led to the design of a Web-based reading environment that fundamentally extends the technology of text by allowing readers to manipulate text in unique ways (Kidwai, 2009, see also AlAgha & Burd, 2009; Triantafillou, Pomportsis, & Demetriadis, 2003; Wolf, 2003). The design of the reading environment was informed by Kintsch's Construction-Integration (CI) model (Kintsch, 1988; van Dijk & Kintsch, 1983); Paivio's dual coding theory (Sadoski & Paivio, 2004; see also Ainsworth, 1999); research on the role of metacognitive processes such as comprehension monitoring (Palincsar & Brown, 1984; Pressley & Ghatala, 1990; Pressley & Harris, 2006), note-taking (Kiewra, DuBois, Christian, McShane, Meyerhoffer, & Roskelley, 1991) and summarization strategies (Armbruster, Anderson, & Ostertag, 1987; Pressley, Johnson, Symons, McGoldrick, & Kurita, 1989). Theories in human-computer interaction (Carroll, 2003) informed the design of the user-interface of the Web-based reading environment. In particular, five reading strategies were designed in the reading environment:

(a) *Text-macrostructure (chunking) strategy*: A reader can chunk the instructional unit on the human heart into smaller sections by moving elements that make up the instructional unit into *tabs* that they create on the interface of the Web-based learning environment. A reader can also label these tabs. In this way each tab on the user interface corresponds to a reader-generated *section* of instructional unit. An example of a sequence of steps that a reader would take in executing this strategy is provided below (see Figure 1, Figure 2, Figure 3). It is expected that in the process of reorganizing the instructional unit at the macro-level, the reader would begin to develop a macro-level understanding of the text—the "big picture." Being able to *customize* the instructional unit in this way should also motivate the reader to engage with it deeply.

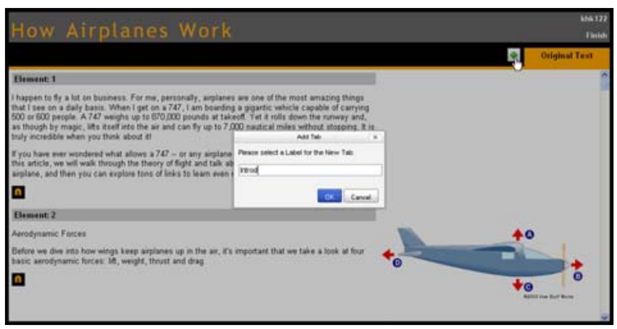

*Figure 1*. Text-macrostructure strategy: Creating a new section (tab on the interface).

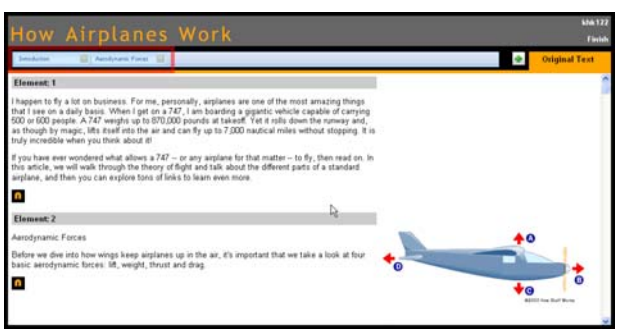

*Figure 2*. Text-macrostructure strategy: Two new sections are created (top-left hand corner).

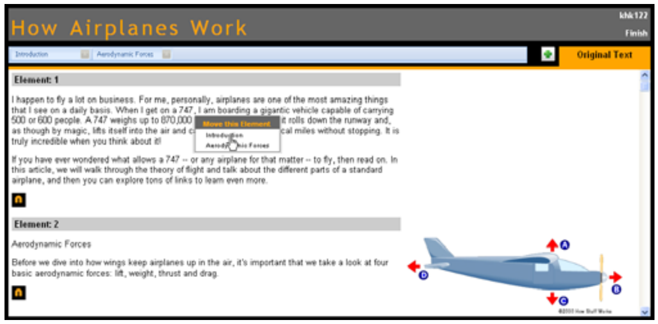

*Figure 3*. Text-macrostructure strategy: An element is moved to a section (tab).

b. *Summarization strategy*: A reader can write summaries for each section (tab) that she creates (see Figure 4). It is expected that in the process of writing summaries the reader would access her *macro-level understanding* of the instructional unit. In the process of writing summaries, gaps in macro-level understanding, if any, would be exposed. In the event the reader found gaps in understanding, she could take action—for example, rereading a particular section of the instructional unit (Armbruster, Anderson, & Ostertag, 1987).

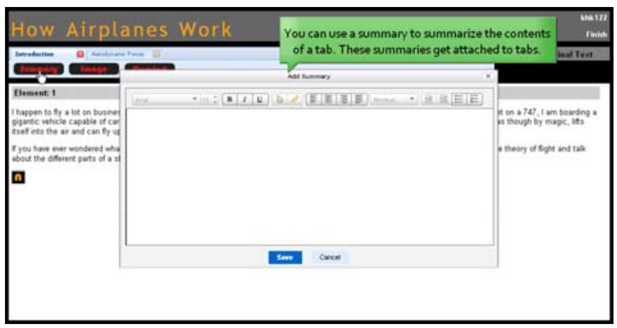

*Figure 4*. Summarization strategy.

c. *Imagery strategy*: A reader can select an image from a library of images that is most representative of the contents of a given section (see Figure 5). This strategy is expected to encourage readers to integrate knowledge across modalities, which in turn should lead to creation of well integrated and robust knowledge representations (Sadoski & Paivio, 2004; see also Ainsworth, 1999).

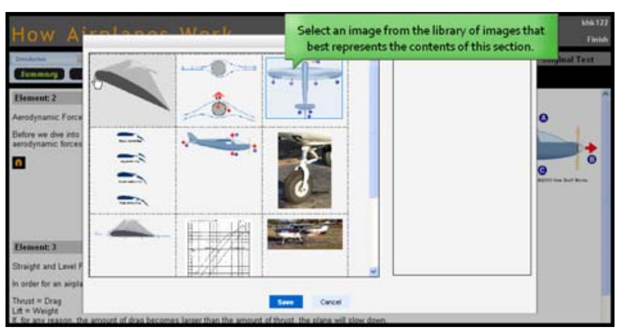

*Figure 5*. Imagery strategy.

d. *Reading self-assessment (comfort-meter) strategy*: A reader can mark on a scale of 1-5 how comfortable she feels with her understanding of each section of the instructional unit (see Figure 6). It is expected that a metacognitively aware reader would realize that not all sections of the instructional unit are equally challenging. On the basis of this knowledge, the reader could decide to allocate cognitive resources to the more difficult sections, for example by choosing to revisit and reread them (Pressley & Harris, 2006; Pressley & Ghatala, 1990).

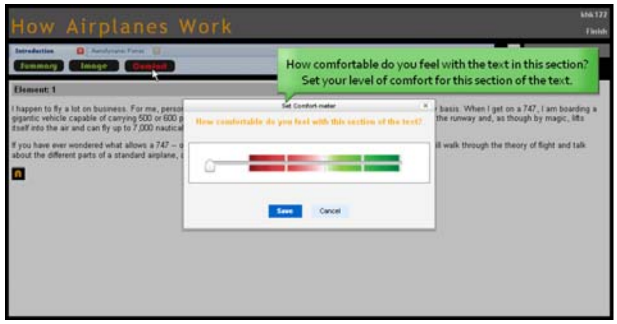

*Figure 6*. Reading self-assessment (comfort-meter) strategy.

e. *Note-taking strategy*: A reader can take notes on an *element-by-element* basis—these notes are attached to the elements that make up the instructional text (see Figure 7). It is expected that note-taking will support comprehension by allowing the reader to externalize her understanding, maintain attention, and provide a summary of the main points for a given element in the instructional unit (DiVesta & Gray, 1972; Peper & Mayer, 1986; see also Kiewra et al., 1991).

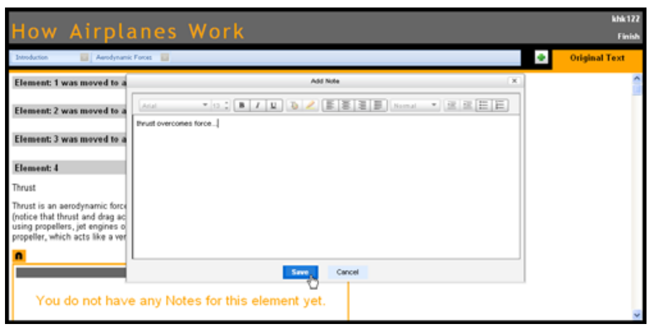

*Figure 7*. Note-taking strategy.

## Research Goals

This research had two purposes: (a) to design and develop a Web-based reading environment that supports the use of a set of reading strategies, and (b) to investigate the impact of this Web-based reading environment on readers' memory and understanding of an instructional unit on the human heart. These purposes led to four major research goals (also see Table 1):

1. Guide the design of a Web-based reading environment that supports the use of a set of five reading strategies.
2. Establish validity and reliability of Web-based measurement instruments that were designed to measure memory and understanding of the instructional unit on the human heart at four levels of knowledge representation—micro-textbase, macro-textbase, micro-situation model and macro-situation model.
3. On the basis of these measurement instruments, determine whether participants who read the instructional unit on the human heart in the Web-based reading environment developed better memory and understanding of the instructional unit when compared with participants who read the same text on a regular Web page.
4. Develop an understanding of participants' use of the five reading strategies in the Web-based reading environment and their experience in the Web-based reading environment.

Table 1. Research goal(s), number of participants, and materials in the four phases of the design-based research investigation

| Phase | Research Goals | Number of Participants | Primary Materials |
|---|---|---|---|
| Phase I | Research Goal 1: Guide the design of a Web-based learning environment. | 10 | Paper prototype of the Web-based learning environment with only the text-macrostructure strategy |

| | | | |
|---|---|---|---|
| Phase II | Research Goal 2: Establish validity and reliability of Web-based instruments that are designed to measure memory and understanding of the instructional unit on the human heart at four levels of knowledge representation—micro-textbase, macro-textbase, micro-situation model and macro-situation model. | 57 | Web-based human heart tests; instructional unit on the human heart presented on a regular Web-page |
| Phase III | Research Goal 1: Guide the design of a Web-based learning environment.<br><br>Research Goal 4: Develop an understanding of readers' use of the five reading strategies in the Web-based learning environment and their experience in the Web-based learning environment. | 43 | Web-based and paper-form of the Web-based learning environment with all five reading strategies; animated demonstration of the Web-based learning environment; Web-based human heart tests; feedback survey |
| Phase IV | Research Goal 3: Determine the impact of reading in the Web-based learning environment on readers' memory and understanding of the instructional text on the human heart.<br><br>Research Goal 4: Develop an understanding of readers' use of the five reading strategies in the Web-based learning environment and their experience in the Web-based learning environment. | 685 | Web-based learning environment with all five reading strategies; two animated demonstrations of the Web-based learning environment; Web-based human heart tests; feedback survey |

Participants in the study were undergraduate students at a large public university in the northeastern United States. Potential benefits of using the strategies in the reading environment include: (a) Cognitive: Strategies such as the text-macrostructure strategy will allow readers to externalize the mental representations that they create as they read and process text. These external representations of the text should free up cognitive resources that would otherwise be used to store and recall these representations from long term memory (Niederhauser, Reynolds, Salmen & Skolmoski, 2000; Paas, Renkl & Sweller, 2004; Paas, Tuovinen, Tabbers & Van Gerven, 2003; Mayer & Moreno, 2003). Cognitive resources that are freed-up could be allocated to comprehension processes. (b) Metacognitive: Writing summaries and setting the comfort-meter will give readers an opportunity to evaluate their understanding of a given section of the instructional text (Schwartz, Andersen, Hong, Howard & McGee, 2004). Metacognitively aware readers could use this opportunity to find gaps in their understanding and take remedial action. (c) Motivational: The ability to customize text can be motivating (Lawless & Brown, 1997; Wigfield, & Guthrie). Strategies such as text-macrostructure, note-taking, summarization, imagery, and reading self-assessment, will allow readers to customize the text to suit their learning style and their level of comfort with particular sections of the instructional text.

## Results

A design-based research methodology guided a series of studies that addressed the research goals in the study. These studies were conducted in four phases. Findings from each of the first three phases of the investigation were used to inform and update the design of the Web-based reading environment, the Web-based measurement instruments, and the research design of the subsequent phase. The investigation culminated in a large-scale quasi-experimental study.

In the Phase I study, participants' use of the text-macrostructure or chunking strategy was investigated with the help of an early-stage paper prototype of the Web-based reading environment. Participants' organization of the individual *elements* that made up the instructional unit on the human heart into *sections,* and the labels that participants gave these sections were markedly *different* across the six participants who completed this study. This evidence indicated that participants in the study made use of the text-macrostructure strategy to develop *unique macro-level representations* of the instructional unit on the human heart. Findings from this study provided support for incorporating the text-macrostructure strategy in the Web-based reading environment. This strategy played a key role in the overall design of the Web-based reading environment.

In the Phase II study, Web-based measurement instruments that measured participants' knowledge of the instructional unit on the human heart at four levels of knowledge representation—micro-textbase, macro-textbase, micro-situation model, and macro-situation model—were designed and validated. Technology used to develop the measurement instruments (implementation of the autocomplete design-pattern, drag-and-drop, and AJAX) and online delivery of measurement instruments was tested. The Web-based measurement instruments developed in this study were used in the subsequent phases of the investigation.

One-on-one sessions with 43 participants were conducted in the Phase III study. Participants were found to engage deeply with the reading task in the Web-based reading environment spending nearly twice as much time reading when compared with participants in the Phase II study who read the instructional unit on the human heart on a regular Web page. In preparation for the Phase IV study, an animated demonstration that provided participants an overview of the user interface of the Web-based reading environment was prepared and tested. Feedback questions related to participants' experience in the Web-based reading environment and the Web-based measurement instruments were prepared and tested. On the basis of data collected from interviews with participants, responses to the feedback survey, think-aloud and video data, numerous updates were made to the user interface and the design of the reading strategies in the Web-based reading environment.

On the basis of observations in the Phase III studies, a decision was made to develop two variants of the animated demonstration for the Web-based reading environment. The first demonstration was similar to the demonstration used in the Phase III studies. The objective of this demonstration was to provide participants an orientation of the user interface of the Web-based reading environment. In addition to providing participants an orientation of the user interface of the Web-based reading environment, the second demonstration provided *explicit instruction* on the five reading strategies.

The Phase IV study investigated the impact of the Web-based reading environment on readers' memory and understanding of an instructional unit on the human heart. Two levels of the independent variable—the Web-based reading environment—were set up: (a) Web-based reading environment with demonstration that *did not include* explicit instruction on the reading strategies (T1); and (b) Web-based reading environment with demonstration that *included* explicit instruction on the reading strategies (T2). In the control condition participants read the instructional unit on the human heart on a regular Web page. The six dependent variables in the study included scores on four tests that measured participants' memory and understanding of the instructional unit on the human heart (micro-textbase, macro-textbase, micro-situation model, and macro-situation model), time spent reading the instructional unit on the human heart, and the time spent responding to test questions. Six research questions were pursued: (a) Did the Web-based reading environment help participants develop better *memory* (micro-textbase and macro-textbase) of the instructional unit on the human heart, and was there an effect of the explicit instruction on reading strategies? (b) Did the Web-based reading environment help participants develop better *understanding* (micro-situation model and macro-situation model) of the instructional unit on the human heart, and was there an effect of the explicit instruction on reading strategies? (c) Did participants in the three experimental conditions spend equal amount of time reading the instructional unit on the human heart? (d) Did participants in the three experimental conditions spend equal amount of time responding to Web-based human heart tests? (e) How did participants use the five reading strategies in the Web-based reading environment and what was their experience in the Web-based reading environment? (f) What was participants' experience with the Web-based human heart tests?

Participants in the Web-based reading environment group with demonstration that included explicit instructions on the reading strategies (T2) performed significantly better ($p < .10$) than participants in the control group on the macro-textbase, micro-situation model, and macro-situation model tests ($p = .076$, $p = .079$, and $p = .012$ respectively). There was no difference in performance on the micro-textbase test ($p = .274$). Performance of participants in the Web-based reading environment group with demonstration that did not include explicit instructions on the reading strategies (T1) was unexpected; they scored lower than participants in the control group on all four tests.

Participants in the two Web-based reading environment conditions (T1 and T2) spent nearly twice as much time reading the instructional unit on the human heart when compared with participants in the control group who read the instructional unit on the human heart on a regular Web page ($p = .000$ and $p = .000$ respectively).

Participants in the Web-based reading environment group with demonstration that did not include explicit instructions on the reading strategies (T1) spent significantly less time responding to questions on the

Web-based human heart tests when compared with participants in the control group and the Web-based reading environment group with demonstration that included explicit instructions on the reading strategies (T2) ($p$ = .001 and $p$ = .001 respectively).

Feedback from participants in the Web-based reading environment groups indicated that they engaged deeply with the instructional text in the Web-based reading environment; many of the participants were able to use the five reading strategies effectively, several participants thought that they benefited from using these reading strategies. Overall, 87% of the participants noted that they had a favorable experience in the Web-based reading environment. There was a significant difference between the Web-based reading environment group with demonstration that did not include explicit instructions on the reading strategies (T1) and the Web-based reading environment group with demonstration that included explicit instructions on the reading strategies (T2) [$\chi^2$ (1, $N$ = 353) = 8.10, $p$ = .004]; 93% of the participants in Treatment 2 (T2) voted favorably, as compared to 83% of the participants in Treatment 1 (T1). Furthermore, 89% of the participants in Treatment 2 (T2) noted that they would have liked to use the Web-based reading environment in the following semester. In comparison, this percentage was only 75% for participants in Treatment 1 (T1). This difference was statistically significant [$\chi^2$ (1, $N$ = 351) = 13.88, $p$ = .000].

Overall, 82% of the participants found the experience of responding to questions on the Web-based human heart tests to be favorable. There was a significant difference between the three experimental groups [$\chi^2$ (2, $N$ = 545) = 16.62, $p$ = .000]. Participants in the control group and the Web-based reading environment group with demonstration that included explicit instructions on the reading strategies (T2) rated their experience to be more positive (89%, 84% respectively) than participants in the Web-based reading environment group with demonstration that did not include explicit instructions on the reading strategies (T1) (73%).

## Conclusion

Reading comprehension is contingent upon the successful execution of a series of cognitive and metacognitive processes. The reading strategies in the Web-based learning environment support a subset of these comprehension processes. Findings from this research stand to inform our understanding of these comprehension processes, and ways in which affordances of current Web technologies can be used to design compelling reading environments and assessments that measure learning that occurs in these environments. The Web-based learning environment also has potential for impacting the practice of reading strategies instruction. According to one participant in the study, "*Yes, I think it [reading environment] not only allowed me to learn a few things about the heart, but it also taught me that I work better when breaking text apart and categorizing the material. It also allows you to actually attach a meaning to the text instead of just reading it*."

# Helping Students Make Controlled Experiments More Informative

Kevin W. McElhaney, Marcia C. Linn

**Abstract:** We examine how encouraging students to *compare* rather than *isolate* variables affects their experimentation strategies and insights. We designed a week-long, technology-enhanced inquiry module on car collisions that logs students' interactions with a visualization. Physics students (N=166) were assigned to conditions that prompted them either to isolate or compare variables. Students responded to pretests, posttests, and embedded prompts that assessed students' understanding of motion graphs and collisions. Both groups made significant pretest to posttest gains. Students in the *compare* treatment used more diverse experimentation strategies than students in the *isolate* treatment. *Compare* students made nuanced interpretations of collision events based on threshold values. Case studies illustrate how comparing rather than isolating helped students use wide-ranging strategies to reach complex insights. The findings illustrate the value of encouraging multiple approaches to experimentation and connecting experimentation to real-life contexts.

## Introduction

This study examines how two different types of experimentation goals led students toward different investigation strategies and insights about a complex science problem. We designed *Airbags: Too Fast, Too Furious?*, a week-long inquiry module for high school physics classes that guides students through an investigation about car collisions. In *Airbags*, students conduct experiments using a visualization to investigate what factors increase drivers' risk for injury from an airbag. The software logs students' experimentation choices and explanations to provide detailed information about their inquiry activities and inferences. This study examines two main research questions: (1) What is the overall impact of *Airbags* on students' ability to interpret and construct motion graphs? and (2) How does prompting students to *compare*, rather than *isolate,* variables in their experiments guide students toward different experimentation strategies and insights?

## Rationale

Early research on scientific reasoning addressed children's ability to isolate variables in knowledge-lean experimentation contexts. For instance, Inhelder and Piaget (1958) designed a task [later adapted by Kuhn and Phelps (1982)] that asked subjects to determine what combination of colorless fluids would yield a specific reaction outcome. Siegler and Liebert (1975) examined the ways subjects determined how an electric train runs on the basis of four binary switches (though in actuality, a researcher operated the train using a secret switch to ensure that subjects would test all 16 combinations). These studies examined experimentation as domain-general logical inference, as subjects had no information on which to base testable hypotheses. In these situations, subjects could make valid inferences only by isolating variables to logically eliminate possibilities.

Over time, research has increasingly examined knowledge-rich contexts and revealed the important role of context-specific knowledge in experimentation. For example, studies show that children are more likely to test plausible rather than implausible hypotheses (Klahr, Fay, and Dunbar, 1993), focus on variables they believe to be causal (Kanari & Millar, 2004), and use experiments to achieve specific outcomes rather than test hypotheses (Schauble, 1996). Though learners' ideas about the investigation context may lead them toward invalid experimental designs or inferences, students may also use ideas productively, such as by narrowing the range of testable values or eliminating implausible explanations. Tschirgi (1980) argued that children's tendency to use "invalid" strategies when determining the ingredients needed to bake a good cake is reasonable, given real-life goals of reproducing positive results (good cakes) and eliminating negative ones (bad cakes). Koslowski (1996) also argued that using prior knowledge to generate and interpret evidence is a good strategy, particularly when understanding mechanisms informs the interpretation of outcomes.

In *Airbags*, students rely on many types of context-specific ideas to draw conclusions. Students' everyday understanding of motion, their physics domain knowledge about motion graphs, and evidence from the World-Wide Web all contribute to the way students design and interpret their experiments. Our previous work on *Airbags* (McElhaney & Linn, 2008) compared students who were constrained to conduct a specific number of trials to unconstrained students. During planning, constrained students attended more to the logistics of isolating variables, resulting in more controlled trials than unconstrained students. Unconstrained students, who attended more to the relationships among collision factors, variables, and outcomes, demonstrated a superior understanding of the situation. This result suggests that incorporating a context-specific understanding into experimentation was more important than employing "valid" strategies.

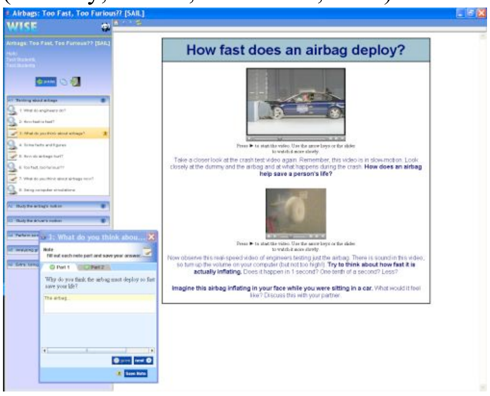
The current study extends our prior work by examining how experimentation goals can highlight the nature of the variables and make students' experimentation more informative. Research shows that goals for experimentation can influence learners' strategies and inferences, such as when children use different strategies to achieve positive outcomes than negative ones (Tschirgi, 1980) or when learners use different approaches for optimization than for rule-generation (Schauble, Klopfer, & Raghavan, 1991). This study draws from research in science instruction showing that comparisons can highlight key features of variables (Clement, 1983; Linn, 2005; Schwartz & Bransford, 1998) and investigates whether goals that encourage students to *compare* variables promote different insights about *Airbags* than goals that encourage students to *isolate* variables.

This study also explores how students come to understand *thresholds* (values of a particular variable above or below which the outcome is independent of the other variables). The presence of thresholds requires students to consider factors other than covariation to achieve a complete understanding of *Airbags*. Though students may readily observe the effects of thresholds by isolating variables, we hypothesized that comparing variables would highlight the distinct characteristics of each variable, helping sophisticated learners achieve a more nuanced understanding of *Airbags* based on thresholds as well as covariation. We also expected that the more familiar and tractable task of isolating variables would be more beneficial for less sophisticated learners.

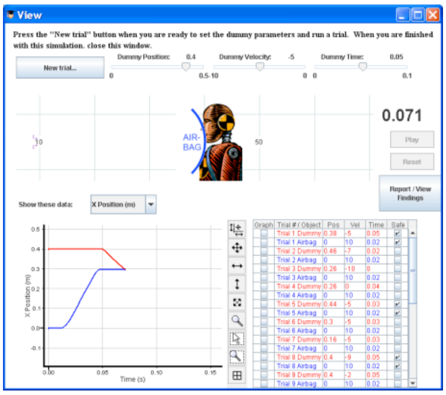
## Methods

### Module and visualization design

We designed *Airbags* (Figure 1a), using the Web-based Inquiry Science Environment (Linn, Davis, & Bell, 2004). *Airbags*' learning goals are (1) how motion graphs represent one-dimensional motion and (2) what factors make airbags likely to injure drivers. Students experiment using a dynamic visualization (Figure 1b) designed by the Concord Consortium (www.concord.org). Students investigate the role of three *collision factors* on the driver's safety by experimenting with three *motion variables*. Table 1 summarizes factors, variables and questions for each treatment condition. To conduct a trial, students select an investigation question (or indicate that they are *Just exploring*), specify the variable values, and run the simulation. For each trial, students judge whether the driver was "safe" (encountered a completely inflated airbag) or "unsafe" (encountered the airbag within its deployment zone). The visualization presents the motion of the airbag and driver using graphs that coordinate with an animation. The visualization also helps students manage their trial history, sort trial outcomes, and compare multiple trials. The software logs students' experimentation choices for subsequent analysis (Buckley, Gobert, & Horwitz, 2006).



(a)



(b)

Figure 1. (a) The first activity of *Airbags*. (b) The experimentation visualization.

Students may use two types of inferences to explain their findings: covariation and threshold values. First, over a particular range of values, each of the three variables covaries with the time that elapses before the driver and airbag collide. Tall drivers, low speed collisions, and a large crumple zone therefore make a driver more likely to encounter a fully inflated airbag than short drivers, high speed collisions, and a small crumple zone. Second, two threshold values (for position and time) determine situations where the likelihood of injury is invariant: (1) short drivers who sit within an airbag's zone of deployment will *never* encounter a fully inflated airbag, and (2) for sufficiently tall drivers, if the duration of the crumple zone exceeds the deployment time for the airbag, drivers will *always* encounter a fully inflated airbag. Responses to embedded assessments indicate whether students attribute their findings to covariation and/or thresholds.

### Study design

Groups in the *isolate* and *compare* conditions received investigation questions that encouraged them to isolate or compare variables, respectively. Except for the investigation questions, the modules used for each condition were identical. We used a pretest/posttest experimental design with embedded assessments and two comparison conditions. We randomly assigned student groups to one of the conditions using a stratified approach to distribute their ability equally across the two conditions. To keep instruction similar across conditions, teachers and researchers focused class discussions on graph interpretations rather than on investigation questions and refrained from guiding individual students on designing experiments.

Table 1: Collision factors, variables, and investigation questions for the *isolate* and *compare* conditions.

| Collision factor | Motion variable | Investigation question | |
|---|---|---|---|
| | | *Isolate* condition | *Compare* condition |
| Driver height | Position | Are TALL or SHORT drivers more likely to be injured by a deploying airbag? | Does the DRIVER'S HEIGHT make the biggest difference in whether the driver is injured? |
| Collision speed | Velocity | Do HIGH or LOW SPEED collisions make drivers more likely to be injured by a deploying airbag? | Does the COLLISION SPEED make the biggest difference in whether the driver is injured? |
| Car crumpling | Time | Does MORE CRUMPLING or LESS CRUMPLING make drivers more likely to be injured by a deploying airbag? | Does HOW MUCH THE CAR CRUMPLES make the biggest difference in whether the driver is injured? |

## Participants

Physics students (N=166) at five socially diverse high schools in the United States studied *Airbags*. Most students worked in dyads on the module (unpaired students worked alone). Students were usually grouped with other students of nearly equal ability. Most teachers had taught the topic using previous versions of *Airbags*.

## Data sources and scoring

### Pretests and posttests

Ten constructed response pretest and posttest items assessed students' ability to interpret and construct graphs of one-dimensional motion in a context outside of *Airbags*. We administered pretests individually to students the day before the beginning of *Airbags* and posttests within a few days of completion. We scored pretest and posttest responses from zero to four using knowledge integration rubrics (Linn, Lee, Tinker, Husic, & Chiu, 2006) that measured how well students connected characteristics of motion to the features of motion graphs.

### Embedded assessments

*Use of the Control-of-Variables Strategy (CVS).* We used students' experimentation sequences (as captured online in log files) to compute a CVS score, the percentage of each group's trials that were part of a controlled comparison between successive trials using the variable appropriate to the chosen investigation question. We used only trials that specified one of the three investigation questions (i.e. not *Just exploring*) for this score. This proportion score indicates the extent to which students mindfully used CVS to investigate the three questions.

*Interpreting and constructing Airbags graphs.* Twelve items asked students to interpret motion graphs from the visualization or generate graphs that represented a collision situation. Each group received a COLLISION GRAPHS score that captured how well they connected characteristics of the graphs to the events in a collision. We scored these explanations from zero to five using knowledge integration rubrics.

*Understanding of covariation and thresholds.* Three items prompted students to explain their answers to the three investigation questions listed in Table 1. We used these responses to determine whether each group attained a covariation-based and/or thresholds-based understanding of the *Airbags* situation. To examine how frequently students attributed their findings to covariation, we counted the number of responses by each group that described covariation between the factor or variable in question and elapsed time before the driver encounters the airbag. To examine how frequently students attributed their findings to thresholds, we counted the number of responses by each group that used at least one of the thresholds in support of their finding.

### Videorecords

We videorecorded 12 dyads as they engaged in the experimentation activity, so that we could closely examine the discussions that occurred during experimentation within specific dyads. We chose two of these dyads for a case comparison to illustrate how the investigation questions they received influenced their experimentation strategies and insights. A more detailed description of these two dyads and the reasons we chose them for analysis follows the presentation of the results of the comparison study.

# Results

## Impact of *Airbags* on students' understanding of motion graphs

Students made moderate, significant pretest-posttest gains [M = 29.99, SD = 6.66 (pre); M = 32.76, SD = 5.96 (post), $t(128) = 5.17$, $p < .001$ (two-tailed), $d = 0.44$]. Gains were positive for all five schools, and significant for four of the schools. Low prior knowledge learners made the greatest gains. The gains indicate that *Airbags* was successful in helping diverse learners interpret and construct motion graphs. The gains are impressive considering that all students had completed a kinematics unit shortly before studying *Airbags*, and they represent value added to a traditionally taught kinematics unit.

The difference in posttest scores between the two conditions was not significant. We did not expect differences because the experimentation activity generally comprised just 10-20% of the total time spent on *Airbags*. Students in both conditions therefore had many opportunities to improve their graphing knowledge other than by experimentation. Furthermore, there were no significant differences between the conditions on the COLLISION GRAPHS scores, suggesting that the *isolate* and *compare* prompts were equally effective in helping students connect the characteristics of the *Airbags* graphs to the collision events.

To examine subtle impacts of experimentation goals on students' strategies and insights, we sorted student groups into low, middle, and high prior knowledge tertiles using the mean pretest score for each group. Our exploratory analyses show variation in students' strategies and inferences by tertile.

## Impacts of prior knowledge on students' strategies and inferences

CVS scores showed that the high tertile groups conducted a significantly higher proportion of controlled trials than the low and middle tertile groups [M = .79, SD = .30 (high), M = .45, SD = .35 (low/middle), t(79) = 4.39, $p < .001$ (two-tailed)]. This difference suggests that high prior knowledge students as a whole were more focused on controlling variables in their investigations.

Overall, about 30% of the students generated covariation-based explanations of the collision events. The percentage was somewhat higher for the high (38%) and middle (36%) tertile groups than for the low (19%) tertile groups, but this difference was not significant, indicating that a covariation-based understanding of *Airbags* was accessible to students at all prior knowledge levels. However, just 2% of low and middle tertile students generated thresholds-based explanations, compared to 31% of the high tertile students. A Wilcoxon rank-sum test showed that the difference in the average number of thresholds-based explanations was significant [M = .59, SD = .98 (high), M = .038, SD = .28 (low/middle), U = 3.78, $p < .001$]. This result suggests that only sophisticated learners were able to achieve a thresholds-based understanding of *Airbags*.

## Impacts of experimentation goals on students' strategies and inferences

CVS scores showed significant differences between the conditions only for the high tertile students [M = .94, SD = .06 (*isolate*), M = .70, SD = .35 (*compare*), t(27) = 2.22, $p = .035$ (two-tailed)]. A close examination of these data revealed that while virtually all the *isolate* groups devoted nearly all their trials to controlled comparisons between successive trials, one-third of the *compare* groups used at least half their trials for other strategies. (The case comparison that follows will illustrate some of these strategies.) This result suggests that though most students used similar approaches to investigate the *isolate* and *compare* questions, the *compare* questions led some high prior knowledge students to use alternative strategies to CVS in their investigations.

There were no differences in the number of covariation-based explanations between the two conditions, indicating both conditions were equally effective in leading students toward a covariation-based understanding of *Airbags*. However, we observed significant differences in the number of thresholds-based explanations for the high tertile students. Just 8% of the high tertile *isolate* groups generated thresholds-based explanations, compared to 44% of the *compare* groups. A Wilcoxon rank-sum test showed that the difference in the average number of thresholds-based explanations for high tertile students was significant [M = .091, SD = .30 (*isolate*), M = .89, SD = 1.13 (*compare*), U = 2.09, $p = .037$]. This finding suggests that the *compare* questions promoted a thresholds-based understanding of *Airbags*, though this difference occurred only with sophisticated learners.

# Case comparison

We use a case comparison to illustrate some ways the *isolate* and *compare* tasks might have led sophisticated students toward different experiences with the *Airbags* visualization. We chose two similar high-tertile dyads for a case comparison. The students in these dyads were enrolled in the same honors physics curriculum with the same teacher and had similar pretest and posttest scores. Furthermore, all four students were concurrently enrolled in calculus and thus had strong mathematics skills. Because the student population and array of schools used for this study was highly diverse, no single case can represent the "typical" experience students have with *Airbags*. These cases rather aim to illustrate how the *compare* questions might have prompted sophisticated students to consider aspects of the *Airbags* situation that the more traditional *isolate* question might not have.

## Case 1: Brett and Eric (*isolate* condition)

### Overview

Brett and Eric (pseudonyms) studied the *isolate* version of Airbags. They conducted 10 total trials. For their first four trials, they chose *Just exploring* as their goal, during which time they explored outcomes for default and extreme values of all three variables. They devoted the last six trials to conducting a pair of controlled trials for each of the three investigation questions. Their experimentation session lasted about 10 minutes. This analysis focuses on the three controlled trial pairs.

### Trials 5 & 6: "He's going to be safe, obviously"

In trials 5 and 6, Eric and Brett investigated whether tall or short drivers are more at risk. In trial 5, they examined the outcome for a short person. The following excerpt illustrates their variable choices for trial 6 and their interpretation of the two trials:

(84) E: …Short or tall. And now we have to move the guy back, cause he's taller. So we gotta keep everything except position. So move him back some. Like right there.
(85) B: He's going to be safe, obviously.
(86) E: He might not, let's just check. [They run trial 6.] Yeah. So mark that as safe. OK, put the graphs for the previous two. [They compare the graphs of trials 5 and 6]
(87) B: They're both safe.
(88) E: Yeah. So let's go to the next question.

Two things are apparent from this exchange. First, because trial 5 produced a "safe" outcome, Brett knew that the outcome of the trial 6 would also be "safe" before conducting it. However, rather than choosing a set of values that would provide them with more information, they simply ran the test. Second, in these two trials they achieved the same "safe" outcome, failing to provide strong evidence for the effect of the position variable on the risk to the driver. Further tests aiming to illustrate conditions that led to an "unsafe" outcome would have better informed their understanding. However, their variable choices and the brevity of their discussion about the results suggest they are focused more on isolating variables than on gaining insight about the situation.

### Trials 7 & 8: "We can only change one of them, we can't change multiple ones"

The following exchange occurred immediately after isolating the velocity variable in trials 7 and 8:

(93) E: …since we're doing, like, experiments, we can only change one of them, we can't change multiple ones.
(94) B: Yeah.
(95) E: Cause like in real life, there would be a combination of all three.

Eric's comments shed light on their commitment to using CVS throughout the activity. Eric believed that they were prohibited from using other strategies (though at no point does *Airbags* suggest how students should conduct their trials). Furthermore, the distinction he made between their experiments and "real life" indicates he believed these other strategies would be permissible in other contexts. Though Eric did not elaborate on what he meant by "a combination of all three", his words suggest that by isolating variables they aim to fulfill expectations imposed on them by the culture of classroom science.

### Trials 9 & 10: "Just go low first"

Brett and Eric used their final two trials to isolate the time variable. This exchange occurred as they decided how to conduct these two trials:

(97) E: So--more or less crumpling. So keep the velocity constant. So then, if there's less delay, that means more crumpling. So then, yeah let's do less crumpling.
(98) B: That's more crumpling.
(99) E: That's…yeah. So just go low first. Like there's low crumpling, almost no crumpling.
…
(103) E: OK, so then, that was low speed, so this is high speed. All right.
(104) B: More crumpling.
(105) E: Yeah, more crumpling.

To begin, Eric incorrectly stated the relationship between the crumpling factor and the time variable. Though this error could be conceptual, Eric's subsequent request to "just go low first" suggests that the correct relationship was unimportant to him. Because the precise nature of the relationship between the factor and the variable (direct or inverse) would not change how they employed CVS, the only decision Eric believed they need to make is whether to test the "low" or the "high" value first. Next, even after being reminded of the correct relationship, Eric attributed the time variable to the wrong factor entirely (speed, rather than crumpling). By this time, Eric was no longer attending to the nature of the variables and appears to have sequestered their experimentation strategy from their understanding of the *Airbags* context. At this point, the variables might as well have been X, Y, and Z rather than position, velocity, and time.

## Case 2: Joann and Linda (*compare* condition)

### Overview

Joann and Linda (pseudonyms) studied the *compare* version of *Airbags*. They began their experimentation by carrying out an initial plan to isolate each variable. They quickly abandoned that approach and employed other strategies such as testing extreme values and incrementally varying individual variables. Their experimentation session lasted about 30 minutes. This analysis will focus on three excerpts that illustrate the evolution of their investigation strategies and the insights they achieved by using these diverse approaches.

### Trials 1 - 4: Abandoning CVS

Joann and Linda used their first three trials to isolate the position variable and test its full range. As they decided on the values for the fourth trial, Linda began to reconsider their approach.

(41) L: I don't know. Maybe we just test ummm, like, test the position at, like, three different points. That's just so—that's just so many tests, never mind….

At first they were discouraged by the sheer length of their proposed approach, but after choosing some intermediate values for trial 4 and discussing the outcome, their discussion about the "effect" of the car crumpling empowered them to abandon their initial strategy:

(82) J: Then it all falls back to what we said originally, the crash, the speed of the crash dictates if position and dummy time, you know, the crumpling of the car would have an effect.

(83) L: Yeah. I don't understand why we have to do different tests for each three different sections [investigation questions]. You know? You click on them and be like whatever trials for this, kind of. 'Cause it looks like we're kind of figuring it out as we're looking at this.

Here, the *compare* questions promoted a discussion about the relative "effects" of the variables on the outcomes that the *isolate* questions, by their very nature, were unlikely to promote. The discussion about effects appears at least in part to have led Linda and Joann to abandon their initial approach. Unlike Brett and Eric, they had prioritized "figuring it out" over conducting "whatever trials" that were expected of them for each investigation question. At this point, they took a different approach toward making sense of the *Airbags* situation.

### Trials 5 - 7: Exploring extreme values

In trials 5, 6, and 7, Joann and Linda explored extreme values of the velocity and time variables. In trial 5 they simulated a "high impact crash", setting the velocity to the "fastest possible." In trial 6, they "try it with dummy time if we put it at, like, zero." In trial 7, they tested the maximum crumple zone ("All the way?"). This sequence culminated in an important observation Joann made as they examined trials 6 and 7:

(137) J: Well, I guess, dummy time can also have an effect with position, cause like I'm saying, if you have no dummy time, then how close you are to the steering wheel matters a lot.

Again, only the *compare* questions would prompt Joann make this insight about how much the proximity to the steering wheel "matters". In this case, the extreme value approach illustrated to Joann that the effect of time on the outcome may depend on the value of position. Though this initial understanding of the interaction between position and time was at this point incomplete, it became increasingly sophisticated through continued experimentation and discussion, eventually leading to a highly nuanced understanding of the threshold values.

### Trials 8 - 11: Incremental variation

Beginning with trial 8, Joann and Linda changed approaches once more to examine the effects of minute changes to the variables. From trial 8 to trial 9, they decreased the time by the smallest possible increment. After not finding anything conclusive, they incrementally adjusted the velocity in trial 10. Comparing trials 9 and 10 revealed to them nearly identical graphs and led to the following exchange:

(175) L: …So then that one doesn't make much of a difference.
(176) J: No. OK.
(177) L: So the speed didn't make a difference in that—
(178) J: Oh. Doesn't that counteract what we first said? ...I mean, contradict?
…
(190) J: I'm thinking that, he doesn't start moving until, I don't know, I can't put it in words. Even though he's moving faster, by even a little bit, it doesn't really have much of an effect because then, the amount of time….

Observing the similarity between the trial 9 and trial 10 graphs made them realize for the first time that their initial hypothesis (that speed would have the largest effect) was incorrect. Joann was almost able to explain why, but could not quite articulate the precise reason for the insensitivity of the outcome to the velocity. However, using trial 11 to retest the situation once more with the highest allowable velocity value crystallized their understanding of the time threshold:

(207) L: So it's the same, the speed doesn't change anything, it's the same graph we just had.
(208) J: Oh, in that case, cause he won't start moving until—he won't start moving *period* [verbal emphasis] until—this has already been inflated no matter how fast he's going. Yeah. Because he won't start moving until .06 seconds has gone by.
(209) L: Right.
(210) J: So he could be moving at 100,000 miles an hour and he won't hit it until the airbag's already inflated, according to how we set this up.

One revealing aspect of Joann's and Linda's last four trials is that they do indeed constitute use of CVS. However, they conducted these controlled trials in a different way (using incremental variation) and for a much different purpose (to compare the magnitude of effects) than for their earlier controlled trials, or for Brett's and Eric's controlled trials. Not surprisingly, they were also much more informative than the other trials. The design of these trials made use of their previous insights, and their use of CVS emerged spontaneously as the best way to further their understanding of the situation, rather than as a strategy they learned in science class.

After conducting trial 11, Joann's and Linda's understanding of the situation was so complete, they did not require any additional trials to succinctly characterize the relative effects of position, velocity and time on the outcome, on the basis of threshold values:

(227) J: …if we move it closer to the steering wheel, then dummy velocity and dummy time wouldn't matter, because as the airbag starts inflating, he'd be in the way…
…
(238) J: And, he waits that certain amount of time for the airbag to inflate, then velocity doesn't matter.

## Discussion

*Airbags* benefited learners across the distribution of prior knowledge, albeit in different ways. Learners with initially poor understanding of motion graphs made large gains in their abilities to interpret and construct motion graphs, and they were able to generalize their knowledge from *Airbags* to other motion contexts. However, these students' experimentation choices and responses to embedded prompts show that many of them struggled to investigate the questions systematically and reach meaningful insights. On the other hand, learners with initially strong understanding of motion graphs had less room for improvement in that area, but conducted experiments that led to more valid inferences. In particular, the *compare* questions helped the most sophisticated learners examine key distinctions between the variables, such as the magnitudes of the effects of each variable on the outcome.

The stark differences between the two cases illustrate how the *isolate* and *compare* questions led students to reason about the *Airbags* situation. For Brett and Eric, the *isolate* questions appeared to provoke a "schoolish" interpretation of the task. They viewed the task as a simple covariation problem (a common task in school science), and as a result they limited themselves to a predetermined pattern of using CVS rather than spontaneously employing diverse strategies to investigate new questions. They prioritized validly implementing CVS over gaining insight. They sequestered their understanding of the *Airbags* situation from their investigation strategy and, more generally, from their conceptions of the *Airbags* task and the real life practice of science. Though their strategy was "valid" (as judged by criteria often imposed by classroom science), it was not especially informative. Their analysis did not go beyond a superficial characterization of the variables.

In contrast, the *compare* questions prompted Joann and Linda to incorporate a wider range of strategies to elucidate variation patterns. They conducted trials intending to understand the relationships between variables and outcomes and the mechanisms that governed these relationships. Though their initial efforts to use CVS did not yield useful ideas, in the end they spontaneously used CVS to achieve a nuanced understanding of *Airbags* by building on ideas they refined using other strategies. In this way, Joann's and Linda's use of CVS during their final four trials evolved naturalistically as a way to investigate questions that arose from their previous trials. The *compare* questions encouraged Joann and Linda to deeply consider the nature of the variables and to make important and meaningful distinctions between them.

The complexity of Joann's and Linda's analysis illustrates why we observed differences between the conditions only for high prior knowledge students. Joann and Linda needed highly sophisticated knowledge of experimentation strategies and graph interpretation in order to reach their advanced level of understanding. Less sophisticated students likely lacked sufficient knowledge either to distinguish the *compare* questions from the *isolate* questions or to adequately investigate either type of question. Future research will examine how to refine the guidance to help more typical students conduct informative experiments.

## Conclusions and Implications

This study investigated the effect of encouraging students to compare rather than isolate variables. In *Airbags,* students who were guided to *isolate* variables often missed important insights by limiting their analysis to one variable at a time. Prompting students to *compare* variables led to a more nuanced understanding of the *Airbags* situation particularly for high prior knowledge students, achieved at least partly by using diverse experimentation strategies.

Our findings point to the value of providing opportunities for multiple approaches to experimentation rather than guiding students only to isolate variables. The findings suggest that instructional designers should balance guidance designed to promote CVS with opportunities to explore the nature and meaning of the variables. Designers of instruction should select problems where subtle distinctions such as thresholds are necessary for complete understanding. Many everyday problems such as decisions about drug dosage require an understanding of thresholds. Our study demonstrates the value of connecting experimentation to real-life contexts such as airbags, where students can appreciate connections between science instruction and everyday life.

This study also illustrates the value of providing students with graphical representations to help them make valid inferences from their experiments. Our detailed analysis of the ways students reasoned with the *Airbags* visualization revealed that the graphs were essential for comparing multiple trials, revisiting previous ideas, and interpreting collision events. How graphing tools should be designed to support scientific reasoning merits further study.

# Fading Instructional Scripts: Preventing Relapses into Novice Strategies by Distributed Monitoring

Christof Wecker, Frank Fischer, University of Munich, Leopoldstr. 13, D-80802 Munich
christof.wecker@psy.lmu.de, frank.fischer@psy.lmu.de

**Abstract:** During the fading of instructional scripts learners might relapse into their initial novice strategies after script prompts are withdrawn. One possibility to overcome this problem could be a learning partner providing distributed monitoring of the performance of the strategy suggested by the script. In a 2-factorial experiment with the factors fading and distributed monitoring that involved 126 students of educational science we investigated whether during the fading of an instructional script there is a moderating effect of distributed monitoring on the performance of the strategy and thereby on the acquisition of the cognitive skill of argumentation. Strategy knowledge was fostered best by the combination of fading and distributed monitoring. Distributed monitoring also kept the performance of some aspects of the strategy at higher levels during fading, which was positively related to the acquisition of strategy knowledge.

## Theoretical background

### Argumentation as a cognitive skill

In the literature on cognitive skill acquisition, a skill is typically regarded as a system of procedural knowledge that can be described by a set of production rules (e. g. Newell, 1990; Anderson & Lebiere, 1998). Each single procedural knowledge component described by a production rule can fulfil at least one of two functions: It can regulate the execution of the skill by setting subgoals, or it can directly contribute to performance by helping accomplish these subgoals (cf. Anderson, 1987). The main mechanism for acquiring a unit of procedural knowledge according to these theories is applying it (Anderson & Lebiere, 1998).

Argumentation competence can be regarded as a cognitive skill. On the basis of a cognitive task analysis, the ability to arrive at a counterargument against the relevance of someone else's argument for a specific claim (as one aspect of argumentation competence) can be described as a series of subgoals that can be accomplished by procedural knowledge that implements argumentation schemes (Wecker, 2008): (1) the identification of a claim in someone else's utterance, (2) the identification of an argument put forward to support the claim, (3) the identification of the type of the claim, (4) the identification of the type of the argument, (5) a check of the fulfilment of the conditions of relevance of the argument with respect to the claim, and (6) the formulation of a counterargument on the basis of the results of the analysis conducted in steps 1 to 5. Accordingly, the specific aspect of argumentation competence mentioned above involves strategy knowledge about this series of steps.

Learners may be supported by means of an instructional script to apply such a strategy while engaging in collaborative learning (e. g. Stegmann et al., 2007). As long as they do not master the strategy, they use general-purpose productions to interpret these instructions (Taatgen, Lebiere & Anderson, 2006) and set the corresponding subgoals in accordance with them. In this phase, learners do not yet apply the strategy knowledge themselves since control of performance is exerted completely by the script that guides them. Consequently, this kind of perfomance contributes little to the acquisition of strategy knowledge according to the assumptions of skill acquisition theories mentioned above. In order to strengthen strategy knowledge, learners need to use it to self-regulate their performance. Fading can provide them with opportunities to do so.

### The fading of instructional scripts

Very diverse kinds of instructional support can be faded, ranging from stimuli and prompts (Riley, 1995) to steps in worked-out examples (Renkl & Atkinson, 2003). In most of these cases, fading proved effective for learning (e. g. Schunk & Rice, 1993; Renkl, Atkinson & Große, 2004). However, the kinds of instructional support faded in these studies are quite unlike instructional scripts. These are more akin to scaffolds; collaboration scripts can actually be regarded as a kind of socio-cognitive scaffolding (Carmien, Fischer, Fischer & Kollar, 2007).

Fading has always been regarded as an integral part of scaffolding (Wood, Bruner & Ross, 1976; Pea, 2004; Puntambekar & Hübscher, 2005). So far, only a couple of studies on the effects of the fading of scaffolds have been conducted, with mixed results. Leutner (2000) conducted two experiments on the effects of fading on the acquisition of software skills. One provided evidence for beneficial effects of fading, the other indicated decreased performance in the process of fading. McNeill, Lizotte, Krajicik and Marx (2006) demonstrated a marginally significant positive effect of fading on knowledge about the principles of scientific explanations. In a study by Lee and Songer (2004) the fading of scaffolds had no effect on the quality of explanations in the posttest, but the quality of explanations during learning decreased over time while scaffolds were faded.

From the perspective of cognitive skill acquisition these results do not come as a surprise: As long as there is unfaded support, learners do not practice the application of strategy knowledge to self-regulate their performance. As soon as support is faded, they are immediately required to jump in and exert self-regulation of their performance, which they had no opportunity to practice before. A way out of this paradox may be available in collaborative situations.

### The role of distributed monitoring

When support previously available from an instructional script is gradually withdrawn, successful performance requires learners to take over control of their activities. A full cycle of control involves planning, monitoring and adapting one's steps as part of a strategy. This task may overwhelm learners if they are supposed to take responsibility for all of its parts at once. In such a situation, the idea of distributed metacognition (King, 1998) proves useful: Specific components of control may be distributed among collaborating learners. For example, a learner can be freed from the task of monitoring his or her own application of a strategy and receive feedback on the performance from a learning partner. As soon as he or she wanders off track, such feedback can be used in subsequent cycles to plan the single steps in accordance with the strategy to be internalized.

### Research questions

Accordingly, this study focused on the following research questions:
(1) What are the effects of fading and distributed monitoring on the acquisition of strategy knowledge?
(2) What are the effects of fading and distributed monitoring on the performance of the strategy suggested by the script in the course of time?
(3) What is the relation between the performance of the strategy and the acquisition of strategy knowledge?
It was assumed that fading will play out its full potential to foster the acquisition of strategy knowledge only when combined with distributed monitoring. The hypothesized mechanism behind this effect is self-directed (i. e. unguided) performance of the strategy suggested by the script, which may be kept up by distributed monitoring.

## Methods

### Participants

The participants of the study were 126 students in courses in educational science and teacher preparation who attended a lecture with the title "Introduction to Educational Psychology". On average, they were 23.3 years old (SD = 3.9). Of them, 73.8 % were female and 26.2 % were male. They were randomly paired to dyads who discussed on separated online discussion boards during a collaborative learning phase.

### Design

A 2x2 design with the factors fading and distributed monitoring was implemented (see table 1).

Table 1: Design of the study.

| **Distributed monitoring** | **Fading** | |
|---|---|---|
| | *Unfaded script* | *Faded script* |
| *Without distributed monitoring* | 15 dyads/30 persons | 18 dyads/36 persons |
| *With distributed monitoring* | 13 dyads/26 persons | 17 dyads/34 persons |

### Learning task, material and environment

The two learners in each group dealt with cases on the application of Weiner's attribution theory in a text-based online discussion board. They were told that they were discussing analyses of these cases in groups of four and that two of the other learners had the task to write these analyses. The learners themselves were asked to write critical replies to each of theses analyses and could discuss any questions that came up during this task on the discussion board. In fact, six case analyses with at least two questionable claims were posted to the board under the names of two simulated group members at fixed points of time. As a preparation for this collaborative learning session, the learners read a three-page text on Weiner's attribution theory and a four-page text on how to generate counterarguments for the critical replies.

A script supported the learners in all four conditions in the process of formulating counterarguments against the prepared case analyses by providing instructions on how to analyze the argumentation in the case analyses to discover problematic assumptions. The script contained three kinds of information: sequence information, argument schemata and application support (see figure 1). *Sequence information* describes the process of analyzing the argumentation in the prepared case analysis and the construction of a critical reply to it. The steps of the strategy to arrive at a counterargument were mirrored in the interface as prompts that changed according to the state of the editing, and specified the next step. *Argument schemata* contained information on what types of argument are appropriate to support the identified type of claim and what conditions of relevance need to be fulfilled for an identified pair of argument and claim, which was crucial for the assessment of the argumentation in the case analysis. They were implemented by means of selection fields for the type of the claim and the argument as well as by a prompt for the assessment of the conditions of relevance. *Application support* was provided by means of explanatory sentences for the terms used in the prompts and selection fields of the script as well as examples for the respective types of propositions. They were displayed in the interface directly next to the respective control elements.

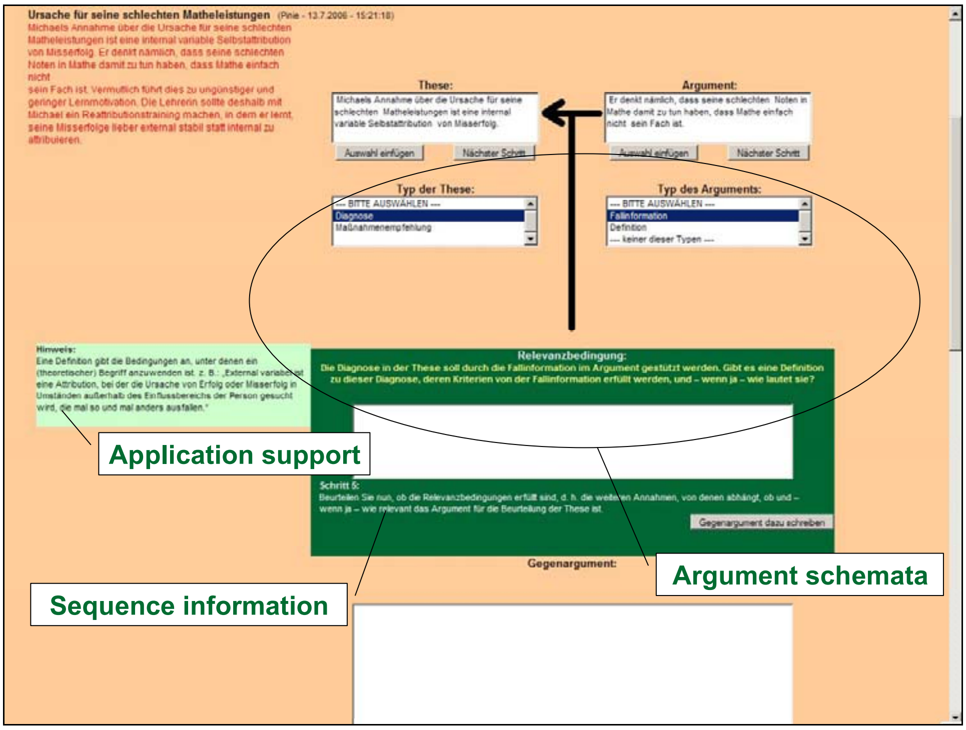

Figure 1. Implementation of the script for the formulation of counterarguments.

## Independent variables

### Fading

In the conditions *with faded script* components of the interface were removed based on the number of critical replies posted. The following fading regime was used: The *application support* disappeared completely after two critical replies had been written. *Sequence information* prompts were faded by replacing two randomly chosen prompts per round by the request “Please perform this step on your own.”, starting with the composition of the third critical reply. This means that after five critical replies only this unspecific request was shown before each step. With respect to the *argument schemata* “later” elements had to be faded first because for the branching of the support for different argument schemata unequivocal input was required: First the specific question concerning the fulfilment of the conditions of relevance (step 5) was replaced by an unspecific one. From the forth critical reply on, the dropdown field for the type of the argument did no longer contain any options, but the learners had to fill in the type of the argument themselves. From the fifth critical reply on, the dropdown field for the type of the claim did no longer contain any options, but the learners had to fill in the type of the claim themselves. After five critical replies had been posted, the interface did not change as a function of the number of critical replies any more, no matter how many messages were written. After 70 minutes, finally the students were provided only with a simple text box for the formulation of their critical replies to the case analyses as customary in asynchronous discussion boards.

In the conditions *with unfaded script* the interface for the composition of critical replies remained unchanged throughout the learning phase.

### Distributed monitoring

In the conditions *with distributed monitoring*, one of the learnings had the task to provide the other one with feedback for each of his or her critical replies, based on which the other learner was asked to revise his or her critical reply. During the formulation of this feedback, the learning partner was supported by the interface: By simply clicking on check boxes, a message about the completeness of the six steps of the strategy for the construction of a counterargument, on the appropriateness of the identification of the types of claim and argument, and on the correctness of the answer to the question concerning the conditions of relevance could be composed. Furthermore there was the opportunity to add text remarks. In the condition with faded script and distributed monitoring, the distributed monitoring was continued after the fading had started.

In the conditions *without distributed monitoring*, the learning partners were neither asked nor supported to provide feedback on the critical replies.

## Dependent variables

### Strategy knowledge

Strategy knowledge was measured by means of a task with open answering format. The learners were asked to describe their strategy for checking the relevance of an argument for a claim and formulating a counterargument against it. The learners' unsegmented answers were coded for the occurence (0 – absent/1 – present) of each of the six steps of the strategy implemented in the script. One further coding item captured the correctness of the sequence. The agreement of two coders for these coding variables ranged from 76 % to 90 % (median: 86 %); Cohen's $\kappa$ ranged from .46 and .70 (median: .51). Therefore, the objectivity of the codings can be regarded as sufficient (cf. Orwin, 1994, p. 152). The seven coding items were added up to form the scale for strategy knowledge with a possible range from 0 to 7. The seven items were internally consistent (Cronbach's $\alpha$ = .93).

### Performance of the strategy

Performance of the strategy was measured based on five single variables indicating for each critical reply for each of five of the six steps of the strategy whether this step had been performed (1) or not (0). The last step was omitted since it coincided with composing the message, which is performed in any reply irrespective of the strategy applied. For the first four steps, the corresponding adherence variables were taken directly from logfiles. The adherence variable for the fifth step of the strategy was coded (percentage agreement: 99 %, Cohen's $\kappa$ = .98).

The overall scale for the performance of the strategy was formed in two steps: First, for each of the five steps the proportion of all messages in which the step had been performed was calculated (also separately for all messages before and after the fading of support). Finally, the indicator for overall performance of the strategy was computed by adding the five variables for the performance of the single steps and could range from 0 to 5. Its reliability was rather high (Cronbach's $\alpha$ = .86).

## Procedure

Data were collected in a series of sessions of three hours of length with up to 20 students each. These were distributed over two rooms; learning partners who collaborated online sat in different rooms. After a short introduction into the purpose and procedure of the study, the participants filled in an online questionnaire for control variables and read printed texts on attribution theory and on how to construct counterarguments. They could keep them until the end of the learning phase. The collaborative learning phase started with a demo video on how to use the learning environment. After a short break, an 80-minute collaboration phase in the different experimental conditions followed. Finally, the learners completed online post-tests.

## Statistical analysis

Data were analyzed with individual students as the units of analysis. From each dyad, one member was selected who had not provided distributed monitoring. Furthermore, a hierarchical-linear analysis of the performance of the strategy over the course of time was conducted with single messages (the critical replies) as the units of analysis. The significance level was set to 5 % for all analyses.

# Results

## Effects of fading and distributed monitoring on the acquisition of strategy knowledge

The descriptive results for the acquisition of strategy knowledge in the four conditions are displayed in table 2. An analysis of variance with strategy knowledge as the dependent variable and fading and distributed monitoring as independent factors shows that strategy knowledge was significantly higher in the faded script conditions than in the unfaded script conditions, which corresponded to a medium size effect of fading, $F(1; 62) = 6.32$; $p < .05$; partial $\eta^2 = .09$. Likewise, a significant medium to large size effect of distributed monitoring on strategy knowledge in favour of the conditions with distributed monitoring compared to the conditions without distributed monitoring was detected, $F(1; 62) = 8.20$; $p < .01$; partial $\eta^2 = .12$. The small to medium size interaction effect of these two independent variables was marginally significant, $F(1; 62) = 3.21$; $p < .10$; partial $\eta^2 = .05$. However, the main effects are largely due to the superiority of the condition with the faded script along with distributed monitoring. Students in this condition significantly outperformed the students in the three other conditions on the strategy knowledge test.

Table 2: Means and standard deviations of strategy knowledge in the experimental conditions.

| | | | *Strategy knowledge* | |
|---|---|---|---|---|
| *Distributed monitoring* | *Fading* | *N* | *M* | *SD* |
| Without distributed monitoring | Unfaded script | 15 | 0.79 | 1.81 |
| | Faded script | 18 | 1.47 | 2.13 |
| With distributed monitoring | Unfaded script | 13 | 1.46 | 2.30 |
| | Faded script | 17 | 4.24 | 2.88 |

## Effects of fading and distributed monitoring on the performance of the strategy suggested by the script

Research question 2 asked whether fading and distributed monitoring affect the performance of the strategy suggested by the script in the course of time . The temporal development of the performance of the strategy was analyzed by means of a hierarchical-linear analysis. The level-1 growth model predicted the performance of the strategy during the formulation of message t from person i on the basis of the temporal position of message t:

$$y_{ti} = \pi_{0i} + \pi_{1i} \cdot (\text{number of message}_t) + e_{ti}$$

Intercepts (base levels) and slopes (growth rates) varied substantially between students, intercepts: $\chi^2(62) = 229.73$; $p < .001$; $\rho = .34$; slopes: $\chi^2(62) = 120.79$; $p < .001$; $\rho = .02$. As can be seen from the intercept for number of message presented in table 3, however, on average there was neither an increase nor a decrease in the performance of the strategy suggested by the script over time.

The explanatory level-2 model used the experimentally manipulated variables fading and distributed monitoring to predict both the base level (intercepts $\pi_{0i}$) and the growth rates (slopes $\pi_{1i}$) of the performance of the strategy for person i:

$$\pi_{0i} = \beta_{00} + \beta_{01} \cdot (\text{fading}_i) + \beta_{02} \cdot (\text{distributed monitoring}_i) + r_{0i}$$
$$\pi_{1i} = \beta_{10} + \beta_{11} \cdot (\text{fading}_i) + \beta_{12} \cdot (\text{distributed monitoring}_i) + r_{1i}$$

As can be seen from table 3, the base level did not vary significantly as a function of either fading or distributed monitoring. The average individual growth rate in the condition with the unfaded script without distributed monitoring (basal growth rate), however, was significantly below zero, indicating a decrease in performance of the strategy in this condition. While fading did not significantly affect this growth rate, distributed monitoring significantly raised this negative growth, yielding an approximately constant level of performance of the strategy in the corresponding conditions ($-0.08 + 0.11 > 0$). The proportion of variance in slopes accounted for by the explanatory model was 6 %, which was still significant, $\chi^2(62) = 117.59$; $p < .001$, indicating that there may be further factors that substantially contribute to it.

Table 3: Hierarchical-linear analysis of the development of the performance of the strategy triggered by the script as a function of fading and distributed monitoring.

| *Growth model: Prediction of the performance of the strategy $y_{ti}$* | $\pi_1$ | *t* | *p* |
|---|---|---|---|
| Number of message | -0.03 | -1.18 | .24 |
| *Explanatory model:* | | | |
| *Prediction of the base level $\pi_{0i}$ in the growth model* | $\beta_{0q}$ | *t* | *p* |
| Fading | 0.21 | 1.39 | .17 |
| Distributed monitoring | 0.09 | 0.57 | .57 |
| *Prediction of the growth rate $\pi_{1i}$ in the growth model* | $\beta_{1q}$ | *t* | *p* |
| Basal growth rate (without fading and distributed monitoring, *intercept* $\beta_{10}$) | -0.08 | -2.19 | .03 |
| Fading | 0.01 | 0.24 | .81 |
| Distributed monitoring | 0.11 | 2.45 | .02 |

The role of distributed monitoring for the performance of the strategy suggested by the script was analyzed separately in the conditions with the faded script by means of an analysis of variance for repeated measures with performance of the strategy as the dependent variable, distributed monitoring as a between-subjects factor and fading as a within-subjects factor with the two values before fading and after fading, i. e. the performance of the single steps of the strategy was averaged over all messages from each participant written before support for the particular step was faded and over all messages written after support for the particular step was faded, and aggregated over the five steps of the strategy (see figure 2).

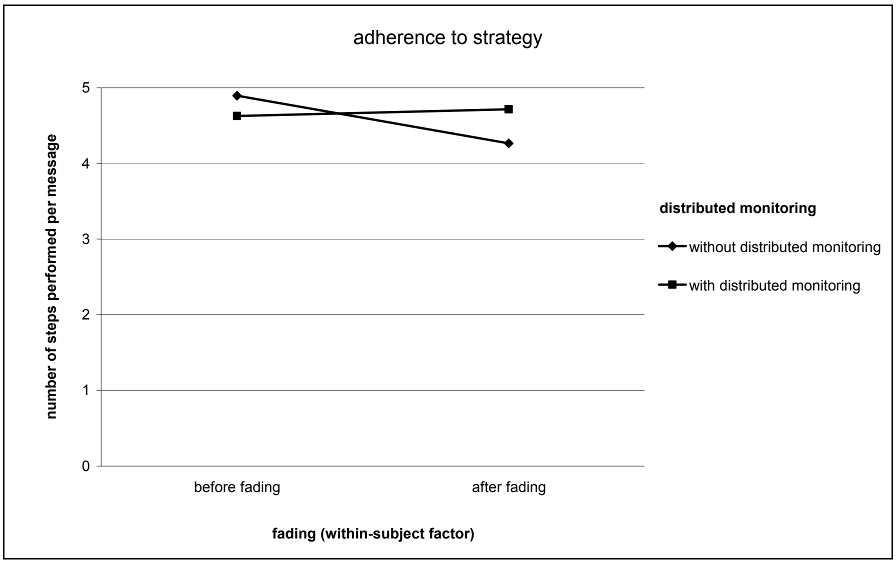

Figure 2. Average proportions of messages in which the strategy as a whole was performed before and after fading (separated for the conditions with and without "distributed monitoring").

A decrease in the performance of the strategy was found that reached the boundary of significance, $F(1;\ 31) = 4.16$; $p = .05$; partial $\eta^2 = .12$. However, this decrease occurred only in the condition without distributed monitoring, as indicated by a significant interaction between the within-subjects factor fading and distributed monitoring, $F(1;\ 31) = 7.38$; $p < .05$; partial $\eta^2 = .19$.

Exploratory analyses on the level of individual steps of the strategy revealed that these effects were mainly due to the learners' performance of the last two steps of the strategy: Both for the identification of the type of the argument and the check of the fulfilment of the conditions of relevance there was a decrease after the fading of the corresponding support in the condition without distributed monitoring, identification of the type of the argument: $t(15) = 1.97$; $p < .05$ (one-sided), check of the fulfilment of the conditions of relevance: $t(15) = 2.32$; $p < .05$ (one-sided). For the identification of the type of the argument the interaction effect between the within-subjects factor fading and distributed monitoring was marginally significant, $F(1;\ 31) = 3.06$; $p < .10$; partial $\eta^2 = .09$, while for the check of the fulfilment of the conditions of relevance the corresponding interaction was significant $F(1;\ 31) = 5.27$; $p < .05$; partial $\eta^2 = .15$.

## Relation between the performance of the strategy and the acquisition of strategy knowledge

Between the performance of the strategy and the acquisition of strategy knowledge there was a significant small correlation, $r = .22$; $p < .05$. Because on average there were no differences in the performance of the strategy between the four experimental conditions, this finding does not explain the differences in the acquisition of strategy knowledge between the experimental conditions.

As argued before, the performance of a strategy while learners are guided through its single steps rather than performing them in a self-directed way, should contribute little to the acquisition of strategy knowledge. What is expected to contribute to the acquisition of strategy knowledge is the performance of the strategy in phases in which support has been withdrawn and learners have the opportunity to practice the self-regulation of these steps, which occurred to a larger extent when they received distributed monitoring, as described in the previous section. Accordingly, separate correlations between the performance of the single steps *before and after* the fading of the corresponding support and strategy knowledge about these specific steps were calculated. These are reported for the last two steps because, as described above, for these two there were differences in performance in the course of time between conditions with and without distributed monitoring: Performance of the step of the identification of the type of the argument before the fading of the corresponding support and strategy knowledge about it were not significantly correlated, $r = -.15$; *n. s.*, whereas performance of it after the fading of the corresponding support was marginally correlated with the corresponding knowledge, $r = .30$; $p < .10$. Most importantly, the difference between these two correlations was significant, $z = 1.71$; $p < .05$. Similarly the performance of the step of checking the fulfilment of the conditions of relevance before the fading of the corresponding support and strategy knowledge about this step were uncorrelated, $r = .00$; *n. s.*, while performance of it after the fading of the corresponding support again was marginally correlated with strategy knowledge about it, $r = .33$; $p < .10$. In this case, the difference between the two correlations was marginally significant, $z = 1.59$; $p < .10$.

## Discussion

The main findings of this study indicate that the performance of the strategy implemented in a script may decline over time, especially if components of the script are faded. It could be demonstrated however, that it can be kept on a continuously high level by means of peer support such as distributed monitoring. The performance of the strategy was shown to be related to the acquisition of strategy knowledge, particularly in phases in which components of the scripts have been faded and accordingly the learners have the opportunity to practice the self-regulation of the steps of the strategy. This provides an explanation for the beneficial effect of the combination of a faded script with distributed monitoring on the acquisition of strategy knowledge.

The current study extends our understanding in several ways. With respect to the effects of collaboration scripts, it replicated the finding that scripts are appropriate means to trigger specific learning activities (Weinberger et al., 2005; Kollar et al., 2007; Stegmann et al., 2007), even after the fading of components of the script. It could be shown, however, that the level of performance of the script can be kept at an even higher level by providing distributed monitoring.

With respect to fading, thereby an important condition of its effectiveness was identified: Learners may need further support to take advantage of the opportunity to self-regulate their performance. This finding might contribute to a clarification of the reasons for the varying effects of fading reported in previous studies on fading (cf. Lee & Songer, 2004; McNeill et al., 2006; Leutner, 2000).

This opportunity to practice the self-regulation of the steps of a strategy may not be sufficient if learners fail to take advantage of it. Distributed monitoring can be regarded as one potential way to raise learners' self-regulatory activities in accordance with the strategy implemented in a script even after the fading of the components to support it. Accordingly, distributed monitoring can be one way to make use of collaboration during the acquisition of complex skills in computer-supported collaborative learning. It is also one option for adapting support to the current needs of learners because the learning partner providing distributed monitoring will only jump in with corrective feedback when there is divergence from the strategy to be internalized.

This study went beyond standard practice in research also in a methodological respect by analyzing learning activities diachronically by means of multi-level analyses of the temporal development of specific quality aspects of learning activities instead of aggregating indicators of the quality of learning activities over the whole learning phase (e. g. Weinberger et al., 2005). Thereby it can more closely account for the causal structure of the single learning events influenced *by the independent variables*. This should be pushed even further by relating single learning events to learning outcomes since the way in which learning activities might affect *learning outcomes* was still analyzed on the basis of such aggregated indicators. How this can be done is a topic for further discussion.

It is an important limitation of the present study that argumentation skill was not measured on the basis of perfomance in argumentative situations but by means of a declarative test of strategy knowledge about how to arrive at a counterargument against a position advanced by a learning partner. Furthermore, the study captured only rather short term effects of learning with a faded script and distributed monitoring. As it was conducted under laboratory conditions, the claims put forward in this paper still are in need of validation for more natural learning environments.

Accordingly, future research should focus on effects of fading and distributed monitoring not only on declarative strategy knowledge but also its application in the context of executing argumentation skill. Effects of longer-term interventions on immediate learning outcomes as well as their retention over more extended periods of time should be studied, preferably in field contexts with more authentic kinds of collaboration. Further research should also test the theoretical claims put forward in this study with other domain-general learning outcomes such as online search competence, which is currently being undertaken (Wecker, Kollar, Fischer & Prechtl, 2010). Finally, ways to adapt the fading of a script to a learner's current competence level would be a very promising direction to explore.

Based on the findings from this study it can be recommended that scripts should be faded out to provide learners with the opportunity to practice the self-regulation of skilled performance (as suggested by Pea, 2004; Puntambekar & Hübscher, 2005; and others). This recommendation has to be supplemented by the caveat, however, that it is important to keep learners' performance of the strategy to be acquired at a high level in these self-regulated phases. Collaboration may be exploited to accomplish this goal.

Thus, fading may be a way to move from a high degree of support to self-directed learning with authentic tasks. In this process the acquisition of competence can be considered as an internalization of control that has been exerted socially by peers before.

**Abstract:** This paper describes the use of journals in a general education chemistry course for elementary education majors. In the journals, students describe their understanding of a topic, its development, and its connection to their lives. The following types of reflections were identified in student journals: action, prior knowledge, project ideas, text resources, classroom events, and monitoring of knowledge. A multiple linear regression analysis of total course points earned versus student GPA, ACT score, number of reflections made for each reflection type, and total number of reflection made throughout all journals was used to determine the significance of the type of reflections made by students in relationship to their chemistry content understanding. The results indicate that students who reflected more on classroom events and those who monitored their knowledge correlated positively with a higher content knowledge. However, reflecting on text resources had a negative correlation to students' overall chemistry content knowledge.

## Introduction & Theoretical Background

This paper reports an investigation of student journal writing as a regulator of student metacognition in a general education chemistry course. Journal writing provides an opportunity for learners to understand their own learning process, to increase their active involvement in learning, and to gain personal ownership of their learning (Moon, 1999). Writing journals encourages self-thought, which allows for the development of metacognitive practices and the promotion of new learning by evaluating prior experiences. The use of journal writing in the science classrooms allows students to reflect on their actions, prior experiences, text resources, classroom events, and current knowledge, with reflection referring to "those intellectual and affective activities in which individuals engage to explore their experiences in order to lead to new understandings and appreciations" (Boud, Keogh, & Walker, 1985). Also, reflection in writing has a strong metacognitive component that helps students monitor their learning (Bangert-Drowns, Hurley, & Wilkinson, 2004). Previous research indicates the importance of having students reflect upon their current knowledge and understanding (Brown, Bransford, Ferrara, & Campione, 1983; Puntembekar & Kolodner, 1998; Davis, 2003). Writing assignments incorporating reflection on content knowledge enables students to formulate a better understanding of unprocessed materials and events and to document how their learning occurs, increasing connections with prior knowledge. Also, using productive reflection in the classroom promotes the knowledge integration process by expanding ideas and allowing students to identify the weaknesses in their knowledge. The nature of the assignment and the prompts given to a student are import for this. Davis (2003) found that students who reflected on generic prompts had a more coherent understanding as they worked on complex projects than those students that reflected on direct prompts.

The present study examines a chemistry course for pre-elementary education majors that includes journal writing assignments in which students respond to generic prompts to present their understanding of certain key topics and to reflect upon their own experiences with the topic. Our study focuses on the types of reflection students exhibited in their journals and how these relate to student content knowledge in the course. We also studied the choices students make with generic prompts that are aimed at developing a metacognitive perspective in their writing. The theoretical framework for this study is composed of metacognition and writing-to-learn perspectives. Metacognition refers to the knowledge concerning one's own cognitive processes (Flavell, 1979). Brown (1987) related metacognition to the learners' knowledge, awareness and control of the processes by which they learn. It was determined that metacognitive learners are able to recognize, evaluate, and reconstruct existing ideas (Baker, 1991). These findings of Brown and Baker represent two views of metacognition currently known as the knowledge and regulation of cognition. Learning is said to occur when new data or information presented to a student conflicts with what he or she already knows and give the student a chance to change their mind to think differently (Cracolice, 2005).

Several different kinds of assignments have been used to promote metacognition in chemistry learning (Rickey & Stacey, 2000). This included the deliberate use of a thinking frame (Mattox, Reisner, & Rickey, 2006), student documentation of their thinking through heuristics such as concept maps (Novak & Gowin, 1984), student work in extended problem solving situations (Cooper *et al*, 2008), and working in using extended writing within laboratory work (Greenbowe & Hand, 2005; Wink & Choe, 2008). The theoretical framework of writing to learn is used in this work because it characterizes the components involved when students respond to an opportunity to write about scientific topics. The writing to learn framework has been used in work by Britton (1970) and Emig (1977). In this approach, learning is supported and assessed by students' writing about their developing ideas. One of the most common forms of writing to learn is done by informal personal journal responses related to educational experiences such as literary readings, scientific experiments, videos, or from discourse with others (McCrindle & Christensen, 1995). The process of writing journals helps with the process of understanding relationships among ideas, knowledge transformation and construction of new meaning (Wallace, 2007; Klein, 1999). A major goal of the course was for students to be able to construct ideas and generate connections between concepts to make sense of the ideas rather than simply memorizing isolated facts. Another goal was to improve students' scientific literacy by having them write about the learning of science and to consider how they process information. The writing to learn strategy will help students achieve these goals. It has been shown that students develop conceptual growth through the process of writing, including parallel metacognitive growth in the learner (Mason & Buscolo, 2000).

In the course, students experienced writing-to-learn in the context of their journal work. Journals are well known in the K-12 literature, including the work of Davis (2003) that also contributes to the methodology of our work. She showed that prompts for student reflection promoted knowledge integration which occurs as learners expand their repertoire of ideas, identify weaknesses in their knowledge, and combine knowledge integration processes together. Journal writing is also used in the college science classroom, for example in a study of reflective journal writing within a first year university biology class (McCrindle & Christense, 1995). Students were randomly assigned to either write reflectively in their "Learning Journal," or produce a scientific report every week during the last five weeks of the course. The students in the journal writing group were given instructions and prompts as to the form of their journal writing. Results indicated that those students who did write reflectively on the content of their learning and the process of their leaning reported a more sophisticated conception of learning and had a direct impact on their metacognitive awareness. Similar research on lab report writing produced similar results (Keys *et al*, 1999).

## Method

### Participants

The participants consisted of 76 students from two offerings of the course (Fall 2007 and Spring 2009), called *The Chemical World*, who gave consent for their work to be included in a research program. Different instructors taught each course. Virtually all of these participants were enrolled in the pre-service elementary education program of the university and they took the course as part of a natural science general education requirement (Varelas *et al,* 2008), which included this course. Out of the seventy-six participants seventy-four were females and two were males, reflecting the existing gender distribution in the course. Students attend a one-hour lecture twice a week held by the instructor and a three-hour laboratory section led by a graduate student. Students are assessed by a student introductory essay, six student journals, student portfolios, unit and final exams, lab reports, assigned topical projects, and a big theme project (Wink *et al*, 2009). The present study focuses on the journal assignments, which are the major place for students to describe developments in their understandings of chemical content.

### Task and Procedure

The students submitted a total of six journals, approximately biweekly, throughout the course. The journal topics that were assigned consisted of material the students covered in lecture or lab in their previous weeks of class. The approximate length of each journal was 700-900 words. The journal entries on various topics of chemistry provided an opportunity for students to reflect on their current understanding and how they came to this understanding. They were also a place where students communicated with and received feedback from the instructor. The prompts for the journals were consistent throughout the semester, with only a single assignment sheet given out at the beginning of the course. Hence, the prompts fit the category of "generic," (Davis 2003), permitting students to work in different ways within a simple scaffold. Students were instructed to include five components in their journals and were given a rubric documenting the layout and value of each component. The first three components all related to a content topic in the course and are the focus of this research. The first component prompts enabled the students to write about their current understanding of a topic. Here the students were able to express, in writing, what they know about the topic and how they know it. The second component required the students to present specific examples of chemistry and chemical substances in relation to the topic. Following this, the third journal component prompted students to make connections by writing about what the topic might mean to them in their personal history, current experience, or future plans, with frequent reference to their everyday life or career choice.

The fourth and fifth components of the journals covered other aspects of their work and are outside of the scope of this paper. Specifically, the fourth component required that students write about their ongoing work on a "big theme project," developing an idea that would become part of an individual final course project reflecting an aspect of chemistry of interest to them (Wink *et al*, 2009). Finally, students wrote a section of their journal reporting their progress in the course. In this section students expressed the concepts or skills that they find unclear or struggle with, how they were progressing, what was working for them, and what external factors were causing them trouble. They were told that a good journal would consist of approximately 700-900 words total, though many students exceeded that number.

Student journals were first coded for the types of reflection on understanding of the six journal topics. The coding scheme for journals is shown in Table 1. This was created from a coding scheme for student reflection in journals that was derived from Davis' study of student reflections on generic and direct prompts (Davis, 2003). This enabled us to code for the *types* of reflections found within the student journals. Each reflection written by the student was coded with the non-hierarchical indices 1-6 to note the type of reflection. Two coders independently coded students' journals for reflections. There was a 92% interrater-reliability between the two coders.

Table 1: Coding for Student Reflection in Journal Responses

1. Reflection on actions: involves thinking about what ways of behaving are most appropriate, as well as contemplating very general goals.
2. Reflection on prior knowledge: involves thinking specifically about prior experiences in which knowledge was gained.
3. Reflection on project ideas: involves thinking about the conceptual ideas presented in the project itself (Mineral, Nutrition, and Big Theme)
4. Reflection on text resources: involves thinking specifically about information presented in the textbook, lab instructions, or handouts.
5. Reflection on classroom events: includes thinking rendered from individual experiences from lectures, labs, and discussions from peers, teaching assistants, and the instructor.
6. Reflection on knowledge: indicates a focus on monitoring or improving one's understanding

Lastly, during the second course offering, students completed the Metacognitive Activities Inventory (MCA-I) developed by Cooper, Sandi-Urena and Stevens (2008) at the end of the semester. This survey represents a way to see if students are metacognitive during problem solving tasks in chemistry. The results of this survey and the reflection made by the students will be compared to see if those students who are actively metacognitive during problem solving are also metacognitive during writing.

## Data Analysis and Findings

### Journals

Throughout the semester students wrote a total of six journals. Six different reflections were apparent in the journals after reading through them, listed in Table 1. All journals were coded for these reflection types. Examples of student reflection responses for the six coded categories are shown in Table 2.

Table 2: Examples of student reflection code

| Reflection Type | Example from Student Work |
|---|---|
| Action | I find if I take the extra time to figure out how to do each problem and read the chapters, I could be well off and prepared. The only problem is managing enough time to set aside for chemistry. |
| Prior Knowledge | Over the last weeks we have learned unit conversions in the metric system in class. I grew up in Germany and used the metric system all my life and am used to the system. It is easier to use and convert in the metric system because it is all powers of ten. I am confident in my understanding of the common prefixes used. |
| Project Ideas | I think that in order to do my individual project it is necessary to know how to work with unit conversions because this will help me understand better how much of each chemical is put in food to make it grow faster and better. |
| Text Resources | I came to understand the properties about polarity and functional groups of organic compounds through reading chapter 9 in Chemistry for Changing Times. Reading the book gave me a basic idea about what functional groups are and what it means to have polarity. |
| Classroom Events | The labs have helped me understand better how scientists work because I have to follow the same procedures/steps they use in order to complete the labs. In order to do the labs I have to think like a scientist and this is very interesting and fun. |
| Knowledge | I feel very confident about my progress in class so far because I am been able to understand how the cycles work and their importance to our survival. I am able to analyze the cycles and point out where each of the four spheres takes place and why. |

## Regression Analysis

To understand how the journals might impact learning, we did a multiple linear regression analysis of the sum of all points earned in the course as the dependent variable against student: GPA prior to course enrollment, ACT composite score, the number of reflections made for each of the six codes in the six journal entries, and the total number of reflections made in each of the six journal entries as the independent variables. This analysis sought to determine which variables correlate significantly with student content knowledge of chemistry. The analysis was done for each of the two classes and an aggregate of both classes. Before the two class sets of data were combined and analyzed, a comparison was done between them to see if there were any significant differences between the students in the two courses. An independent t-test was conducted on prior GPA, ACT composite score, and course grades given to the students. There was no significant different between the two classes in prior GPAs ($t(74) = 0.140$, $p > 0.05$), ACT ($t(74) = -1.210$, $p > 0.05$) and course grades ($t(74) = -0.743$, $p > 0.05$). Each class was given the same set of assignments and covered the same chemistry material. Student course grades derived from the total number of points the student earned during the semester. Both of the two classes had a total of 1075 points that a student could earn. The students' GPA that was used for this analysis was their GPA prior to the semester in which they took the course.

The linear regression model for all three data sets (Fall 2007, Spring 2009, and Aggregated Data) shows a relation between student course grade and four predictor variables, shown in Tables 3-5. This signifies that between 58% and 63% of the variance in student course grade is explained by student prior GPA and three types of reflections made by students in journal writing. The first predictor variable is the students' prior GPA. A high prior GPA is a good prediction of doing well in the class. Student reflection on classroom events (Code 5) and on their knowledge (Code 6) correlated positively and significantly with higher performance in the course. Student reflection on textbook, handouts, and worksheets (Code 4) correlated negatively and significantly with higher course performance.

Table 3: Fall 2007 regression analysis for prediction of course grade based on student GPA, ACT, reflection type, and total number of reflections during Fall 2007

| Significant Predictor Variables | β |
|---|---|
| Prior GPA | .731 |
| Code 4 | -.144 |
| Code 5 | .052 |
| Code 6 | .086 |

*Note:* Regression equation: Grade = .409 + .731(GPA) - .144(Code 4) + .053(Code 5) + .086(Code 6), ($R = 0.794$, $R^2 = 0.630$)

Table 4: Spring 2009 regression analysis for prediction of course grade based on student GPA, ACT, reflection type, and total number of reflections during Spring 2009

| Significant Predictor Variables | β |
|---|---|
| Prior GPA | .551 |
| Code 4 | -.020 |
| Code 5 | .038 |
| Code 6 | .034 |

*Note*: Regression equation: Grade = .593 + .551(GPA) - .020(Code 4) + .038(Code 5) + .034(Code 6) ($R = 0.764$, $R^2 = 0.584$)

Table 5: Aggregated data regression analysis for prediction of course grade based on student GPA, ACT, reflection type, and total number of reflections

| Significant Predictor Variables | β |
|---|---|
| Prior GPA | .590 |
| Code 4 | -.031 |
| Code 5 | .033 |
| Code 6 | .075 |

*Note*: Regression equation: Grade = .315 + .590(GPA) - .031(Code 4) + .033(Code 5) + .075(Code 6) ($R = 0.783$, $R^2 = 0.613$)

## MCA-I Survey

The Spring 2009 class of the *Chemical World* was given the Metacognitive Activities Inventory (MCA-I) survey to see if students who were metacognitive during problem solving were also metacognitive in their writing. This 27 item self-report instrument assesses students' metacognitive skillfulness when solving chemistry problems and may be used as a diagnostic tool in deciding to implement interventions by the instructor (Cooper, Sandi-Urena and Stevens, 2008). Students select their agreement with the items from a 5-point Likert scale (1, strongly disagree to 5, strongly agree). The score was reported as a percentage of the maximum number of points attainable. The higher the percentage a student received relates to a higher metacognitive awareness the student has during problem solving activities. The percentage of the maximum number points for each student was correlated against each of the six reflection types, and the total number of points the student received in the class. The results of these correlations are shown in Table 6.

Table 6: Correlations of MCA-I Survey

| Variables | MCA-I Score |
|---|---|
| Code 1 | -0.041 |
| Code 2 | -0.034 |
| Code 3 | 0.061 |
| Code 4 | -0.436** |
| Code 5 | 0.512** |
| Code 6 | 0.574** |
| Total Course Points | 0.564** |

Note: N = 45, *$p < .05$, **$p < .01$

The results of the correlations analysis reveal that students who reflected more on textbooks, homework, and worksheets tend to be less metacognitive during problem solving activities ($r$ = -0.436, $p$ = 0.03). However, students who reflected more on classroom activities ($r$ = 0.512, $p$ = 0.00) and reflected on their own knowledge ($r$ = 0.574, $p$ = .000) tend to be more metacognitive during problem solving activities. Lastly, students who did well in the course and who are assumed to have a high chemistry content knowledge ($r$ = 0.564, $p$ = 0.00), tend to also be more metacognitive during problem solving activities. Therefore, students who are highly metacognitive in their writing by reflecting on interactions within the classroom (Code 5) and on their current knowledge (Code 6) of the chemistry content tend to be more metacognitive when they are engaged in problem solving of chemistry problems.

## Conclusion

The objective of this study was to determine the effect of journal writing in a natural science course for pre-service elementary education majors. It is not common in science classes for students to be able to write down their learning process of a certain science topic and integrate this to formulate a final understanding. Reaching this point of reflection in their journal helps students self-regulate their learning. The use of journals in the classroom provided students an opportunity to become self-regulators of their learning. These entries made by the students helped facilitate discussion with the instructor that might not have happened in the classroom or laboratory. Having the instructor aware of student thinking can help guide students in the right direction to correctly monitor their understanding. This reflection process is important for the instructor to reflect back on. Cooper *et al* (2008) noted that it is essential for not only the student to be aware of metacognition but also for the instructor to be aware of how students are learning. Students were able to express what they know and what they are struggling with. Some students even wrote about how they would try and better their understanding if they were finding it hard to grasp the central ideas of the topic. In their writing they also talked about where they developed this understanding from for certain topics such as from prior experiences, the lecture, text resources, laboratory, discourse with peers, the teaching assistant, or the instructor.

Our use of specific codes to categorize different types of reflection revealed that the positive relationship of reflective writing and content understanding depends also on the type of reflection. As noted earlier, students with strong content were very likely to write about their current understanding as developed from their own thinking (code 6) or from classroom activities (code 5). Students who reflected on text resources tend to have a lower content understanding of the chemistry topics in the course. Reflecting on learning from the classroom events provides a better opportunity for students to experience new learning situations by engaging in activities with others. When students reflect solely on text resources they are more likely to be engaged in the activity alone or to take a simple reading of the text and use it as the basis of understanding, and this does not, we believe, provide the student with new experiences to help facilitate change in understanding. A possible threat to the validity of this research is that we did not know anything about the writing of the students coming into the course. Knowing the students' prior writing skills would help us determine how well students are at expressing ideas. If students struggle at this task they may struggle with reflecting on their learning and being able to formulate well structured reflections.

## Implications for Research and Instruction

The journal produced by the student is an artifact that can be used at the end of the semester as a planning resource for exams. The student is aware of the understanding they had by referencing the journal and are able to evaluate their current understanding to see if understanding has changed at the end of the term. At this point the student can monitor what they need to review in order to succeed on exams. This whole process is a good source of self-regulation for students to take part in, and gives them time to sit down and think about their understanding of science topics. Also, it is a substantial and consistent tool for students to learn about themselves as learners.

This research confirmed a relationship between content knowledge and journal writing, supporting the idea that this writing-to-learn activity is valuable as a means of supporting students in the exploration and understanding of their learning processes. It has been noted that the reflection process offers an opening for students to understand their learning process and increase their active involvement in learning (Moon, 1999). It also helps students gain a personal ownership of their learning.

These findings add to the research literature on the analysis of writing-to-learn and reflection in instructional learning of science. The findings show that not all types of reflection correlate with improved learning, which implies that it is essential for researcher to examine the content of specific reflective students, not just overall reflection. Second, the link of metacognition to learning in this work is strengthened by the additional use of the MCA-1 survey as an independent measure of metacognition in problem solving.

There are three implications on writing-to-learn as a result of this research study. First, students may benefit from directed reflections (Davis, 2003). This benefit requires activities, and this is an active classroom (Varales et al, 2008). A major component of direct reflection is knowledge growth within the learner (Davis, 2003). Second, caution about what may be rote recapitulation of textbook material. Lastly, if students know there is a potential direct relation between journal topics and assessment, they may perform better on both.

The second major implication relates to the particular benefit of reflection in both writing and in problem solving. McCrindle and Christensen (1995) also found that journal writing tasks in a science class not only promote metacognitive thought but also helped learners gain more developed cognitive strategies and attain better learning outcomes.

Third, having students write reflective journals is a very good way to detect how they express metacognitive awareness, complementing other strategies (Mattox, Reisner, & Rickey, 2006; Greenbowe & Hand, 2005; Cooper, Sandi-Urena, Stevens, 2008; Keys et al, 1999). But the findings of specific benefits from reflection on knowledge (an explicit metacognitive act) and on activities, but not on the textbook, also suggest that providing an activity-rich environment for students to use as the basis of their reflection is important. These results seem to provide additional support for the effectiveness of learning in a mode where the student actively creates knowledge, often in conjunction with other peers (Cooper, 2005).

# Fostering Online Search Competence and Domain-Specific Knowledge in Inquiry Classrooms: Effects of Continuous and Fading Collaboration Scripts

Christof Wecker, Ingo Kollar, Frank Fischer, University of Munich, Leopoldstr. 13, D-80802 Munich
Helmut Prechtl, Leibniz-Institut für die Pädagogik der Naturwissenschaften und Mathematik, Olshausenstr.62, D-24098 Kiel

**Abstract:** Collaborative inquiry learning can be regarded as a fruitful approach to foster students' scientific literacy for participation in societal debates involving scientific issues. In a four-week field study in biology with 131 ninth-grade students from six classrooms distributed over three experimental conditions, we investigated the effects of a continuous and a fading collaboration script for collaborative online search compared to unsupported collaboration on students' online search competence and domain-specific knowledge. Findings indicate a superiority of a continuous collaboration script compared to unsupported collaboration with respect to both students' online search competence and domain-specific knowledge, whereas the fading collaboration script had a significant positive effect compared to unsupported collaboration only with respect to students' online search competence. These findings extend our knowledge from laboratory research on effects of collaboration scripts on domain-general competences and domain-specific knowledge.

## Scientific literacy as a goal of science education in schools

A main purpose of science education is not so much to educate future scientists or engineers, but rather to prepare all students as responsible citizens for participation in societal debates that involve scientific issues. Current examples of such issues are the prospects and risks of nuclear power, the genetic engineering of crops and other plants for purposes of food production, or preimplantation genetic diagnosis.

For the development of reasoned positions about these questions, scientific literacy is an important prerequisite (Laugksch, 2000), which involves both fundamental knowledge about important scientific principles and the ability to gather and evaluate more specific and recent information that goes beyond what can ever be learned in school. Current information and communication technology has made such information widely accessible. Accordingly, we regard domain-specific scientific knowledge, i. e. knowledge of basic terms, knowledge of important facts and understanding of fundamental explanatory principles, as well as online search competence, i. e. the ability to localize and evaluate relevant scientific information on the internet, as two crucial components of scientific literacy that all students should develop in order to be able to participate in tomorrow's science-related societal debates. To develop instruments for measuring and support for fostering online search competence, we conducted a cognitive task analysis of internet search tasks which ask learners to use the internet to gather evidence they could use to formulate arguments in societal, science-related debates (see Kollar, Wecker & Fischer, 2009). Following that, we validated the resulting model of competence by asking an online search expert, a content expert and a search novice to think aloud during such tasks. Most importantly, the think aloud study showed that both experts, after having built an initial argument sketch, established a scheme for what counted as evidence to support their position and let this evidence scheme guide their internet search behaviour. The novice, in contrast, browsed through the internet in a rather mindless fashion, not much really taking care of relevance, credibility or scientific quality of web site content, finally arriving at less sound arguments that were supported by less reliable information found on the Web.

## Collaborative inquiry learning as an approach to foster scientific literacy

Scientific literacy and its sub-components domain-specific knowledge and online search competence can be fostered in inquiry learning contexts (e.g., de Jong, 2006), which are implemented with the aid of digital media and internet technologies that afford collaboration between students (see Slotta & Linn, 2000). In web-based inquiry learning, students use computer and internet technologies (usually in groups) to work on authentic scientific phenomena or problems in a way similar to scientists. It can be argued that by engaging in such activities, scientific literacy may be developed, since they typically involve elaborating upon domain-specific scientific knowledge and using digital media to gather evidence, which may foster online search competence.

As empirical evidence shows, however, for inquiry learning to be productive, it needs to be structured and scaffolded appropriately (de Jong & van Joolingen, 1998). Therefore, web-based environments include a variety of scaffolds designed to facilitate students' inquiry processes. For example, the Web-based Inquiry Science Environment (WISE; Slotta & Linn, 2000) includes hint questions designed to trigger elaborations, mapping tools to visualize the relations between multiple variables, or background information on the given science problem. As an analysis of WISE and several other web-based inquiry learning environments shows, however, most environments lack support that directly aims at scaffolding the collaboration process between the learning partners. Against the background of empirical research on collaborative learning, which shows that collaboration rarely reaches high quality when it happens spontaneously (Gillies, 2003), the use of scaffolds directed at an improvement of collaboration seems to be warranted.

### Collaboration scripts to support collaborative inquiry learning

One promising way of providing such support is to develop collaboration scripts (Kollar, Fischer & Hesse, 2006; Dillenbourg & Jerman, 2007) and integrate them into web-based inquiry learning environments. Collaboration scripts are socio-cognitive scaffolds that specify activities, sequence them and distribute them among different roles taken over by members of a small group of learners (Kollar et al., 2006).

Despite some research about the effects of collaboration scripts on learning processes (e. g. De Wever, Van Keer, Schellens & Valcke, 2009), their effects on learning outcomes have been investigated mainly in laboratory experiments. Several lab studies about computer-supported collaborative learning during online discussions in a problem-based learning context demonstrated beneficial effects of different kinds of collaboration scripts on students' domain-general competencies (Weinberger, Ertl, Fischer & Mandl, 2005; Stegmann, Weinberger & Fischer, 2007). However, only for some types of computer-supported collaboration scripts, e.g., a peer-review script, beneficial effects with respect to the domain-specific knowledge could be found (Weinberger et al., 2005; Diziol, Rummel, Spada & Mclaren, 2007). In the context of web-based inquiry learning, a collaboration script aimed at helping students to form well-grounded arguments, counterarguments and integrations was developed and integrated at specific points of as WISE curriculum unit (Kollar, Fischer & Slotta, 2007). In line with previous research, this script helped students develop higher levels of the domain-general competence of argumentation, but did not help them reach higher levels of domain-specific knowledge when compared with less structured collaboration. Moreover, it appeared that during the learning process the collaboration script only raised argumentation quality as long as it was present. As soon as the script was "switched off", learners relapsed into their previous argumentation style. In other words, internalization of the argumentation strategy was low, which may be explained by a rather short learning time of 120 minutes. The question whether computer-supported collaboration scripts produce more robust effects when longer learning phases are studied is yet unanswered.

### The fading of collaboration scripts

The laboratory research mentioned clearly indicates a need for finding ways to support the internalization of strategies targeted by collaboration scripts. One such approach is the fading of support, which is considered as part and parcel of scaffolding (Pea, 2004; Wood, Bruner & Ross, 1976). Up to now research on the effects of the fading is sparse, and the results are mixed. In one of two experiments, evidence for beneficial effects of fading was found, whereas in the other one performance decreased in the process of fading (Leutner, 2000). In a second study a marginally significant positive effect of fading was demonstrated with respect to only one of several aspects of knowledge about the principles of scientific explanations (McNeill, Lizotte, Krajicik & Marx, 2006). No effect of fading on the quality of explanations in the posttest was found in a further study, while during the learning phase the quality of explanations decreased in the process of fading (Lee & Songer, 2004).

An empirical study about the effects of the *fading of scripts* showed that fading alone had no positive effect on learning (Wecker & Fischer, 2007). If it was combined with "distributed monitoring" (cf. King, 1998), i. e. when the learning partner was asked to monitor whether his or her peer complied with the strategy induced by the script, a significant positive effect on students' strategy knowledge in comparison to a continuous script was found. However, this study was also conducted as a lab experiment with a rather short learning time.

### Research questions

The summary of the current state of research provided above warrants further consideration whether the effects of small-group collaboration scripts as well as their fading show up also in real science classrooms. Furthermore, it needs to be investigated whether collaboration scripts as well as their fading can foster also domain-specific knowledge, if more extended learning phases are implemented. The opportunity to shift the focus from the application of a domain-general strategy targeted by the collaboration script to the elaboration of domain-specific content to be learned during longer learning phases would warrant such expectations.

Accordingly, our research questions were the following:

(1) What are the effects of a small-group collaboration script as well as its fading on students' domain-specific knowledge?

We expected that in classroom-based inquiry learning over a comparably extended period of time domain-specific knowledge is fostered if collaboration is supported by a collaboration script compared to collaboration without a collaboration script. According to the line of reasoning just presented, a beneficial effect of a fading collaboration script on students' domain-specific knowledge could also be expected.

(2) What are the effects of a small-group collaboration script as well as its fading on students' online search competence?

In line with the bulk of previous findings about the effects of small-group collaboration scripts from the laboratory we assumed a positive effect of a collaboration script compared to collaboration without a collaboration script on students' online search competence. We further hypothesized that a fading collaboration script would have a beneficial effect on students' online search competence compared to both collaboration without a collaboration script and collaboration supported by a continuous collaboration script.

## Method

### Participants and design

The participants were 131 students from six ninth-grade classes from three urban high schools. They were on average 14.7 years old (*SD* = 0.75); 53 of them were girls, 78 were boys. The decision to participate in the project rested with the biology teachers of the classes. However, data from the individual students were only collected if their parents had agreed individually.

Three experimental conditions differing in the amount of instructional support for collaborative online search were compared in a one-factorial quasi-experimental design with the classes as the units of random assignment. The first condition involved no collaboration script, the second a continuous collaboration script, and the third a fading collaboration script (see table 1).

Table 1: Design of the study.

| *No collaboration script* | *Continuous collaboration script* | *Fading collaboration script* |
|---|---|---|
| N = 43 students<br>from 2 classes | N = 34 students<br>from 2 classes | N = 54 students<br>from 2 classes |

### Curriculum unit and instructional setting

The study was conducted in the context of an inquiry-based curriculum unit that spanned seven regular biology lessons, which were preceded and followed by one test session each (see table 2). During the unit, the students were supposed to arrive at a decision about whether they supported or rejected "green" Genetic Engineering, i. e. the genetic modification of plants for the purpose of food production. All lessons in this curriculum unit were led by the regular biology teachers of the participating classes.

Table 2: Procedure of the study and phases of the instructional unit.

| *Cycle* | *Lesson* | *Activity* | *Duration* |

| | 7 | Online search on *health aspects* of "green" genetic engineering<br>Discussion about *health aspects* of "green" genetic engineering | 30 min<br>15 min |
| | 8 | Posttest | 45 min |

The unit started with a short introduction to relevant background domain knowledge from Genetics. To keep the information about the strategy of online search to be acquired constant, the students in all three conditions also received the same introduction to this strategy.

Lessons two through seven consisted of three consecutive learning cycles about three different topical aspects of the discussion about "green" Genetic engineering: one on economic, one on ecological, and one on health aspects. Each cycle consisted of three consecutive steps. First, the students were asked to collaboratively browse through an online library in dyads in order to gather background information about Genetics and Genetic Engineering relevant to the current topical aspect of the discussion. In the second step, student dyads conducted collaborative online searches to support, discard or modify their initial argument concerning the current topical aspect of the discussion according to the strategy they were introduced to before. In these phases of collaborative online search, which took place in lessons three, five and seven, the independent variable was manipulated (see below). In the third step, the teacher led a plenary discussion in which students exchanged their elaborated arguments based on the findings from their collaborative online searches.

Students collaborated face-to-face sitting next to each other. The technical equipment both to access the online library and conduct the online searches comprised a wireless network and one laptop computer with a mouse per student. The students kept these computers throughout the time of each lesson and received the same computer each time, which served two purposes: On the one hand, students were enabled to create documents and to revisit or edit them in later sessions; on the other hand, this procedure facilitated data collection in that it was easy to track which student had worked on which computer.

The online library was implemented as a module in the Web-Based Inquiry Environment (WISE). It comprised three pages with assignments for the three topical aspects of the discussion (economic, ecological and health aspects) and six sections about topics from Genetics and Genetic Engineering designed on the basis of regular ninth-grade Biology school books.

During the collaborative online search phases, the browsers of the collaborating students in each dyad were connected via a software tool named S-COL (Wecker et al., 2009). This allowed for collaborative internet browsing, i.e., during their online searches, both learning partners from each dyad always saw the same web pages, no matter who of them clicked on a link or performed a web search.

## Independent variables

The amount of instructional support for collaborative online search was varied among a condition without collaboration script, a condition with a continuous collaboration script, and a condition with a fading collaboration script.

### No collaboration script

In this condition, the browsers of the two students in each dyad were connected as described. These students received no support beyond the teacher's introduction to the strategy of online search at the beginning of the curriculum unit. This information was equivalent to the information presented in the collaboration scripts in the other two conditions.

### Continuous collaboration script

In addition to connecting the computers of the two partners of a dyad, the S-COL software tool described above was used in the two experimental conditions to display particular prompts on the basis of the type of website the students were accessing (Google start page, Google hit list, any other web site).

In each dyad there were two roles (A and B) that switched after returning to Google (which they were required to use for their searches) from any other web page encountered during the search activities. The collaboration script was implemented as complementary text prompts in the scaffolding areas of S-COL in the browsers of both group members (see left part of the screen in figure 1). The script contained prompts for helping students formulate an initial argument and sketch the information needed, select search terms, evaluate the hit list, localize relevant information on a web page, and write the final elaborated argument. For example, during the selection of search terms, learner A was prompted to suggest a set of terms and discuss them with B, while B had the task to first recall the information they had decided to look for, and comment on A's suggestions for the search terms with respect to their likelihood of yielding suitable as well as inappropriate hits.

### Fading collaboration script

In the condition with the fading collaboration script the same prompts as in the condition with the continuous collaboration script were used to support collaborative online search, but they were gradually removed (faded out) over the whole extension of the curriculum unit depending on the number of online searches the students had performed. After a series of four external web sites accessed, the prompts described before became more unspecific: Initially, the scaffolding area of S-COL contained both the names of the individual steps as well as explanatory text. In the second fading phase, only the names of the steps were displayed. In the final phase, only headings for the actual activity were displayed.

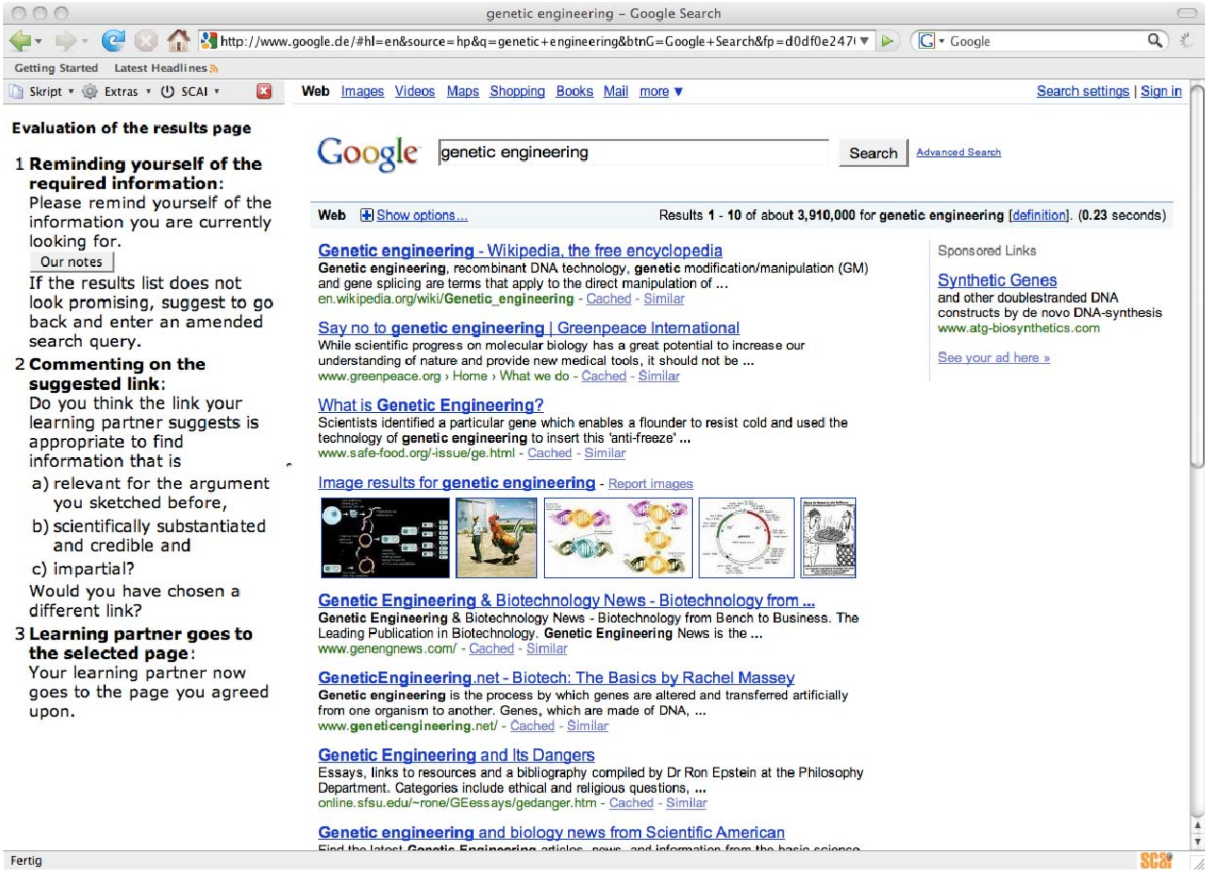

Figure 1: Part of the continuous collaboration script presented along with a Google hit list (collaboration script prompts for one of the two learners displayed in the area on the left; Google hit list displayed in the area on the right)

## Procedure

The procedure of the study was as follows (see table 2): The biology lesson immediately before the start of the instructional unit was used for a 45-minute pre-test for online search competence, domain knowledge and control variables. The following phase was constituted by the seven lessons described above, distributed over a period of three and a half weeks. This phase included the manipulation of the independent variable in lessons three, five and seven. In the biology lesson immediately following the instructional unit, a 45-minute post-test was conducted, which included online search competence, domain knowledge and further control variables.

## Dependent variables

### Domain-specific knowledge

Domain-specific knowledge was measured in the post-test by a test that consisted of 18 items about Genetics and Genetic Engineering. One third of them covered knowledge about concepts, another third factual knowledge and another third understanding of explanatory relations. The items from these three subscales were evenly distributed over different types of answering format (six multiple choice, twelve open). A six-item version of the test with precisely the same structure was used to measure domain-specific knowledge in the pre-test. The answers to the items with an open answering format were analyzed with respect the occurrence of propositions taken from an extremely elaborate expert solution that contained any correct proposition that could conceivably be part of a student's solution For each of these propositions it was coded whether the student's answer contained it or not. Three coders coded 10 % of the material independently of each other to assess the objectivity of the analysis. The average percentage of agreement with respect to the different coding variables was 98 %; Cohen's kappa amounted to $\kappa$ =.94 on average. For each item from the test the proportion of the propositions that were included in the student's answer was determined (values between 0 and 1). These proportions as well as the scores from the multiple-choice items were summed up across the different items, yielding an overall scale for *domain-specific knowledge* ranging from 0 to 18 with a reliability of Cronbach's $\alpha$ = 59). Three subscales ranging from 0 to 6 for *knowledge about concepts*, *factual knowledge* and *understanding* are also used in the statistical analyses. Due to the highly elaborated nature of the underlying expert solution, even low scores indicate substantial knowledge.

### Online search competence

Online search competence was measured by a task in which the students were asked to describe in as much detail as possible how they would use the internet to form a position about a specific sample issue without actually doing so. In the pre-test, the sample issue the students could use for their description was whether mobile phone transmitters should be forbidden in the neighbourhood of day nurseries. In the post-test, the corresponding issue was whether nuclear power plants should be abandoned. The answers were pre-structured by means of a two-column table of up to eight rows. The left-hand column was to be used for the description of the single steps involved in the search, whereas the right-hand column was to be used for the description of the evaluative criteria to be applied in combination with the specific steps. Both pre- and post-test were coded for the occurrence of each individual element of a general expert solution that contained all the steps as well as all the evaluative criteria from the strategy explained to the students in all three conditions in the introduction and suggested by the collaboration script in the conditions with continuous or fading collaboration scripts. The average percentage of agreement with respect to the different coding items was 96 %; Cohen's kappa amounted to $\kappa$ =.65 on average. An overall scale for *online search competence* was formed by counting the positively coded variables, with a reliability of Cronbach's $\alpha$ = .57. Separate scales for *knowledge about single steps* and *knowledge about evaluation criteria* were also formed (with some coding items excluded from both subscales). As in the case of domain-specific knowledge, even low scores indicate considerable amounts of competence due to the complexity of the underlying expert solution.

### Statistical analysis

The significance level was set to 5 % for all analyses. All analyses of variance or covariance were conducted with the manipulated instructional support as one independent factor and the classrooms as a further independent factor nested within the experimental conditions. The covariates used were significantly correlated with the dependent variables.

## Results

### Research question 1: Effects of a small-group collaboration script and its fading on students' domain-specific knowledge

With respect to the effects of the two collaboration script versions on students' domain-specific knowledge, analyses of covariance were conducted with the overall domain-specific knowledge scale and the subscales for knowledge about concepts, factual knowledge and understanding as dependent variables, classes nested within the three kinds of instructional support as well as the kind of instructional support as independent variables, and the overall domain-specific prior knowledge as a covariate. As can be seen from table 3, with respect to all four dependent measures students from the condition with the continuous collaboration script outperformed both students from the condition without a collaboration script and from the condition with the fading collaboration script. A significant main effect of the kind of instructional support was detected for the overall scale of domain-specific knowledge ($F$(2; 124) = 7.66; $p$ < .01; partial $\eta^2$ = .11), which amounts to a medium to large effect. A planned comparison between the condition without a collaboration script and the condition with a continuous collaboration script was significant, $F$(1; 72) = 5.49; $p$ = .02; partial $\eta^2$ = .07. The planned contrast between the condition without a collaboration script and the fading collaboration script did not reach significance in the expected direction, $F$(1; 92) = 2.64; $p$ = .11; partial $\eta^2$ = .03.

Further analyses revealed that the detected effect of the kinds of instructional support is due to parallel patterns of significant effects of approximately medium size in all three subscales of domain-specific knowledge: knowledge about concepts, $F$(2; 124) = 4.54; $p$ = .01; partial $\eta^2$ = .07, factual knowledge, $F$(2; 124) = 3.27; $p$ = .04; partial $\eta^2$ = .05, and understanding, $F$(2; 124) = 4.98; $p$ = .01; partial $\eta^2$ = .07.

With respect to one of the scales of domain-specific knowledge, knowledge about concepts, also substantial between-classroom variance was found ($F$(3; 124) = 4.27; $p$ = .01; partial $\eta^2$ = .09) which may be caused by factors beyond our experimental conditions, e.g. the teacher's behaviour or the class climate.

### Research question 2: Effects of a small-group collaboration script and its fading on students' online search competence

With respect to students' online search competence, analyses of covariance were conducted with the overall online search competence scale and the subscales for knowledge about single steps and knowledge about evaluation criteria as dependent variables, classes nested within the three kinds of instructional support as well as the kind of instructional support as independent variables, and the overall prior online search competence as a covariate. Table 4 shows that descriptively students in the two conditions with the continuous and the fading collaboration script outperformed students in the condition without a collaboration script on the overall online search competence scale as well as the two subscales knowledge about single steps and knowledge about evaluation criteria. The main effect of the kinds of instructional support with respect to the overall scale was significant and of medium size, $F(2; 124) = 5.16$; $p = .01$; partial $\eta^2 = .08$. Both the planned comparison between the continuous collaboration script and no collaboration script, $F(1; 72) = 9.97$; $p < .01$; partial $\eta^2 = .12$, and the planned comparison between the fading collaboration script and no collaboration script, $F(1; 92) = 7.17$; $p = .01$; partial $\eta^2 = .07$, were significant. However, the final planned comparison between the fading collaboration script and the continuous collaboration script was not significant, $F(1; 83) < 1$; $p = .81$; partial $\eta^2 < .01$.

Table 3: Means and standard deviations of the dependent variables in the three experimental conditions.

| | | *No collaboration script* | | *Continuous collaboration script* | | *Fading collaboration script* | |
|---|---|---|---|---|---|---|---|
| | | *M* | *SD* | *M* | *SD* | *M* | *SD* |
| **Domain-specific knowledge** | **Pretest** | **0.67** | **0.72** | **0.68** | **0.68** | **0.78** | **0.69** |
| | **Posttest** | **3.58** | **1.53** | **4.54** | **1.81** | **3.14** | **1.88** |
| **Knowledge about concepts** | **Pretest** | **0.14** | **0.23** | **0.07** | **0.18** | **0.19** | **0.28** |
| | **Posttest** | **1.49** | **0.77** | **1.95** | **0.93** | **1.40** | **1.00** |
| **Factual knowledge** | **Pretest** | **0.12** | **0.32** | **0.09** | **0.29** | **0.11** | **0.32** |
| | **Posttest** | **0.90** | **0.79** | **1.26** | **0.68** | **0.90** | **0.75** |
| **Understanding** | **Pretest** | **0.42** | **0.49** | **0.52** | **0.54** | **0.47** | **0.54** |
| | **Posttest** | **1.19** | **0.84** | **1.33** | **0.74** | **0.84** | **0.76** |
| **Online search competence** | **Pretest** | **3.46** | **2.10** | **3.03** | **2.43** | **3.59** | **2.33** |
| | **Posttest** | **2.65** | **2.27** | **3.68** | **2.41** | **3.85** | **2.65** |
| **Knowledge about single steps** | **Pretest** | **2.35** | **1.48** | **2.06** | **1.76** | **2.39** | **1.77** |
| | **Posttest** | **1.74** | **1.48** | **2.56** | **1.66** | **2.61** | **1.94** |
| **Knowledge about evaluation criteria** | **Pretest** | **1.00** | **0.82** | **0.85** | **0.86** | **0.96** | **0.82** |
| | **Posttest** | **0.86** | **1.08** | **1.03** | **1.11** | **1.06** | **1.04** |

Further analyses demonstrated that the significant effect with respect to the overall scale is due only to an effect of the kinds of instructional support on knowledge about single steps, $F(2; 124) = 5.49$; $p = .01$; partial $\eta^2 = .08$. There is no significant corresponding effect with respect to knowledge about evaluation criteria, $F(2; 124) < 1$; $p = .41$; partial $\eta^2 = .01$.

With respect to all scales of online search competence, i. e. the overall scale of online search competence ($F(3; 124) = 4.19$; $p = .01$; partial $\eta^2 = .09$) as well as the subscales of knowledge about single steps ($F(3; 124) = 2.96$; $p = .04$; partial $\eta^2 = .07$) and knowledge about evaluation criteria ($F(3; 124) = 3.42$; $p = .02$; partial $\eta^2 = .08$), however, there was also substantial between-classroom variance corresponding to medium effect sizes.

## Discussion

The results indicate that the collaboration script approach (Kollar et al., 2006) could successfully be transferred to structure web-based collaborative inquiry learning in real secondary school classrooms. Indeed, the collaboration script was powerful enough to lead learners to higher levels of both domain-specific knowledge and online search competence than unsupported collaboration. Probably, the script helped learners to engage in higher-level internet search processes and also to show a deeper elaboration of the domain-specific information provided in the online project library. Possibly, the high-level evaluation of information prompted by the collaboration script raised the learners' awareness of the need to produce arguments of a high domain-specific quality so that they could stand during the plenary discussions, which may have contributed to a deeper elaboration of domain-specific information that could be found online.

With respect to the effectiveness of the fading of the collaboration script, however, results are mixed: It did not add to the positive effects of the continuous script on students' online search competence, and did not even lead to better results with respect to domain-specific knowledge than the unstructured control group. Obviously, fading alone does not seem to be enough to foster the internalization of a search strategy but very likely needs to be combined with further instructional support (cf. Wecker & Fischer, 2007). For example, it might be helpful to have the teacher from time to time model crucial steps of the search process in front of the whole class (see Rosenshine & Meister, 1994), so that the students are reminded of the strategy the script presented before it is faded (which we are currently investigating in a follow-up study).

Finally, it deserves mention that on most dependent measures we found considerable variance between classes. Thus, further aspects of the learning situation (such as teaching style or class climate) definitely have an impact on the success or failure of collaboration scripts in web-based collaborative inquiry learning. Future research should clarify what classroom variables influence students' learning outcomes.

**Abstract:** In this paper, we look at how the construction of two types of professional portfolios supports engineering student learning. To frame "engineering learning," we use the dimensions brought together by Stevens and his colleagues: disciplinary knowledge, identity, and navigation. We present data from a comparative study in which students constructed one of two types of professional portfolios and provided data through extensive questionnaires. In this analysis, we look at their answers to the first question on the questionnaire ("What did you take away from this experience") in terms of the extent to which the students reported insights about disciplinary knowledge, identity, and navigation as a result of portfolio construction activities and the nature of the insights reported.

## Introduction

As with other forms of professional education, the goals for engineering education are complex and the lists of outcomes or competencies are extensive (e.g., ABET learning outcomes, conclusions from national policy reports such as ENGR 2020, Rising above the Gathering Storm, Grand Challenges). To meet the challenges of a dynamic, rapidly changing global milieu, the engineering education community has been exploring various pedagogical innovations such as problem-based learning and integrated first-year curricula, to provide students exposure to the kinds of complex, multifaceted learning experiences that more closely resemble situations they are expected to face as engineering professionals. Portfolio construction is an activity that has been advocated as valuable in supporting reflection on these and other learning experiences. While the body of work on the educational benefits of portfolio construction has been growing in other disciplines, work remains to be done to help fully understand how portfolio construction can enhance engineering learning.

In this paper, we present data from two portfolio interventions requiring different amounts of time and resources on the part of students and educators, to determine the engineering learning that might be possible given investment in such activities. To examine student learning from a perspective that complements the complex challenges of the present age to engineering education, we used a three dimensional approach proposed by Stevens and his colleagues, to include accountable disciplinary knowledge, identity, and navigation. We found this to be a useful framework for understanding what students perceived to be important benefits of portfolio development.

## Portfolios in engineering education

Portfolios are frequently understood as a collection of student work with a purpose. Among the many reasons driving interest in portfolios are the following: student knowledge is represented by their own work, students can take control of gauging the quality of the work, and the processes of selecting and explaining work in a portfolio can create opportunities for reflection.

Portfolios are not new to engineering education. The various portfolio projects being reported represent goals that are diverse, implementations that range from course to institution-wide, and variation in the extent to which reflection is emphasized. For example, Eris (2007) explored the potential of portfolios to capture significant types of design knowledge, Williams (2002) focused on a systematic process for setting up a portfolio framework that is oriented toward a particular competency in engineering education and supports reflection, Campbell and Schmidt (2005) described an institution level initiative that goes beyond assessment toward career planning as a goal and has reflection as a key feature, and Knott and colleagues (2004) reported on multiple university-level portfolio initiatives along with data on student experiences in these initiatives. Such a snapshot suggests the level of interest in portfolios and the range of uses. Barrett (2007) provides useful ways of laying these uses. For example, she differentiates the idea of using portfolios for assessment *of* learning or assessment *for* learning, and she draws distinctions between a positivistic approach for using portfolios (i.e., providing documentation of true knowledge) and a constructivist approach (i.e., providing a venue for helping students construct understanding). It is not always easy to determine which paradigm is prominent in the portfolio uses in engineering education.

In our work, we are interested in what happens when creation of the portfolio is framed as construction of an argument about the ways in which one is prepared to contribute to future engineering practice, specifically the realm of engineering practice that is of personal interest. Operationally, we have students instantiate this argument in the form of a portfolio containing a professional statement and multiple annotated artifacts. We explain the professional statement as a written narrative in which students explain the ways in which they are prepared to function as an engineer and which functions as the core of the argument. Artifacts are products and by-products of experiences that support the claims made in the statement. Annotations are explanations of artifacts, the experience that gave rise to them, and the link from the artifact to one or more claims.

There are clearly many ways to think of what such a task means theoretically. For example, seen from a lens of situated learning and legitimate peripheral participation (Lave and Wenger, 1991), this notion of portfolio construction invites students to frame or reframe prior experiences as legitimate peripheral participation in the practices of engineering (e.g., linking prior communication experiences in any setting to the kinds of communication that will be required in engineering practice). Clearly such a task is likely to be easier for some experiences than others. For example, an internship at an engineering company or participation in a capstone design project is likely to have much similarity to engineering practice, and thus the portfolio activity may simply involve being able to articulate the ways in which the experience contributed to being prepared. For other experiences, such as being in a leadership role in a sorority or spending a quarter in a music appreciation class, the challenge involves better *understanding* as well as articulating the possible ways in which the experience contributed to preparation for engineering practice. While much work on education is moving toward having students have educational experience that are more “like” engineering practice, it is still important to remember that students are having lots of experiences (some we control, some we do not)—experiences that can be contributing to their preparation for engineering practice and that giving students opportunity to frame the experiences as preparation has the potential to have educational significance.

In our studies, we have been exploring such questions of educational significance as well as questions of educational feasibility (i.e., what resources are required) in relation to different instantiations of this overall idea. Different instantiations involve different ways of constraining the task and different ways of providing students with support. For example, one way of constraining or not constraining the task involves deciding the scope of experiences across which students are invited to base their argument about their preparation. This has led us to explore *cross-curricular engineering portfolios* (CCP) in which students reflect on all of their experiences to date as well as *course-based engineering portfolios* (CBP) in which students focus on how the experiences associated with a specific course have contributed to being prepared. Our program of research has focused on student construction of these two types of portfolios (e.g., Turns, Cuddihy and Guan, submitted; Eliot and Turns, accepted; Guan and Turns, 2007; Lappenbusch and Turns, 2005).

These variations clearly differ in terms of educational feasibility. For example, course-based engineering portfolio activities could be added as a required assignment to any existing course, thereby not requiring significant change to the curriculum. Incorporating a cross-curricular engineering portfolio activity into the student educational experience is not as straightforward. In addition, the larger scope of the cross-curricular engineering portfolio suggests a need for more resources. As a result of such issues, over the past six years, we have studied students constructing these types of portfolios within as well as outside classroom settings

The differential educational significance of these two framings of the portfolio is also open question. Across our studies, we have collected data via observations, interviews, and surveys and our analyses of the data have used a variety of lenses in order to fully understand the role that this intervention can have. For example, we have analyzed our data from a writing-to-learn perspective, a community of practice perspective, an epistemic space perspective, and an identity perspective. Across this work, we have consistently noted that students engaged in constructing these types of portfolios have significant educational experiences and an effort to fully understand these experiences would require a broad framework. The contribution of this paper is to apply such a broad framework to data from our newest study, a comparative study in which student participants constructed one of the two types of portfolios and then told us about their experience through an extensive, open-ended survey.

## Disciplinary knowledge, Identity, and Navigation

In a recent paper, Stevens and his colleagues argued for the value of looking at three dimensions of engineering learning when thinking about the challenges of helping students become engineers (Stevens et al., 2008). These three dimensions--disciplinary knowledge, identity, and navigation--individually and in combination present a rather comprehensive view of how students conceptualize engineering knowledge and themselves as engineers, as they move into, through, and beyond their undergraduate engineering education. Stevens *et al.* present this three-dimensional model as a means for examining the experiences and development of engineering students from the analyst's perspective and illustrate the model with insights developed from ethnographic research. As we will show, the three dimensions may also provide a framework for students to reflect on and characterize *their own* experiences and development.

As Stevens and his colleagues point out, much work on disciplinary education has focused on characterizing and comparing the knowledge of disciplinary experts and student novices. In engineering, for example, researchers have focused on the critical role of design activity to engineering practice and have explored issues such as how expert engineers engage in design, how students engage in design, and how to help engineering students travel the path toward design expertise.

Stevens *et al.* take a significant turn in examining disciplinary knowledge as malleable and situational, rather than the relatively stable and progressively acquired body of knowledge assumed by expert-novice comparisons. They propose the concept of accountable disciplinary knowledge to highlight the idea that while disciplinary knowledge might be defined relative to the profession, the knowledge that is considered "accountable" or relevant changes over the course of a student's academic career. For example, while lifelong learning is considered critical to effective functioning of a professional engineer (i.e., see ABET accreditation criteria), students may not be held accountable to such a notion in the early years of their undergraduate education (or throughout their undergraduate years, for that matter) in favor of bodies of knowledge, like physics or even engineering design, that are more established in the literature and therefore easier to assess. Stevens *et al.* offer the example of engineering education in a particular large public institution that was the subject of their in-depth ethnographic inquiry. The character of knowledge for which students at this institution were accountable changed over the course of their years in college. In their first two years or so, students were assessed largely on their ability to solve discrete closed-ended textbook problems on their own, while in their upper-class years, students were assessed largely on their ability to tackle open-ended ambiguous problems while working in teams. The consequence of such a structural shift in what "counts" as knowledge, not unusual in U.S. engineering programs, is illustrated by the second-year student who found it difficult to reconcile his experiences in a research lab with what he believed would be important for his application to an engineering department.

Influenced by situated learning theory, Stevens *et al.* also assert the importance of identity in understanding engineering learning. Here, identity is not only how a person thinks of herself as an engineer, but also how a person is identified with engineering by others. Thus, identity development is an interactive process involving an individual's efforts to develop a conception of self as an engineer, and the larger community's growing recognition of the individual as an engineer (or not an engineer). As students develop a sense of what does or does not count as engineering, they develop a sense of self as more or less "engineer-like" according to how much or little they find themselves doing what they think counts as engineering. Likewise, others around them identify students as engineers more or less depending on the extent to which the student is doing what others perceive to count as engineering.

This two-sided process is illustrated by Stevens *et al.* in their observations about students at the institution in which they conducted their ethnography. For example, gaining increasing access to limited educational resources served to support the students' growing identities as engineers; while on the other hand, the competitive admissions process at the university (students have to apply to an engineering department during their sophomore or junior year) impeded students' identification as engineers, as they tended to refrain from committing to engineering until a department committed to them. One consequence of such structural conditions is that individuals' identification with the profession may weaken as they worry about admissions.

The third element of the three dimensional view, navigation "focuses on how a person moves through the personal and institutional pathways as an engineer-in-the-making to be officially recognized in one or more ways as 'an engineer,' pathways that are cut along both official and unofficial routes" (Stevens et al., 2008, pp. 356). Navigation provides "a way to talk about how other people and institutional resources play a role in a particular individual becoming an engineer or not" (Stevens et al., 2008, pp. 356). Navigation would include obligatory passage points, official routes, unofficial routes, and detours. For example, an obligatory passage point might be a particularly difficult pre-requisite course and an official route might include taking the required courses in an engineering department. At the same time, there are many unofficial pathways and detours, including internships, summer jobs, extracurricular activities, that can be the greatest sources of variation in students' experiences, engineering learning, and development. Such navigational flexibility can expand the possibilities for a student. For example, working at an engineering job gave one student access to a number of individuals who provided mentoring and additional opportunities for him, not necessarily available to other students.

### Something that happens? Something you can control?

We agree with Stevens and his colleagues that these three dimensions hold great promise for thinking broadly about how engineering students become engineers. What we also wonder is the extent to which these dimensions can be used to characterize the ways in which an intervention helps students take control of their own development. The idea implicit in such a question is that these elements are not only significant for characterizing what has happened to a student along the way, but can also be variables over which a student may have some measure of control. How effectively can students think broadly about the knowledge that they possess and recognize that subsets of their knowledge are accountable for certain situations? To what extent can thinking explicitly about such an issue actually affect the state of disciplinary knowledge? To what extent can trying to explain one's preparedness to be an engineer to someone else affect one's own identification with engineering? To what extent can students effectively monitor their own pathways, making sense of where they have been and adjusting their direction as they move forward? Our experience suggests that students can have agency in these matters, and that this agency can be supported through professional portfolio development activities.

## Approach

In our study, students created either a course-based professional portfolio (CBP) or a cross-curricular professional portfolio (CCP) and shared their portfolio construction experience with us via an extensive online survey. For this paper, we used the three dimensional framework introduced above as a basis for analyzing their response to the first and broadest question on the survey, "what did you take away from this experience?"

### Procedure

All participants attended workshops where they were given instructions and support for creating their portfolios. Participants in the cross-curricular portfolio intervention group attended four 90-minute workshops during the fall of 2008, while participants in the course-based professional portfolio intervention group attended two 90-minute workshops during the winter of 2009. In both cases, workshops were devoted to instructions for creating a professional portfolio and opportunities to peer review one another's work. In the course-based portfolio condition, because of the timing, participants only had the opportunity to peer review the final portfolio. In contrast, participants in the cross-curricular portfolio condition had the opportunity to peer review elements of the portfolio, like the professional statement or specific annotations, as they were developed, as well as the completed portfolio as a whole. Admittedly, these two conditions differed not only in the type of portfolio being constructed, but also the "time on task" and the extent of peer review feedback. The decision to configure the two conditions in this way was based on what was deemed a minimum scale implementation of each type of portfolio as part of an effort to help the engineering community understand what could be possible with these interventions.

A single individual served as the facilitator for all sessions. In addition, to ensure consistency across the sessions, the facilitator's role in these workshops was highly scripted. In particular, the facilitator offered little or no information about the criteria for choosing portfolio content or possible future uses for the portfolio itself. Participants often asked such questions in the workshop and in these cases the facilitator was instructed to turn such questions over to the group for general discussion.

### Participants

A total of 69 undergraduate engineering students participated in the study, 37 in the cross-curricular condition and 32 in the course-based condition. Collectively, the participants ranged in age from 18 to 44 years, with a median age of 21 years. There were approximately the same number of females and males in the study. Because of the relatively small number of participants, we chose to ask students whether they considered themselves underrepresented and over 50% said yes. Participants indicated that they were from a variety of engineering disciplines.

### Data collection

The primary data collected in this study was in the form of extensive online questionnaires that elicited information about the students' experiences of constructing their portfolios. These questionnaires were administered during the final workshop sessions to manage the quality of the data collection. Students spent between 35 and 45 minutes completing the survey. In this exploratory paper, we focus on analyzing the students' responses to the first question—"What did you take away from this experience?" We chose this "take away" formulation rather than a formulation that asked directly about learning (e.g., "what did you learn") for a variety of reasons. Our goal with the first question was to get a sense of students' learning broadly. However, recent work on personal epistemology has helped point out that students themselves have ideas about what counts as knowledge. On our part, we have seen evidence of such issues in other students, when, for example, students described how a portfolio construction activity helped them become more aware of what they know and helped them to see the connections among their different courses and learning experiences, yet subsequently said that they "hadn't really learned anything." In our choice of asking about take-aways, we wanted to try to bypass potentially constrained ideas about what counts as knowledge and learning.

## Data analysis

We used a combination of deductive and inductive analysis of the student "take-away" responses to explore a) the extent to which students reported insights related to disciplinary knowledge, identity, and navigation, b) the nature of these insights, and c) how insights reported by students differed across the two portfolio interventions.

We are using the term deductive analysis to refer to the process of filtering the data relative to each of the three dimensions from the framework introduced earlier. In addition, because initial inspection of the data suggested the prevalence of comments directly related to the portfolio, we added a fourth coding dimension.

- Disciplinary knowledge: a) literal references to "skills" or "knowledge," b) references to other terms that can be considered surrogates for skills and knowledge such as "qualifications" and "qualities"
- Identity: a) literal references to being "an engineer" either in their own eyes or in someone else's eyes, b) references to personal sense of self and "who they are"
- Navigation: a) literal references to "experience," b) references to specific types of experiences such as projects, courses, etc., c) references to accomplishments and achievements because such terms typically refer to experience delineated by a superior quality
- Portfolio: a) references to some aspect of the portfolio experience such as having the portfolio or the process of constructing the portfolio

The two first authors independently coded each student response as related or unrelated to each dimension based on the guidelines presented above. A single response could be coded for multiple dimensions. Reliability was high as measured by Cohen's kappa (0.77 for Disciplinary knowledge, 0.91 for Identity, 0.68 for Navigation, and 0.94 for Portfolio). The lowest value—the value for Navigation—was the result of one coder including mentions of specific courses as a part of navigation. This broader view was adopted for the final coding, and the remaining disagreements were resolved by the first author. Since we were interested in comparing the prevalence of these insights across the two conditions, the coding was done blind to the condition so that preconceptions about the conditions could not influence the coding outcomes.

We used an inductive analysis to characterize the nature of the insights associated with each dimension. The goal of this analysis was to identity themes in the responses coded as related to each dimension. In the results section below, we describe these themes and illustrate the themes using the students' response.

## Results

As depicted in Table 1, the Navigation and Portfolio dimensions were similarly prevalent in the data—both appeared in around 65% of the *overall* set of responses. The dimensions of Identity and Disciplinary Knowledge were less prevalent but still prevalent to a notable degree (i.e., 22% and 30% respectively) in the *overall* responses. In terms of differences between conditions, the prevalence was similar for Disciplinary Knowledge and Portfolio. The CCP condition had a much higher prevalence of Identity and Navigation, while the CBP condition had a much higher prevalence of portfolio-only responses—responses that did *not* address any of the three primary areas of interest (i.e., disciplinary knowledge, identity, navigation). In the remainder of the results, we describe the themes present in responses coded within each dimension. We start with disciplinary knowledge as a category of interest that was not different across conditions, then discuss navigation since it was present but different across the conditions, and then turn to identity which was different across the conditions and almost absent in the CBP condition. We end with comments on the portfolio themes.

Table 1: The percentage (and counts) of the responses addressing each dimension (i.e., extent)

| | Overall (n=69) | CCP (n=37) | CBP (n=32) | Comparison |
|---|---|---|---|---|
| Disciplinary knowledge | 30% (21) | 27% (10) | 34% (11) | CCP < CBP |
| Identity | 22% (15) | 32% (12) | 9% (3) | CCP >> CBP |
| Navigation | 62% (43) | 68% (25) | 56% (18) | CCP >> CBP |
| Portfolio | 65% (45) | 68% (25) | 63% (20) | CCP ~ CBP |
| ---Portfolio Only | 30% (21) | 19% (7) | 44% (14) | CCP << CBP |

## Disciplinary Knowledge

Three themes emerged from inductive analysis of the twenty one responses coded as related to disciplinary knowledge. First, the students' responses showed marked attention to the issue of "accountability" of their knowledge. Most frequently this took the form of identifying or thinking about the portion of their knowledge most relevant to employers or recruiters, but some students also thought about the portion of their knowledge relevant to "professional practice," to "engineering," and to their "engineering career."

- A sense of what skills and valuable experiences I have that I can bring up when talking to recruiters, interviewers, etc. to make myself a stronger candidate; A realization that these experiences/skills that make me a strong candidate are not limited to technical experiences/skills. Examples from other academic disciplines and nonacademic pursuits are also valuable, as are examples related to my major that show nontechnical skills (ability to work in a group, time management, etc.)
- I feel like I can look at a course differently now. What I mean by that is that I can look at a current class and ask myself "what marketable skills am I gaining from this class."

Second, the student responses also suggested that the activity of constructing the portfolio helped students to gain a better sense of the body of knowledge that they had been able to develop by this point in time. In some cases, this was characterized as an inventorying process, while in other cases there was an element of discovery. Such awareness creates a basis for thinking about what knowledge might be accountable to some group.

- However, my chief take-aways from this experience is my realization that I have actually produced a lot more ""artifacts"" than I had remembered. This allowed me to go back and look at the skills I've managed to develop over time. …. (Inventory with a hint of discovery)
- "Building an engineering portfolio helped me to view my completed coursework from a professional perspective as opposed to an academic one. It gave me the opportunity to rethink what I learned and added to the value of the material covered in the course… " (Discovery)

Third, students also reported insights concerning the process for doing the first two activities. Such insights included recognizing the scope of accountable knowledge and how a course can be used to demonstrate knowledge, and even a recognition of the importance taking the time to do such thinking.

- A realization that these experiences/skills that make me a strong candidate are not limited to technical experiences/skills. Examples from other academic disciplines and nonacademic pursuits are also valuable,
- I feel like I can look at a course differently now. What I mean by that is that I can look at a current class and ask myself "what marketable skills am I gaining from this class."
- I haven't really taken the time to think about what it is to be an engineer and show how I have those skills

## Navigation

In the 43 responses that were coded as related to navigation across the two conditions, students 1) revisited experiences they had already had, 2) expressed that they had developed a greater appreciation for their experiences, 3) articulated a broader understanding of the experiences that are relevant to navigation through engineering, and 4) discussed plans for directing future paths. Unsurprisingly, the CBP responses were more likely to emphasize course-specific experiences, although they frequently talked about courses in generally rather than simply the course on which they had focused the portfolio, while the CCP responses emphasized experience more generally.

Several students described how the portfolio development process encouraged them to revisit their prior experiences. For one student, portfolio development simply "forced me to review all of my experiences" while another student "gained a deeper understanding of my professional experience." In addition, students said they developed greater appreciation for the experiences they had had. Some students expressed this greater appreciation in terms of realizing they had accomplished more than they thought, as with one student who wrote, "My chief take-away from this experience is my realization that I have actually produced a lot more "artifacts" than I had remembered." Another student "gained more insight into what I could prove from experiences…. I realized they showed more about me than I had realized before."

Students also described how their understanding of the relevance of their many experiences had expanded, "how everything that I have done up 'til now has some kind of value in the engineering field." This broader conception of relevant experiences, coupled with greater appreciation for such experiences, led students to consider their value: "all my experiences could potentially be documented for future benefits." In looking back at their experiences, students also were compelled to look forward, as one student who planned to continue reflecting on her learning experiences said, "I need to think about each project or assignment as something that is helping me to become a better engineer." In addition to those students who planned to continue reflecting in the future, some students planned to take greater control of their future paths. One student wrote, "I discovered that I needed more to show that I was an engineer. I will now be looking more closely at internships…" In addition to "thinking about everything I have accomplished," some students are also inclined to look forward, at "things I wish to accomplish by the time I graduate…"

Navigation, described by Stevens *et al.* as the dimension that may introduce a great deal of the variation among students' experiences, learning and development, here is shown to present opportunities for students to exert greater control over their learning. Some students say that the portfolio development activity has enabled them to re-think and organize their prior pathways, and be more intentional about those pathways they follow in the future.

## Identity

Since most of the identity-related responses were associated with the CCP condition, a comparative analysis is not strongly warranted. It is possible to note, however, that the three CBP identity-related responses were quite different in emphasis and covered much of the space of the twelve identity-related CCP responses. Of the fifteen responses that were coded as related to identity, most (12) were associated with the CCP condition. Two major themes emerged from inductive analysis of the fifteen responses coded as related to identity. These themes were 1) a changed personal sense of identification with engineering and 2) a changed sense in the ability to explain one's preparedness for engineering. In the process of identifying oneself with engineering, as one student wrote, "I've had to go back and evaluate myself and what I have done as an engineer," some students gained greater identification as an engineer. This same student added, "What I'm mostly going to take out of this is what I have discovered about myself and how everything that I have done up till now has some kind of value in the engineering field." Another student wrote simply that portfolio development, "helped me define who I am as an engineer."

Furthermore, students recognized the importance of being able to explain or prove their preparedness for engineering, as one student wrote, "I have learned how to think about the things I have done in my classes in a way to present myself as an engineer. I learned how to draw on my experiences to come up with specific proofs of my qualities." Another student commented on the value of "having some basis/artifacts for the claims that I am a good engineer." The process also caused students to plan future action toward developing the ability to demonstrate their preparedness. Through reflection on their experiences, some students felt, as one expressed, "I discovered that I needed more to show that I was an engineer. I will now be looking more closely at internships and will be saving assignments." Another recognized the need to pursue "more activity that related to my career as an engineer."

Students' responses also illustrated the two-sided process of identity development as described by Stevens *et al.*, with the individual developing a sense of self as an engineer at the same time and in interaction with others forming a perception of that individual as an engineer. For example, one student wrote, "Sharing with others my experiences and their experiences helps me understand where I stand relative to other engineers in my community." Another also found value in comparisons across other engineers, "I got to look back what I have done as an engineer, and how it may differ from other engineers."

We may assume that the two-sided process of identity development described by Stevens *et al.* is always in play as students interact with their environment, and therefore it is no surprise that the process continues through portfolio development as an educational intervention. The difference here is the possibility for students to look upon their own developing professional identities as the subject of reflection, drawing connections between what they do and who they are becoming. By making sense of these relationships, students gain awareness of the control they can have over their pathways, and thus become more deliberate in developing and claiming their professional engineering identity.

## Portfolio

Two major themes emerged from inductive analysis of the forty-five responses coded as related to portfolio. These themes were 1) having the portfolio and 2) having a process for creating a portfolio. First, students drew attention to the simple fact that they gained from the experience a physical portfolio. Some students went even further and described the portfolio as an organizing tool, and sometimes even specifically to share with others (e.g., "A portfolio that I can present to future employers and academic admissions boards"). The students also students reported gaining knowledge about the "fundamentals of how to build a portfolio" and a sense of how creating a portfolio is related to other types of writing they have learned about (e.g., "Creating a portfolio is quite similar to any other paper I've been writing. You make an argument--Professional statement, annotations--and you support your argument--artifacts"). Some students linked the process of creating a portfolio with having one, by describing the portfolio they created as a starting point for developing future portfolios such as in the following quote: "I am taking away a foundation for a future engineering portfolio if I wanted to start one, as this one is a solid foundation then only polishing would be needed at this point." It was interesting to note the number of portfolio-only responses associated with the CBP condition.

## Discussion and Concluding remarks

In this paper, we showed how the three dimensions of disciplinary knowledge, identity, and navigation can be used to make sense of what students reported taking away from two types of portfolio construction activities. We were able to code much of the data using these dimensions and then identify themes within each dimension. For example, students reported greater awareness of their own knowledge and how to think about what is accountable at any point, stronger identification with engineering, and a broadened sense of what could be included in the engineering pathway to date and ideas about how to manage the pathway in the future. These results suggest that portfolios can help students take greater responsibility for their education. The relatively small scale of these interventions (particularly when compared to large scale curricular change) makes these results even more compelling. The comparative emphasis of this study is intended to provide information for creating portfolio assignments that meet available resource requirements (i.e., the amount of time available) and also help students focus on important learning goals. In our work, the results suggest that educators who are interested in helping students think directly about identity issues should consider the cross-curricular portfolio over the course-based portfolio.

We believe the results presented here may underestimate the extent to which students had insights relative to each dimension since we analyzed only a small amount of information from each student. Because our questionnaire was more extensive, we will be able to explore this conjecture in future analyses. What we will not be able to explore directly is whether students would have had these insights without the portfolio intervention. While it does seem plausible that some students would have such insights eventually, it nevertheless seems valuable to know that portfolio construction can help students along in this process. This work contributes to the scholarship on portfolios as an educational intervention, efforts to understand engineering learning broadly, and, of particular importance, efforts to help empower engineering students to take charge of their education.

**Abstract:** In consecutive years, a fifth grade teacher of a self-contained classroom enacted five-week Earth sciences units that included learning activities focusing on the interpretation of seismograms and the location of earthquake epicenters. In one class, the unit utilized an *embedded* design that situated learners within the spatial and temporal extent of the phenomenon during the epicenter determination activities. In the other class, while the activity set remained the same, the embedding features were removed. Students in the embedded condition demonstrated greater learning gains than their non-embedded counterparts in pre-post assessments of student skill, declarative knowledge, and conceptual understandings, even among topics unrelated to the determination of epicenters. Post-activity student interviews evidenced strong preference for the immersive, asynchronous, and temporal staging components of the embedded condition.

## Introduction

In designing classroom-based learning activities to support science inquiry, one of the most significant challenges is the choice of strategies through which learners might engage with the phenomenon under study. While technologies as old as the printed page have expanded the modalities of engagement and broadened the range of accessible phenomena, they sometimes do so at the cost of some distancing of the learner from the phenomena themselves. As a consequence, learners sometimes lose the opportunity to experience some of the challenges—and excitement—inherent in conducting investigations.

In this paper we report the results of a quasi-experimental empirical study of learner outcomes associated with an activity structure that seeks to shape learner inquiry experiences by *embedding* them within the spatial and temporal extents of the scientific phenomenon of a series of earthquakes. Spatial embedding is implemented by introducing the conceit that the classroom itself is a (scaled) area of seismological activity situated on a tectonic plate boundary. Over the course of about a month, learners experience a sequence of simulated earthquakes—"RoomQuakes"—at unpredicted times, embedding them within the (scaled) temporal course of the phenomena. Students are challenged to locate the plate boundary bisecting the classroom by reading simulated seismograms from seismometers situated around the classroom and using trilateration to combine those results in a way that permit them to determine the epicenters of the seismological events.

In previous reports, we have described the "embedded phenomena" framework (Moher, 2006) and described learner outcomes for a similar RoomQuake unit relative to a no-treatment control (Moher, 2008). Here we extend that work by contrasting the learner outcomes of a fifth grade classroom engaged in an Earth sciences unit on earthquakes incorporating the embedding strategies described above with those of a second class, taught by the same teacher, that received the same instruction and enacts the same set of activities within a *non-embedded* framework. In this second condition, the seismological inquiry is centered on the determination of a fault line in southern California based on the sequential massed analysis of an historical series of earthquakes, using maps rather than the classroom space as the locus of trilateration. Learners were assessed before and after the unit across multiple outcome spaces, including skill in the interpretation of seismograms the use of trilateration, and understandings of the temporal, spatial, and intensity distributions of earthquakes. We also assessed structural and causal content domain understandings associated with the surrounding instructional unit, such as the structure of the Earth and the causes of earthquakes, that were not directly associated with the fault-line determination activities. After the unit, we probed the impact of embedding by posing hypothetical choices between the treatment learners had received and the alternative treatment. In the following we report on these outcomes and discuss their implications for our understandings of how specific elements of the "embedding" might impact learning.

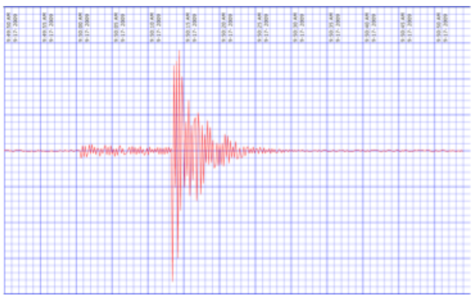

Figure 1. Simulated strip-chart seismogram used in RoomQuake.

## RoomQuake

In the embedded version of RoomQuake, students adopt the pretense that their classroom is an active seismic field, and that a series of earthquakes is expected over the course of several weeks within that field. Computers running conventional browsers, served from our laboratory, act as simulated seismographs (Figure 1) that depict continuous strip-chart recordings (seismograms) of local vibration, where locality is conditioned upon their specific placement of the computers within the classroom. Most of the time, the seismograms reflect a low level of background vibration. At (apparently) unpredictable times, rumbling speakers at each seismograph signal the onset of an earthquake. Upon this signal (or as soon thereafter as classroom instruction permits), students move to the seismographic stations to read the waveforms.

Reading the seismogram recorded at a single location provides two critical pieces of information: the magnitude of the event, and the distance (but not direction) of the event from the recording station. Determining the epicenter of an earthquake requires readings from multiple sites, which may be combined together through the process of trilateration to obtain a location solution. In the embedded version of RoomQuake, we use calibrated dry-lines anchored at the seismographs to sweep out arcs of potential epicenter loci; the solution is obtained when the students at the end of those lines converge at a common point. Once the location and magnitude have been determined, the teacher hangs a color-coded (representing magnitude) Styrofoam ball from the ceiling at the epicenter point, providing an historical record of the event series, and students update poster-based representations of the temporal and intensity distributions of the events (Figure 2).

Figure 2. Photo of classroom hosting embedded version of RoomQuake. Styrofoam balls on the ceiling mark event epicenters, color-coded by magnitude. Wall charts are used to track timing and magnitude of event series.

## Embedding as an Activity Design Strategy

### Spatial Embedding

A central component of our framework is the conceit that the phenomenon under investigation is unfolding within the confines of the classroom itself. This is not an obvious choice, nor necessarily the correct one. When studying seismology, for example, many learning researchers would argue that authenticity demands that the discourse be situated in a scientifically accurate geographic framing; we should be talking about earthquakes around the Ring of Fire, for example. We conjecture, however, that by situating the phenomena "in here" rather than "out there" we might increase learners' emotional interest in the phenomena, and leverage incidental associations between the simulated and real worlds (e.g., "the epicenter was right over my desk"). Moreover, we hope that by situating the imaginary phenomena within the classroom space students can build on their accumulated knowledge of the physical, social, and cultural features of the environment as they undertake a new type of activity.

Another feature of our approach is the decision to maximize the nominal spatial extent of imagined phenomena by scaling them (up or down) to fill the physical space of the room. From a perceptual perspective, we hope to increase the salience of the phenomena for learners (Collins et al., 1991; Yantis & Egeth, 1999). On a more practical level, we also believe that this strategy can reduce congestion in the classroom by allowing students to use the entire floor space as they conduct their investigations.

In embedded phenomena, access to the representation of the state of phenomena is physically distributed throughout the space of the classroom. We believe that this offers three important benefits. First, it creates multiple natural contexts for students to engage in discourse with peers and teachers (Vygotsky, 1978) concerning the phenomenon. Second, it reinforces the important science concept that understanding the state of a phenomenon might not be possible from a single observation, but may require multiple probes from different vantage points that require aggregation and coordination to come to full understanding. Third, we expect that by requiring physical movement from one part of the room to another in order to obtain complementary data we might reinforce memory by associating it with a physical action (Wisneski, et al., 1998).

Our strongest motivation, however, draws from a desire to physically immerse learners within the experience (Dede et al., 1997); in our framework, not only are the phenomena embedded in the space, indeed the learners themselves are embedded within the phenomena. The importance of embodiment has strong advocates both in psychology (Johnson, 1987; Clancey, 1997; Clark, 1997; Glenberg, 1997, 1999; Winn, 2003) and human-computer interaction (Dourish, 2001). Embodiment approaches argue that "thought grows from action and that activity is the engine of change" (Thelen, 1995). In this perspective, cognition arises specifically through bodily interactions with the world. Learning that pairs action and knowledge, or engagement in goal-directed actions, particularly within social contexts (Lindblom & Ziemke, 2007), is viewed as necessary for higher cognitive capacities of thought and understanding to develop.

### Temporal Embedding

The embedded phenomena framework engages the issue of time along two important dimensions: duration and persistence. The long time course of these deployments offers three important benefits. First, it opens the door to the study of phenomena that unfold slowly, requiring investigative processes unlike those used in most classroom science work. A second potential benefit lies in the value of time for students to become meaningfully involved in the enterprise of scientific investigation: different learners engage in activities at different paces. Our prior classroom experience (Moher, 2008) led us to expect that while highly motivated, achievement-oriented students would readily become engaged in our activities, other students would need time to move, in Lave and Wenger's terms, from the periphery to the center of the community of scientific practice (Lave & Wenger, 1991). The persistent representation of phenomena, combined with the spatial immersion, further promotes the goal of engaging all students; for all but the most dedicated non-participant, it eventually becomes easier to participate in an activity that impinges on his or her perceptual system all the time, wherever they look, than to ignore it, particularly when respected peers are engaged in the activity. Finally, by spreading interaction with the phenomena over multiple episodes we hope to take advantage of the potential of temporally distributed instruction over “massed” instruction with respect to recall and motor skill development (Donovan & Radosevich, 1999; Cepeda et al., 2006). It is important to note that effects of spacing and learning with respect to more complex material are less well understood (Dempster, 1989).

Persistence brings at least three additional benefits. First, by continually representing phenomena, we create the opportunity to reinforce the concept that, in nature, important state changes are not always synchronized to fixed schedules, that “things happen when they happen” (asynchronously with respect to the flow of instruction), and that scientists (particularly in observational sciences) are often at the mercy of events rather than the other way around. Second, persistence provides opportunities for "incidental" learning in much the same way that foreign vocabulary words adorning classroom walls may result in learning without explicit reference during formal instruction. We argue that the role of "student in the classroom" inherently demands the ability to attend to multiple concurrent threads of activity; at the same time that a teacher is speaking, a student might be working on a laboratory project, avoiding a spit-wad propelled in their direction, tracking the progress of a playground basketball game visible through the classroom window, and receiving an oral invitation to an after-school event from the student at the next desk. By adding an attentional channel that promotes curricular goals, we address the human need for variety and offer a potentially productive alternative to the normative instructional flow. Finally, by interleaving salient simulations with regular instruction, we surreptitiously expand students' opportunities to engage with additional science content.

## Method

We investigated the alternative learning conditions with two cohorts of fifth grade students across subsequent years with the same teacher in a Midwestern U.S. elementary school. The teacher had previously conducted three RoomQuake units. The two cohorts were randomly assigned to condition with 27 students in the embedded condition and 18 students in the non-embedded condition. There was attrition of one student in each condition due to incomplete data.

Both classes received the same lessons during their regular science periods on Earth science concepts including the background on the Earth’s layers and composition, the existence of tectonic plates, and the geological features that relate to the interactions of these plates.

Both classes also completed a series of 15 earthquake activities where they computed the epicenter of earthquake events from simulated seismograms. The main manipulation was in how the students engaged in these activities across the two cohorts. Students in the “classroom embedded, temporally-distributed” condition experienced a series of 15 simulated earthquakes (“RoomQuakes”), each presumed to occur within the physical space of the classroom. The simulation was effected by placing four 24” iMac computers around the classroom; each computer served as a simulated seismograph which depicted a continuously running strip chart recorder of ground vibration *for that exact location in the classroom*. Between events, the seismographs displayed simulated random noise; when a RoomQuake occurred, however, they traced out unique characteristic waveform (seismogram) corresponding to the expected vibration at their specific locations due to an event at a particular location in the classroom. The earthquake events occurred at unexpected times during the school day over a four-week period and were signaled by a low-frequency rumbling sound generated by the speakers in the computers.

In the non-embedded condition, students also worked with a series of 15 earthquakes, however, these were not simulated, nor were they presumed to be occurring in the physical space of the classroom. Instead students used the computers to access historical seismogram data from 15 earthquakes that occurred in Southern

California. For this condition, each computer represented a different seismograph station in Southern California and the four iMac computers were placed all in a row. The screens displayed snapshots of single seismogram readings and the students were able to go forward or backward through 15 snapshots representing the 15 different earthquake recordings. Students completed this set of activities as a single unit during their normal science time (it generally took a couple class periods to complete the set).

For each event in both conditions, students working in small teams were responsible for determining the epicenter and (Richter) magnitude of each earthquake and cataloging information about the event. By reading the seismogram at each seismographic station, students were taught how to determine the magnitude of the event, and the distance of the event from that station. They learned that earthquakes generate multiple waves that travel at different rates; and that the latency between arrival of two of those waves, P and S, is proportional to the distance between the earthquake and the seismograph. Magnitude can be determined by comparing event distance with graph amplitude. A reading from a single station, however, is insufficient to locate the epicenter, since it does not provide directional information. In order to obtain a solution, students needed to combine the distance information from multiple (at least three) stations through the process of trilateration.

In professional seismologic practice, trilateration is performed through the process of determining the common point of intersection among three or more circles, requiring a level of mathematical sophistication beyond that held by our learner group. To simplify this process for the students, the embedded class used calibrated dry-lines anchored at each of the seismographic stations to sweep out arcs reflecting the locus of solutions from the individual seismic stations until they found the location in the room where the endpoint of their measures coincided. Alternatively, in the non-embedded condition students used calibrated strings that were anchored at each of the seismographic stations on their large maps of Southern California to find the endpoint where all the measures coincided.

The unit also used workbooks that gave students practice with data recording methods and various kinds of symbolic representations of the data. Three types of public displays were also created. For the embedded group, the locations of the events were recorded by hanging Styrofoam balls from the ceiling at their epicenters, color-coded to reflect the event magnitudes. In the non-embedded group, however, students located the earthquake epicenters on a large map of Southern California and used color-coded stickers to reflect the magnitude. Two other public data representations were also maintained using colored sticky dots on large wall posters: magnitude frequency distribution (the number of earthquakes of magnitude 3, 4, 5 and 6) and a timeline of the events. The embedded condition had access to these representations through out the entire unit, while the non-embedded condition only saw them during science classes when working with the earthquake data.

## Learning Goals and Measures

The learning goals of the RoomQuake unit were focused in three areas: (1) the acquisition of skill in authentic seismological practice, including the determination of event distance and magnitude, and the use of trilateration to determine event epicenters, (2) the development of an understanding of the distributional characteristics of earthquakes across the dimensions of space, intensity, and time, developed through student observation of the patterns reflected in the emerging historical record of events, and (3) an understanding of target Earth science concepts.

*Skill in seismological practice*. Following the unit, students were individually interviewed and asked to demonstrate their ability to read seismograms and compute epicenters. This included locating the arrival of the P and S waves, determining the distance between the arrivals of those waves, and determining the amplitude. They were also asked to find the magnitude of the earthquake using the data they had already collected from the seismogram. Additionally, students were asked to show the loci of potential epicenters using two different methods. First they had to find the epicenter by means of the method used in their class (either with strings in the classroom or strings on a map) and then as a transfer task they were asked to find an epicenter using three compasses on a piece of graph paper. We also probed declarative understanding of seismograms and trilateration through a series of multiple-choice prompts using a written instrument that was administered prior to, and directly following, the instructional unit.

*Understandings of earthquake distribution patterns in space, time and intensity*. Over time, collections of earthquakes exhibit characteristic distributions in where they occur (along fault lines marking plate boundaries), in when they occur (after-shocks follow large seismic events), and in their magnitude (strong earthquakes are less frequent than mild earthquakes). We probed these understandings through a series of multiple-choice prompts using a written instrument that was administered prior to, and directly following, the instructional unit. The same test was administered to both classes.

*Structural and Causal Earth Science Concepts.* Also included in the written instrument administered prior to, and directly following, the instructional unit we assessed understanding of Earth science concepts with a series of multiple-choice questions. The questions probed knowledge on topics including Earth structure and composition, plate tectonics, and the formation and location of geological features at plate boundaries.

## Results

### Pre/post Comparisons

The results of the pre- and post-activity assessments are shown below in Figure 3.

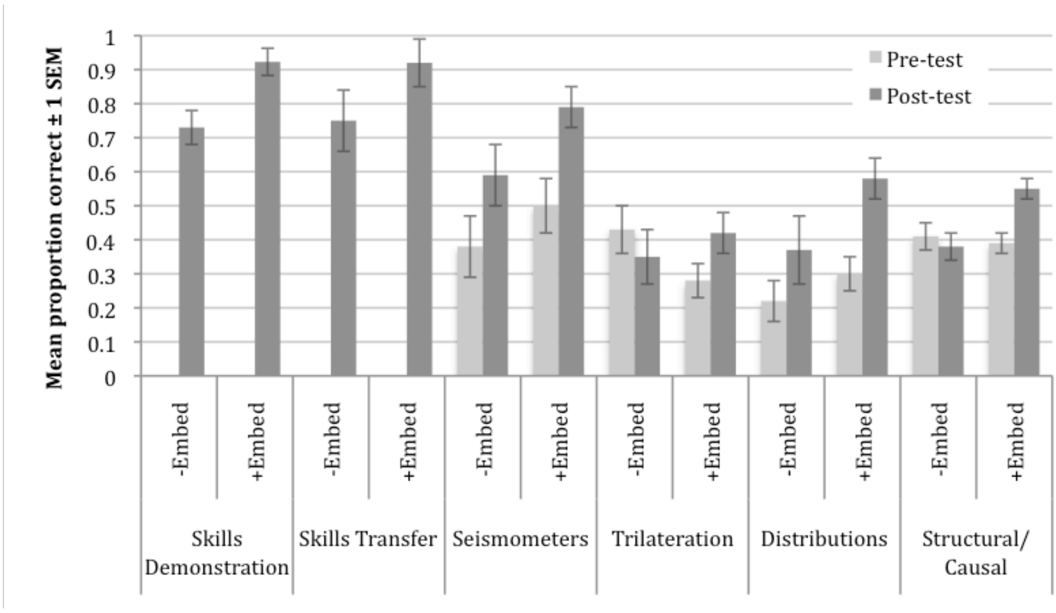

Figure 3. Performance on pre- and post-activity assessments for students in the embedded ("+Embed") and non-embedded ("-Embed") conditions: demonstrations of ability to identify earthquake epicenters, understandings of seismometers and their use, trilateration, earthquake distributions, Earth structures and causes of earthquakes.

*Demonstration of Epicenters.* For this task, students were asked to complete the epicenter tasks using the same methods as they had during RoomQuake (strings in classroom or on maps), as well as to compute epicenters using compasses on graph paper as a transfer task. The results were analyzed with a 2 (embedded, non-embedded) x 2 (same context, transfer context) repeated measures ANOVA. Neither the main effect for context, nor the interaction, were significant. However, the main effect for embeddedness was, $F$ (1, 40) = 5.34, $MSE$ = .125, $p$ < .03. Students in the embedded condition outperformed students in the non-embedded condition on both practiced and transfer skill assessments.

For the remaining assessments, the results are analyzed with 2 (embedded, non-embedded) x 2 (pretest, posttest) repeated measures ANOVAs with pretest and posttest serving as the repeated measures.

*Seismometer Use.* There was a significant main effect for test time, $F$ (1, 42) = 12.7, $MSE$ = .10, $p$ < .01. Students gained from pre- to posttest in their understanding of seismometers and their use. There was a marginal effect for embeddedness, as students in the embedded condition tended to have better understanding of seismometer use, $F$ (1, 42) = 3.76, $MSE$ = .15, $p$ < .06. The interaction, however, was not significant, with similar performance gains across the two conditions.

*Understanding Trilateration.* There was no main effect for embeddedness condition or test time. However, the interaction of these variables did reach significance, $F$ (1, 42) = 3.97, $MSE$ = .06, $p$ < .05 with students in the embedded condition showing greater gains than students in the non-embedded condition.

*Earthquake Distributions.* There was a significant main effect for test time, $F$ (1, 42) = 18.4, $MSE$ = .06, $p$ < .01. Students in both conditions gained from pre- to posttest in their understanding of earthquake distributions. However, neither the main effect for condition, nor the interaction, reached significance.

*Structural and Causal Earth Science Concepts.* Overall there was a significant main effect from pre- to post-test on the understanding of Earth science concepts, $F$ (1, 42) = 5.88, $MSE$ = .02, $p$ < .02, and a marginal effect for embeddedness condition, $F$ (1, 42) = 3.79, $MSE$ = .02, $p$ < .06. These were both qualified by a significant interaction, with students in the embedded condition showing greater performance gains, $F$ (1, 42) = 7.76, $MSE$ = .02, $p$ < .01.

## Student interviews

An examination of the students' responses to the open-ended questions posed during the post-unit interview gives some additional insight into the features of the design that impacted their perception of the activity. In response to an item asking learners to describe "what they did" during the unit, students in the embedded condition focused strongly on the epicenter determination activity, while their non-embedded counterparts were much more likely to respond with descriptions of the other curricular activities included in the unit. To a question about the length of the unit intended to gauge student patience and boredom with the unit, "embedded" students were more likely to express a desire that the unit had been longer, with more "non-embedded" students voicing the opinion that it was too long.

Included in the interviews were several items that asked students to make comparisons between the condition that they experienced and hypothetical alternatives characteristic of the alternative treatment with respect to which would "help you learn about earthquakes and their causes better." In the following we will focus on the responses provided by the students in the embedded condition.

In one item, we asked students whether they would have preferred to have all of the earthquakes "back to back" on consecutive days (the "massed" treatment). In their responses, 22 of the 25 students interviewed indicated a preference for the temporally distributed approach, characterizing it as affording better opportunities for learning.

> Charley: *"The one we did, like which was when you guys did RoomQuakes because we took the time on each one so it helped me learn. I can't learn really fast."*

Asynchrony was perhaps the most appealing design element from the perspective of the learners, all 25 students saying they would learn better from the random earthquakes than ones scheduled at specific times, as suggested in another interview item. In their responses, they focused on realism and the excitement of not knowing when an earthquake was coming:

> Marty: *"It did, because if they were only during science time, that's not how they happen in real life, they only happen in real life, they don't have a certain schedule. In real life, they don't have a certain time that they are going to do it, so that gives you practice for the real world."*
>
> Robert: *"Being a mystery and at different times because, well like having a mystery, because for when there is a real earthquake coming you don't even know so you're just doing your work and it's always a mystery."*
>
> Danielle: *"Because of you did them all in a row in a couple days then we would know what to expect and when it would happen, but when you guys did it, it threw us off guard completely."*
>
> Charley: *"It just catches you in headlights, like you really don't know when it is going to come. It just surprises you."*

When asked whether the activity might have been more valuable as a learning activity if the trilateration work were done on a map rather than in the physical space of the room, 19 students preferred the latter, characterizing is as more "hands-on," more accurate, and more fun that a map version.

> Jacob: *"In the room because it would be better because it was turning our room into, say, California and we were having earthquakes."*
>
> Ariel: *"I think putting it on the room because it's, you can locate it more easily. Like it is easier to locate. Because you can like see where it is exactly like maybe you might, sometimes you could be off on a map."*

In their responses to this item, several of the students described the visceral impact of the experience in terms related to the presence construct.

> Abby: *"I like the way we did it here, it is like more real life because there are like RoomQuakes actually happening, it is not like we are reading what happens, we are actually in it."*
>
> Nguyen: *"Right here because I can feel it and I can do it right here."*

Jacob's response anticipated the final question in our interview, which asked students if it would be better to characterize the earthquakes as "happening right here in your classroom" or "somewhere else, like southern California." Over half the students favored the embedded treatment, saying that they could "experience more" and that it would be better for learning.

> Michelle: *"Well, I think always visualizing it, more experiencing it is better for people to learn because doing, being able to do it is not the same as being able to see it or hear it or because you will be able to interact with it and you'll be able to feel it. So, it's like an actual earthquake. But, if it is in Southern California you can't feel it and you really don't know if it happened."*
>
> Shaquille: *"Probably in by our classroom because if it is in another state or something, like, it's like you don't know how it is or how it's like and a RoomQuake is kind of like an earthquake and you can actually feel how it sounds like."*

In contrast, six of the students preferred the hypothetical alternative treatment, characterizing is as "more realistic," a better way to learn more about other places, and more fun to imagine being somewhere far way. The remaining students expressed no preference.

## Discussion

While the number of subjects and variability of performance limited the power of the design, taken as a whole the study provides support for the claim that the spatial and temporal embedding elements employed in RoomQuake had a positive impact on learner outcomes. Students in the embedded condition consistently outscored their non-embedded counterparts on post-test assessments, with significant gains in several areas.

At the outset of the instructional units, none of the students had prior experience with the interpretation of seismograms or the use of trilateration to resolve distributed readings. Given the multiple opportunities for developing these skills, we were not surprised to see that students were proficient at these tasks at the conclusion of the units. We were surprised, though, at the significantly better performance demonstrated by the students in the embedded condition, since students in both treatments were given the same number of practice opportunities. The difference in performance cannot be attributed to a mismatch between the practice during the unit and during the assessment, since students used the same media for demonstrating the trilateration process (either calibrated dry-lines or strings on a map) that they had used in class in learning the skills.

What then, could account for the difference? While the classroom teacher organized students into teams for the epicenter determination activities and encouraged students to rotate roles within those groups, ultimately the choice of whether and how to participate rested with the individual learners. One possible explanation is that the opportunity to engage in the activity might have been diminished in the non-embedded case because it was more difficult to share responsibilities; determination of the epicenter, for example, required only a single student in the non-embedded condition whereas a pair of students (one anchored at the seismograph, one sweeping out arcs at the other end of the dry-line) was required in the embedded condition. An alternative explanation is that the motivation to participate in the non-embedded condition was damped by the fatigue or boredom induced by the massed scheduling, predictability, or less physical nature of the activity, or by the more restrained "impact" of the fruits of their labor on the accumulating inquiry evidence base.

The significant pre-post gains on the items related to seismometers and their uses, we believe, might be direct outcomes of the real-time and embodied nature of the embedded condition. In the embedded condition, students had the opportunity to witness the differential arrival of P- and S-waves at the simulated seismometer both visually (a change from "flat-line" to higher-amplitude graphs) and aurally (the rumble accompanying the arrival of the first wave). This may have reinforced their understandings of the seismometers as responsive instruments whose relative performance was dependent on their (differential) distances from the simulated seismic events.

Post-test performance on the trilateration items showed only weak gains for students in the embedded condition, and in fact a small loss for students in the non-embedded condition. We suspect that these results may be an artifact of the assessment items, which situated students in a transfer task requiring them to identify the loci of points defined by cartoon characters looking for one, two, and three items located around them, a task some students had difficulty in interpreting.

Students in both groups improved in their declarative understandings of the distributions of earthquakes, with students in the embedded group showing about twice the level of improvement from pre- to post-test assessment. Here we suspect that the salience of the representations of the empirical data (Styrofoam balls hanging from the ceiling and large posters with representations of the formative data at the front of the room), combined with the longer time course of the data collection process, worked to learners' advantage in recognizing the emerging patterns.

The most surprising result was the significance of the difference in learning gains on the Earth science concepts (structure and causes of earthquakes) between the two groups. It is important to keep in mind that the learning activities associated with these concepts were identical in both classes, and were decoupled from the activity associated with the determination of event epicenters, in that the earthquakes themselves were merely the surface manifestations of underlying structures and processes not explicitly represented by our technologies.

While the "embedded phenomenon" strategy incurs minimal technology and materials costs, its use in classrooms demands significant preparation and scaffolding effort on the part of teachers. A necessary prerequisite to broader use of the technique is the existence of an evidentiary base that associates its use with positive learner outcomes across teachers and science content domains. The research presented here represents the first products of an ongoing counter-balanced multi-classroom, multi-domain research study that will be completed in 2010.

**Abstract:** This paper presents a case study in which a middle school science teacher modifies her classroom instruction and teaching materials using the Structure, Behavior, and Function (SBF) representational framework to transfer her reasoning about one natural system (an aquarium ecosystem) to another natural system (human cells and body systems).

Promoting an understanding of complex systems is a difficult yet important component of scientific literacy (Sabelli, 2006). Through emergent processes and localized interactions, the behaviors of a system's components affect its overall function (Jacobson & Wilensky, 2006). These interactions are often dynamic and invisible which make them difficult for learners to understand and presents challenges for teachers (Feltovich et al.,2001 Hmelo-Silver et al., 2007).

The Structure-Behavior-Function (SBF) conceptual representation allows students to understand the relationships between the structures, behaviors, and functions of systems and to map SBF across multiple levels. In the science classroom, academic researchers have developed tools utilizing the SBF representation as a way to teach about multiple complex systems (Hmelo-Silver et al., 2007; Liu & Hmelo-Silver, 2009). Structures are defined as the components of a system, behaviors as the mechanisms or processes that occur within a system and functions as system outputs (Goel et al, 1996; 2009). We present a case study of a teacher who appropriated the SBF conceptual representation that was originally introduced by a team of researchers, to create tools to meet her curricular needs. The focus of the study is to understand how the teacher transferred the use of the SBF representation between two different curriculum units. Some of the common critiques against the classical approach of transfer have put the spotlight on questions related to the conditions that facilitate transfer, the context of instruction, and the pertinent cues that learners need to be able to identify that signal the application of appropriate problem solving strategies (Lave, 1988, Bransford et al., 2000; Mestre, 2003). The study looks at transfer under two alternate perspectives and the possible synergy between using multiple perspectives to study transfer.

Our study considers transfer from both an actor oriented approach (Lobato, 2002, 2006) and a preparation for future learning perspective (Bransford & Schwartz, 1999) to investigate the teacher as learner applying knowledge in a new area. We look at the influence of previous activities and procedures adopted by a learner to construe similarities in new situations (Lobato, 2006). In particular our interest is in understanding how a teacher constructs the relationships and similarities between two systems; one provided by researchers and one designated by the teacher. Adopting an actor oriented perspective requires considering which connections the learners make, on what basis, and how and why those connections are productive (Lobato, 2002). Evidence for transfer from this perspective is found by scrutinizing a given activity for any indication of influence from previous activities. Additionally, we investigate how a greater understanding of SBF might have contributed to transfer from a preparation for future learning (PFL) perspective. This provides a framework for evaluating the quality of particular kinds of learning experiences (Bransford & Schwartz, 1999). The PFL perspective allows us to uncover strategies that have been adopted to interpret a new situation; "Interpretation of the situation invariably involves some use of a previous experience it cannot be reduced to a simple replication of that experience" (Broudy, 1977, p. 11). Integration of these two perspectives on transfer was crucial to understanding the importance of activities and experiences (from an actor oriented perspective) which prepare the learner to develop new concepts that, in this case, focuses on transfer between complex systems.

## A Case of Transfer: The Instructional Context

The context for this study is a technology-intensive curriculum unit that helps middle school science students learn about an aquarium ecosystem using SBF as a conceptual representation. The learning environment is comprised of two parts; (1) Reptools toolkit and (2) The Aquarium Construction Toolkit (ACT). The RepTools toolkit includes a function-oriented hypermedia (Liu et al, 2007) and NetLogo computer simulations (Wilensky & Reisman, 2006). The hypermedia (Figure 1) introduces the aquarium system with a focus on function and provides linkages between structural, behavioral and functional levels of aquariums. In addition, two NetLogo simulations are included to make the macro and micro level behaviors visible to the learners. The second component to the learning environment, ACT, allows students an opportunity to organize their understanding about complex systems by explicitly identifying structures, behaviors, and functions in both an SBF table (Figure 3) and through concept mapping which allows relationships to become explicit (Figure 4). This gives the students an opportunity to understand both individual mechanisms and the meta-level concepts related to complex systems (Goel et al, 2009)

In this study, we highlight a particular case in which a teacher participant, Ms. Y, who has been working with the SBF Aquarium curriculum for more than five years, developed her own instructional tools using the SBF representation and computer-tools to meet her classroom teaching needs. In the fourth year of enacting the SBF Aquarium curriculum, Ms Y used the SBF representation as an instructional tool to teach about the cell and human body systems (digestive, reproductive, respiratory etc.). The result, in collaboration with another science teacher from the same school, Ms. T, was the creation of a human body system hypermedia modeled after the function-centered aquatic hypermedia.

## Methods

To characterize how the SBF representation is appropriated by Ms. Y and to understand the processes by which the teacher transfers these tools to other domains, we adopt a qualitative approach. An interview with the teacher and video analysis sessions were conducted to understand (1) why the teacher transferred her understanding of SBF to new instructional domains and (2) how she transferred these understandings. We held an interview session with Ms Y after she had completed teaching about both the systems. The primary focus of the interview was to understand how she conceived the idea of extending the computer-based representational tools beyond what was expected from her, the influence of her prior knowledge during this process and her attempts to prepare herself to solve new challenges. After the interview transcription, we looked for evidence of mechanisms for transfer and how the teacher constructed similarities between aquarium and body systems.

To understand the nature of transfer in Ms. Y's teaching of the content, we selected representative clips of critical events from Ms. Y's classroom that demonstrates evidence for using the SBF as a tool to teach about another complex system. These video clips included whole class discussions that Ms. Y has with her students while (1) introducing the SBF concept for the aquatic ecosystem the year before she created the cell/body unit (2) introducing the SBF concept for the aquatic ecosystem the year she employed her cell/body unit and (3) explanation of SBF and modeling of the cell/body unit. These clips include three classroom interactions for all three time interactions under evaluation. These video data were analyzed using Interaction Analysis (IA), which involves collaborative viewing of video clips of a group of researchers to examine the details of social interaction (Jordan & Henderson, 1995). The basic goal of IA methodology is to use the video data to understand the means by which people interact in social environments and how, if any, learning takes place. We conducted nine IA sessions successively to collaboratively review the selected video clips, describe observations, and generate hypotheses.

## Results

### Teacher Created Hypermedia

Ms Y., in collaboration with her colleague Ms. T, created a hypermedia in the form of an interactive PowerPoint of the cell and body systems mirroring the aquarium hypermedia developed by the research team (Figures 1 and 2). The teacher hypermedia outlines the different structures in the system along with leading 'why' and 'how' questions. The 'how' questions are directed towards understanding the behavioral aspect of system components and the 'why' questions focus on functions. The teacher created hypermedia was developed as additional learning resources to textbooks to connect cell systems to higher order body systems. Neither the body system hypermedia nor the use of modeling these systems using the ACT software was planned by the research team; the teachers did this of their own volition.

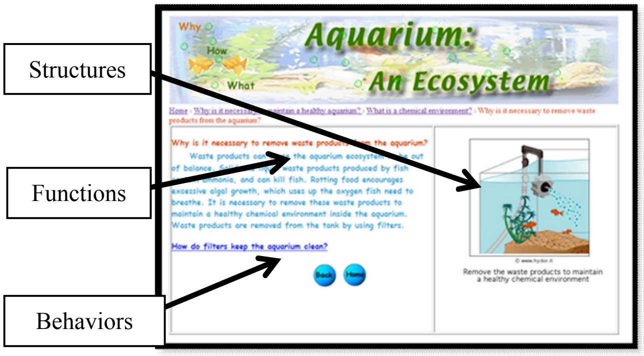

Figure 1. Researcher-developed hypermedia

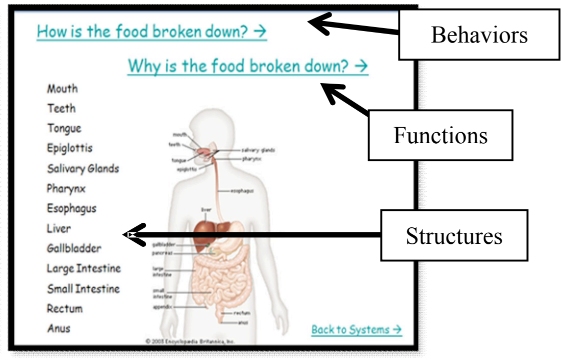

Figure 2. Teacher-developed Hypermedia

## Identifying similarities through the SBF lens

Ms Y's initiative to extend and appropriate our research and develop additional classroom tools led us to consider the process of transfer. We intended to understand the processes she adopted to draw similarities between what she had been teaching for several years (the aquatic ecosystem) to the current unit she developed (cell and body systems). Adopting an actor oriented perspective helped us to articulate which connections she makes, on what basis, and how and why those connections are productive (Lobato, 2002). A PFL approach allowed us to understand how her learning experiences may have prepared her to apply the SBF representation when she created her new hypermedia. Our hypothesis, based on the interview, is that she used the SBF as a tool to trace similarities across complex systems. For example, consider the response when both Ms Y and Ms T were asked about the utility of their hypermedia:

**Researcher**:…what is the purpose of the Hypermedia you guys came up with? And how does it help you teach about complex systems?

**Ms. Y.**: Okay, first we were teaching the cell. And we also have to teach body systems especially in the new standards, so its going to work out that we're actually covering both of those. But they teach the cell as an isolated entity. And we were saying that you know the whole body is made of cells and you know you teach the systems separate, you teach the cell separate, and then we just name the parts of the cell and tell what each part does. And there's no connection about how the parts interact, interact with each other in the cell, let alone how the cell interacts with the whole body.

**Ms. T**: Because kids don't even know that each- Like you're bodies is made up of cells, they just think of it as cells.

**Researcher**: Everything discrete?

**Ms. T**: Right. .., everything's separate and that you know, the idea that everything is made up of different types of cells and the cells work together; they just don't get that, at all.

**Ms. Y**: Right, and it's a hard concept to get. So, what we were thinking about is like the kids actually think when they eat food it breaks down and then leaves the body. They don't get that the food has to go to the cells and the cell actually works and creates energy from this food and then there's a waste and it sends that back to the body for it to be excreted. So we're trying to give them not only the names of the parts and what each part does individually but how it needs to work-

**Ms. T**: I would say we're trying to bring in the behavior into it. They get the structure, we teach part the function, but there was never that behavior why does it need to do what it does….

**Ms. Y**: And we're doing the behavior not only of the cell itself but behavior of all the systems and then the behavior of the whole body. And the cells are all part of that whole body.

This excerpt highlights that Ms. Y understood that the cells are an integral part of the body systems and cannot be taught in isolation. She discusses that systems in the body are not disconnected and have complex mechanisms which allows for higher order operation. It is apparent that she understands how structures within a system perform multiple behaviors in order for it to function effectively. Owing to the strong connection to the SBF representation, we felt it critical to observe the learning trajectory she adopts to refine her understanding of the SBF as a conceptual tool. This led us to analyze Ms. Y introducing the SBF concept (via IA sessions) over multiple years to determine how she may have refined her own understanding of SBF as a basis to then extend it into a new area.

## Refining SBF as a Conceptual Tool

Upon examining Ms. Y's classroom introduction of SBF over time, analysis of the video suggested that her understanding of the SBF representation as a conceptual tool changed. She adopted several distinct strategies to introduce the topic of complex systems ranging from discrete (the year before she developed her unit), to acknowledging complexity (the year she developed her unit), and finally providing a systems perspective with her new cell/body unit. The year before developing her new unit, she began her introduction to the SBF representation by mentioning the new terminology being used to discuss the system, however, she introduced structures, behaviors, and functions as individual constructs that should be dealt with discretely. In the following year, she promoted the SBF representation as a comprehensive perspective, acknowledging it as a conceptual unit. Finally while introducing it within the context of the unit on cells and body she explains it as a system, complete with nested subsystems and stressed the importance of inter-relatedness.

Ms. Y's early introduction to SBF suggests a focus on linear connections. This is shown by the way in which she fills out the ACT SBF table (Figure 4) in front of the classroom. As a way to connect ideas about the Structure, Behaviors, and Functions, she drew clear conceptual lines between one structure at a time and all the behaviors exhibited by that structure as the following example shows:

**Ms. Y:** We just named them all yesterday ... The heater, the fish, the plants. Those things are called the structure. The next word we're gonna use is Behavior. The behavior is what the fish do. What do the things do in the tank? And the next word we're gonna use is Function, okay? So what I want to do today … to start with structure and behavior….. So, I made a chart and …The first column is the structure, or the parts. So everyone write down one of the things in the fish tank is fish. and the second column I wrote was behavior, and the third column I wrote was function. We're going to start with this second column which is behavior. When I ask you the behavior of something, I want to know is what does it do?

**Ms. Y:** "What do fish do?" Swims, eats, breathes, and poops. Okay, all fish swim. That is their behavior okay. They swim. What else do fish do?

**Andy:** Breathe

**Ms. Y:** They breathe. What else do fish do?

**Andy:** Eat..

This excerpt indicates that, after covering structures the day prior, she begins by describing the meaning of the term 'behavior'. This was immediately followed by establishing all linear connections between the structures (fish) and the multiple behaviors (swims, eats, breathes, poops) that this structure exhibits. After promoting an understanding of the behavior exhibited by the structure (fish), she then drew another relationship between each individual behavior to the last column to indicate the behavior's function.

Over time, Ms Y's introduction to the SBF concept became richer and more complex. In the excerpt below taken from the year after she developer her unit, she describes SBF as interconnected entities within a system, rather than discrete elements on a worksheet:

**Ms. Y**: Okay, now, let's do the filter.…. I'm gonna do the filter with you and then you're gonna do one on your own. Alright, so… what does the filter do? What does the filter do? Jim what does the filter do?

**Jim**: Um, cleans out the tank

**Ms. Y**: Cleans the tank. Or cleans the "what part of the tank?"

**Jim**: The water in the tank?

**Ms. Y**: All right, so the filter will clean the water. Okay? Now, why does it clean the water?

**Jim:** So it can put more oxygen into the water?

**Ms. Y:** No. That's another thing that it does. It actually, because it's spinning around, because it's spinning like this, it's actually, one of the things it does- we could make a second bullet- is it adds oxygen to the water. Now, this part here, why does it do it? First of all, I want to stop right here. The filter is this big grey thing here. Right? Now, first of all, how does it work? What's this big tube doing? *[Points to picture of filter on the screen.]*

**Pat**: Sucking up the water

**Ms. Y:** Sucking up the water. Then the water comes up here, right? And it gets sucked up and it goes back here and it pours back down. When it flushes back over that's when the oxygen from the air can get pulled back into the water. Okay, so how- you said it cleans the water- how does it do this?

**Pat:** Well, it has in the filter. The filter has like chemicals and stuff… well like, (inaudible) right here, we're gonna start with the fish tank. This bag, because right here..

**Ms. Y**: What do you think is in this bag?

**Pat:** Bad stuff

**Ms. Y**: Well, eventually the bad stuff is going to get in here, but actually there's charcoal in here, gravel in here. And then when the water flows through it, can it catch all the big chunks?...Maybe the fish feces and stuff like that? So, and then see how it spins back down here? Water splashes and it's pulling in the oxygen. So now… Alright, so now, why does it clean the water? What is the point of cleaning the water? Because of the what? Right, it keeps clean water for the who?

The class went on to discuss the fish and the plants, and how the filter aerates the tank and what the filter does for the whole system. In this example, when Ms. Y discussed the behaviors (cleans water in tank) and function of the filter (by collecting feces from fish) she was guiding students' answers to S, B, and F simultaneously and filling in the chart appropriately rather than focusing on any one aspect in isolation. Ms. Y also used student answers to generate more questions that linked what (Structure) and why (Function) questions throughout her classroom discussion, highlighting the complexity of how the system works.

Later in the same year, when introducing her unit on the cells, Ms Y emphasized how the SBF within a system work as a whole across multiple levels, not directly, but implicitly by leading questions as seen from the example below:

**Ms. Y:** Eventually what we want [the researchers] to do for us is allow us to model systems within systems. What happens if I can click on the cell and zoom in on that and put the cell parts in there? Because they don't have the ability to zoom right in on that one part, are there any ideas on how to connect the cell through modeling to the other body systems? Because you also want to go and look at the function. What do you think?

**Lucia:** Umm, what about if you like umm put a picture of the cell.

**Ms Y:** Yeah but I want to drive everything to the cell because that's, you know, the whole body operates to get things to the cell, you know that right? But then I also want to show what the cell does inside once you send the food there. So how can I show that part? How can I show it on this graph? Okay. You know how this is a system. The body parts and the cell is its own little mini system, how can I show the stuff inside the cell? Should I circle all the mitochondria right around the cell? Or should I pull the cell out and make that part separate? **…**Okay so here on this side we'll do all the body parts connected to the cell, and over on this corner do you want to do the cell again and show the inside of the cell..

These excerpts demonstrate the process of refining of Ms. Y's thinking about the SBF concept as a conceptual tool. Whereas earlier, her focus was primarily in working with living organisms in the aquarium (fish), she later introduced a new level of complexity by trying to relate the influence of non-living structures on other living organisms. She was still focusing largely on structures but she does make connections to behaviors and functions. In addition, she helped students understand that one structure may have multiple behaviors and functions. Comparing her SBF introduction of the cell system here to that of the aquatic ecosystem in the earlier unit, she presented it to the class as an entire system and not as fragmented pieces as S, B & F with linear connections. In addition, when applying SBF to the cell, Ms. Y introduced a meta-perspective by explicitly explaining that the task was to represent their ideas through modeling. Moving away from the isolated task provided in earlier in the context (i.e., filling out the table by first listing structure followed by behavior, and then function) Ms Y explained that the students are going organize their knowledge in the table graph. By placing emphasis on the modeling tool and providing students with the starting point of the structure, the cell, Ms Y explains that the task is to develop a representation of their ideas about the human body system, using the table to organize their ideas and providing the students with leading questions that she had provided earlier when talking about the SBF in the aquarium unit.

This process of transition led us to believe that Ms Y. was an active learner herself. As she explored the aquarium hypermedia and talked about SBF representations in her class, she frequently asked questions to the research team and her colleague Ms. T., to refine her understanding. We think this experience had two effects. First, it helped her identify and address the gaps in her understanding, which prepared her for future learning. Secondly, it shed light on the processes that she as an actor (learner) use to construct similarities between the aquatic ecosystem and cell system (Lobato, 2002).

## Recognition of Teacher as a Learner

In the interview, Ms. Y indicated that since the beginning of her involvement in the project, her knowledge has continually developed. She explained that she was the primary source by which information was passed from the research team to the students and that, over time, she felt that she has become more competent in this role. Effective learners learn to look critically at their current knowledge and beliefs (Bransford, Brown, & Cocking, 2000) instead of making old responses by simply associating new information to the existing concepts or schemas. In the following excerpts from the interview, she acknowledges her lack of mastery over the content and is aware that she refined her ideas of the SBF representation and the aquarium unit which lead to adoption of the new unit:

> Okay, my knowledge of this still develops every year because it's knowledge that [Project PI] had and it- you know- was her angle on something and then I had to try to understand what was going on in her head. So it's taken me many years of practice and talking to [Project PI], talking to [researchers in the room], to kind of get this. And I still do not feel like I'm really solid on it, but I get it more and more each year.

These statements demonstrate Ms Y as a learner in her classroom as she was looking critically at her current knowledge and beliefs (Novick, 1988). This experience prepares her to deepen her understanding of the content, and revise her ideas as she gathers new information.

## Appropriating Salient Features of the Aquarium Hypermedia

When asked about what parts of the Hypermedia she found useful in her own development, Ms. Y felt that working with the same piece of software for 5 years allowed her to incorporate key features within the hypermedia she created. Although her hypermedia does not possess the technological and conceptual sophistication of the aquarium hypermedia, it prepares her for refining her model along a trajectory of increasing expertise (Figures 3 and 4). Moore & Schwartz (1998) suggest that even if students generate representations that are not entirely correct or are faulty, these experiences help them in noticing critical features of experts' representations. This process is important from an actor-oriented transfer framework, as it enables her to see the connections between two situations by identifying the salient features of one learning environment (Lobato, 2002). The excerpts below demonstrate how she is expanding upon her knowledge to integrate important characteristics from the aquarium hypermedia:

> I would say that I definitely liked how each question lead to another question because that's how we modeled ours was every question gave an answer but then lead to another question and another question and another question.

The above excerpt highlights a key feature of the aquatic hypermedia of linking different concepts via leading questions. The students can learn about the behaviors and functions of different structures by browsing these questions.

Another important feature of the hypermedia is its presentation. Each section comprises of a brief description accompanied by a visual image. The following excerpt highlights the fact that Ms Y used it as a parameter while constructing her hypermedia:

> We also used just short pieces of information because I think the kids get bored if you put too much it's overwhelming. We used pictures and then we also had it not only lead to different the next one and the next one but it bounced back sometimes a design in the hypermedia too.

It is clear that as Ms. Y. identified the relevant features of the aquarium hypermedia. This process of experimentation is also helping her clarify her own thinking (Bransford et al., 1990) about the concepts that she is placing within the new hypermedia contexts. It is notable that she transferred other features of the hypermedia structure beyond SBF, including the use of guiding questions as well as the use of short pieces of text accompanied by simple and relevant graphics.

## Appropriating ACT to Model a New System

In addition to appropriating aspects of the Aquarium Hypermedia, Ms. Y also appropriated the ACT program so that students could model body systems in the same fashion as they had for the aquarium system. After students read through the body system hypermedia, they were instructed to develop SBF tables and concept maps using the ACT software (Figures 3 and 4). The following excerpt highlights Ms Y's intentions of evaluating student understanding when placed into the ACT program:

> …at first she [PI] came and she was just testing the kids knowledge and that I was not really involved and then we started, actually we started originally started talking about the cell and the

> body so that was one of the things then she got the idea of the respiratory system because that was an area she worked in and then she, this slowly develops into you know the NetLogo and the Hypermedia then structure, function, behavior, and I think for me it was all just disjointed all the pieces were here and I was just trying to keep up with her. And then…the ACT program helped a lot because it sort of put everything together for me in the end, like okay, here's all the knowledge that the kids have been getting along the way, here is proof that they got it. And for me it was just a slow process of absorbing everything and you know kind of understanding it until I could you know turn key it and then we could turn around and together make another Hypermedia with it

We think that this exemplifies the importance of the ACT software as a capstone to allow for student understanding of the new system to become explicit. This example from the interview, and the classroom task of modeling body systems in ACT, indicates that Ms. Y possessed the confidence to organize the new ideas generated by her hypermedia into SBF terms using the tool and the importance. Additionally it also highlights her ability to appropriate the ACT tool as the final classroom task to evaluate knowledge generated by the hypermedia as a way to organize student ideas about complex systems.
