The most relevant contribution our study makes to the current research on alternative approaches to transfer (Lobato, 2004, 2006; Bransford & Schwartz, 1999) is to further expand on the notion of looking at new ways for understanding learning trajectories. As we observed Ms. Y's transition over multiple years our focus was not in assessing mastery over content knowledge but on the processes she adopted during this transition. In terms of learning trajectories, our results highlight the fact that Ms. Y is looking critically at her current knowledge and gradually evolves to an experienced novice within that content area. Data analysis from earlier years reveals an early understanding of the SBF as a conceptual tool. However, she actively sought resources (fellow colleague, Ms. T; project PI; other researchers present in the classroom) to help her understand the interconnections between SBF. Her increasing confidence in the content area, coupled with collaboration, resulted in her being highly motivated to extend the research tools. From a PFL perspective both these processes are vital as she is able to revise her current knowledge and beliefs and it sets the stage for her to analyze and appreciate critical features of the new information presented to her (Bransford et al., 1990; Moore & Schwartz, 1998). This process of analyzing her own beliefs and strategies also targets the active nature of transfer, which is an important part of PFL. The initiative she took in applying her SBF understanding to teaching a new unit demonstrates her ability to revise and rethink the current situation to suit her current goals. Even the hypermedia she created echoes the same pattern of organization as that of the Aquarium Hypermedia. From a PFL perspective this is valuable as it reveals the importance of activities and practices that are beneficial for "extended learning" rather than on one shot task performances (Bransford & Schwartz, 1999). The analysis presented in this study suggests the possibilities of extended research within the field of nontraditional approaches to transfer. In our case, teacher adoption and appropriation of a learning framework was an exciting by-product of scholarly research because it indicates promising evidence that classroom interventions can be sustained and built upon to be appropriated given specific curricular need. Additionally, our analyses characterize that under the correct conditions, some teachers may be motivated to create their own learning tools when the knowledge is transferred to a new domain, thereby extending the reach of classroom interventions.

**Abstract:** Do different disciplines cultivate different epistemologies? We draw on the epistemological framework of D. Kuhn et al. that delineates three perspectives: absolutist, maintaining that knowledge is objective and immutable; multiplist, maintaining a radical relativism; and evaluativist, maintaining a qualified relativism. We conjectured that typical instruction in the humanities would tend to foster evaluativist views more than typical instruction in the sciences. Twenty biology majors and twenty history majors evaluated competing accounts in biology, history and judicial contexts. Structured interviews concerning these accounts were used to assign each participant an epistemological view in each discipline. These results were considered in conjunction with learners' reports of their educational experiences. We were disappointed to find that there was an overall tendency toward absolutism. Our main finding is that students are distinguished by major and epistemological view, and that typical history instruction more than typical science instruction seems to foster evaluativist views in history.

## Introduction

Learners' epistemologies are of increasing concern to learning scientists. What learners believe about the certainty and simplicity of knowledge, and about the source and justification of knowledge influences how they approach knowledge construction and learning (Hofer, 2004; Schauble, Glaser, Duschl, Shulze, & John, 1995; Songer & Linn, 1991). Schooling and level of education appear to be a strong factor in the development of these beliefs (Kuhn, Cheney, & Weinstock, 2000; Schommer, Calvert, Gariglietti, & Bajaj, 1997). Although developmental patterns have been associated with grade level, it seems that educational experiences rather than age explain most differences in epistemological views. Unique educational experiences are associated with epistemological perspectives that depart from that grade-level's norm (Smith, Maclin, Houghton, & Hennessey, 2000), and classrooms with different curricular foci at the same grade level can be characterized by different epistemological belief patterns (Tabak & Weinstock, 2005).

Moreover, there is increasing evidence that epistemological views are discipline-specific, that is, the same individual may hold different beliefs about science than about art or psychology (Hofer, 2006). Despite differences between disciplines, there seems to be some measure of regularity concerning beliefs within and about particular disciplines. This suggests that learning experiences are key in shaping epistemological views, and that different disciplines cultivate different beliefs about the nature of knowledge. In this paper, we report on a study that examined whether different disciplines, college-level biology and college-level history, fostered different approaches to knowledge. Specifically, we compared the ways in which biology majors and history majors evaluated competing-claim scenarios in biology, history and judicial domains. In addition, we explored whether students' approaches to these tasks and any differences among them seem related to students' accounts of their college learning experiences.

## Background

### The Absolutist, Multiplist, Evaluativist Framework

We approach this exploration of biology and history majors' epistemological views from the framework advanced by Kuhn and her colleagues (e.g., Kuhn & Weinstock, 2002). This framework is consistent with a number of approaches in developmental psychology's investigation of personal epistemology (Hofer & Pintrich, 1997). The framework distinguishes between three approaches to knowledge: (1) "absolutist"—the conception of knowledge and knowing as objective and absolute, (2) "multiplist"—regarding all knowledge as subjective and relative and, therefore, indeterminate because of multiple points of view, and (3) "evaluativist"—a qualified subjectivity that integrates subjective and objective aspects of knowledge, permitting a degree of evaluation and judgment of knowledge claims. Table 1 elaborates some of the beliefs about the certainty of knowledge, the source of knowledge and the justification of knowledge that are associated with each of these perspectives.

Table 1: Characteristics of epistemological views along central dimensions of the nature of knowledge

| | Absolutist | Multiplist | Evaluativist |
|---|---|---|---|
| Certainty | Knowledge is certain. Any uncertainty results from error or insufficient information. | There is no certainty. | There is no certainty. But, one account may be more trustworthy if there is more evidence to support it. |
| Simplicity | There is one single correct account based on self-evident facts. | There are multiple accounts. | There are multiple accounts each containing different types of information, arguments, and interpretations. |
| Source | Knowledge comes from experts or authority that are able to discern the objective reality. | Knowledge derives from opinions. | Knowledge is constructed. |
| Justification | Facts either prove or disprove knowledge claims. | Knowledge claims can never be truly defended, because all opinions are equally valid. | Preponderance of valued sources of evidence. |

## Why Adopt this Developmental Framework in the Learning Sciences

This framework has been employed mostly in the area of developmental psychology. In the learning sciences, research on epistemology has focused more closely on particular disciplines, predominantly science, and has focused on the distinction between absolute and dynamic or constructivist views of science/knowledge (e.g., Hogan, 2000; Songer & Linn, 1991). We have found that the Kuhn et al. framework has refined our understanding of epistemological perspectives within particular disciplines, and especially in science. In particular, this conceptualization reveals nuanced distinctions that might exist in students' specific conceptions of the nature of science, by pointing to two perspectives that can fall under a constructivist or dynamic view of science. For example, learners who note that two scientists can look at the same data and arrive at two different but correct explanations may be attributed with a dynamic view of science. Yet, when viewed from the Kuhn et al. framework, there are two possible epistemological views that might underlie this position: a multiplist or an evaluativist perspective. This distinction has important implications for learning in the disciplines, and most notably in inquiry-based science, because of its impact on an individual's inclination to critique and refine explanations.

Being inclined to judge the value of a claim or explanation rests on a consideration of knowledge as a product of construction. If knowledge is considered immutable, then it makes more sense to simply assimilate the new information, than to question the strength of its warrants or explanatory power (Songer & Linn, 1991). This depicts an absolutist perspective, and this depiction is a point of convergence between the prevalent approaches in the learning sciences and in developmental psychology. Yet, even if knowledge is considered constructed, there may not be much motivation to critique it if radical relativity, multiplicity, is espoused. That is, if people believe that all claims are equally valid then critique may seem like a pointless exercise. This is in contrast to scientific practice, where explanations are continually critiqued and refined in order to arrive at the most parsimonious explanation that explains the widest range of data or phenomena. This type of practice is motivated by seeing knowledge as constructed but subject to adjudication. Or, in other words, on adopting an evaluativist perspective. In sum, an evaluativist, but not a multiplist perspective would be commensurate with science learning goals, but this distinction would not be perceptible in the absence of the Kuhn et al. lens.

## The Present Study

We conducted the present study as a follow up to earlier surprising findings. In an earlier study we compared epistemological perspectives between a “regular” school and a science-centered school that has an extended project and inquiry oriented science curriculum. We had expected students in the science-centered school to tend more toward evaluativism, especially in science. However, these students actually tended toward absolutist views in science (citations omitted for blind review). This led us to consider why an emphasis on science might lead to absolutist views. We conjectured that the emphasis on science made broader societal beliefs, such as the belief in the superiority and certainty of science more salient, and that these broader scripts shaped learners' views about science. In response to our surprising findings, we also began to explore learning in other disciplines, and further conjectured that instruction as it is typically carried out in the humanities, and especially in art, would foster evaluativist views to a greater extent than typical science education. There is a measure of irony in this line of conjecture – in the sense that the disciplines that are less privileged in society, such as art in comparison to science cultivate the epistemological views that are more valued (at least from a Western social science perspective).

Therefore, we set out to compare the epistemological views of students in a scientific discipline and in a humanities discipline. We focused on biology and history as a function of access to participants, and of our prior research experience. We expected history majors to tend more toward evaluativism than science majors. We expected students to have differentiated views concerning their own and other disciplines. As we noted in the introduction, prior research has documented discipline-specific and differentiated epistemological views (Hofer, 2006). Many of these studies employed questionnaires that ask participants about how knowledge claims are handled in different disciplines. We were interested in examining how learners' epistemological views come into play and guide their decisions in contextualized reasoning tasks. Questions about a discipline might trigger stereotypes and societal scripts, but performance on a task, we thought, was less susceptible to these threats. So, we decided to compare students' views by comparing their reactions through structured interviews to competing accounts in their major discipline, in the other group's major discipline, and in an everyday context.

## Methods

### Participants

We interviewed ten university biology majors and ten university history majors in a university in Israel. The students were in their second or third years of study. Undergraduate studies in Israel in the humanities, social sciences and natural sciences are three years long, so third year students in particular were at the final stages of their undergraduate disciplinary education. Importantly, undergraduate studies in Israeli universities are very discipline-focused, that is, almost all of the coursework in completed within the department of their major. This often includes various "service courses," for example, students majoring in education, psychology and sociology may each take a statistics course, but they will not take the course in the statistics department, rather they will take the course in their respective departments. This lends more support to attributing any differences found between biology and history majors to their disciplinary socialization. It also suggests that any disciplinary socialization that we may find may be stronger than in more interdisciplinary contexts (such as the emphasis on a rounded education in liberal arts that is found in many colleges in the United States).

### Task

Our task draws on earlier work by Kuhn and Weinstock (2002), who presented participants with competing accounts of historical cases. Our task included three scenarios from three different disciplines: biology, judicial, history. The biology case was adapted from learning environment design work by Linn and colleagues (Linn, Clark, & Slotta, 2003). The judicial case was loosely adapted from a case used in earlier studies (Kuhn, Weinstock, & Flaton, 1994) to assess argument skill (the original cases were abridged and selective versions of actual cases). The history scenario was adapted from the Kuhn & Weinstock study. . The three disciplines were chosen so that each participant will engage with a scenario from their discipline of study, a scenario from the other group's discipline of study, and a scenario from an everyday domain. Each of the three scenarios depicts competing accounts of the same events. Figure 1 shows an English translation of the biology scenario. Each scenario was followed by a post-task epistemology interview that targeted the participants' views of the dimensions of personal epistemology, mainly the dimensions of certainty, source and justification of knowledge. Figure 2 shows the post-task epistemology interview guide for the biology task. There were only slight variations in the post-task epistemology interviews to accommodate the different disciplines, for example, whether historians or scientists were named in the questions. We also questioned participants about their learning experiences, and in particular, whether they had encountered discrepant accounts as part of their major area studies. Figure 3 shows this post-task learning experiences interview guide.

Across North America frogs are being found that have major physical deformities. Some frogs have deformed eyes. Others have misshapen or multiple legs -- or they are missing their legs altogether! The following are two brief accounts of why the frogs are being deformed.

A brief account of why the frogs are being deformed
By G. Agmon
Scientist investigating the frogs

North American frogs have been found with deformed legs. The deformed frogs have cysts in the area from which their legs develop. These cysts are caused by parasites. The parasites enter the tadpole early in its development and burrow into the area from which their legs develop. As the tadpole develops into an adult frog, the cysts caused by the parasites interfere with normal development, and the frog develops with leg deformities such as multiple legs or no legs.

In order to test whether the parasites cause the deformities in the frogs, small plastic beads were surgically implanted into tadpoles in the location where cysts were observed in adult frogs -- in the area of the body from which legs develop. Many of the frogs that developed from these tadpoles had multiple legs and feet coming out of the area in which the plastic bead was implanted. Parasites in the water are causing these deformities in the frogs.

A brief account of why the frogs are being deformed
by M. Moyal
Scientist investigating the frogs

In recent years, North American frogs have been found with deformed legs and eyes. Chemicals in the water are causing deformities in the North American frogs. The chemicals in the water come in contact with the tadpoles while they are developing, and this contact causes a reaction that interferes with normal development. As a result, the adult frogs that develop from these tadpoles have deformed body parts.

In order to test whether the suspected chemical was in the water, a sample of water from the area where the frogs live was taken. The water was treated with a substance that is known to cause a reaction with the suspected chemical, and the expected reaction did indeed occur. In order to test whether this chemical can cause the observed deformities, the chemical was applied to normal tadpoles, and the frogs that developed had deformities similar to those observed in the North American frogs.

Figure 1: Biology scenario adapted from Linn et al.

Explain in your own words what is going on with the frogs?
- Can you elaborate?

Are the two scientists' explanations significantly different?
- What are the differences between them?

Is it possible that both explanations are correct?
- If not, why?
- If so, how is it possible?
- Is one of the scientists' explanations more correct?

Can someone be certain about what is causing the deformities in these frogs?
- If so, how?
- If not, why not?

Would a third scientists' explanation concerning the frog's deformity be different from the two explanations that you just read?
- If so, why?

Figure 2: Post-task epistemology interview for the biology scenario

When you think about your studies here in college thus far, what seems important to you?
What stands out?

Have you changed in the way you approach knowledge, thinking or problem solving, not just in your studies? What do you think brought about these changes?
[Probe for types of educational experiences, and for educational contexts – college, high school, etc….]

In your studies, have you ever encountered a situation similar to the task you just did where there are two similar, but somewhat conflicting, accounts or explanations for the same event?
Can you describe that situation?
What did you think about it at the time? [didn't think much of it, seemed natural, found it confusing]
Do you think differently about it now than you did then? How so? Why?

Figure 3: Post-task learning experiences interview

### Procedure

A number of research assistants interviewed the participants. Each scenario followed the same sequence: The research assistant gave the participant a sheet of paper with the scenario and gave the participant a few minutes to read through the scenario. When the participant felt that they had read the scenario carefully, the research assistant interviewed them following the post-task epistemology protocol for that task, in a structured interview style (see Figure 1 for an example of the biology interview). The order of the scenarios varied across participants. After all three scenario interviews, the research assistant continued with the interview following the post-task learning experiences interview (see Figure 2). The sessions were audio recorded.

### Analysis

The interviews were transcribed and coded. Transcripts, devoid of identifying information, such as the subject's major, were segmented into statements. Each statement was coded as exhibiting an absolutist, multiplist or evlautivist perspective, based on the characterizations summarized in Table 1 For example, attributing differences between the discrepant accounts to error or lack of skill would be coded as absolutist, attributing differences to equally valid opinions would be coded as multiplist, and emphasizing interpretation over opinion would be coded as evaluativist. These response-level codes were used to assign an overall epistemological perspective per scenario to each interviewed participant. About 20% of the interviews were coded by a second coder with a high degree of agreement between the coders.

The learning experiences interview was not coded. Rather, after each participant was assigned an overall epistemological view, we grouped the learning interviews by major and epistemological view. We examined the interviews to see whether there were similarities in the learning experiences reports and whether these similarities corresponded to epistemological assignment, and or major.

## Findings and Discussion

The results of the epistemological view assignments are presented in Table 2, a capital letter “X” under the corresponding column denotes the epistemological assignment: A—absolutist, M—multiplist, E—Evaluativist. For some participants it was difficult to make a firm decision about their epistemological assignment, therefore, they were coded as being mid-way between two views. This is indicated in the table by two lower case letters “x” positioned midway between two columns.

We found that both biology and history majors tended to be absolutists in all disciplines, most pronouncedly in the judicial discipline, which was outside both group’s area of study. This is surprising, because prior research suggests that the majority of people maintain multiplist positions (Hofer & Pintrich, 1997; Kuhn et al., 2000). History majors were markedly absolutists in the biology scenario, tended markedly toward evaluativism in the history scenario, and tended markedly toward absolutism in the judicial scenario. Biology majors showed a clear pattern only in the judicial scenario where they were markedly absolutists. They also tended toward absolutism in both the biology and the history scenarios. We speak of these patterns cautiously, because our sample is small so assertions concerning patterns are prohibitive, especially in the absence of statistical tests.

The main finding is that history majors but not biology majors exhibit within their discipline of study an epistemological perspective that is distinguished from their views in the other disciplines. Moreover, the history majors’ view in the history scenario, their discipline of study, tended toward an evaluativist perspective, which is considered to be a more productive view in academic contexts. The difference between history and biology majors in the overall patterns of epistemological assignment, and the difference within the history majors’ assignments in their discipline of study versus other disciplines, suggest that history and biology students have different learning experiences and that these experiences give rise to different epistemological views when contending with discipline-specific content. It also suggests that epistemological views, and evaluativist views specifically, can be cultivated through instruction.

We do not have baseline data for these participants documenting their perspectives prior to their college education, so there remains some question about whether these patterns can be attributed to their college experiences. In addition, one could argue that there is a form of self-selection at play here that conflates the results. That is, it may be that people who maintain certain views tend to pursue certain majors. However, if this were the case we would not expect to see the type of within-major outside-of-major trends that we seem to be seeing for the history majors. Of course, these questions need to be probed more rigorously with a broader study that includes this type of baseline data. Nonetheless, we believe that the findings from the learning experiences interview lends support to our findings and claims, despite these methodological limitations.

Table 2: Epistemological view assignment per scenario per participant

| | Biology Scenario | | | History Scenario | | | Everyday Scenario | | |
|---|---|---|---|---|---|---|---|---|---|
| Major | A | M | E | A | M | E | A | M | E |
| History | | | X | | x | $x_a$ | X | | |
| History | X | | | | X | | | X | |
| History | X | | | | x | x | X | | |
| History | X | | | | x | x | x | x | |
| History | X | | | | x | x | * | * | * |
| History | X | | | | x | x | x | x | |
| History | * | * | * | | x | x | X | | |
| History | | | X | | | X | | x | x |
| History | * | * | * | * | * | * | x | x | |
| History | X | | | X | | | x | x | |
| Biology | | | X | X | | | X | | |
| Biology | X | | | | | X | X | | |
| Biology | X | | | X | | | X | | |
| Biology | | X | | x | x | | X | | |
| Biology | | | X | X | x | x | | | X |
| Biology | * | * | * | X | | | X | | |
| Biology | X | | | | | | X | | |
| Biology | X | | | | | | X | | |
| Biology | * | * | * | * | * | * | * | * | * |
| Biology | X | | | | | X | | X | |

The participants' responses to questions concerning their educational experiences at the university also show distinctions between history and biology majors. All of the history majors noted that they had encountered situations similar to those presented in the scenarios, where the same phenomenon or event is explained through competing accounts. Only four biology majors reported encountering competing accounts in their classes.

The History majors responded immediately, assuredly and fluently that they had encountered competing accounts in their studies, and easily provided specific examples. They seemed to associate this idea of competing or multiple accounts with "what History is."

For example:

> "Ah, actually yes. There are a lot of cases like that that show you some event and then ((two undecipherable words)) another direction and then you need uh to decide uh which interpreter you go for more. I usually just combine the two interpretations. Present uh there are some that say this and there are some that say that and I try uh not not to say anything conclusive. Which explanation is more acceptable. Because some think this and some think that. History is not an exact science. That is you can't uh say what is right and what is wrong. Anyone can come with his interpretation." [History major, translated from Hebrew]

> "(Laughing) of course I did. That's what you do in history. (Interviewer: Can you describe the situation). Yes, if I need to hand in a paper on two different sources that I need to compare and check who wrote from what perspective did he write, from what era did he write, and who paid him to write…so like I need to think about these things". [History major, translated from Hebrew]

The Biology majors hesitated, and were hard pressed to provide examples. Some biology majors referred to a different concept, such as being presented with different accounts on an exam and having to identify the correct one (i.e., multiple choice questions), or noted that there are proteins that have two different functions.

Despite their familiarity with the notion of competing accounts, the history majors did not express ideas concerning principled ways of critiquing competing accounts, and for favoring one account over the other. Most of the history students noted that individuals simply have to choose for themselves what seems to suit them most. For example (sic, translated quotes): "…if one book strengthens your view and another that weakens your view, then you will obviously go with the one that strengthens your view…" or "I hold on to what works for me, what I believe in and that's that. I know that both are uncertain." In this respect, the history majors reflected more of a multiplist than evaluativist perspective.

Our findings are commensurate with our expectations that instruction can play an important role in cultivating epistemological views, and that typical instruction in the arts and humanities is more focused on multiplist and evaluativist views than typical science instruction. This is ironic, because as we have noted in the background section, it is the evaluativist perspective that is most commensurate with science learning goals. The overall tendency toward absolutist perspectives is rather disappointing. It is also somewhat disappointing that the history majors seem to lack a disposition to critique, which we posit would be part and parcel of a full and complex evaluativist perspective.

## Conclusion

This study was exploratory. It served mostly to point to profitable research directions, than to provide firm ground for conclusions. We studied a small number of participants, and employed only a single measure. In addition, our knowledge of the instruction underlying the views we explored is limited to narrow self-reports. Our goal is to follow this initial study with a broader investigation. We intend to combine written instruments administered at a large scale with smaller scale interviews, and to complement student self-reports with instructor self-reports and classroom observations. We expect that such a study would enable us to make stronger claims about disciplinary differences in the cultivation and adoption of epistemological views, as well as point to the particular instructional strategies that seem to foster these views. Our hope is that these endeavors will help us understand how instruction and learning environments can advance the refined development of evaluativist perspectives.

# Fostering Mathematical Inquiry: Focus on Teacher's Interventions

Mara V. Martinez and Wenjuan Li
University of Illinois at Chicago

Abstract: Previous research has emphasized the need to better understand and articulate the demands in the work of teaching mathematics entailed by an inquiry-based approach. It is in this context that, first, we describe an inquiry task intended to provide high school students the opportunity to construct algebraic proofs. Second, as students work on the problem, we map students' inquiry process. More, we identify elements common to students' inquiry process and current views of how mathematics knowledge is constructed. Last, we illustrate the teacher's interventions intended to sustain students' inquiry. Among these, we identified: (1) helping students re-focus their inquiry, (2) helping students select mathematical tools, (3) accepting students' provisory ideas, (4) recognizing the potential in students' ideas and promoting the student to showcase the idea, and (5) reviewing a property using an additional example to preserve the original challenge for students.

## Introduction

In the United States, the mathematics instruction that most students experience in today's classrooms embodies myths that misrepresent the nature of mathematics as well as what it means to learn and do mathematics. Mathematics textbooks, pedagogical practices, and current assessment policies work in concert to perpetuate the idea that mathematics is the discipline of certainty. This is despite current reform efforts as voiced in the NCTM Standards (National Council of Teachers of Mathematics, 2000) and as articulated in standards-based NSF-funded curricula. These documents advocate for a shift in emphasis from routine skills and factual knowledge to, posing and solving a variety of math related problems, reasoning and communicating mathematically, and appreciating the value of mathematics. Mathematical inquiry, also known as inquiry-based learning, discovery learning, or inquiry-based teaching, is an approach to teaching and learning that intends to engage students in authentic mathematical activity for the purpose of learning about what is entailed in doing mathematics. However, creating a classroom atmosphere and designing instruction to promote mathematical inquiry presents many challenges for the teacher (Goldman, Radinsky, Tozer, & Wink, in press; Lampert, 1995). For instance, individual students are interested in different questions or taking different approaches to the problems, but the teacher must teach the class as a whole. Or, students are inclined to use informal language or everyday life language in the inquiry process, but using formal language or precise disciplinary language is a major goal of learning in discipline. To facilitate inquiry learning, teachers need to know more about students' inquiry process and their thinking in different stages as well as effective scaffolding strategies that connect students' thinking with mathematics.

Therefore, the first goal of this paper is to describe an inquiry task that intends to provide high school students' an opportunity to learn about algebraic proof (Martinez, 2008). Second, to map students' inquiry process. And, last, to illustrate the teacher's intervention intended to sustain students' inquiry. Before addressing the goals, and to contextualize this study, it is necessary to revisit in more detail the nature of inquiry, mathematical inquiry, challenges associated with the implementation of and inquiry based approach, and research questions that still remain open in the field.

## Framework

### Inquiry

*Inquiry* based learning is a pedagogical approach largely embraced across disciplines and goes back in time as far as Socrates (Goldman, et al., in press) "Inquiry learning foregrounds the questions rather than the answer and places the focus on learning in the learner, not in the material that can be transmitted by the teacher" (Goldman, et al., in press). This is in opposition to the more predominant behaviorist view of learning that reduces learning to the acquisition of ready-made facts through listening, memorizing, and practicing. In an inquiry based learning approach, students in addition to learn the discipline, they would also learn habits of mind (e.g., form and pursue questions and the tendency to think critically, among others.)

In agreement with Lampert (1995), *mathematical inquiry* is an approach to curriculum and instruction that gives the teacher the responsibility for introducing content in a way that is illuminated and modified in response to students' questions and ways of thinking about that content. Specifically, the teacher defines the focus of inquiry by posing problems to the class while students take an active part in acquiring knowledge by generating not only answers, but formulations of problems, definitions of the terms of discourse, and analyses of alternative solutions. Such approach assumes a constructivist epistemology (e.g., von Glaserfeld, 1991) while at the same time integrating contributions from supporters of viewing mathematics as a humanistic discipline (e.g., Ernest, 1991). Moreover, it builds upon Dewey's and Peirce's view of knowledge as "a process of inquiry motivated by doubt" (Siegel & Borasi, 1994). Following Borasi (1994), mathematical inquiry calls for highlighting ambiguity and uncertainty in the mathematical content studied so as to generate genuine conflict or doubt, and, consequently, the need to pursue inquiry. Indeed, doubt and anomalies, namely something that contradicts our expectations, are considered motors for inquiry.

An inquiry stance has implications in the way that not only learning and teaching are conceptualized, but also mathematical knowledge (Siegel & Borasi, 1994). In fact, mathematical knowledge is fallible and created through a non-linear process in which the generation of hypothesis plays a key role; also, the production of mathematical knowledge is a social process and truth is constructed through rhetorical practices. For instance, as evidenced in Lakatos (1976), *once* the original theorem of Euler's on the characteristic of polyhedra was *proved*, it was challenged by several counter-examples yielding revisions on both premises of the theorem and definitions used in its proof. Clearly, this position is contrary to the view of mathematics as certain, objective, and unproblematic. Absolutist, Logicism, Formalist, Intuitionist and Platonist argue that mathematics is a body of absolute and certain knowledge; the truths of mathematics are universal; and mathematics is discovered but not invented (Ernest, 1998). In an inquiry epistemology, mathematics is regarded as a humanistic and cultural product; mathematics knowledge is fallible; and the results of mathematics are a changeable social product (Ernest, 1998).

## Inquiry in the Mathematics Classroom

School mathematics is often presented as a body of absolute and certain knowledge. Learning mathematics in school is about knowing facts and procedures, and getting the right answers as quickly as possible (Lampert, 1990). Richards (1991) argued that the problems in school mathematics are habitual and unreflective and the discourse of school mathematics is just "number talk". On the contrary, mathematical inquiry is about encouraging students to ask mathematical questions; to solve mathematical problems that are new to them; to propose conjectures; and to be active participants in the construction of mathematical arguments (Richards, 1991). Central to the inquiry classroom is to offer students the opportunity to experience the uncertainty in the mathematical content, the nonlinear development in constructing mathematical knowledge, and to generate questions and to justify their answers (Siegel & Borasi, 1994).

Research centered on student thinking (Lampert, 1995) suggests that in this type of environment, the teacher's job should be a relatively simple matter of refining and connecting informal understanding with what we want students to learn in school. Research conducted on inquiry-based classrooms focusing on the work of teaching indicates otherwise.

Goldman et al. (in press) identify three challenges related to the classroom instructional context and the teacher's guidance. First, the teacher's level of preparedness to guide inquiry-learning projects; indeed, effective guidance of inquiry activities requires that teachers understand both the process and the content of the inquiry. Second, teachers need to shift norms of classroom discourse away from the traditional pattern (teacher initiation, student response, and teacher evaluation) to shared construction of reasoned arguments. Third, teachers need to move students' everyday language to a more formal language as it is used in the discipline.

Lampert (1995) identifies several tensions that a teacher navigates in an inquiry based mathematics classroom. For instance, individual students are interested in different questions, but the teacher must teach the class as a whole. Also, students' inquiry may push them deeply into one topic, but the teacher is responsible for their knowledge of a broad range of topics. Additionally, students' conjectures push them in different directions through the subject matter, but the teacher is responsible of keeping track of who knows what and what they still need to learn. Further, students may develop idiosyncratic systems for structuring their understanding, but they are also supposed to learn to communicate with a wider community that shares well-established conventions. In an inquiry-based classroom, teachers construct discourse in response to student activity, thus their responsibility is much grater. Therefore, teachers who want to teach in an inquiry based approach need to be able to navigate these tensions.

From a research perspective, little attention has been paid to the challenges of the teaching practice that must be addressed in this type of classroom environment, and how teachers navigate them. Specifically, less attention has been given to "how" to guide the inquiry process once students were engaged in it. It is in this context that this paper focuses on teacher's interventions intended to sustain students' inquiry process when conjecturing and producing an algebraic proof in a high school mathematics class.

# Methodology

## Teaching Experiment

The data was collected in the context of a teaching experiment conducted in a high school in the greater Boston in Massachusetts by the first author of this paper. One of the goals of the teaching experiment was to offer students the opportunity to conjecture in a context other than geometry[1], to use algebra as a tool to prove, and to produce algebraic proofs. It was intended to provide students the opportunity to experience proof as a way to understand "why" a mathematical phenomenon happens. In other words, in constructing the proof students would have the opportunity to access the reasons that make the mathematical statement true.

The teaching experiment consisted of a total of fifteen lessons. All lessons were video taped and all students' written work was collected. In addition, all small group conversations were audio taped. This allowed having an understanding of the class both at a macro level (whole group) and at a micro level (small group and individual students). Also, all students were interviewed individually twice; once half-way-through the teaching experiment and a second time at the end of the teaching experiment.

A group of nine students, who were in 9th and 10th grades, participated throughout the teaching experiment. Students worked in the same group of three for the duration of the fifteen lessons. Lessons were one hour long and were hold in addition to their regular mathematics class. During the fifteen lessons students worked on a set of seventeen *Calendar Algebra Problems* designed by the first author of this paper. The qualitative analysis[2] presented later is based on one of the three groups participating in the teaching experiment. In what follows, a description of the subset of data that is the focus of this paper is presented along with a detailed description of the problem that students solved during the first two lessons of the teaching experiment.

## The Calendar Algebra Problem

As mentioned earlier, students worked on approximately 17 problems as part of their participation in the project. In this paper, data reported in this paper stems from students' work on the first Calendar Algebra Problem (Figure 1).

Problem 1
Part 1: Consider a square of two by two formed by the days of a certain month, as shown below. For example, a square of two by two can be

| | |
|---|---|
| 1 | 2 |
| 8 | 9 |

These squares will be called 2x2 calendar squares. Calculate the difference between the products of the numbers in the extremes of the diagonals.
Find the 2x2 calendar square that gives the biggest outcome. You may use any month of any year that you want.
Part 2: Show and explain why your conjecture is true always.

Figure 1. Problem 1 from the Calendar Algebra Problems.

Students were provided with calendars corresponding to years 2005-2008 accompanying Problem 1-Part 1 (Figure 1). As part of their work on Part 1, students had to analyze the nature of the outcome of the described calculation (subtraction of the cross product). It was expected that students would anticipate some kind of variation in the outcome in relation to the set of days where the operator is applied. This would contradict students' findings as a result of their exploration of the problem. The outcome is always -7 independently from where (i.e., within a month, across months, and across years) the square is located. This contradiction was intended to function as a *motor for inquiry* (Siegel and Borasi, 1994). The ultimate educational goal of Part 1 of Problem 1 was to get students to produce conjectures (correct and incorrect) about the behaviour of the outcome (i.e., number obtained as the result of the subtraction of the cross product) as it relates to the location of the square in the calendar.

After each group of students produced their conjectures, Part 2 of Problem 1, students had to gather evidence to show that their conjecture was indeed true. In addition, students had to figure out *why* this phenomenon happens, and whether this is *always* going to be the case.

## Data Analysis

Data was analyzed qualitatively taking a grounded theory approach (Glaser & Strauss, 1967), which is a bottom-up approach. In other words, starting from the data theoretical relationships and categories are constructed. As mentioned above, in this paper, a map of students' inquiry process is generated based on the work on problem 1 of one group of three high school students. In addition, among the teacher's interventions we identified and analyzed the interventions that were intended to sustain students' inquiry process.

## RESULTS

### The non-linearity of students' inquiry process

Analysis of the group's discussions revealed the non-linearity of students' inquiry process. According to current epistemological perspectives (Ernest, 1998; Lakatos, 1976; Siegel & Borasi, 1994), mathematical knowledge is constructed through a complex process that involves several stages and includes the production of conjectures, examination of examples and counterexamples, arguments and counterarguments, reformulation of conjectures, redefinitions of terms, evaluation of theories, among others. This is in contrast with a more traditional epistemological view where the mathematician constructs a conjecture, proves the theorem, and as a consequence, truth is established forever. This is what we call linear process. It is characterized by a lack of loops going back to review or question prior accepted knowledge.

Indeed, students went through the following stages: Interpretation of the problem, conjecturing process, agreement on the conjecture to prove, determining how to prove the conjecture, proving the conjecture using algebra, and finally evaluating the implications of their work onto their mathematical knowledge.

Students started exploring the problem by using specific examples. Students will do this by placing the 2x2-calendar square in different places within a month, and in different months. As a result, they conjectured that the outcome would be always -7. This was in contradiction with their expectations. Initially, they had assumed that the outcome would vary depending on the location of the square. This has been described in the literature as follows "most often this feeling of doubt arises when an anomaly- something that doesn't make sense in light of existing beliefs- is encountered" (Siegel & Borasi, 1994, p.222). In this episode students encountered an anomaly, something that contradicts their expectations. This anomaly functions a motor for inquiry.

In what follows, students justified their conjecture stating: "it is -7 because there are 7 days in a week". Students are aware that this is not a proof; however, it seems that the fact that a week has seven days warrants the construction of their conjecture, and in a way, is reassuring. This is what Lakatos (1976) refer to as "conscious guessing" in the process of production of mathematical knowledge. Following Siegel and Borassi (1994), this "guess" enables to set in motion the process of knowledge production.

Once the proving process was set in motion, they seemed to agree that they needed to produce a general argument, probably using algebra. In doing so, students tried different paths, some of them correct and some incorrect. One of the incorrect attempts involved using a linear function when it was not the correct mathematical tool to use. At this point, the teacher stops by the group, and without questioning directly the correctness of the strategy, helps them to shift direction (Episode 1 in section below). The teacher's intervention helped them to make explicit and gravitate towards the idea of using variables so that they can continue working on it.

The next challenge that students faced was how many, and which independent variables to consider to have a complete algebraic model of the situation. First they used two independent variables to represent the numbers in the 2x2-calendar-square when, indeed one independent variable is needed. Once again, the teacher stopped by and helped students' to continue their inquiry process (Episode 2 in section below).

After that, students wrote the expression $a(a+8)-(a+1)(a+7)$ to represent in a general way the calculation performed on the 2x2-calmdar-square. Students were able to distribute transforming the expression $a(a+8)$ into $a^2+8a$. However, things did not go as well with the negative sign of the second term, namely $-(a+1)(a+7)$. At this point, the teacher intervened by recalling an example to illustrate how the negative sign would impact the expression (Episode 3 in section below). After overcoming this challenge, students constructed and algebraic proof showing why the outcome is always -7 independently of the location of the 2x2-calendar-square.

Students' inquiry describes a non-linear process, or what Lakatos called "a zig-zag" path. In this process, students conjectured, revised conjectures, gathered evidence, formulated and reformulated their ideas, devised strategies and re-evaluated them based on feedback provided either by the teacher, their findings, or peers. Students' inquiry process resembles current views of the production of mathematical knowledge. Contradiction functioned as a motor to engage students in inquiry. Students structured their work base on a "conscious guess" and produced mathematical knowledge upon it. In what follows, teacher's interventions are analyzed in the light of scaffolding or sustaining students' inquiry process.

## Teacher's interventions intended to sustain students' inquiry

Teacher's interventions play a key role in sustaining students' inquiry process. However, little attention has been paid to the role of the teacher in sustaining students' inquiry once they are engaged in it (Chazan & Ball, 1999; Lampert, 1995). Given that teacher's discourse is constructed in response to student activity, the teacher's responsibilities and intellectual demands are substantial. The analysis yielded five teacher's interventions intended to sustain students' inquiry process. In what follows, these interventions are identified and illustrated.

### Episode 1: Helping students to re-focus their inquiry

1 Student 2 (S2): It's … these the numbers increase at a constant rate right
2 S2: That's why it's always -7.
3 Teacher (T): So your hypothesis is that it doesn't matter where you place the square, you are going always to obtain minus 7, that is you hypothesis? Ok. So, how do you gather evidence to prove that? That is your problem now. How did you do? How did you come to that idea [outcome is always -7]?
4 Student 1 (S1): Did examples.

Interpretation: As part of their inquiry, students analyzed the underlying mathematical structure of the calendar, concluding that it was linear. Even though this is correct and potentially useful, the teacher interpreted that the students were focusing mostly on the writing of the linear relation. In addition, it seemed that students were aware of the link between the existence of a linear relationship and the fact that the outcome is always -7, as evidenced in the dialogue (lines 2 and 3). However, there was no evidence that students were analyzing *how* and *why* having a linear relation connects to their conjecture (i.e., the outcome is always -7). This indicated to the teacher that students probably thought that the mere existence of the linear relation was *sufficient* evidence to prove their conjecture. Therefore, the teacher brought back to the conversation the conjecture and the question "How do you gather evidence to prove that?" At the same time, the teacher wanted to link this last question to how they had arrived to their conjecture. This was an attempt to promote students to continue building on the examples they had used and, perhaps, construct specific linear relations among the elements of the 2x2-calendar-square. Note that the teacher here tries to sustain students' inquiry process by *returning* the question "how do we prove this?" and, by selecting a portion of their work (i.e., examples used to construct their conjecture) that had the potential to continue building the mathematical relations needed to prove.

### Episode 2: Helping students select mathematical tools and accepting students' provisory ideas

1 T: Ok let's try something then. Can I write in this one? So, what we need to do is to gather information here… How can you show that for any number, this [difference between numbers that are the same column in the calendar and in consecutive weeks is 7] is going to be true?
2 S2: Oh I get it, so we do 'x'
3 T: Ok you can try.
4 S2: All right so like different variables.
5 S2: 'a' 'b' 'c' 'd', ok
6 S1: So, it doesn't matter, in a square is always …
7 T: Why did you come up with the idea of using letters?
8 S2: Using variables?
9 T: Yes, variables.
10 S2: Because if you have a formula that shows that they'll always be the same then it will work for anything so actually
11 T: Ok so try to work on that and see whether that gives us something solid to prove.

Interpretation: Until now, students had made great progress by finding out that in all the examples they tried the numbers in the first row of the square are exactly a week apart (i.e., seven days) from the corresponding numbers below (e.g., $\begin{matrix}2 & 3\\ 9 & 10\end{matrix} = \begin{matrix}2 & 3\\ 2+7 & 3+7\end{matrix}$). However, they were not sure how to represent the relationship mathematically capturing all cases, namely they were looking for a general expression. The teacher intervened by asking a question that included the phrase "for any number" (line 1) with the underlying hypothesis that this would help them to connect with algebra. As a result, one of the students suggested to use "x", linking the problem to algebra. The teacher wanted to check whether they understood why "using x" would work (line 7). As evidenced in the student's response "if you have a formula that shows that they'll always be the same then it will work for anything" algebra was being used in a meaningful way. The teacher intervention helped students to identify the mathematical tool that they needed by re-stating what they were trying to do and, deliberately, including the phrase "any number". By helping students to identify a potentially useful mathematical tool, students were able to continue their inquiry process; therefore the teacher's intervention sustained students' inquiry.

In addition, note that when students suggested the use of four distinct independent variables "a, b, c, and d", even though this idea could have been identified by the teacher "as incorrect or incomplete", the teacher accepted it as a provisory idea. This intervention (accepting the idea) gave students the opportunity to students to further refine the idea by themselves as a result perhaps of their later work. More, students' identification of 4 variables indicates progress in terms of their inquiry process; at this point, they do know that they are working with four variables. They still have to figure out that these four variables are indeed related among them (i.e., a, b=a+1, c=a+7, and d=a+8). This type of teacher intervention, accepting students' provisory knowledge, helps sustain students' inquiry process to that extent that gives students the opportunity to refine their "incomplete" ideas further.

## Episode 3: Recognizing the potential in students' ideas and promoting students to showcase their ideas

1 S2: I think that *a* and *b*… *b* is *a plus 1.* So if we make that 'a' plus 1 then we can cancel out both *a's* and that can be 1
2 T: Oh, did you hear his idea? Say it again please.
3 S2: All right so if we change 'b' to 'a' plus 1 cause that's what it's equal to then we can cancel 'a' and then just have 1 here
4 S3: I guess that'd work. Yeah.

Interpretation: One of the students in the group proposed the idea that *b* is indeed *a plus 1*. The teacher recognizing the potential of the idea in advancing students' work, had him re-stating it for the other group members. Thus, this intervention, first recognizing the potential of the student's idea, and second by showcasing it, helps students to advance their inquiry.

## Episode 4: Reviewing a property using an additional example to preserve the original challenge for students

1 T: What is the impact of this minus in the signs of the elements here? Do you remember that?
…
2 T: Ok. […] Let's say that we have this example here -(3+x), if I want to make disappear the parentheses and this minus there do you remember what we do? Do we remember the rule to change the signs?
…
3 T: I will remind it to you, I will remind it to you, don't worry, don't worry. …
…
4 T: Yes? Ok so that is your challenge now. Here [pointing to the minus sign in -($x^2$+8x+7)], how does this negative here impact the signs here? And, in that way you can get rid of the minus here and the parentheses and continue working in order to cancel,

which was your idea.
5 S3: Ok
6 T: Try that challenge now please.

Interpretation: Students did not remember how to distribute the minus sign in the expression "-($x^2$+8x+7)". In order to help them, the teacher, created another example (i.e., -(x+3)) and remind them how the distributive property works. In doing so, she reminded them how to distribute the minus sign purposely using an expression different from "-($x^2$+8x+7)". This intervention did not take away students' opportunity to apply the property once they remembered how it works. Once the teachers intervened, students knew how the property worked and still had the opportunity to do it by themselves.

In summary, the following five teacher interventions intended to sustain students' inquiry were identified: (1) helping students re-focus their inquiry, (2) helping students select mathematical tools, (3) accepting students' provisory ideas, (4) recognizing the potential in students' ideas and promoting the student to showcase the idea, and (5) reviewing a property using an additional example to preserve the original challenge for students. Employing these strategies, the teacher did not take away from students the intellectual challenge of the inquiry and provided support in response to and built upon students' activity. In doing so, the teacher's interventions sustained students' inquiry.

## Conclusion

First, we provided a description of a task designed to foster students' mathematical inquiry. Specifically, it was intended to provide high school students' an occasion to learn about algebraic proof. The Calendar Algebra problem was designed to provide students the opportunity to experience a contradiction between, their expectations, and their findings as result of their exploration of the problem. Students' experienced this contradiction and functioned as a *motor for inquiry* (Siegel and Borasi, 1994). Second, we mapped students' inquiry process. Further, we identified elements of students' inquiry process that are described in current epistemological views of the nature of mathematical knowledge (e.g., non-fallible, it is produced through a non-linear process). Last, we identified and illustrated five teacher interventions (e.g., recognize the potential in students' ideas) that helped students sustain their inquiry. This is relevant to the field, given that little attention has been paid to how teachers guide students' inquiry once they are engaged in it (Chazan & Ball, 1999; Lampert, 1995). Still, we need to know more about how teachers construct and implement assignments that engage students in mathematical inquiry. We also need to know more about teacher's interventions that foster or hinder students' inquiry process. Once the field systematizes these results, they have the potential to inform the preparation of pre-service teachers and develop programs to better support in-service teachers to implement inquiry-based learning in mathematics.

(1) In the United Sates, proofs appear mostly exclusively in the geometry curriculum in high school.

(2) The analysis was conducted in all groups participating in the teaching experiment. Given space restrictions we illustrate our findings with the analysis of one of the three groups. We chose this group given that the results that we wanted to illustrate appeared all as part of the work of this group.

# The Effectiveness of Reading Comprehension Strategies in High School Science Classrooms

Phillip Herman, University of Pittsburgh, pherman@pitt.edu
Kristen Perkins, Northwestern University, kristen-perkins@northwestern.edu
Martha Hansen, Evanston Township High School, hansenm@eths.k12.il.us
Louis M. Gomez, Kimberley Gomez, University of Pittsburgh
lgomez@pitt.edu, kgomez@pitt.edu

**Abstract:** Reading strategies have been shown to increase comprehension for younger learners. As students move to middle and high school, there is little opportunity to learn about, practice, and apply these strategies in classes, particularly in the content domains like science. Nonetheless, there is a growing national consensus that high school content area teachers need to better integrate discipline-specific reading supports throughout the curriculum. We evaluate the effectiveness of an effort to integrate reading comprehension strategies in biology classrooms. Students' independent proficiency with the strategies predicted science achievement, even when controlling for prior reading achievement. These results provide evidence that strategies are effective and practical in intact science classrooms. We discuss the implications of the findings for the design of content-area literacy instruction. Finally, we describe our efforts to refine the design of the strategy supports based on the empirical results.

## Learning to Read and Reading to Learn

Reading is a complicated cognitive process that is likely the most important competency acquired in all of schooling. As students move from the early elementary years through high school and beyond, the focus changes from 'learning to read' to 'reading to learn.' Many middle and high school students fail to make this transition. That is, many students can decode individual words on a page but are unable to successfully comprehend the sentences and paragraphs that make up academic text. Based on an influential theoretical model of reading comprehension, we could say that these students are unable to build an adequate text base (direct representation of the semantic structures of text) and situational model (integrated reordering of text content with prior knowledge) (Kintsch, 1998), which represent readers' constructive understanding of the meaning of text. It is well known that American students struggle to read academic texts. About 70% of American eighth-grade students performed below the *proficient* level on the National Assessment of Educational Progress reading tests in 2003 (National Center for Educational Statistics, 2005). Students who struggle to read to learn remain at a disadvantage throughout school and later in life as more desired careers require workers to be able to independently read new material, integrate that material with existing models of understanding of a domain, and generate ideas from the new understanding. In the work described here, we detail an intervention that grew out of our multi-year effort to support high school science teachers as they work to increase students' disciplinary learning by focusing on targeted reading comprehension strategies that students use as they engage with high school science texts. We describe the reading comprehension strategies teachers and students used in intact high school biology classrooms, present some of the research base on the use of comprehension-building strategies with older students, and present a rationale for the embedding of reading comprehension strategies in content domains like science. We provide evidence of the effectiveness of the strategies based on performance of students on two assessments of science achievement. Finally, we take initial steps to revise the reading strategies based on the empirical findings. Our work is particularly congruent with the goals of the ICLS conference that stress how discipline-specific learning needs to be accounted for in effective learning interventions.

### Reading Comprehension Strategies in Science

Contemporary models of reading stress that in order to derive meaning from text, readers rely on both text-driven and knowledge-driven processes (Goldman & Rakestraw, 2000) in which they make connections between elements in a text, their understanding of the text, and between the text and prior knowledge (Wittrock, 1990). A reader must actively construct understanding by integrating existing and new knowledge in part through the application of flexible strategies that help foster, monitor, regulate, and maintain comprehension (Alexander & Jetton, 2000). A number of studies have demonstrated that students' understanding of and memory for text can be strengthened through explicitly teaching students multiple comprehension strategies (Pressley, 2000). Some common reading strategies include paraphrasing, self-questioning, reflecting, marking structures of text, summarizing the gist of text, teaching others about a text, etc.

When learned well, strategies have been shown to increase comprehension. Even so, there is evidence that high schools rarely provide opportunities for students to learn and practice effective reading strategies

(Langer, 2001). Part of the problem is that as students move into domain-specific classrooms in high school, content teachers are often underprepared to meaningfully support reading comprehension generally and domain-specific reading in particular (Gomez, Herman, & Gomez, 2007). Several teachers have reported to us that it should primarily be the responsibility of middle school English teachers to get students “ready to learn science.” High school science teachers are under pressure to cover science content standards. Still, science teachers are frequently frustrated by students’ inability to learn from texts, even if they are not sure how to address the problem. We have found that science teachers will often assign reading to students, but then didactically teach the “important content” (Gomez, Herman, & Gomez, 2007). This approach fails to hold students accountable for independently accessing and learning from text. This marginalizing of text in science is extremely unfortunate given how central reading to learn science is to any meaningful definition of scientific literacy (Norris & Phillips, 2003). One’s ability to comprehend science content from reading is important to the work of scientists in the field, as well as critical to promoting scientifically literate citizens. Although there have been influential calls to action to better integrate literacy within the content domains (Biancarosa & Snow, 2006), there remains little practical advice for content-area teachers that is theoretically and empirically grounded in the disciplines. An important goal of our work is to demonstrate that when students have the chance to learn, practice, and apply reading comprehension strategies that are deeply coupled to domain learning goals and domain practice, content learning will increase along with students’ ability to independently read to learn.

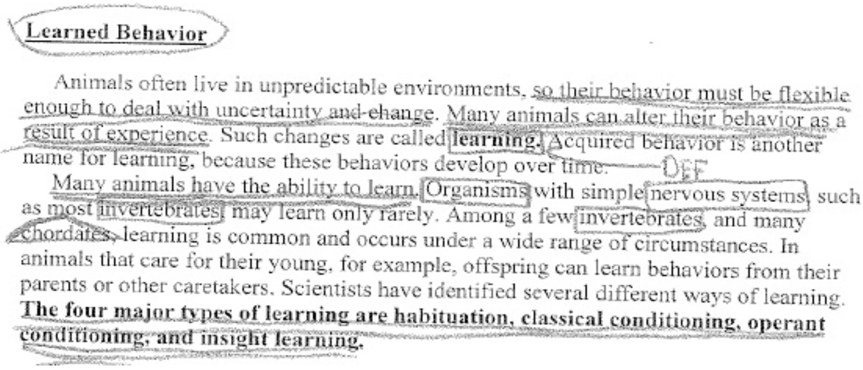
## Reading Strategies: Structure, Reflection and Gist

Science readers should have a corpus of strategies they can use prior to, during, and after reading to learn from text. Students benefit when they are taught to apply comprehension strategies when they read (Anderson, 1992; Collins, 1991). Through repeated transactions with texts and by collaborative analysis and discussion with peers, students can better internalize and ultimately take ownership of reading strategies (Pressley, et al, 1992; Biancarosa & Snow, 2006). When internalized and used frequently, strategy use can lead to large positive effects on text comprehension (Anderson, 1992). The strategies we support (described in detail below) are designed to help students identify the general structure of texts as well as critical discipline-specific elements such as main and supporting ideas, how scientific arguments are constructed in text, what counts as scientific evidence, etc. (Gomez, Herman, & Gomez, 2007). In addition, the strategies should help students know how to reflect on, analyze, and organize text so that elements can be examined and critiqued for understanding and communication (Herman et al, 2008). Finally, students should also know how to summarize a text to integrate new and prior knowledge into one holistic representation of their understanding. This summarization strategy helps students communicate their understanding of the gist of what they have read, and to make the connections between new and prior knowledge explicit (Kintsch, 1998).

The reading strategies implemented in these science classrooms are intended to increase reading comprehension and science learning by developing students’ metacognitive reading skills to increase active and conscious processing of text. Though there are many conceptualizations of metacognition in the literature, we focus on developing students’ conscious control of their cognitive processes (i.e., self-regulation) (Pressley, 2000), including planning, selecting, and using appropriate strategies; monitoring reading comprehension; analyzing the effectiveness of reading strategies; and changing reading behaviors when necessary (Ridly, Shutz, Glanz, & Weinstein, 1992). We conjecture that increases in metacognitive reading skills will allow students to comprehend more challenging text. Over time, as teacher support fades and reading strategies are internalized, students will be able to read challenging texts more independently. Ultimately, these conscious reading strategies will develop into reading skills (Afflerbach, Pearson, & Paris, 2008). Next we describe each of the three classes of reading strategies in detail.

### Annotation

Text annotation is a strategy to make an author’s message more explicit to the reader. Students are taught how to identify and mark important information, and disregard irrelevant information. Students typically annotate (by marking on the text) one or more text elements such as difficult vocabulary words and embedded definitions; main ideas/arguments and related supporting ideas/evidence; and headings, transitional words, and other signposts. Initially, teachers explicitly model this annotation process, but over time reduce their scaffolding for annotation so that students can independently annotate texts. Figure 1 is an example of a student’s annotation from one of the two texts used in the study described later.



**Learned Behavior**

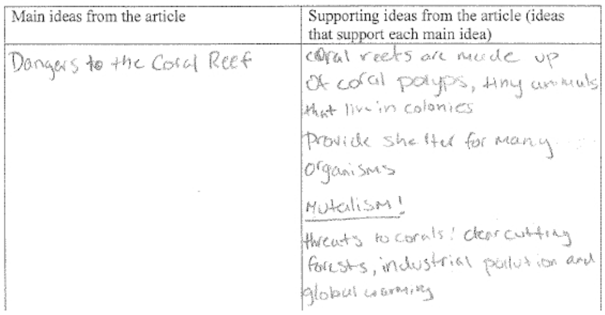
Animals often live in unpredictable environments, so their behavior must be flexible enough to deal with uncertainty and change. Many animals can alter their behavior as a result of experience. Such changes are called **learning.** Acquired behavior is another name for learning, because these behaviors develop over time. DEF

Many animals have the ability to learn. Organisms with simple nervous systems, such as most invertebrates, may learn only rarely. Among a few invertebrates, and many chordates, learning is common and occurs under a wide range of circumstances. In animals that care for their young, for example, offspring can learn behaviors from their parents or other caretakers. Scientists have identified several different ways of learning. **The four major types of learning are habituation, classical conditioning, operant conditioning, and insight learning.**

Figure 1. Example of a Student's Annotation.

## Double-Entry Journals

A double-entry journal (DEJ) (See Figure 2) is a reader-response log that provides a structure for students to monitor and document their understanding of science texts. The DEJ provides students with an organizational tool that suggests corresponding categories of information that students extract from the text, rearrange, paraphrase, and use to reflect on their understanding. The variety of DEJ structures allows teachers to focus students' reading on an important idea or skill that is particularly relevant for a given text (vocabulary, main ideas with supporting ideas, relating information in the text to prior knowledge, etc.), thus coupling the DEJ (and students' attention) to the targeted content learning goal.



| Main ideas from the article | Supporting ideas from the article (ideas that support each main idea) |
|---|---|
| Dangers to the Coral Reef | coral reefs are made up of coral polyps, tiny animals that live in colonies<br>Provide shelter for many organisms<br>Mutalism!<br>threats to corals: clear cutting forests, industrial pollution and global warming |

Figure 2. Example of a Double-Entry Journal.

## Summarization

Summary writing is a critical scientific skill. It requires the reader to effectively digest new information and communicate it in a way that makes sense to her as well as to an external audience. Summarization is a particularly difficult task when students are trying to make sense of texts that exceed their nominal reading level, as is the case for many high school students. In summarizing, students must comprehend the text, identify main ideas, differentiate secondary ideas, integrate new knowledge with prior knowledge, and condense the information in a succinct and logical way.

## Reading Strategies, Science Learning, and Scientific Literacy

Being a competent science learner requires students to learn about science from texts in many forms, including readings, graphs, charts, and other representations of phenomena, processes, and data. Reading to learn science, though certainly not the only competency that accounts for success in school science learning, is nonetheless a constitutive element of students' success in high school classrooms and beyond. In fact, almost any definition of scientific literacy includes the ability to read texts to understand scientific phenomena and thought (Norris & Phillips, 2003). Teachers and students make the strategies science-specific by the tasks they engage in with the strategies. For example, though a double-entry journal could be used in a History class to analyze the causes of a particular war, it is used in science to help students better understand how good scientific arguments require explicit forms of evidence. In this sense, though the *forms* of the strategies are generic, our work has been to deeply couple them *in function* to science learning objectives and scientific literacy.

# The Present Study

Few studies to date have focused on evaluating an ongoing program whose goal is to boost science achievement by focusing on science-specific applications of reading comprehension strategies in intact science classrooms. Most studies of reading strategies have been episodic and somewhat uncoupled from classroom learning goals. Furthermore, few studies have taken place at the high school level (Cromley & Azevedo, 2007), and almost no studies have linked strategy use to domain learning. Strategy interventions have not typically been designed to be discipline specific but rather generic, in the sense of being applicable across disciplines. In this work, we also want to provide an empirical (not just theoretical) base for the design of strategy supports for learners. We want evidence that the annotation, DEJ, and summary activities that we prescribe are effective in increasing science learning. To do so requires revision of the design of strategies, which were initially based on theoretical models of what students should attend to in readings. An important goal of this work is to better understand the connection (both theoretically and empirically) between reading comprehension and domain achievement. Our approach is to support science teachers as they contextualize the reading comprehension strategies in the discipline of biology.

## Research Questions

1. Is proficiency with the reading strategies related to science achievement?
2. Does proficiency with the reading strategies predict achievement above and beyond on-entry reading ability?
3. Can the empirical results in this study inform the refinement of science-specific reading strategy design?

## Participants

All of the work reported here took place during the 2008-2009 school year at a large suburban high school abutting Chicago, IL. Approximately 2,950 students attend the school with 48% being Caucasian, 36% Black, 11% Hispanic. Thirty-four percent of the students are classified as low-income based on eligibility for free or reduced lunch. Approximately 70% of graduates in recent years attended college. In 2005, the school adopted the broad goal of integrating literacy across the content areas. Starting in 2007 administrators and instructional leaders (including a co-author who is chair of the science department) met with our research team to develop a literacy initiative specifically for the science department. Based on what we learned from our prior work focused on embedding literacy in science classrooms (Herman et al, 2008), we worked with a pilot group of biology teachers to introduce ways to couple literacy activities to science learning goals. During the 2008-2009 school year, the intervention expanded to every biology classroom. All biology teachers were provided with ongoing professional development and coaching (by a co-author who had been a high school science teacher at an earlier research site). Fifteen science teachers and approximately 860 students participated in the study.

## Design of the Assessment

Teachers and students in all participating classrooms used the three reading strategies throughout the fall of the 2008-2009 school year (Annotation, Double-Entry Journaling, and Summarization). In January and June of 2009, we administered a one-day assessment of strategy proficiency and science achievement. 752 students were present on both dates and completed both sets of assessments. The design of this assessment was informed by our prior work (Herman et al, 2008), in which we used a point-in-time assessment to gauge how well students were independently able to use the literacy strategies while reading science texts, and the resultant effect on science achievement. It is worth stressing that the assessments described here measure both students' *independent* understanding of, and proficiency with, the reading strategies as well as their *independent* understanding of the science content in the readings. The format of the January and June assessments was identical: Students were randomly assigned one of two readings ("Learned Behavior" or "Coral Reefs") and randomly assigned (within classrooms) to use one of the three strategies while reading the text. Finally, students completed a 10 item multiple choice science assessment that was based on the content in each of the readings. Students used the same class of strategy during both assessment days but the reading and science assessments were crossed so that if a student completed an annotation of the Behavior article in January, they would be assigned to complete an annotation of the Coral article in June. Though we designed and administered two assessments four months apart in order to understand something about growth trajectories in strategy acquisition, that is not the focus of this paper and space limits prevent us from presenting the longitudinal analysis. Instead, the assessment results are grouped together for the analyses presented here.

## Coral Reefs and Learned Behavior

The two readings were chosen from the students' biology textbook. They represent two genres of science texts that students are exposed to: The Learned Behavior text is a more traditional expository reading, whereas Coral Reef is a magazine-type article, representative of the type of chapter inserts that are included in the textbook. In addition to genre differences, the texts were chosen because neither of those topics would be covered in the science classrooms for the duration of the study, thus reducing the likelihood of prior knowledge effects on the science achievement assessment.

## Science Achievement Assessment

For each reading, 10 multiple-choice items were developed. To develop the candidate items, we first analyzed some of the science learning objectives for students that were encapsulated in the content of the texts. We then used those science learning objectives to generate individual items that would assess students understanding of the science content. The construction of this assessment was disciplined by two constraints: 1) As much as possible, we did not want prior knowledge to allow students to answer any of the items so as to better couple success on the items to successful reading of the passage, and 2) We wanted classes of items that varied in difficulty and we wanted that difficulty to be approximately the same across passage assessments. To ensure that the effects of prior knowledge were minimized, we designed a measure that listed the major concepts from each reading and asked students to rate their familiarity and understanding using a Likert-type scale. We gave the prior knowledge measure to 54 students, and piloted the candidate items on 98 students who would not be in the classrooms of the study, but who had covered the same biology content the prior year. These students did not have access to the Behavior or Coral readings; they only completed the multiple-choice items. Based on those results, we altered the item stems, the distracters, and the answer choices. Examples of the items that made up the assessment at three levels of difficulty (Recall, Application, Synthesis) are presented below.

1. (Recall) Which of the following is not associated with operant conditioning?
2. (Application) How does a slow growth rate impact the survival of the coral reef?
3. (Synthesis) Coral polyps would be prevented from obtaining food in the presence of:

## Scoring

To measure strategy proficiency, two of the authors developed a rubric for each reading and for each strategy. Thus, for the Coral article there was a separate rubric for Coral annotation, Coral DEJ, and Coral summary. The rubrics were designed to measure those elements of, say, an annotation, that were deemed by the researchers to be important for correctly answering one or more of the 10 science achievement questions. Figure 3 is a list of examples of the elements that were used in the different rubrics.

**Annotation** – Did the student…?

- Box the vocabulary word *mutualism?*
- Double underline the main idea: "Coral reefs make up a natural ocean habitat that is rich in diversity."

**DEJ** – Did the student include…?

- Main idea #1: "The four major types of learning are habituation, classical conditioning, operant conditioning and insight learning."
- Supporting idea #2: "Many animals can alter their behavior as a result of experience. Such changes are called learning."

**Summary** – Did the student…?

- Make a connection between runoff from clear-cutting forests and the blocking of light for the habitat?
- Use the vocabulary word *mutualism?*

Figure 3: Example Elements From Scoring Rubrics

Two of the coauthors scored all student strategy work. To ensure the reliability of scores, the two investigators scored 20 identical student work samples to determine the inter-rater reliability of rubric-based scores. When scores were disparate (less than 85% agreement), the scorers talked through their understanding of the rubric and student work. The rubrics were then modified to reflect this shared understanding. The scorers then processed another independent sample of strategy examples, and inter-rater reliability increased to acceptable levels. This reliability check was done for each of the six rubrics.

# Results

*Descriptive statistics* for all measures are in Table 2. The reading percentile is the national percentile rank on a standardized test of reading for each student. This percentile is used as a covariate and represents on-entry reading achievement. The students vary widely in reading ability but the mean of 66.91 indicates on average they are above the 50$^{th}$ percentile nationally on reading. The strategy proficiency scores indicate a wide range of proficiency. For each element, a student may receive a 0 or 1 (except for a few items on the annotations that allowed for a 0, 1, or 2). The strategy proficiency scores represent the total score across all the elements in a particular rubric (i.e., the Behavior annotation). It is worth noting that in some cases not one student was able to receive all possible points on the strategy rubrics. The Coral science achievement assessment was slightly more difficult than the Behavior assessment, even though we made every effort to make the two assessments equally difficult.

*Correlations* were calculated so that we could determine, for all students who completed a Behavior annotation in either January or June, whether their strategy score was correlated with science achievement. Every strategy for both readings was correlated with performance on the science assessment. The correlations were significant ($p<.01$ in all cases). Correlations for Behavior ranged from .23 for Annotation to .42 for both DEJ and Summary. For Coral the range was from .35 for both Annotation and DEJ to .33 for Summary. The correlations are more consistent (within each reading) for DEJ and Summary than they are for Annotation. The Behavior annotation correlation was the smallest (.23) though it was still significant.

*Stepwise Regressions* were performed to determine whether strategy proficiency predicts science achievement even after entering prior reading on a standardized exam as a covariate in Step 1. The results of these regressions are highlighted in Table 3. In each model, strategy proficiency predicted unique variance in science achievement above and beyond what reading alone predicts. Because reading is presumed to be a consistent predictor of performance on most academic outcomes, including science, these results may indicate the value of the reading strategies as a means of raising both science achievement and reading comprehension. In some cases, the amount of variance explained by strategy proficiency above and beyond reading was not large (2% of the variance for Behavior Annotation; while in other cases the effect was larger, as in the case of Behavior Summary (7% of the variance). Because we included a "strong" covariate, these numbers are somewhat encouraging in that they suggest that proficiency with the strategies might be helping students learn more science, even if they are struggling with reading.

*t-tests and ANOVA*: We conducted an analysis of each element of each rubric independently of each other to determine if particular items on the rubric "mattered more" in predicting science achievement. In prior work (Herman et al, 2008) we found an inconsistent relationship between annotation score and achievement. In this study, annotation score did predict achievement. In follow-up analyses to our main study, we essentially conducted a simple differential item analysis. For example, on Behavior Annotation item #3, students would receive either a 1 or 0 depending on whether they identified a main idea in the Behavior reading by underlining it. We analyzed the total science comprehension score to determine if there were differences in that score based on whether students received a 0 or 1 on item 3. We grouped all students into two groups for each item and then compared the science score for each group. We used t-tests when the items were scored 0 or 1 and a One-Way ANOVA when scored 0,1, or 2. Though we realized that by using more than 20 comparisons, we were likely to allow for increased likelihood of Type I errors, we were primarily interested in exploring patterns in the predictive utility of elements of the rubrics. So, for Behavior Annotation, there were 30 items on the original rubric and our empirical analysis indicated that only 8 of those items differentiated students reliably on their total science scores. Once we identified those 8 elements, we recalculated the correlation of strategy proficiency with achievement based on those 8 items instead of the original 30. Though we would expect the correlation to increase because our method necessarily would lead to less variance in the predictors, we wanted to gauge how strong those correlations would be for possible future revisions of the annotation format. In this case, the correlation rose from .19 to .36. In all cases, for both readings and all 6 strategies, the correlations rose with the lowest being .32 and the highest being .43. For each strategy we now have an empirically based subset of items that better discriminates the total science score (not each question on the science test but the mean on the 10 items for each student). The number of revised elements for each strategy compared with the total number of elements for each, is as follows: Behavior Annotation 8/30, DEJ 12/16, Summary 7/12, Coral Annotation 17/27, DEJ 8/18, and Summary 8/18. In each case, a substantially fewer number of items does a better job of predicting the science score.

Table 1: Descriptive Statistics of Variables in the Study

| | N | Possible Range | Actual Range | Mean | Std. Deviation |
|---|---|---|---|---|---|
| Behavior Annotation | 210 | 0-37 | 2-37 | 20.66 | 6.07 |
| Behavior DEJ | 212 | 0-16 | 0-14 | 5.06 | 2.74 |
| Behavior Summary | 187 | 0-12 | 0-9 | 3.91 | 2.30 |
| Coral Annotation | 209 | 0-36 | 1-34 | 15.70 | 7.28 |
| Coral DEJ | 209 | 0-18 | 0-14 | 6.74 | 3.03 |
| Coral Summary | 189 | 0-18 | 1-15 | 6.26 | 2.98 |
| Behavior Assessment | 856 | 0-10 | 0-10 | 6.34 | 2.05 |
| Coral Assessment | 844 | 0-10 | 0-10 | 6.06 | 2.08 |
| Reading Percentile | 856 | 1-100 | 1-100 | 66.91 | 28.01 |

Table 2: Regressions for 6 models: Predicting science achievement from strategy proficiency and reading.

| **Behavior** | Models* | F | Adjusted $R^2$ (Reading only) | Adjusted $R^2$ (Reading + Strategy) |
|---|---|---|---|---|
| Model 1* | Reading Achievement + Annotation | 41.07 | .27 | .29 |
| Model 2* | Reading Achievement + Double-Entry Journal | 63.71 | .37 | .40 |
| Model 3* | Reading Achievement + Summary | 42.33 | .25 | .32 |
| **Coral** | | | | |
| Model 4* | Reading Achievement + Annotation | 36 | .23 | .26 |
| Model 5* | Reading Achievement + Double Entry Journal | 46.65 | .31 | .33 |
| Model 6* | Reading Achievement + Summary | 59.37 | .37 | .39 |

*p<.02 for each predictor in each model

## Discussion

Several findings from this study are worth highlighting. Students who successfully used reading comprehension strategies while reading a science text performed better on a measure of science achievement. That is an important finding for the adolescent literacy and science education research community as well as for practitioners who might wonder about whether the support of reading in high school science classrooms is possible, practical, and useful. This study indicates it is useful to regularly incorporate explicit instruction in reading comprehension strategies in science classrooms, not as a way to primarily improve students' reading abilities, but as a means of increasing science achievement. Science teachers (and other content-area teachers) need better ways to support reading in the disciplines. All too often in science class, readings are ignored or marginalized. Teachers are not to blame for this. Most schools of education provide high school science teachers with almost no preparation for supporting reading in science. Teachers need to know and be able to scaffold a variety of effective reading comprehension strategies that can help increase science learning. This kind of work requires extensive, practice-based, and ongoing professional development.

This study also shows that reading plays an important role in science achievement. The regression models indicate that reading achievement is a significant predictor of science achievement. This finding, though not unexpected, is important because it adds to the understanding of how reading achievement matters for various formats of science assessment, for a variety of learning goals and science text genres. A demonstration of how much reading matters can be a powerful way to spur science teachers to acknowledge and ultimately take some ownership of students' reading abilities in science. We have seen in prior work (Authors, 2007) that science teachers do take ownership over reading when they have a repertoire of teaching strategies that they can utilize and when, as in this case, they can see the significant connection between reading and science achievement. The measure in this study is very similar to other classroom measures of science achievement. We acknowledge that the measure used is not a "pure" measure of science achievement; it is also a measure of reading comprehension. However, we suggest that many classroom assessments of science learning are reading-dependent in meaningful ways.

Student proficiency with any of the strategies was related to student performance on the science assessment. This is worth noting, particularly because that relationship holds even when on-entry reading ability is a covariate in the regression models. Strategy proficiency predicts unique variance in science achievement even when controlling for reading. Based on the adjusted $R^2$ s, reading achievement and strategy proficiency account for between 26% and 40% of science achievement. In prior work (Authors, 2008), we found that proficiency with annotation, though correlated with science achievement, did not predict science achievement when accounting for on-entry reading. We suspect that the reason annotation inconsistently predicts achievement might have to do with the variety of ways that students have learned to annotate. It is possible that only certain elements of annotations matter to comprehension because students may not be actively engaged in completing all the elements of an annotation with all readings. To better understand whether this is true, we conducted some further analyses of our data and identified the subset of elements of the annotation that most differentiated student science achievement. For example, as we mentioned earlier, for the behavior annotation, 8 of the 30 elements significantly differentiated students who did better or worse on the science achievement. The prior research indicated that annotation strategies have utility if they help students recognize and leverage the structures of text for understanding. But, the results of the preliminary analysis presented here indicate that perhaps only the content-focused steps in annotation (like marking main ideas or differentiating specific evidence that supports a particular argument) is important in increasing science learning, and that the more conceptual-focused steps (like circling a heading or subheading) are less useful. There is some evidence that the revised elements are more content focused than conceptually focused. The empirical evidence about strategy efficiency is very important because any intervention that stresses reading comprehension will have to be implemented in real classrooms by busy science teachers. It will require ongoing effort to support schools so they routinely use comprehension-focused, discipline-specific reading strategies in science. Teachers need to be sure they help students learn science. We have provided initial evidence that they do.

Perhaps the major challenge to improve reading in the domains in high school is not discovering new strategies that work but rather researching ways to impact school practice through the kind of research described here. Learning science research can be an important resource in the transformation of science instruction. Much is known about how to teach early elementary reading, and many schools have now put into practice what was only a research agenda a decade or two ago. We do not know nearly as much about high school reading, but we have some good ideas to put into place. Learning scientists need to collaborate closely with schools to make more routine what we know to be effective. Explicit attention to comprehension-focused reading strategies is probably one piece of a good solution to the challenge of supporting reading to learn competencies. This study makes some progress in providing evidence about the utility of strategies, but also goes beyond that by examining how the instructional versions of strategies might be altered by empirical evidence. This could be the most important, if preliminary, contribution of this work. The reading strategies movement was based in large part on a theoretical model of how strategies could help readers. In the case of annotation, it was based on a largely theoretical assertion that readers could better leverage the structures of texts in order to better comprehend text. Good readers seem to better leverage the structure of texts. So, we (and others) designed annotation supports based on that insight. But now we are able, in part by the empirical analysis presented here, to begin to revise and better understand how to link reading activity support to specific science learning. This is an important future direction of this work.

# Making Knowledge Building Moves: Toward Cultivating Knowledge Building Communities in Classrooms

Katerine Bielaczyc, Learning Sciences Lab, NIE Singapore, *kateb369@gmail.com*
John Ow, Innova Primary School, Singapore, *john_ow_eu_gene@mac.com*

**Abstract:** A major emphasis within the Learning Sciences has been to explore ways to create classroom cultures that mirror disciplinary cultures. The central focus of our own research has been on how teachers and students navigate the epistemological shift from traditional didactic classrooms to classrooms that function as *knowledge building communities* (Scardamalia, 2002; Scardamalia & Bereiter, 2006). We ground our inquiry in *Ideas First*, a design-based research program focused on creating a knowledge building community in science within a Singapore primary school (Bielaczyc & Ow, 2007; Ow & Bielaczyc, 2007, 2008). In Ideas First we view engagement in the disciplinary practices of science through the theoretical lens of *epistemic games* (Collins & Ferguson, 1993; Morrison & Collins, 1995). In order to support reflective discourse among teachers and students around epistemic game play, we have created a set of dialogic tools centered on specific types of knowledge building moves. We illustrate the design features of the tools and their role in fostering participation in knowledge building communities in science.

Education in the Knowledge Age calls for socializing students into the world of work with knowledge (Bereiter, 2002). A major emphasis within the Learning Sciences has been on investigating ways to create classroom cultures that mirror disciplinary cultures, thus socializing students into working with knowledge in ways consistent with disciplinary norms and practices (e.g., Gresalfi & Cobb, 2006; Herrenkohl, et. al., 1999; Songer, 2006). Such a framing is founded on theoretical perspectives emphasizing learning as a process of enculturation, with a focus on *learning to be* rather than simply *learning about* (Sawyer, 2006; Thomas & Brown, 2007).

In our own research, we have been interested in how teachers and students navigate the epistemological shift from traditional didactic classrooms to classrooms that function as *knowledge building communities* (Scardamalia, 2002; Scardamalia & Bereiter, 2006). For the past several years we have been engaged in a design-based research program in a Singapore primary school. *Ideas First* is a two-year science program co-designed with primary school teachers that has been operating in fifteen grade 3 and grade 4 classrooms since 2006 (Bielaczyc & Ow, 2007; Ow & Bielaczyc, 2007; 2008). The program is based on the vision of a knowledge building community where students work to advance the science understanding of the classroom community through engaging in collectively building knowledge in response to problems of understanding.

Knowledge building communities involve not only participating in knowledge building practices, but also engaging in reflective discourse on participation (Bielaczyc & Collins, 1999; 2006). Such meta-level discourse among participants is critical for agency, identity, and creativity within a dynamic community whose goal is to continually advance at the edges of the community's understanding. In Ideas First we have introduced several means of supporting reflective discourse. In the present paper we describe a particular set of tools meant to support inquiry into specific types of knowledge building moves among both teachers and students. We illustrate the design features of the tools and their role in fostering participation in knowledge building communities in science.

## The Need for Dialogic Tools to Support Inquiry into Knowledge Building

Creating disciplinary cultures in classrooms is challenging because enculturation necessitates an immersive approach. If the classroom currently reflects a traditional didactic culture then change must occur along many dimensions of social and technological infrastructure (e.g., Bielaczyc, 2006; NRC, 2007). When the teachers are themselves new to such a culture, classroom change becomes even more challenging. In Ideas First we chose to work with teachers across all the grade 3 and 4 classes within the school in order to foster a community of teachers that could support each other locally, as well as connect to teachers and other educational stakeholders in the international knowledge building community[1]. In order to foster teachers' development as a knowledge building community and agents of change, as designers we wanted to create supports for critical, reflective discourse --- tools that provided both a lens for looking at the work of the knowledge building community and that helped participants develop a language for talking about it.

Like many designs, we have found that classroom videos provide a powerful means of reflection (e.g., Goldman, et. al., 2007). Further, *Knowledge Forum*, the online environment designed by Scardamalia and Bereiter to support knowledge building (Scardamalia, 2004), also provides a means of visualizing not only students' work with disciplinary content, but also processes of knowledge building. Knowledge Forum records participants' work with ideas using the View feature, a public space where knowledge objects (multi-media content within the database that is represented via icons such as *Notes, Rise-Above's,* and *Build-On's*), their interconnections, and other organizational representations of the knowledge objects (e.g., timelines, maps) are visually displayed. The processes of knowledge building are thus captured in a visual form as the participants' work evolves.

However, while viewing rich visual spaces such as videos and Knowledge Forum where the work of the community occurs in all its "blooming, buzzing confusion" is important, we have found that it can be very difficult for teachers (and students) to "see" the critical events and features (refer to Frederiksen, et. al, 1998 for similar findings in teacher video clubs). Thus we wanted to complement the reflections on classroom videos and Knowledge Forum by creating a set of tools that focused on critical aspects of knowledge building. We thought that a powerful focal point for discussion would be "knowledge building moves," a way of conceiving possible actions to advance knowledge within a given problem space. Further, we wanted to create tools that could be used by *both* teachers and students to engage in inquiry about critical aspects of knowledge building. It should be noted that Knowledge Forum has a growing suite of tools (the Analytic Toolkit) that provide representations of knowledge building activities within the database, thus supporting rich, reflective discourse (Zhang, et. al., 2009). However, because computers are not readily accessible to students and teachers in their classrooms, we constrained our designs to mobile, physical artifacts that students and teachers could easily share.

As stated earlier, we felt that it was critical to work together with the community to develop not only a lens for seeing, but also a language for discussing new concepts. In the early years of the project, when we spoke with teachers about socializing students into working with ideas, it seemed that the notion of "working" was taken as some laborious set of tasks or indicative of routines or procedures. Hence, it became important to find ways to convey work with ideas in knowledge building communities as creative and playful. One useful framework for supporting discourse grounded in playfulness and creativity is *epistemic games* (Collins & Ferguson, 1993; Morrison & Collins, 1995). Using this framework, we have created a set of tools for engaging teachers and students in inquiry into knowledge building moves. We describe these tools in more detail below.

## Knowledge Building Communities and Epistemic Game Play

In creating the theoretical lens of *epistemic games* (Collins & Ferguson, 1993; Morrison & Collins, 1995), Collins and his colleagues are concerned with characterizing the ways in which members of a community of practice work to construct knowledge. *Epistemic games* refer to strategic play with disciplinary knowledge and are based on the study of disciplinary communities such as Physical, Biological, and Social Scientists (e.g., the Cost-Benefit-Analysis Game, the Systems-Dynamics Game). The overall goal is to support learners in developing *epistemic fluency*, developing an understanding of the moves, constraints, and strategies for working with various forms of knowledge.

In Ideas First, we view epistemic game play as being of two major kinds. The first concerns science representational games involving target structures such as classification trees and graphs. The second concerns knowledge building games involving goal states such as the creation of knowledge useful for explaining a problem of understanding. The first kind correspond to those described by Collins and Ferguson (1993) where the game involves constructing a fixed representational target or *epistemic form*, such as playing a Multi-factor-Analysis Game with an And/Or Graph. The second are those where there is no specific epistemic form targeted, such as the Theory-and-Evidence Game (Collins, in press; Morrison & Collins, 1995).

Although we do not use the actual term "epistemic games," we do frame knowledge building in Ideas First in terms of game play and knowledge building moves. Scientists advance their understanding of problems in many ways. One way we represent play with ideas is the "Progressive-Investigation Game" (Figure 1). This representation is meant to capture a type of knowledge building progression that occurs both in the offline setting and online in Knowledge Forum. Carrying the game metaphor further, we discuss with teachers the similarity to sports teams where both full-length games and targeted practice sessions are a continual part of a player's development. Similarly, Ideas First involves a constant cycling of action and reflection in learning to play knowledge building games in science. In order to support teacher and student inquiry into knowledge building moves we have created two specific tools that isolate parts of the full Progressive-Investigation Game for practice and reflection, *Think Cards* and *hypothetical game-configurations*.

Think Cards can be thought of as concrete "game pieces" to facilitate game play (Figure 2). To provide consistency between offline and online game play, the cards are based on Knowledge Forum Notes (Scardamalia, 2004). The Think Cards are used to support one sequence of knowledge building moves that might be used to advance understanding of a problem --- generate an explanation for a problem and then gather new information that can be used to improve this explanation. Think Cards physically reify students' explanations (*My Idea is…*), the new information that they bring to their inquiry (*New information…),* questions that drive their inquiry (*INTU* stands for "I need to understand"), and improvements that they make to their explanations (*A Better Idea is…*).

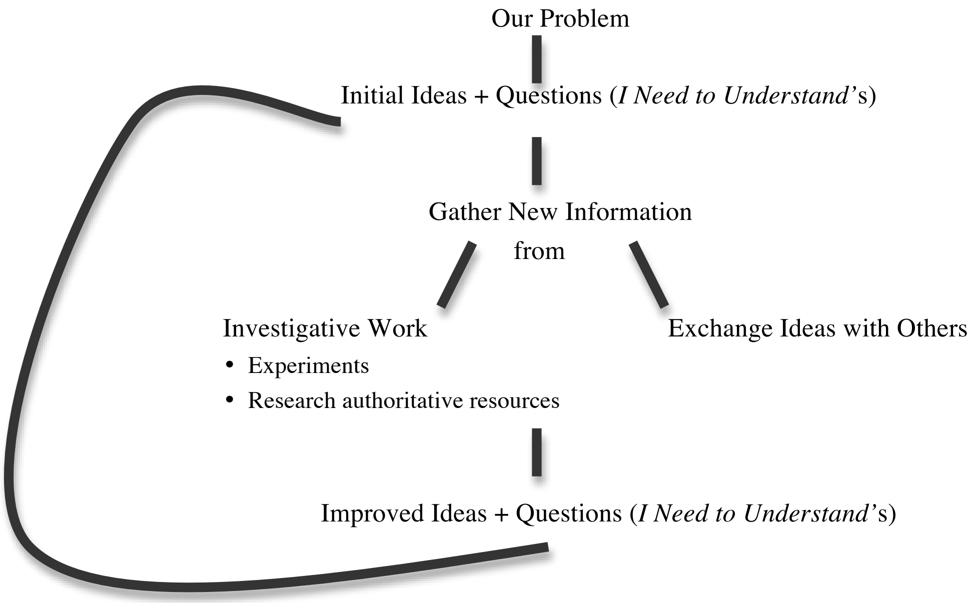

Figure 1. The basic flow of the "Progressive-Investigation Game"

Hypothetical game-configurations are used to reflect on the knowledge building moves made possible by a particular configuration of knowledge objects. The configurations consist of "snapshots" of hypothetical student work in Knowledge Forum, meant to capture game play at a fixed point in time in order to engage the community in asking: given this configuration, what types of knowledge building moves would best contribute to advancing our knowledge? Some configurations focus on single moves, such as presenting a possible initial explanation generated in response to the problem the students are working on. Students then generate a knowledge building move meant to advance this initial idea. There are also more complex game configurations that present not only a possible initial explanation in response to a problem, but also provide a series of possible knowledge building moves. In this case, students both evaluate the quality of the provided moves and generate a possible next move that contributes to the progressive improvement of ideas. In all cases, students each work on the same hypothetical game-configurations so that they can then compare and contrast their proposed knowledge building moves in whole-class discussions about issues such as what makes a "good contribution" and what does it mean to advance the community understanding.

Our design argument is that in full-blown game play in spaces such as Knowledge Forum and classroom discourse, it is difficult for beginning learners to see critical events and features, thus making it difficult to develop the necessary epistemological perspectives on community practices and an understanding of the moves, constraints, and strategies for working with various forms of knowledge (i.e. epistemic fluency). The Think Cards are used in the early months of Ideas First. After students have moved into full-game play in Knowledge Forum, the hypothetical game-configurations are introduced as a means of examining specific elements of epistemic game play, permitting further practice and reflection on participation in community knowledge building. The continued use across grades 3 and 4 makes it possible to highlight particular knowledge building moves such as how to advance an explanation or how to synthesize ideas, which are then related to student work in Knowledge Forum. We provide more detail on our use of the Think Cards as a reflective tool in the Ideas First program in the remainder of the paper.

## Think Cards: Learning to Make Knowledge Building Moves

The Think Cards are used in the first two units of Grade 3 (months 1 - 3). This is students' first formal science experience in primary school. The unit opens with a whole class discussion of "How do Scientists make sense of the world?" and highlights the underpinnings of Ideas First, such as working as a science community to understand questions that we have about the world and how, like Scientists, we keep working to improve our ideas and explanations. The Think Cards are used to support actions consistent with this framing, but are limited to the *initial idea-new information-improved idea* sequence of knowledge building moves. The goal is to challenge the prevailing classroom culture where students' written responses tend to be viewed as static entities that either match a predetermined "model answer" or not. Instead, the first Think Card, *My Idea is…*, is used to encourage students to write down their initial idea, with teachers setting the classroom norm of respect for others' ideas and not worrying if one's idea is correct. These ideas are then shared in the public space (via the Whiteboard, or in small-group discussions) in order to make visible the diversity of ideas that are now available as resources for the whole community. Because of curricular time constraints[2], students work on a problem of understanding that is provided to the whole class (e.g., How do we know if something is a "living thing"?). However students are encouraged to continually record their own questions (the *I Need to Understand…* section at the bottom of the cards) and to use the processes modeled with the class problem to advance their understanding of these questions.

The *New Information…* Card is used to introduce a possible knowledge building move toward progressively improving an initial idea. Rather than using resources to "find the answer," the focus is on using books, videos, the Internet, and other people as resources to improve initial ideas. In many classes, students begin bringing resources from the public library and home to share with the class. Class discussions center on issues such as why certain resources are useful (with some classes discussing the trustworthiness of science content in sources such as children's cartoons and television shows) and the mechanics of note-taking, which is a new skill for these 9 year-olds. Students also discuss the practice of citing resources (including people) in order to return to sources if necessary.

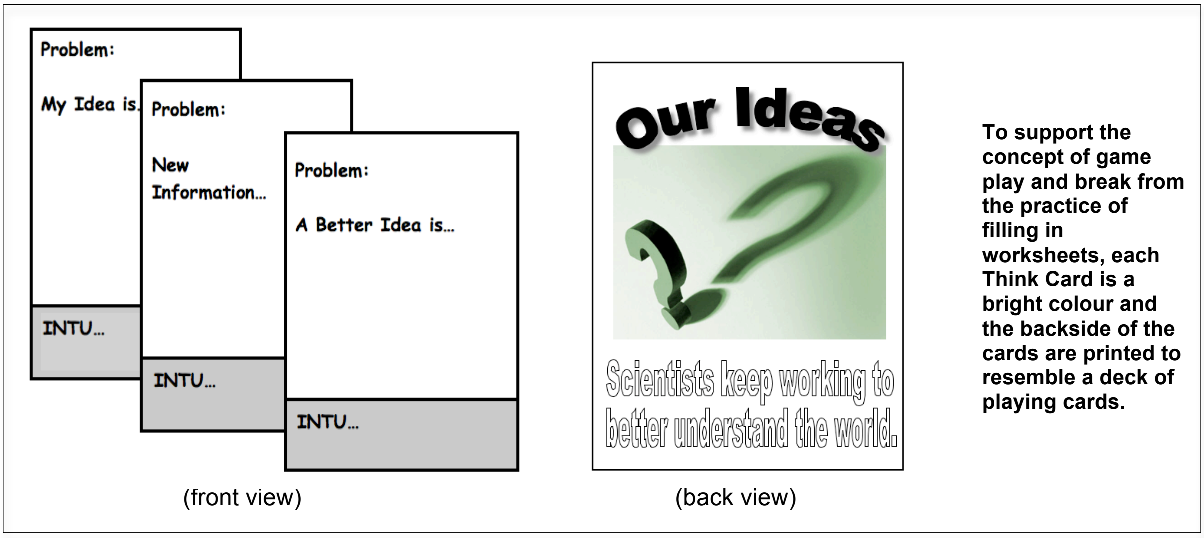

Figure 2. Ideas First Think Cards

The use of the Think Cards occurs over several weeks. The initial idea cards lead into research with various resources to collect new information centered on the class problem, but also including individual questions. Students generate as many New Information Cards as they wish, and share them with the class through whole-class and small-group discussions. This, in turn, leads to access and exchange of information across cards. This work culminates in *A Better Idea is…* Card, where students work to synthesize their learning into an improved explanation of their initial idea. This knowledge building move opens up a space for discourse concerning the meaning of idea improvement. For example, are we interested in looking at improvement in terms of comparison to the initial idea, or solely with regard to the quality of the end product?

The small, mobile nature of the Think Cards make it easy for children to work with their ideas --- jotting down notes in the library or during discussions, spreading their cards out to examine the collection of ideas, literally "exchanging ideas" with others, etc. We believe that it is important that a child can physically accompany the written form of his or her idea into a group discussion, thereby disrupting the conception that a written idea is a static response to a question when the child holding the Think Card is asked by peers to further elaborate the idea or the child defends the idea when it is challenged. The Think Cards also make visible the diversity of ideas that students generate for a particular problem of understanding and that can be collected from various resources, and the multiple pathways possible in moving from initial ideas to construct new knowledge.

Many of the visual affordances (in contrast to the physical) that we discuss here are also available in Knowledge Forum. Such similarity is seen as critical in order to create a consistent developmental trajectory within a semiotic space where knowledge and sources can be questioned and problematised --- from physical knowledge objects in a child's hand that co-located agents can act upon (months 1 - 3 of Ideas First), to "concrete" knowledge objects in the virtual space of Knowledge Forum that can be acted upon by multiple agents (months 4-24 of Ideas First), to broader disciplinary knowledge worked upon by members of the science community.

## Teacher Reflections on the Use of Think Cards

Over the course of the year, teachers in both the Grade 3 and Grade 4 levels meet for bi-weekly reflection sessions. One of the Grade 3 sessions during Unit 1 focused specifically on the use of Think Cards, with the eight teachers all writing written reflections and then sharing their perspectives in an open discussion. Here we briefly illustrate their descriptions of classroom experiences.

One teacher described the Think Cards as a "tool to initiate children into the Ideas First culture," and highlighted that their use "Helps the teacher reinforce the idea that "all ideas are important" by encouraging them to write down their thoughts, whether or not they think they are right." Other descriptions related to culture building included "Students get to experience the processes real Scientists go through in the work," and "*A Better Idea Is…* Card is good as pupils start to rephrase the main content's ideas with vocab and language like scientists. "

The teachers' reflections indicated that they used the Think Cards not only to help students participate in knowledge building practices, but also to engage in reflecting upon the nature of their participation and the ways in which knowledge is built. Based on initial analyses of the teacher responses, two categories emerged concerning the ways the Think Cards helped to support student reflection on knowledge building: *how to engage with ideas and advance understanding* and *how students can serve as resources for each other*. We briefly describe these two areas below.

## How to Engage With Ideas and Advance Understanding

Based on interviews with the teachers of this school over the four years of the project, the typical classroom experience for these students involves answering questions (either verbally or on worksheets) and receiving positive or negative feedback with an explanation. The underlying processes for developing their own explanations are rarely made visible, beyond "studying" or "working harder." Learning that there are processes that can be undertaken to advance one's understanding is thus critical for helping students learn how to engage with knowledge. The teachers describe how the Think Cards introduced students to specific approaches to advancing their ideas and enabled students to see the growth of their ideas:

> *The cards allow pupils to take step-by-step approach in researching their ideas and problems.*
>
> *Helps students to appreciate their own work and observe how they had "grown" in their understanding of a problem.*
>
> *When pupils put their 3 cards together, they can see how their ideas have grown from rather vague and haphazard to something more detailed and specific to the problem or question.*

One teacher told of how using the Think Cards to reflect on their growth of understanding helped her students to "value the process":

> *I saw a shift in their attitudes toward the cards. When we first started out with the Think Cards they were asking me, "Why are we doing this?" And then, um, I had one session with them where they laid out their cards together after they completed one topic. And I got them to sort of like celebrate, or appreciate, the work that they had done individually and at the same time go around and see what their other friends have done. So, um, and to particularly look for how they had grown in their understanding of the problem. So, from there they saw that there was value to what they are doing. So by the time I gave them the second set of cards they quite readily worked without any more of these questioning.*

Through examining their work with Think Cards --- coming to understand that an idea can be a starting place rather than a terminal answer, observing that knowledge can be constructed via multiple pathways, discussing the similarities and difference between what they do and what scientists do --- the intention is for students to better understand not only the processes of knowledge building, but also their agency for participating in such practices (what Scardamalia (2002) refers to as "epistemic agency").

Although the teachers found it helpful that the step-by-step approach of the Think Cards provided an entry point into the processes of knowledge building, the teachers also felt it was important that such an approach did not lead to students following this sequence in a routinised manner, but instead led into more versatility in knowledge building. For example:

> ***Miss H****: I think at this stage when they first just started in this I think they need a little, some steps. So by the second set of cards they are quite comfortable. ...But I think that, um, as they get the hang of this, that the other Thinking Phrases*[3] *can start coming through. They need not follow this, um, steps, steps they have to follow, later on [inaudible] start using other Thinking phrases.*

***Researcher-Facilitator**: So you already foresee a time …*

***Miss H**: Yeah. Because I don't want them to just be thinking this way. First the yellow* [My Idea is card]*, then the purple* [New Information card]*, then the, the, yeah… I think in real life we don't do this, um, all the time. We need them to be very versatile in their thinking as well, not just thinking sequentially but perhaps concurrently with other issues that are popping up.*

It is critical when using supportive processes to guide student introduction to epistemic game play that the processes not be reduced to simple steps to be followed, but instead are viewed as moving students onto a trajectory leading to greater creativity.

## How Students Can Serve as Resources for Each Other

Working together and serving as resources for each other are critical aspects of playing epistemic games in knowledge building communities. With regard to how to serve as resources for each other, the teachers described ways of using the ideas of others in one's own explanations or contributing to each other's advancements, as well as strategies for synthesizing ideas and resolving conflicts. One of the ways they did this was by connecting student use of the cards to the various design principles of Ideas First[4]. For example:

*I strongly feel that the Think Cards help in Principles 3—"Working together to improve ideas."*
- *Students share ideas aloud, teacher writes on board*
- *Other students who do not have the idea will write in their Think Card and see their ideas <u>GROW.</u>*

*It* [Think Cards] *is handy and enables pupils to pass them around to share their ideas.*

*If ideas written on board has misconception, getting second or third student to rephrase the idea promotes Principle No.5—"Moving ahead…and help…"* [The community can only move ahead if we help all of the members of our community to move ahead] *where pupils themselves clarify their peers' idea. If this happen where 2 pupils help one another in clarifying his/her peer's ideas, tr* [teacher] *will write both names in brackets, to acknowledge their contribution.*

Although the Think Cards focus on "My Idea" and "My Better Idea," the teachers indicate that they keep the focus on *our* ideas through keeping ideas visible as public resources for all and through encouraging peers to exchange their ideas and help each other. Such a focus is related to Scardamalia's (2002) notion of "collective cognitive responsibility," a shared responsibility for advancing the community's understanding.

## Supporting Teacher Reflections

In addition to supporting student reflections on knowledge building processes, working with the Think Cards also supported teacher reflections on pedagogy. For example, in the written reflections, one teacher raised his own *I Need to Understand* questions for the other teachers to consider:

*INTU: How do we assess where we as teachers are in terms of the learning of our students? As a community, I feel that we have to move on as a class to create meaning of the lessons and the knowledge that we have built upon. However, how do we determine the cut off time to move on to a different of the lesson if we are constrained in terms of time?*

Further, the teachers got into a discussion about teaching problems that came up in their classes. One example involved students who write "textbook entries" on their cards rather than their own ideas. Another concern involved students who "got all the key science ideas in the first Think Card" and then they didn't know what to do for their New Information card so they wrote copious notes from other resources. These teacher exchanges led to examining more deeply the types of classroom practices and contexts that needed to be created to support knowledge building.

The teachers' discussion of their experiences touches upon the interplay of the nature of disciplinary practices, pedagogy and classroom enactments, and student participation and understanding. We feel that continued engagement in dialogue centered on such interplay is critical in order to support teachers in the creation of classroom knowledge building communities and toward an ever-deepening understanding of what Hogan and Corey (2001) call the "composite culture":

> The "composite culture" represents the classroom culture of science that students actually experience, which is a mixture of ideals of professional science practice… and pedagogical ideals… as filtered through the realities of classroom life and scientific practice. Finally, students' perspectives feed back into shaping the composite culture of the classroom. (p. 216)

This is also consonant with teacher education research on supporting the professional development of beginning elementary science teachers through focused dialogue regarding "(1) engaging in science, (2) organizing instruction, and (3) understanding students" (Mikeska, Anderson, and Schwarz, 2009, p. 678). The teacher discourse indicates that Think Cards can serve as a tool to support dialogue at the intersection of science knowledge building practices, classroom actions, and student understanding.

## Conclusion

The use of Think Cards and hypothetical game-configurations permits guided practice and reflection concurrently with engagement in playing full versions of epistemic games such as the Progressive-Investigation Game. These tools are meant to work in conjunction with Knowledge Forum and video-based reflections in order to help teachers and students to problematise their participation in knowledge building communities. The advantages provided by the Think Cards include physical possession, which creates a strong sense of ownership and the ability to accompany one's ideas into social interactions in order to engage in extended discourse. Students are easily able to exchange ideas and lay out the cards in various configurations in order to see how different ideas are related. One disadvantage over Knowledge Forum is that physical limitations make it difficult for students to see how their ideas fit into the overall structure of the work of the whole class, and students are limited in the ease of creating different "views" on the knowledge base.

Beverly Caswell, a Canadian teacher who worked with the knowledge building communities model in her elementary science classes for many years, describes how as her students learned the processes of knowledge building that "it is almost as if they are thinking 'finally someone is letting us in on the rules of the game of science'" (Caswell & Bielaczyc, 2002). The work described in the present paper concerns ways to put Ideas First classrooms on a trajectory consistent with more skilled and creative playing of the epistemic games of Science. The research contributes to the growing literature on ways to create classroom cultures that mirror disciplinary cultures. Think Cards and hypothetical game-configurations scaffold scientific knowledge building processes, contributing to work with pencil-and-paper based scaffolds (e.g., McNeill & Krajik, 2009) and computer-based scaffolds (e.g., Bell & Linn, 2000). The work presented here captures only a small slice of the Ideas First design and of our work in facilitating a shift from didactic classrooms toward classrooms that function as knowledge building communities. In future work we plan to extend our analysis to classroom discourse around the epistemic game play described here, along with a more in-depth examination of the ways that students use the Think Cards and game-configurations in relation to their work on Knowledge Forum.

## Endnotes

(1) Refer to www.ikit.org
(2) In Singapore, the school year comprises four 10-week sessions. In this school there were 2-2.5 hours of Science scheduled per week in Grades 3 and 4 and an exam period at the end of every 10-week session. There is also a national curriculum specifying science objectives to be covered in preparation for the Primary School Leaving Exam (PSLE), a national high-stakes exam given at the end of Grade 6.
(3) Thinking Phrases are based on the scaffolds found in the Knowledge Forum software. In Ideas First, the Thinking Phrases include: *My Idea is, New Information, A Better Idea is, INTU, Evidence for this Idea, Pulling Our Ideas Together,* and *A Different Idea is.*
*(4)* Scardamalia (2002) outlines 12 design principles for knowledge building communities. In Ideas First we have consolidated these into five key guiding principles. The teacher quotes refer to two of these five principles: *Principle 3: We work together to improve our ideas* and *Principle 5: The community can only move ahead if we help all of the members of our community to move ahead.*

# Multiple Conceptual Coherences in the Speed Tutorial: Micro-processes of Local Stability

Brian W. Frank, University of Maine, 5709 Bennett Hall, Orono, ME 04469-5709, brian.frank@umit.maine.edu

**Abstract:** Researchers working within knowledge-in-pieces traditions have often employed observational approaches to investigate micro-processes of learning. There is growing evidence from this line of work that students' intuitive thinking about physical phenomena is characterized more so by its diversity and flexibility than its uniformity and robustness. This characterization implies that much of the dynamics of students' thinking over short timescales involve processes that stabilize local patterns of thinking, later destabilize them, and allow other patterns to form. This kind of "change" may only involve dynamics by which the system of intuitive knowledge settles into various states without changing the system structure itself. I describe a case study in which a group of college students shift their thinking about motion several times during a collaborative learning activity. Instead of focusing on micro-processes of change, I describe these dynamics in terms of mechanisms that contribute to local stability of students' conceptual coherences.

## Introduction

Conceptual change research in the seventies and eighties largely began focused on characterizing the singular and often flawed ideas that children and students espouse about domain-specific phenomena (Driver & Easley, 1978; Posner, Strike, Hewson, & Gertzog, 1982; Carey, 1986). From this perspective, it was largely assumed that unitary knowledge structures–naïve theories (McCloskey, 1983), alternative frameworks (Clement, 1983), or ontological categories (Chi, 1992)–describe important aspects of novice misunderstandings and that these misunderstanding must give way to other structures in a progression toward expertise. In contrast, more research in the past two decades has focused on characterizing the *diversity* of ideas that children and students employ for making sense of physical phenomena and the nuanced *contextuality* of these varied ideas across time and setting (Strike & Posner, 1992; Smith, diSessa, & Roschelle, 1993; Hammer, Elby, Scherr, & Redish, 2004). From this perspective, it has largely been assumed that a substantial component of expertise involves the gradual refinement and repurposing of existing knowledge–phenomenological primitives (diSessa, 1993), conceptual and epistemological resources (Hammer, 1996), or even pieces of ontological knowledge (Gupta, Hammer, and Redish, accepted).

Both of these perspectives have largely made *change* a central problem to be explained by research. Much of the prior research has focused on broad processes and conditions for change, while the latter has focused on micro-processes of change. In this paper, I focus on describing student understandings as reflecting *multiple local coherences* (Hammer et al, 2004; Rosenberg, Hammer, & Phelan, 2006; Scherr & Hammer, 2008). This specific term is intended to capture the notion that understanding and behavior are often quite variable, while still exhibiting stabilities that are local to moments and settings. While much of this existing work has focused on epistemological coherences, I focus here on describing local coherences that concern the substance of students' thinking. This perspective shifts attention away from seeking only explanations of change and toward explanations of how understandings cohere in specific moments and settings. Locally coherent patterns of student thinking are to be explained in terms of mechanisms that stabilize these patterns. This perspective is explored through an analysis of students' multiple conceptual understandings during a collaborative learning activity in an introductory college physics classroom.

## Interpreting What Distance Means in the Speed Tutorial

Before discussing the theoretical and epistemological considerations for this work, I want to motivate this discussion through an example of student reasoning that is the focus of this study. Two vignettes below are taken from a student discussion during a collaborative learning activity in introductory college physics. The students are in a tutorial—a common instructional format in introductory physics classrooms where students are expected to work together through a conceptual worksheet. In this particular tutorial (a modified version of a tutorial from McDermott, Shaffer, and the Physics Education Group at the University of Washington, 1998), a group of four college students discuss "tickertape" representations of motion.

Tickertape refers to a long strip of paper that can be used to create a record of an object's motion by attaching the paper to the moving object. They are commonly used in physics classrooms to teach students concepts about velocity and acceleration. The record of the motion is produced as the paper is pulled through a tapping device that marks the paper at a constant rate. In this tutorial, strips of tickertape represent the motion of a cart that was recorded prior to class (see Figure 1 for a cartoon schematic). Each student has been given a small strip cut from the entire tickertape that represents the same amount of time (i.e., has the same number of dots) but represents different speeds (i.e., have varying length).

Figure 1: Cartoon Schematic for How Tickertape Strips were Made Prior to Class

Below, the students discuss how the amount of time taken to generate each of their different strips compares, and incorrectly decide (as many groups initially do) that the shorter strips represent less time.

Beth: Obviously, it takes less time to generate the more closely spaced dots.
John: So you are saying it takes less time to make the shorter segments?
Beth: Yeah.
Kate: How can you tell?
Beth: You can tell because it's a shorter distance.
Paul: It's a shorter segment.

The students discuss this conclusion for several minutes, pointing out other features of the strips that support this conclusion. They soon move on to the next part of the worksheet that involves doing some calculations based on distance measurements. After finishing these calculations, the students are prompted by a specific question in their tutorial workbook to reflect upon their assumptions in doing these calculations.

Kate: I think we also assumed in that these were made by the speed at which the paper traveled through the tapper, which was different for each paper.
John: Right, cause if you move it really fast then *[quick movement of hand]*
Beth: That's true! It could depend on how fast the ribbon was pulled *[moves hand]*
Kate: We're assuming that umm-
Beth: That the length is proportional to-
Kate: -The speed at which the ribbon was pulled through.

These two vignettes involve student understandings that are substantively quite different. In the first, students interpret distance as conveying information about time. In the second, students interpret distance to mean speed.

It seems natural, given the obvious change in students' interpretation of what distance means, to ask, "What caused the students to change their thinking?" This focus seems especially relevant since they changed their understanding from an incorrect one (thinking that the distance indicates time) to a correct one (that the distance indicates speed). We might consider several plausible accounts of what caused the change: (i) the particular question from the worksheet triggered them to think meta-cognitively about what they had been doing, (ii) engaging in the measurement exercise enabled the students to attend to and coordinate new aspects, and (iii) Kate was privately thinking the correctly the entire time and only now found a way to have her ideas introduced and considered. Each of these answers may hold some truth in explaining the change in students' collective understanding. The question about change, however, may be misleading.

It turns out that the students don't change their thinking on the matter this one time. Several minutes after the end of the above transcript, Beth brings up again the idea that the shorter strips take less time. Kate, who initially introduced the idea that the speed causes the different distances, seems to now agree with Beth. As the tutorial goes on, the group works to regenerate their understanding that distance must be related to the speed and not the time. However, this is not the last change. As the students go back to a previous page to erase their wrong answers, one of the students is again convinced of their earlier idea. It's not entirely clear that the students ever resolve the issue completely during the instructional period. Instead, their understanding seems to vary between these two distinct ways of making sense of the strips of paper as representations of motion.

For the researcher, trying to understand the cause of just a single moment of change in the students' thinking now becomes a problem of explaining multiple changes back and forth. The seemingly straightforward question, "What caused the students to change their thinking?" may not only be difficult to answer, it may be misleading in its premise. For starters, there might not be a simple or single causal explanation for any of these transitions. In addition, the apparent change in the students' thinking might not reflect change to the structure of students' intuitive knowledge at all. Instead, the changes we observe might only reflect dynamic transitions among competing understandings that each exhibits some local stability. Understanding the local stabilities themselves becomes a central problem for researchers to address. The aim of this paper is to describe how the students' initial understanding may be stabilized through a variety of different mechanisms.

## Theoretical Orientations

The shift in perspective I am advocating coincides with an underlying assumptions that distinct patterns in student thinking reflect dynamic stabilities and that these stabilities require explanation. The stability of student thinking need not be due to the existence of a robust belief or mental category, but rather due to how real-time activity creates self-sustaining patterns of thought. The notion of real-time activity has often been discussed dichotomously with respect to human behavior and learning—either encompassing individual, cognitive activity (e.g., connectionism) or as distributed, social activity (e.g., activity theory). In this section, I briefly discuss relevant aspects of these individual and activity perspectives.

### Activity among Knowledge Agents

From individual cognitive perspectives, complex knowledge systems approaches describe activity as occurring among fine-grained knowledge structures. Minsky (1986), for example, conceptualized the individual mind as a society of mindless "agents"—numerous in kind and in their interactions. Agents, like schemata more generally conceived (Bartlett, 1932/1995; Rumelhardt, 1980), can be thought of as cognitive elements for perceiving, doing, and remembering. These pieces come together in various ways to generate and represent thinking. One kind of knowledge piece that has been discussed quite extensively is diSessa's (1993) phenomenological primitives—bits of knowledge reflecting our intuitive sense of mechanism. In the above transcript, we might think of the students' inference about the shorter strips taking less time as resulting from the intuition that *less distance implies less time*. This bit of knowledge for relating space and time is part of how the students interpret and make sense of the strips as representations of motion.

Beyond just describing kinds of knowledge, diSessa distinguishes between two properties of intuitive knowledge systems that he calls *cuing priorities* and *reliability priorities*. These two properties drive mechanisms that activate and stabilize ideas in particular contexts. Phenomenologically, cuing priorities describe the likelihood that a given piece of knowledge will activate in a given context, while reliability priorities describe the likelihood that a given piece will remain active in a given context. In the above example, we see the idea "shorter strips take less time" becoming focal in the conversation and then persisting for several minutes beyond the transcript.

Structurally, if one thinks of knowledge elements in terms of a network, reliability is related to the number of activation pathways leading away from and then back to a given knowledge element. In other words, a given idea can be made more stably active (in a given setting) because other "nearby" ideas support its sustained activation. Thus, the relationships and interactions among many ideas serve as one kind of mechanisms by which patterns of thinking are self-sustaining over a period of time. With the transcripts above, we whether other ideas arise during their conversation that help to support their continued thinking that the shorter strips take less time, as well as how the context supports the cuing of those ideas.

### Activity among Participatory Agents

From a more distributed and social perspective, activity-theoretical and other situated approaches describe activity as occurring among persons and artifacts, not among entities of the mind. In many respects, this view represents an oppositional stance to the above knowledge-based accounts. Lave (1988), for example, in describing the variety of mathematical practices, denies the existence of mental constructs such as arithmetic. Despite this dichotomy, there are those who do attempt to capture both knowledge and participation views in their accounts of students' thinking (e.g., Roschelle, 1998) or have advocated for their commensurability.

One major difference between knowledge- and participation-based accounts concerns the typical unit of analysis. The unit of analysis for situated perspectives is often described as the entirety of *persons-in-settings* (rather than individuals or individuals' knowledge). It is more focused on observable unfolding social activities (than knowledge use) and how these activities arise within social settings that are defined by the activity (and not by platonic outsider descriptions). Beyond just focusing on humans, these perspectives focus on describing how material artifacts mediate aspects of that activity (Engestrom, 1987), provide affordances for action (Greeno, 1998), and shape semiotic fields (Goodwin, 2000). In the vignettes above, the students do not only have different understanding. They also interact with each other and their settings in quite different ways.

Different patterns of action and social collaboration, taking place within changing material settings, can be understood to constrain and support activities that also differ in terms of the *substance of the ideas* to which activity is oriented. Embodied cognitive perspectives, for example, emphasize how human understandings have a strong basis in bodily action (e.g., Thelen & Smith, 1994). Pointing is an action that might support ideas for understanding objects and their spatial relations, while dynamically moving one's hand through space might better support ideas for understanding trajectory and cause and effect relations. Similarly for social collaboration, establishing joint attention as part of collaborative action might afford different epistemic activities than establishing mutual attention. Such social cues help individuals to *frame* (Scherr & Hammer, 2009) activities.

Taken together, the affordances of artifacts and the patterns of participation that take shape around them serve as mechanisms by which activities stabilize in settings. By carefully considering the substance of ideas to which these activities orient as well, the analytical task undertaken in the next section is to explain the stability of students' understanding in terms of both knowledge- and participation-based mechanisms.

## Explaining the Local Stability of Reasoning

The goal of this section is to develop an explanatory account of the stability of the students' initial thinking in terms of real-time processes. I describe several knowledge- and participation-based mechanisms that plausibly contribute to the stability of students' thinking and connect these claims to specific evidence.

### Knowledge Based Mechanisms

#### Contextual Feedback from Setting

One way in which the students' initial thinking that "shorter strips take less time" stabilizes is due to how particular micro-features of the context support the continued activation of underlying intuitive knowledge. Several aspects of the particular context in which students discuss their ideas support the persistence of the idea that *less distance implies less time*: the specific language of the worksheet question, the salience of length differences among the tickertape strips, and a congruence of part-whole relationships on the strips.

The particular question from the worksheet reads, "How does the time taken to generate one of the short segments compare to the time to generate one of the long ones?" Beth immediately states, "Obviously, it takes less time to generate the more closely spaced dots." The particular phrasing of the question not only draws attention to the distance features of the strips, it uses the words "shorter" and "longer" to do so. These specific words are relevant, because they are used flexibly in everyday language to both refer to distance and time (but no other concepts). The ambiguity of these words closely ties with the intuition that *less distance* ("shorter") *implies less time* ("shorter"). The students repeatedly use those words while discussing their initial ideas.

The students' understanding is also supported by features of the tickertape strips. By far, the most salient feature of the strips is that they are different lengths. One can observe this when standing far away, without closely inspecting the details of where the dots are located. The salience of this feature supports students' initial and sustained attention to distance features of the strips, which has been shown to preferentially cue the idea that *less distance implies less time* over other competing ideas when students are asked to made judgments about duration (Frank, Kanim, Gomez, 2009). In the transcript, after Beth initially gives her answer, the students explain that they can tell its less time because the strips are shorter. As they explain this, the students can be seen reaching toward the strips and indicating distances on the strips with their fingers and pencils. These statements and gestures show that students are closely attending to this salient feature in support of their initial understanding.

A second feature of the strips that contributes some stability arises from the fact that each of the strips has the same number of dots. When inspecting the strips, students do not only attend to the total length of the strips, but also to the length of the spaces between dots. Because each strip has the same dots, this means that the longer strips are made up of longer pieces, and the shorter strips are made up of shorter pieces. As students shift their attention from the entire length to the length of the parts (or vice versa), students see the same information. Shorter strips or shorter parts imply a shorter amount of time. Evidence that this shift in attention does not disrupt the students' thinking, and may in fact stabilize it, comes from a part of their conversation that happens shortly after the end of the first transcript above.

Kate: When we are talking about segments, are we like not thinking about how long the total paper is? Are we just looking at the marks. Are we supposed to be considering
John: I'm guessing they like mean from here to here. *[pointing with pencil between marks]*
Kate: Like I wonder why like the papers are all different lengths.
Beth: Cause none of these papers are the exact same si-ize. Except for these two *[pointing]*
Paul: Right because I think *[moving hand toward the center]* they all have the same amount of dots *[pointing to several locations on one of the strips]*.
Beth: Oh-oh
Paul: I think they all have six dots.
Beth: Oh do, they?
Kate: Is that true? 1, 2, 3, 4, 5, 6 *[pointing to successive dots on a strip]*
Paul: So, it's a shorter amount of time for a shorter piece of paper

Kate asks if they are supposed to be looking at the distance between the "marks" or the total length. As the students coordinate between these two features (realizing that there are six dots on each), the students maintain their understanding that the shorter strips take less time.

### Structural Feedback from Other Knowledge

The students' initial understanding is also stabilized through the recruitment of other ideas that support its persistence. Two specific ideas arise together with the idea that the shorter strips take less time. One is that *bunched up means faster,* and the other is *faster implies less time.*

Students attend to the length of the entire strip and to the length of its parts, but they also attend to the "density' or overall proximity of the dots to each other. These students, as well as many others, describe the bunched up patterns as "faster" and the more spread out patterns as "slower". The words "faster" and "slower" used here is another example of ambiguous and flexible use word meaning, similar to how "longer" and "shorter" are used in reference to the distance and time. The students notice "more dots happening in less space" and describe this pattern as "faster". However, the same word is used by these students to describe a greater speed and also a lesser the amount of time, and therefore provides some ambiguity about its meaning.

Both immediately before and after the students discuss that the shorter strips takes less time, several of the students refer to the shorter strips (with the more closely spaced dots) as faster:

Beth: Nobody has the exact same rate
John: *[pointing to the shortest strip]* So I guess that's the fastest.
… (and then later in their discussion)…
Beth: How do you know how to arrange –
Kate: Ahh. The shorter the segments the faster the speed
John: Yeah.
Paul: Also shorter the paper, it's the same thing.

Here we see the students using the word faster to identify shorter segments. The idea *bunched up means fast* can be understood to work together with another idea that arises. In this case study, and many others described elsewhere (Frank, 2009), we see evidence that students discuss the idea that *faster implies less time.* Beth explicitly discusses this idea during their discussion at a slightly later time when she says, "Wouldn't yours be going slower than mine, because it took more time to make that same?" Her statement implies that a shorter strip goes slower because it takes less time, which she and the other students had established earlier as being known because the strip was shorter (bunched up). A single strip is thus conceived of as being short, bunched, and fast, with the words "short" and "fast" having multiple meanings that overlap.

These three elements of intuitive knowledge– *less distance implies less time, bunched up means faster*, and *faster implies less time*– are all connected through their linguistic and conceptual overlap. Ideas of *less distance* and *less time* are bound by a linguistic overlap with the words "longer" and "shorter". *Less distance* and *bunched* are bound by their conceptual overlap with a spatial sense of proximity. *Bunched* and *less time* (and even notions of speed) are bound by their linguistic overlap with the word "faster" and "slower". This network of ideas can be understood to exhibit stability through the mutual relationships among its parts.

These knowledge-based mechanisms describe how relationships among specific elements of knowledge and contextual features provide some stability to their understanding, contributing to its persistence over time. In the following section, I describe aspects of activity that provide stability in different ways.

## Participation Based Mechanisms

The previous section largely focused on mechanisms that concern how knowledge elements remains active due to interactions with features of context and with other elements of knowledge. In this section, I discuss how the students' thinking is stabilized through processes by which students interact with each other and with artifacts.

### Feedback among Interactional Behaviors

Students' collective interactions with each other and with various artifacts around them show distinct patterns that are relevant to understanding their activity. For the first fifteen minutes, the students collectively move in and out two broad clusters of interactive behavior. These behaviors largely occur together among all the individuals, with some exceptions. The two distinct patterns are (i) behaviors oriented toward their worksheets (see Figure 2)- a pattern described by Scherr and Hammer (2009)- and (ii) behaviors oriented toward the strips at the center of the table (see Figure 3).

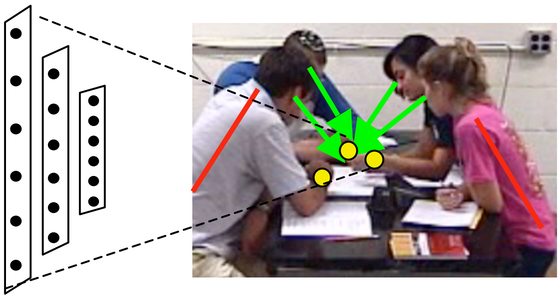

Figure 2. Student Behaviors Oriented toward the Strips

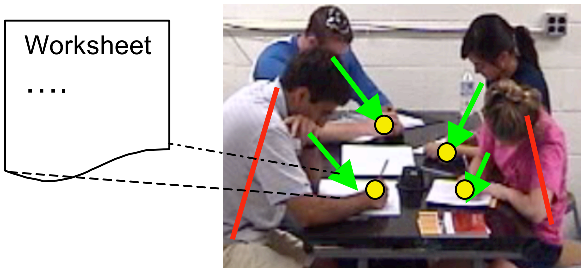

Figure 3. Student Behavior Oriented toward Worksheets

These behaviors support important aspects of the students' activity, which establish and stabilize a setting for their discussion. The tickertape-oriented behaviors are characterized by patterns of interaction that involve directing gaze, gesture, and bodies toward the strips at the center of the table. Students lean in, look inward, and position their hands at the center of the table. The students' clustering in this behavior is dynamically stable in the sense that any one student's behavior is coupled to the behaviors of the others. As students lean toward the center and point to strips and locations, other students look in that direction, and mirror these actions by leaning in and pointing to features as well. While individual students opt in and out, the collective structure of participation persists over much longer time scales. The worksheet-oriented behaviors are characterized by different patterns of interaction: hunching over, looking down, and using hands to write and point to worksheet locations. This pattern also exhibits a dynamic stability.

What is striking about the students' behavior during this time is the remarkable synchrony with which they move in and out of these two patterns. It is a highly coordinated (but not centrally directed) activity of noticing and describing patterns and then writing down answers to specific questions. This activity of establishing joint attention to community objects may be understood to couple to the substance of their ideas as well. Their initial understanding during this time concerns inferences drawn from noticing and comparing features of the strips (e.g., *short distance means short times* and *bunched up dots means fast*). These externalized behaviors for establishing joint attention are part of the dynamic by which the students access ideas and employ strategies used for noticing, describing, and comparing patterns across the strips.

Importantly, during this time, the students' neither discuss aspects of the physical motion of the strips, nor do they engage in any significant moments of mutual attention, as they do later. The above behaviors contrast with their later behaviors, where they orient their behaviors to each other—sitting up right, looking to each other, and gesturing in animated ways.

## Material Affordances and Constraints

The two patterns of collective behaviors above, which help to characterize the students' initial activity, take place in a particular material setting that provides affordances for these behaviors. The students themselves play a role in constructing this setting. In particular, during the time that the students' initially persist in thinking that the shorter strips take less time, the strips are located and arranged at the center of the table. The students moved the strips to this location and arranged them in order by length at the very onset of the tutorial. This centralized location allows the students to collectively orient to the strips and sustain an activity of pointing out and describing features of the strips.

The arrangement in the side-by-side fashion serves two purposes. First, it offloads much of the task of noticing and remembering to the setting. Second, the arrangement has affordances for particular kinds of gesture. Students gesture in various ways (pointing with a finger, indicating a space with two fingers, etc), but all of the gestures are deictic. These embodied actions may support students' ideas for thinking about objects and spatial relations among parts (the density of dot, the number of dots, etc.)

The anchoring of their activity to the strips as material artifacts and the dynamic stability of their collective behaviors feed into many of the knowledge-based mechanisms described in the previous section. Their individual behaviors couple to each other and to material objects. These behaviors help to sustain particular patterns of attention and action upon the strips. These behaviors support their use of specific intuitive knowledge. In one sense, we can think of the stability of students' thinking as coupled to a physical stability of the world. The strips, once placed at the center of the table, remain put until some actively moves them again. Similarly, the students have located their worksheets so that they are closely hugged to their bodies, making it easy to coordinate their dual activity between noticing and describing, and filling out their worksheets. The students seamlessly move back and forth between these two patterns of behavior repeatedly during the first ten minutes of tutorial. Their careful attention to just the visual properties of the strips (i.e., not to any sense of motion) in order to answer specific worksheet questions takes place in a dynamic setting that supports its persistence.

Just as students' thinking and behavior during the first episode contrasted with their later thinking and behaviors, the students' material setting later is different as well. Their later understanding happens in a setting where the students have separated and decentralize the strips. This change to their material settings provides new opportunities for embodied action and participation that did not occur before. In the second vignette, where Kate explains how the strips were made, Kate can be seen lifting a strip off the table and physically enacting the pulling of the strips by the cart. In doing so, the other students in the group look to Kate. The students engage in a new pattern of mutual attention as they discuss aspects of the physical motion which made the strips. This is the first time they engage in significant mutual attention, and is part of the dynamic by which they in articulate and listen to more complex ideas.

## Discussion

The primary goal of this paper is to characterize the stability of a single group of students' initial thinking during a collaborative learning activity in terms of a variety of micro-processes that together help to sustain one possible understanding for several minutes. A full analysis of these dynamics would also need to include an account of the mechanisms that contribute to their later thinking as well, but is beyond the scope of this paper. Given the dynamic changes apparent in their understanding during the tutorial, I claim that it is productive to focus on explaining the local persistence of understanding, rather than to begin with focus on causes of change.

One distinguishing feature of this analysis is its focus on explaining this stability both in terms of how elements of students' intuitive knowledge are reliably activated in the setting and in terms of how students' interactional behaviors dynamically constitute and stabilize aspects of this setting. I claim that the students make their initial inference about the tickertapes based on a shared intuition that *less distance implies less time*. There is evidence that each of the students makes sense of the situation using this idea at various times, and often times they do so together. I describe how particular features of the context (as characterized by the existence of specific features on worksheet question and on the strips themselves) contribute to activation of that knowledge, and also describe how other knowledge recruited to make sense of the situation provide a stable "network" of ideas for making sense of the patterns they notice. This network of ideas, however, arises within a social context of discussing patterns and writing down answers to worksheet questions. During their initial discussion, the students orient their gazes, gestures, and bodies toward the collection of the strips at the center of the table and toward the worksheets in front of them; but they do not engage in behaviors of mutual attention until much later. This activity of noticing and describing patterns to be written in their worksheets is both stabilized by the students' specific behaviors in this activity (to which they collectively orient) and by the location and arrangement of material artifacts that are central to the activity.

This characterization, while focused on explaining the stability of the students' initial pattern of thinking, does provide insight into the dynamics of their subsequent understanding as well. Instead of seeking explanations in terms of "causes" for the change, we can, instead, see how the various constraints imposed by their activity change. These changes in the constraints of their activity provide opportunities for new patterns to take hold with their own local stability. The students' new thinking co-evolves with changes to their patterns of attention (now to physical mechanisms involved in the motion), changes to the location of material objects (the strips become separated and within several of the students hands off the table), and to the patterns of interactional behavior (now they look at each other as they articulate complex ideas). Just as there may be not single cause for the local stability of the students' thinking, their may be not single explanation for why the students' thinking changes either. Across the entire tutorial, there are many changes that are more-or-less continuously changing over time. Coming to understand which aspects of activity are merely ephemeral and which continue to exert influences is a major goal of further research in this direction.

Beyond this particular case, considering students' intuitive thinking as reflecting multiple conceptual coherences may be useful for describing stabilities of thinking and behavior that seem to persist on longer time scales (e.g., Why do students appear to hold on to robust misconceptions?). It may be possible to both account for the variability of student understandings while also describing how, in particular contexts, it can settle into patterns indicative of common and robust misconceptions. This program might be achieved through careful attention to the multitude of cognitive and social mechanisms that contribute to the local stability of reasoning as it occurs within activity.

## Acknowledgments

The research described here was conducted at the University of Maryland. I'd like to thank Rachel Scherr, David Hammer, Joe Redish, Andy Elby, Ayush Gupta, Luke Conlin, Renee Michelle Goertzen, and Michael Wittmann for their helpful conversations. The research has been funded in part by the National Science Foundation under Grant Nos. REC-0440113 and REC-0633951. Any opinions, conclusions, or recommendations expressed in this material are those of the author and do not necessarily reflect the views of the National Science Foundation.

# Gaining an Insider Perspective on Learning Physics in Hong Kong

Jan van Aalst, The University of Hong Kong, Hong Kong, SAR, China, vanaalst@hku.hk

**Abstract:** This study provides an exploration of physics teaching and learning in a classroom in Hong Kong. The goal of the study was to understand how to develop Bereiter and Scardamalia's knowledge building approach for Asian contexts in away that is sensitive to Asian values. The paper reviews some aspects of learning physics in Asia from a Confucian-heritage perspective, and then reports a case study of physics learning with Knowledge Forum. Participants were 82 Form 4 (Grade 10) students taking two successive versions of a physics course. Data collected included classroom observations, measurement of physics learning, reflection, epistemic beliefs, attitudes toward science, and use of Knowledge Forum. The findings open up a number of questions for further research.

## Introduction

Work in classrooms based on the major educational approaches produced by the learning sciences is still at an early stage in Asian contexts, particularly approaches that make extensive use of collaboration, inquiry, and classroom discussions. However, to advance from this position does not merely involve *adapting* Western approaches to Asian contexts, which may lead to misinterpretations of how learning occurs there (Biggs, 1996). Rather, the premise of this paper is that it would be useful to develop an insider perspective on the learning sciences, based on a study of the values underpinning educational practices, review of research on Asian classrooms, extensive classroom observation, and a critical examination of perspectives from the learning sciences. With an insider perspective, we may then develop educational approaches in ways that build on Asian values and accomplishments, without inflicting what Ann Brown called "lethal mutations" (Brown & Campione, 1996).

This paper reports on a two-year exploration of this kind focusing on the teaching and learning in two successive Physics courses (Form 4 or Grade 10) taught by the same teacher; the context for this exploration was a research program on knowledge building (Scardamalia & Bereiter, 2006). The researcher reviewed the literature on cultural influences on science education in Confucian-heritage countries (mainly China, Korea, Japan, Taiwan, Singapore, and Malaysia), used ethnographic methods to observe classes, and measured wide range of variables thought to be relevant to knowledge building. Assessments measured physics knowledge, reflection on knowledge, attitudes towards science, and epistemic beliefs. Assessments of physics knowledge included capabilities considered important by the Physics Education Research (PER) community—detailed knowledge of concepts, and ability to develop explanations that refer to physics principles and causal mechanisms. The goal of the paper was to *benchmark* performance by the classes studied against international studies of physics learning and knowledge building, and to gain an understanding of how to evolve the knowledge building approach. Suggestions for development are outlined in the conclusion section.

## Cultural Considerations

External examinations are important in the West and influence teaching, but they have far greater cultural significance in the East. From the Han Dynasty (206 BC-220 AD) to the end of Imperial China, the *Keju*, a set of government examinations was used to select people from all walks of life for government positions (Amano, 1990). Preparing oneself for these examinations involved years of effort and commitment, but when a person passed them it led to upward social mobility and was a matter of great pride and advantage for their family. As an ancient Chinese idiom states, "Although studying anonymously for 10 years, once you are successful, you will be well-known in the world." The influence of Confucianism has decreased throughout the 20th century, but the emphasis on effort and accomplishment and their relationship to honor and social mobility have endured, producing societies that remain more hierarchical than in the West. Scholars have observed that moral self-perfection and social development are the most important educational goals, ahead of intellectual achievement (Gao, 1998; Lee, 1996; Li, 2009). Lau and colleagues concluded from a recent study of management issues in science classes in China, Israel, and Australia that Chinese teachers were more likely to mention that "learning to respect authority was a significant outcome of education" (see Lewis, Romi, Qui, & Katz, 2005, p. 731).

In present-day Hong Kong, students present themselves for the Hong Kong Certificate of Education Examination (HKCEE) at the end of Form 5 (Grade 11). Consistent with the above cultural influences, these examinations have a high standard. For example, of 29,713 students taking the 2008 Physics examination, only 4.6% received an 'A', 30.4% between 'A' and 'C', and 77.6% any passing grade (Hong Kong Examination and Assessment Authority). HKCEE results are very important for social mobility. Many employers require at least five passes for clerical positions, and HKCEE results are taken into consideration, besides university results, in applications to postgraduate programs. Standards in other Asian jurisdictions are similar. In a study of Chinese teachers (Gao & Watkins, 2002), one teacher commented that performance on matriculation examinations is "the most important even the only aspect by which the school assesses my teaching" (p. 65). These authors assert: "If the performance of students is not as good as expected, their teachers, principals and the head of the local government education department are all punished" (p. 71). Clearly, in implementing innovative educational approaches, teachers cannot afford to jeopardize examination results. Although in Hong Kong substantial curriculum and assessment reforms are in progress, there is no evidence that the high standards will be adjusted.

These conditions have a profound impact on classrooms. For example, Gao (1998) found that in China many teachers teach a three-year physics course in two years, reserving the final year for review and practice for the examination. Teachers may also schedule extra lessons and homework during school vacations. These practices are used because although daily teaching focuses on understanding of physics, this is not thought to be sufficient for the level of precision and detail at which students are examined. Asian teachers prefer didactic approaches, but disagree these are teacher-centered. One Chinese teacher interviewed by Gao and Watkins (2002) said, "If the teacher focuses on encouraging students, setting questions to challenge them, directing them to explore new knowledge, I don't think that means teacher-centered" (p. 73). Chinese teachers also say that classroom learning is not the whole of student learning, that after class student learning becomes more active (Gao, 1998). Several studies conclude that Taiwanese students have few opportunities to discuss their ideas in class (Aldridge & Fraser, 2000; Wallace & Chou, 2001). Aldridge and Fraser refer to a 1984 study on child rearing in Hong Kong, which concluded that attitudes towards filial piety (respects for one's parents and ancestors) was correlated positively with strictness and discipline and negatively with the expression of opinions and independence (p. 214). According to some scholars, Chinese students prefer to learn (comprehend) new material before raising questions about it and discussing it with others (Li, 2009).

Nevertheless, pedagogical approaches have begun to involve more activities and discussions. In a study of Taiwanese and Australian students, Aldridge and Fraser (2000) found that Taiwanese students focused more on the learning task, and the Australian students on the social interactions; although the Taiwanese students perceived their learning environment as more task oriented, they rated it more positively than the Australian students. Wu and Huang (2007) concluded that Taiwanese low-achieving ninth grade students in an interactive environment "did not receive direct support from the teacher that could constantly draw their attention to the content, [and] had fewer opportunities to listen to or engage in thoughtful discussions about concepts" (p. 747). These studies suggest that in Asian contexts it would be difficult to implement a constructivist approach in a Western sense, and that substantial teacher guidance is needed in addition to activities.

It is important to note that international studies of achievement in science such as the TIMSS and PISA consistently place Asian countries well above the international average (Leung, Yung, & Tso, 2005). Clearly, innovative educational approaches should not jeopardize such positive outcomes. Whereas Western observers have considered learning in Chinese classrooms as rote and the positive outcomes as "paradoxical" (Biggs, 1996), scholars now believe that a memorization-understanding strategy proposed by Ferrence Marton can account for the paradox (Chan & Rao, 2009). Preparation for Chinese examinations requires a high degree of practice and memorization, which is facilitated by conceptualization. However, although the results are strong in terms of subject knowledge, the various strategies used to prepare students for examinations may contribute to "learned helplessness" and keep students reliant on teachers. This is why *learning how to learn* has become an important emphasis in curriculum reforms in Hong Kong (EMB, 2000). At the same time, in the 21st century, people need to be able to collaborate and deal with novel situations. Perhaps the learning sciences can make a contribution to innovate learning approaches in Asian schools by developing new approaches to the memorization-understanding strategy that support the development of higher-order thinking and collaborative skills.

## Methods

### Participants

Participants were 82 students from two successive cohorts of a Form 4 (Grade 10) physics course, taught by the same teacher at an English Medium of Instruction (EMI) school in Hong Kong. The school was classified as medium academic achievement based on previous HKCEE results. Lessons were conducted in Cantonese, but all learning materials were in English, and students completed all assignments and tests in English.

### Goals and Design

The study is based on the first year of a two-year physics course; topics taught in the first year included heat and temperature (3 months), mechanics (5.5 months), and waves (1.5 months). The goal of the teacher's work was to explore how to improve on her previous efforts to promote knowledge building (Scardamalia, 2002; Scardamalia & Bereiter, 2006), an approach that involves collaborative inquiry and discourse aimed at advancing collective knowledge in a community. The use of Knowledge Forum®, a web-based inquiry environment, is an important aspect of this. Specifically, the teacher aimed to develop more collaborative discourse in both the classroom and Knowledge Forum, and to improve the integration of the use of Knowledge Forum with classroom learning.

In the first cohort (Class A, 2007 to 2008), students used Knowledge Forum to discuss their own questions about physics content (e.g., a discussion to examine why Eskimos live in igloos, which would intuitively seem cold dwellings). They also used it for discussions about two short projects, in which they collaborated in small groups: designing a solar cooker, and studying motion of their own bodies on a ride at a local amusement park. Both of these projects were heavily guided by the teacher. In the second cohort (Class B, 2008 to 2009) some modifications were made to this design: An interactive white board (IWB) was installed to facilitate easier crossing between classroom talk and work in Knowledge Forum, and the amusement park projects were replaced by projects in which groups of students designed their own experiments to investigate motion through a resistive medium. However, the teacher's workload was heavier that year, and Knowledge Forum was started three months later than in the previous year.

## Data Collection and Analysis

### Classroom Observations

To gain an understanding of the classroom ethos and discourse, the researcher observed double lessons conducted in the physics lab once to twice per month throughout the project; approximately 400 photographs and 20 hours of video were collected. To facilitate discussions with the teacher, several short movies (5-7 minutes each) were produced from these materials. Choices about what to emphasize in these reified the researcher's interpretation of what was happening that was relevant to knowledge building. These movies also were discussed with several other teachers and researchers working on knowledge building in South-East Asia. Interpretations were also revised based on extensive reading of the literature on teaching and learning in Confucian-heritage contexts (summarized earlier). Thus, interpretations were triangulated in several ways.

### Assessments of knowledge, learning process, epistemic beliefs, and attitudes

Extensive data were collected to measure what students were learning and to explore its relationship to work on Knowledge Forum, epistemic beliefs, and attitudes towards science. As much as possible, instruments were used that have been used widely in Western contexts, and that were validated for Hong Kong students. Some additional assessments consisted of assignments designed by the teacher or researcher. Due to space limitations only results for the mechanics unit are discussed here, see Table 1 in the results section.

*Force Concept Inventory (FCI):* This survey remains very popular in the PER community and has been administered to thousands of students (Hake, 1998; Hestenes, Wells, & Swackhamer, 1992). Several items that related to circular motion and projectile motion (which were not part of the curriculum) were removed.

*Learning reflections:* At the end of the mechanics unit students were asked to write a short essays to respond to two questions: "What is your big learning about mechanics?" and "What is the most difficult question you now have about mechanics, and what would you need to know to understand it?" Most students wrote up to one page for each question. Protocols from the heat and temperature unit from Class A were used to develop three scales with acceptable inter-coder reliabilities: *Content Knowledge*, *Everyday Applications*, and *Self-Awareness*. Content Knowledge refers to students' ability to recall the main points of what they had learned about physics concepts and phenomena; at the highest level of the 1 to 4 scale students needed to reveal insight into this knowledge (e.g., point out inter-relationships between ideas). Content Knowledge is a general indication of physics knowledge, whereas the FCI provides detailed information about students' conceptual understanding. Daily Applications similarly assessed students' ability to use their knowledge of physics to explain phenomena from daily life. This ability is needed for the HKCEE, in which students are required to answer questions about a short newspaper article that involves physics knowledge. Self-awareness is a measure of students' ability to identify the strength and weaknesses of their knowledge and how they were able to learn. For simplicity of presentation, we converted the results to percentages.

*In-class tasks*: Two tasks were designed to assess students' understanding and explanations during the unit. A *Graphing Task* was given after the first lesson on motion graphs; students were asked to draw *s-t*, *v-t*, and *a-t* graphs relating to riding a bicycle around the school, and to state their main idea, something they wondered about, and something they wanted to raise for discussion. At the end of the mechanics unit, students used a cartoon involving a horse and cart, in which the horse argues that it is impossible to get the cart moving, and were asked to state, with reasons, whether they agreed with the horse (Explanation Task, N3).

*Epistemic beliefs*: It is assumed that the knowledge building can lead to more sophisticated views about knowing and knowledge. Therefore, epistemic beliefs were measured using a Chinese version of the Epistemic Belief Inventory (28 items on 7-point Likert scale, see Schraw, Bendixen, & Dunkle, 2002). The questionnaire was validated using 484 Hong Kong students taking Form 3 and Form 4 science courses. Exploratory and confirmatory factor analysis revealed three factors with acceptable reliability: *Innate Ability*, *Simple Knowledge*, and *Quick Learning* (alphas 0.75, 0.68, and 0.66). Li (2009) suggests that Chinese learners do not hold Native Ability beliefs but the relatively clear factor structure suggests that Hong Kong science students *do* hold them. Preliminary analysis showed that there were no statistical differences between pre-test (start of the school year) and post-test (end) results; therefore, only the post-test data are reported.

*Attitudes Toward Science*: A 14-item questionnaire (5-point Likert scale) was used to measure attitudes towards science such as anxiety and interest at the end of the year. It was validated using 101 Form 4 science students taking science (Chronbach alpha 0.93).

*Contributions to Knowledge Forum*: Six indicators of contributions to Knowledge Forum were measured (see Table 1 for details). These have been used widely in previous studies involving Knowledge Forum.

## Results and Discussion

### Classroom ethos and discourse

The four pictures in Figure 1 are intended to illustrate the learning environment that was observed and then enhanced by introducing an IWB.

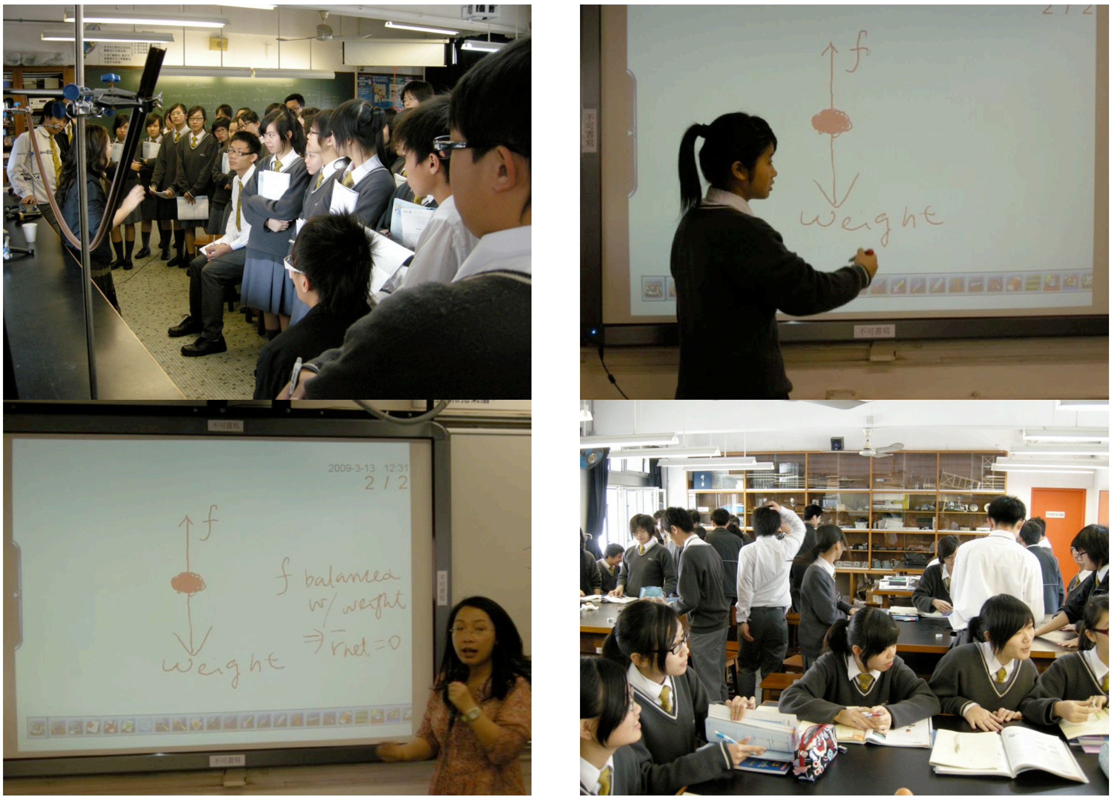

Figure 1: Classroom Environment

At the *top left*, the students gather around the teacher, who is demonstrating an experiment involving conservation of energy; the concept has already been studied, but this time there is not enough time or equipment for the students to do the experiment in small groups. Although the students are not doing the experiment themselves, the teacher's explanations and questioning lead them to consider the "critical details" of the situation (Viennot, 2003); students may demonstrate their engagement by replying to some questions in unison. The picture at the *top right* illustrates a social practice that the teacher has cultivated, in which students first explore ideas in their small groups, and then come to the front of the room to share and explain their ideas to the class. In the picture, the student is preparing her board work before explaining it to the class. Chinese learners tend to consider things privately before sharing their own thoughts publicly and avoid the possibility of "losing face" (Li, 2009), so this kind of practice is difficult to achieve. The teacher developed the practice over approximately one month in quite a structured way. First, students developed their ideas in the privacy of their groups, and two students were called to the front to present their group's ideas. Over time it became more spontaneous, and the presentations led to dialogue, in which other students questioned the presenters or helped them improve their explanations. At the *lower left*, the teacher reinforces the main points in a short and focused presentation. During a discussion driven by students' ideas there often are blind alleys and multiple explanations; although the students mostly figure out the correct explanations, there is a danger that minor points became salient for students or that flawed explanations are remembered. Thus, the teacher reviews what has been accomplished and what is most important to remember; in this, she is using the ideas and writing contributed by students as the raw material for her own explanations. Finally, the *lower right* shows something typical of Western classrooms. There is no obvious focal point in the classroom, and many things are going on simultaneously. At such moments we typically find the teacher assisting students (e.g., getting materials for them, help to fix problems).

With this brief depiction I want to suggest that a learning environment developed in which student ideas and working to getter to develop and improve explanations were central. In this environment, students had much work to accomplish independently, but the teacher played an essential role in providing the supports needed to make their efforts worthwhile (Hmelo-Silver, Duncan, & Chinn, 2007). These developments occurred in both classes and are important to knowledge building. However, there were two problems. (1) In Class A it was difficult to connect work on Knowledge Forum with the classroom discourse; students worked on Knowledge Forum after school and the database was not accessible to them during their small-group discussions. This problem was addressed for the second cohort by installing an IWB, and making one laptop computer available during class to each small group for reviewing the Knowledge Forum database. (2) The approach required considerably more time, and made it more difficult to cover the curriculum. Perhaps fuller integration of Knowledge Forum and classroom discourse may address this problem to some extent, if some of the work to develop explanations can be moderated and completed successfully in Knowledge Forum.

## Descriptive Statistics

Descriptive statistics are shown in Table 1.

Table 1: Descriptive Statistics

| Measure | Class A (2007 to 2008) | | Class B (2008 to 2009) | |
|---|---|---|---|---|
| | M | SD | M | SD |
| FCI pretest | 32.8 | 18.7 | 29.6 | 12.8 |
| FCI posttest | 47.0 | 15.5 | 47.1 | 21.0 |
| FCI normalized gain | 0.16 | 0.33 | 0.26 | 0.28 |
| Content Knowledge | 55.6 | 18.1 | 42.7 | 16.3 |
| Everyday Applications | 61.5 | 14.6 | 59.2 | 19.8 |
| Self Awareness | 66.1 | 18.1 | 61.6 | 17.0 |
| Graphing Task (bicycle) | 53.6 | 19.2 | 36.7 | 11.3 |
| Explanation (N3) | 50.0 | 31.6 | -- | -- |
| Innate Ability posttest | 3.28 | 1.25 | 3.77 | 1.26 |
| Simple Knowledge posttest | 4.23 | 0.91 | 4.17 | 1.05 |
| Quick Learning posttest | 2.59 | 0.93 | 2.81 | 1.12 |
| Attitude to Science posttest | 4.17 | 0.45 | 3.69 | 0.57 |
| Notes Created | 21.5 | 9.33 | 10.2 | 4.88 |
| % Notes Linked | 70.9 | 11.7 | 68.0 | 18.3 |
| % Notes Read | 5.81 | 2.94 | 18.3 | 16.6 |
| Views worked in | 9.14 | 2.29 | 4.73 | 0.90 |
| Revisions | 4.79 | 4.64 | 5.63 | 8.21 |
| Scaffold Uses | 20.3 | 27.1 | 8.78 | 4.95 |

The following observations can be made: (1) The FCI results were consistent with previous research for traditional teaching. For example, Hestenes et al. (1992) studied results from 612 Arizona high school students and obtained a mean pre-test score of 27% and a posttest score of 48%. In a meta-analysis including 1113 high school students, Hake (1998) referred to normalized gains (gain divided by maximum possible gain) as small. However, Hestenes et al. also found that posttest results frequently exceeded 60% if an "active learning" approach was used (normalized gain > 0.45). Suppapittayaporn, Emarat, and Arayathanitkul (2010) also obtained a normalized gain of 0.45 for Grade 10 students in Thailand who used an approach that combined peer learning with structured inquiry. These studies suggest that although the normalized gains that we observed were consistent with traditional teaching, larger values should be possible with a research-based active learning approach like knowledge building. (2) The results for the three learning reflection scales and two in-class tasks are included mainly to pilot test these instruments. They had appropriate properties for use in future design experiments (e.g., mean, SD, and discrimination). In both classes, mean scores were highest for Self-Awareness and lowest for Content Knowledge. (3) In both classes, epistemic beliefs ranged from Innate Ability (strongest) to Quick Learning (weakest). This finding is somewhat surprising because the literature suggests that Chinese learners do not have strong beliefs in native ability, but rather believe in effort Li, 2009). (4) Indexes of participation in Knowledge Forum in Class A were low compared to other studies (Niu & van Aalst, 2009; van Aalst, 2009), which suggests that the use of Knowledge Forum was not optimal. The improvement in the Percentage of Notes Read from 5.81% to 18.3% can be attributed to the new strategy to use laptop computers during class to access Knowledge Forum. Other differences between the cohorts are spurious due to the later start of Knowledge Forum.

## Analysis of Correlations

To test for predictive relationships among the variables, the measures of contribution to Knowledge Forum were combined using exploratory (principal components) factor analysis, and path models were constructed for each cohort. For Class A, Notes Created, Percentage of Notes Read, Views Worked In, Revisions, and Scaffold Uses were factorable into a single factor, *ATK Productivity* (KMO = .771), which explained 62.8% of the variance of the five included variables. For Class B the indicators were less factorable (KMO = .618). There were two factors that explained 69.5% of the variance, the first being similar to ATK Productivity, and the second having the highest factor loading for Percentage Notes Linked. But the second factor was not clearly interpretable as some of its marker items had factor loadings exceeding 0.30 on the first factor. This result suggests that contributions to Knowledge Forum in Class B were more complex than in Class A—although less extensive. Only the ATK Productivity factor was used for the path models.

Due to the small sample sizes the path models are used only in an *exploratory* sense, and only the most promising predictive relationships are reported. These need to be considered suggestive and would need to be verified in a study of a substantially larger sample. The most interpretable results were as follows:

- *ATK Productivity* was the strongest predictor of *Content Knowledge* in Class A (weight $w = 0.54$, $p < .001$), but it did not predict the *FCI normalized gain* ($p > .10$). This suggests that writing notes with ideas relevant to the subject made a strong contribution to general content knowledge, but was insufficient for gains in detailed conceptual knowledge, such as measured by the FCI. FCI gains were only a weak predictor of content knowledge ($p < .10$), which suggests that the two measures captured different aspects of knowledge. In Class B, ATK Productivity did not predict Content Knowledge or FCI normalized gains, but this can be attributed to the lower ATK Productivity scores.
- In Class A *Content Knowledge* ($w$=-0.48, $p < .001$), and in Class B *Everyday Applications* ($w = -0.43$, $p < .01$) were strong inhibitors of *Self-Awareness*. This can be explained if high-performing students on Content Knowledge/Everyday Applications were less reflective—perhaps more sure of themselves—than low-performing students. Verbal responses from the Graphing Task support this interpretation.
- Only weak relationships between the epistemic belief measures and other variables were found. In Class A, *Quick Learning* predicted a decrease in *Attitudes towards Science* ($w = -0.35$, $p < .05$), and *Innate Ability* predicted performance on the N3 explanation task ($w = 0.33$, $p < .05$). The first result is expected because physics does not involve quick learning; the second result may again indicate that students who were confident in their knowledge and attributed this to their ability were more likely to be able to provide correct explanations. In Class B, epistemic belief measures did not predict any other measure, but the poorer result on the Graphing Task was a strong predictor of slightly less favorable Attitudes toward Science ($w = 0.49$, $p < .001$). Thus, limited success on academic tasks early in the unit may be a stronger inhibitor of attitudes towards science than epistemic beliefs.

## Digging into the In-Class Tasks

The idea with the in-class tasks is that they can easily be incorporated into teaching and provide additional data points regarding students' knowledge, explanations, and problem solving as a unit unfolds. It is therefore worth looking more deeply into what they reveal about student thinking. The following informal analyses were completed only for Class A.

For the *Graphing Task*, scores from the graphs were used to divide the class into below median and above median groups. Verbal responses were then analyzed for each group, using the following categories: procedural, graph feature, conceptual question, higher-order thinking, and problem posing. For example, 'procedural' referred to procedures such as how to use motion detectors and formulas, and 'graph feature' indicated that a student had correctly described a graph feature. A question was coded higher order thinking if it sought understanding at a conceptually higher level, for example, if a student said s/he needed a clearer understanding of the relationships among the graphs or introduced a conceptual issue that had not been considered before, such as whether a vertical section of a *v-t* graph could be exactly vertical. Responses for "I would like to raise …" were coded *problem posing* if they raised a conceptual problem.

The results indicated that: (1) Above-median students wrote shorter responses (40 words on average, compared with 60), and more often used formulas or symbols. (2) Almost all students provided at least one correct description of a graph feature. (3) The below median asked many conceptual questions (15, compared with 7 for the above median group). This result is encouraging because it suggests that below-median students were engaged with the concepts to be learned, even if they did not understand them deeply at the time. (3) Above median students made more procedural statements and problem statements. (4) Both groups asked few statements coded as higher-order thinking.

Students' responses to the *N3 Explanation Task* were divided into four categories: agreement with the horse (incorrect); disagreement without providing an analysis based on physics principles, or with an incorrect analysis; disagree with a mostly correct analysis (minor errors), and disagree with a fully correct analysis. Results showed that almost all students came to the correct conclusion (which is common sense), but relatively few used physics principles to construct their argument (14 of 41 students). Nevertheless, ten students provided a completely correct argument. Although these results are somewhat disappointing for an active learning approach—the issue that was probed is fundamental to understanding Newton's third law—there was scope for the diffusion of accurate knowledge within the class. Knowledge Forum can facilitate this diffusion.

## Conclusion

The goal of this study was to explore how knowledge building could be developed in a way that is sensitive to Asian values and practices. It was argued briefly that although the influence of Confucianism has been declining in the 20th century, the major goals of education in Asia continue to be self-improvement and upward social mobility, and that the HKCEE is a difficult examination. To cope with the level of difficulty, students use an approach that combines efforts to understand with memorization and extensive practice, and teachers reserve extensive instructional time for practice for the examination (Chan & Rao, 2009; Gao, 1998). In this kind of cultural context, although students may interact with each other, it is unlikely that the teacher would implement a primarily activity-based approach—whole-class teaching and teacher guidance remain important (Wu & Huang, 2007). The four pictures in Figure 1 depicted the mix of teacher guidance and student agency achieved in the two classes of this study. The approach the teacher developed included didactic whole-class instruction, eliciting the ideas of students, student-student talk, the teacher's work to emphasize critical details, and independent work by students. It is proposed that this environment is a significant step towards an interactive learning environment suitable for Hong Kong schools.

The study used a variety of measures to study students' performance, and led to many insights into how knowledge building may be developed or studied in Asian contexts. I briefly reiterate three points.

First, although result in terns of conceptual knowledge were acceptable in the setting studied, and consistent with research on traditional physics, future work must aim for larger gains. There are good reasons to think that mean posttest scores of approximately 60% are possible (Suppapittayaporn, et al., 2010; Hake, 1998; Wells et al., 1992). As a PER-based approach, knowledge building must ehnace the extent to which students develop conceptual knowledge. The instructional apprioach was focused on conceptual knowledge, but the processes started in the classroom may require extension. It is hypothesized that further development of the approach the teacher began to implement in Class B, which involved creating a more seamless learning environment in which the use of Knowledge Foeum was integarted with classroom events, is nececsary.

Second, the study suggested how this may be accomplished. Productivity in Knowledge Forum (writing and reading notes) made a significant contribution to general physics knowledge, but not to conceptual knowledge. As the path weight for productivity in Knowledge Forum was relatively high, it may not be possible to enhance conceptual knowledge by increasing productivity alone. It is hypothesized that a direct effect from Knowledge Forum on conceptual knowledge may be possible if relational aspects of work in Knowledge Forum are increased (i.e., notes that establish linkages, synthesize progress, and identify rise-above ideas). This would require explicit attention to the development of sophisticated uses of Knowledge Forum (van Aalst, 2006).

Finally, the study showed that these Asian students did have epistemic beliefs, but that these did not interact with the variables studied, particularly contributions to Knowledge Forum. One possible explanation is that other beliefs such as filial piety masked such interactions. But it is also possible that the level of work on Knowledge Forum and other activities were not sufficient to cause changes in epistemic beliefs. Further research would be useful to shed additional light on this question.

**Abstract:** This paper presents data from the beginning process of restructuring a usability-engineering course to incorporate aspects of collaborative-process theory with required course content. Students' collaborative processes were evaluated at the end of the semester in order to identify key areas that instructors would need to support better in future iterations of the course. Overall students were skilled communicators, but lacked ability in areas of planning, productivity and critical evaluation. A closer examination was made of difficulties that students had with critical evaluation and trade-off analysis processes since these were key aspects of the course. Findings from analyses were used to suggest ways that the course could be modified in the future to better prepare students to address these important concepts in usability engineering.

## Introduction

As more emphasis in technology and science classes gets placed on getting students to do well on product-based outcomes, less emphasis is placed on getting students to understand and engage in important learning processes. This is extremely problematic as researchers and field practitioners in science education have emphasized the growing need for and increasing lack of students' abilities to understand and engage in critical processes associated with collaborative intellectual-activity: the ability to communicate effectively, listen and build on ideas, negotiate ideas, and engage in scientific argumentation (Barron, 2003; Driver, Newton, & Osborne, 2000; Felder, Woods, Stice, & Rugarcia, 2000). Such processes, though identified as critical in educational and work contexts, have been identified as a weakness among American students (SCANS, 1991). The attention focused on collaborative skills has led many schools to increase the number of team-based projects, and collaborative activities they require students to participate in. A fundamental problem with this response is that it assumes that students already possess the cognitive and social skills necessary to engage in effective collaborative endeavors and that these competencies will naturally emerge and develop through exposure to collaborative learning environments; this is wrong. Research has shown that individuals are often frustrated by group interactions, waste time (Salomon & Globerson, 1989), or fall victim to a variety of other problems that lead to dysfunctional group-processes (Webb & Palincsar, 1996). This suggests that students need more explicit guidance with collaborative endeavors than is currently typical.

Gaps in knowledge about what constitutes effective collaborative interactions and/or the ability to apply these concepts in practice are particularly problematic at the college level where individual grades may depend on a team's performance. In The College of Information Sciences and Technology (IST), where our participants have spent the last four years, students are expected to work in teams for much of their academic careers, depending on each other for grades based on their collaborative efforts. Given that dysfunctional interactions among team members can lead to many negative outcomes such as lower performance, alienation, failure, and even the likelihood that students will drop out of the group, the course, even the major (Barron, 2003; Hogan, 1999; Light 1990; Rosser, 1998), it stands to reason that over a four-year time span such trends could lead to considerable problems for these students, and many faculty regularly see these problems play out day-to-day. In order to diminish these problems it is necessary to develop students' collaborative competence. Toward this aim, the authors are currently undertaking a restructuring process for a usability-engineering course in the College of Information Sciences and Technology (IST). The goal for the course is to help students understand and apply important concepts of usability engineering and collaborative-competence theory simultaneously. However, time constraints, the breadth of domain knowledge, and student push back make this an uphill battle. This paper represents the beginning of our journey down Dillenbourg's long road (Dillenbourg & Traum, 1999): moving beyond distribution of the task to a shared understanding of it. The work presented here is a specific report based on one small strand of our research that encompasses a much broader data set.

### The usability-engineering course

Usability engineering is defined as the concepts, processes, and practices engaged in the process of developing software systems and applications to ensure that they serve their intended users effectively. To a considerable extent, it mirrors and complements software engineering. Our approach to teaching usability engineering relies on user interaction scenarios as the primary context for analyzing requirements, describing specifications, envisioning designs, developing rationales, creating various sorts of prototypes, and evaluating systems and applications. Our usability-engineering course is organized around a semester-long system development project. The course works its way through a curriculum organized by the flows of the system development process, and student teams define, implement, and test their projects respectively throughout the course. This course has been previously successful with computer and information science students. In 2002, a textbook based on the course was published (Rosson & Carroll, 2002; see http://ist413.ist.psu.edu/ for most recent syllabus and class-by-class activities).

When we designed the usability-engineering course, we carefully devised a list of six main learning goals for our students and came up with various ways that we could implement and assess them (Carroll & Borge, 2007). In this paper we will evaluate students with regards to one of these goals: the ability to build knowledge base through collaborative discussions and refine necessary skills in collaborative groups.

## Four core collaborative capacities

Four core capacities within the realm of collaborative learning were identified from educational research literature (Borge, 2007) and unpacked for students. These capacities were intended to embody an organized theory of goals and objectives students would need to meet in order to work in an effective collaborative environment. These capacities were introduced and incorporated into the students' collaborative work. These capacities were originally created as an attempt to structure group processes to address the many factors that can contribute to group-process problems (Borge, 2007; White & Frederiksen, 2000). Originally presented as roles, they were also a useful way to simplify a complex endeavor, such as collaborative interaction, into more manageable sub-skills that students could learn about, demonstrate to each other, and improve upon through practice (Brown & Palincsar, 1985).

The four collaborative capacities are planning manager, communication manager, critical evaluation & negotiation manager, and productivity manager. Physical tools and activities were developed to support the learning and use of the roles/capacities. One of the primary tools was a guide for students that detailed each capacity: the major objectives, problems students may need to prevent/correct, and strategies that they could use to prevent/correct problems (for examples of the guides see http://ist413.ist.psu.edu/, week-to-week activities, calendar, 2/4, under collaborative roles). These Guides were originally developed for children ages 10-14 years of age, but extensively modified for use in this course for use with usability contexts and college age learners. We used feedback from instructors and students to tailor the language, problems, and strategies to specifically address problems faced by this population of students (Borge & White, 2009). Examples of common problems for this population include: improper use of time during team meetings, lack of critical evaluation, and lack of accessibility to collaborative products in real-time. The updated guides included information to prevent and/or correct such problems.

## Research methods, objectives, and class context

The research objectives for this project were to fundamentally improve how team activities were implemented, supported and structured in a usability-engineering course so as to improve students' ability to both understand and apply important concepts. Since application of concepts is a critical aspect of the research we will focus on the analyses of an in-class activity requiring the application of usability engineering concepts through particular collaborative interactions. We used assessments of students' collaborative processes from these videos and compared them to their final project grades to see whether students' process performance was correlated to students' performance on their team project.

Participants were students enrolled in a senior level usability-engineering course (IST413). Students were divided into eight teams of five-to-six students: two teams composed of two females and four males and six composed of all males. The teams worked together throughout the semester on collaborative in-class activities, collaborative homeworks, and a semester-long usability-engineering project. All students were required to learn about effective collaborative-interactions, and practice applying goals and strategies during these activities. Students learned about the four capacities, their objectives, and ways of promoting effective collaborative interactions (i.e., setting process goals, and using strategies to prevent or correct team-problems). Goals and activities related to the four capacities were incorporated with 13 in-class activities during which students were expected to work together and turn in a deliverable (an activity worksheet). The activities were either tied to the content covered that week, or to the students semester long project. The roles were a required part of the course since activities, collaborative homework assignments, and even some quizzes required students to practice and understand the roles, their goals and strategies. Students' overall collaborative capacities were assessed from video of teams engaged in an in-class activity in week 13 of the course (for details of the activity see http://ist413.ist.psu.edu/, week-to-week, calendar, activity 13 on 2/28). This videotaped activity was a brainstorming and decision-making session that required students to use and apply concepts they had learned throughout the semester: write design scenarios, identify potential user problems, suggest ways to resolve problems with documentation/help design, evaluate trade-offs of proposed designs, etc. We assessed students on their collaborative interactions by using a scoring rubric developed by Borge, 2009 (See Table 1 for the four capacities and objectives that students were assessed on). This rubric is directly connected with the collaborative-capacity guides as the objectives they assess are those proposed in the guides. Out of eight teams seven consented to be included in our research; these teams were used in analyses. There were five objectives for each of four capacities, for a total of 40 possible points. However, one objective in the planning capacity, and one objective in the productivity capacity were not applicable to this activity (those appear shaded in Table 1). Therefore, there was a total of 38 possible points on this measure.

Table 1: The four capacities and their objectives. Objectives not assessed appear shaded.

| Capacities | Objectives |
|---|---|
| 1. Communication | - Most members participate during discussions and quiet members are encouraged to contribute<br>- Team members listen intently<br>- Team members build on each other's ideas<br>- The team works to create a common understanding<br>- Comments are clear, concise, and relevant to the task at hand |
| 2. Planning | - There is a set agenda for the meetings<br>- The team has a long-term plan for the entire project<br>- The team has a set way of providing each other with feedback<br>- The team has set project/interaction goals<br>- The team assigns tasks and responsibilities to ensure that everyone makes equal contributions to the project |
| 3. Critical Evaluation/ Negotiation | - The team considers multiple points of view from various members<br>- The team critiques ideas respectfully and knows difference between positive and negative conflict<br>- The team takes time to evaluate trade-offs of different ideas<br>- The team takes all members into account when deciding which ideas/courses of action to take.<br>- The team keeps track of the ideas that are presented, discussed, and evaluated |
| 4. Productivity | - There is a set method for determining and recording progress<br>- The team does not display off-task behaviors<br>- The team evaluates and works to improve work quality<br>- The team sets time to update each other of their progress<br>- The team turns in high quality deliverables in a timely manner |

Students were familiar with the rubrics, as they had used them to assess themselves at the beggining of the semester. When students completed a video-taped activity, at the begining of the semester, they were asked to watch their videos, score their team with these rubrics, and identify areas that seemed particularly problematic for their team. The scoring system was as follows: 0 = does not fuilfill objective to any degree, 1= has some ability to fulfill objective, but still somewhat problematic, 2= fulfills objective perfectly, could be used as ideal example for other students. Once they identified problem areas they were asked to look through the guides and select strategies to prevent/correct the problems they identified. This activity was used as a means to introduce the roles, their guides, and ways to apply the concepts they presented. It was also a means to familiarize students with the rubric we would use to assess their interactions at the end of the semester. At the end of the semester, students were told that we would assess them with the same rubrics they used at the beginning of the semester and we repeated the same procedures as during the first recorded activity.

## Reliability of the scoring rubric

The results we report are derived from overall scores determined by the first author. however, we assessed the overall reliability of the scoring rubric by training a graduate student to be a second rater. The second rater was presented with the same materials and guides the students were given. Twenty percent of the data set was doubly coded with the following results: Kappa=.69, and r=0.88, n=140, p< .001. Transcripts were not available at this point in the analysis, so the coding was based directly on video clips. The two coders matched exactly on 78.8 % of the items. Most of disagreement regarded teams for which the first author identified modest critical evaluation (score of 1), but the graduate-student coder felt there was no critical evaluation demonstrated (score -9, n/a).

## Transcription of video

Each of the seven 30-minute videos was transcribed following a similar format. Each new speaker utterance and or behavior was numbered, denoting a new "turn". A "turn" ended when a different speaker introduced a new utterance. The students were given pseudo-names in the transcript. Parentheses were used to label nonverbal gestures and events (i.e., leaving the group, making faces, using hands, etc). Brackets were used for codes, time stamps, and notes relevant to the analyses, but not found in the video itself. These transcripts were utilized when the author scored each team's collaborative interactions with the given rubric, and for microanalysis of processes.

## Results

### Teams' collaborative interactions: overall findings

Out of 38 possible points in the assessment, the average score across all seven teams was 50% and the median score was 47.3%. This means that all teams scored in the "average" range of performance, getting mainly scores of "1" on the different objectives in the assessment. Scores of "2" were far less common, except in the communication category. Collaborative performance was not significantly correlated to measures of individual performance (i.e., exam scores, class participation, or overall course grade). However, the collaborative assessment was correlated to performance on measures assessed at the team level: where students worked together on one product and shared the same grade ($r$=.77, $p$<.05). This suggests that improving collaborative performance could lead to improved performance on deliverables created and assessed at the team level.

When we examined how teams performed on each individual capacity, we found that they performed significantly better on one of them. There was a significant difference between how students performed on the communication capacity ($M$=.70, $SD$=.18) and how they performed on the assessment as a whole ($M$=.50, $SD$=.13), $t(6)$=6.8, p<.001). Communication was the students' strongest area reflecting strengths in listening for understanding and building on each other's ideas. In fact we saw very little evidence of parallel talk, where one utterance, or turn, is followed by a different and unrelated utterance.

Table 2. Descriptive statistics of teams' overall performance on capacities:
crit = critical evaluation, com = communication, pro = productivity, and plan = planning.

| | N | Minimum | Maximum | Mean | Std. Deviation |
|---|---|---|---|---|---|
| crit | 7 | .30 | .80 | .5143 | .19518 |
| com | 7 | .40 | .90 | .7000 | .18257 |
| pro | 7 | .25 | .75 | .4464 | .17466 |
| plan | 7 | .25 | .63 | .4107 | .13909 |
| Valid N (listwise) | 7 | | | | |

There were no significant differences between the rest of the capacities and overall performance with students scoring in the average range for all three capacities. Particular aspects of the planning capacity were not evident in student behavior. For example, students largely accomplished the activity problem by problem, with no thought as to what previous information might be helpful, what the goals of the activity were, or how they would ensure that they achieved those goals. Some aspects of productivity were also missing from students' interactions. Even though they were quite good at staying on task and progressing through items quickly, they still did not perform above average in this capacity. Most of their low scores were due to the fact that they 1) did not show evidence that they had set methods for determining and recording progess and 2) failed to evaluate work quality. Many aspects of this activity depended on students pulling on previous assignments and, for the most part, team members were unaware of who was responsible for which tasks. Failure to evaluate work quality was also a problematic and reaccuring theme. Most teams only cared that the answer was "good enough", not that it was the best possible answer. In fact, student teams actually used the term, "good enough" an average of two times during the activity.

The last capacity we would like to discuss is the critical evaluation/ negotiation capacity. Given that many parts of the activity explicitly asked students to engage in evaluation processes, we would have expected to see higher than average scores in this area, but were disappointed to find that only three teams were able to score any 2s in this area, and only one team fulfilled the trade-off analysis objective, demonstrating the ability to effectively apply the concept of trade-off analysis (a process we will discuss later). All other teams scored 0s on this objective.

### Specific problems with the capacity for critical evaluation/ negotiation

Thre was no need for conflict managment or negotiation of differing points of view as students did not seem particularly invested in critiquing or evaluating ideas. Students were very respectful to fellow teammates and there were no instances of intimidation or personal attacks during collaborative activities. Unfortunately, students seemed to be crossing off mental checklists rather than engaging in deeper forms of analyses or argumentation. In fact, students accepted or built upon ideas without stopping to evaluate or challenge those ideas or ask team members to provide rationale for suggestions. Questions, such as, "why do you think we should that" simply were not evident in the team interactions. For the most part, students seemed to lack the ability to step back from problems and evaluate their suggestions as objects of thought. One of the best examples of students' inability to take a step back and think about a problem and its solutions critically came from one of the teams presented below. This particular team was creating a website for a photo club. In this example, the team is working on the second question in the activity.

> *Question 2. Discuss the design scenarios you have prototyped. Choose 2 that you think are most likely to raise problems for learning or use, i.e. where help or other documentation might be required for at least some users. Summarize each scenario briefly, and indicate why you think it might be a candidate for help or training.*

The team (M1, M2, M3, M4, and M5) tries to come up with problems that a user could experience when trying to use their website. Since their website is for a photo club, M3, suggests that they might have problems uploading a picture file. M4 asks M1 to log into the website in order to check for restrictions. M1 tries to log on, but does not remember the password. The rest of the team continues to talk about the potential problem (see Table 3).

Table 3: Team talk as they work to find a solution to a problem in the activity.

1. 00: 20: 24.22 M3: How many picture files can you use?
2. 00: 20: 25.14 M2: It was on the website...
3. 00: 20: 25.25 M1: Yeah where's that at...
4. 00: 20: 33.10 M2: Yeah go to the homepage... yeah, there you go...
5. 00: 20: 35.28 M1: What's the password, anybody...
6. 00: 20: 40.28 M3: Um the other Mike has that, but he's not here... I don't know the password of---
7. 00: 20: 47.13 M4: Why couldn't he make it something easy like one two three four...
8. 00: 20: 49.15 M3: He made it something easy but it was just like---
9. 00: 20: 51.14 M1: Penn State?
10. 00: 20: 52.19 M2: Try it.
11. 00: 20: 54.29 M4: Did he actually send you the---
12. 00: 20: 56.12 M1: No, I just remembered it was something stupid.
13. 00: 20: 57.22 M2: He said it out loud to us.
14. 00: 20: 58.02 M4: Oh... I can't remember!
15. 00: 21: 01.19 M2: Security question?
16. 00: 21: 06.23 M3: Um?... Calendar help training solution, we could just provide like a document that showed you how to do stuff.
17. 00: 21: 26.06 M1: Yeah I'm not sure this is the right, its asking for yahoo ID.
18. 00: 21: 32.05 M3: Even if just [inaudible] the document that shows them where the help is for Flickr.
19. 00: 21: 36.17 M2: That's gonna have a [Inaudible].
20. 00: 21: 37.25 M4: Flickr for beginners?
21. 00: 21: 41.11 M2: Or what happens if you go to the picture page and click on a picture?
22. 00: 21: 50.22 M1: It's asking to, ah, open up.
23. 00: 21: 58.24 M2: [Inaudible] pictures so...
24. 00: 22: 03.05 M1: Um.
25. 00: 22: 07.29 M2: Oh wait.
26. 00: 22: 11.21 M3: What is it?!

The team continues discussing possible problems with uploading pictures in turns 8-11. Meanwhile, M1 still cannot remember the password and asks the team for help (turn 12). In the next 11 turns the team tries to guess the password to no avail. Nonetheless, in turns 25-26, the team marches on, trying to come up with another idea for a problem that a user could experience when trying to use their website, while M1 continues to try to log on. The team proceeded in this manner for two minutes. Unable to resolve the problem and log on, one of the students suggested they simply summarize their previous scenario about a user experiencing problems uploading pictures, but this time add an FAQ or search page to help the user resolve the problem.

What happened here? It seems these students were so engaged in trying to verify a proposed solution to the problem, that they completely ignored the most obvious one: the problem they were experiencing at the moment of not being able to login because no one could remember the password. Forgetting the password is a common problem that many sites simply resolve by allowing you to reset the password. However, for this particular website that solution would not work because all the users share the same password. This was a trade-off that came up in their design, they wanted all the users to be able to link Google Calendars and other aspects of the website to Facebook, but the only way that could work was for all of them to share the same password. This solution gave them want they wanted in a feature without them having to write programming code. However, it had drawbacks as their transcript demonstrated. Identifying these types of trade-offs and thinking ahead for possible solutions was the main goal of the activity, but sadly, not one this team could accomplish. This team was not alone.

## Trade-off analysis

Trade-off analysis is a fairly complicated critical-evaluation process that is also a core concept of usability engineering. It involves weighing design goals (i.e., the needs of your users, ease of use, added features, etc.) with constraints and resources of the design team (i.e., cost to build and maintain, programming demands, client demands, etc.) in order to make the most reasonable decisions. Trade-offs, by definition imply that there is no correct answer, just the best one given design goals and resources; it is a balancing of factors that cannot all be attained simultaneously. Given its centrality to this course it was one of the critical evaluation objectives that students were assessed for as part of the collaborative assessment. This was the only objective in the assessment in which teams received zeroes across the board. Only one team, Team 6, was able to effectively apply the concepts inherent to trade-off analysis. This team will be used to illustrate the difference between how the majority of students engaged in the trade-off analysis process, with what was expected.

In question three of the activity, the students were asked to "Analyze trade-offs associated with your design idea. Consider a variety of issues, e.g. cost to build or maintain, generalization to other scenarios, reactions by users, and so on". Six out of seven teams simply responded by coming up with a list of pros and cons. The teams did not justify their design or why it was the best possible solution. They also did not weigh factors involved in their decision making. Instead, team discussions were more akin to identifying possible problems. The following example is representative of the pattern of interactions that stemmed from teams trying to engage in the process of trade-off analysis. In this team, members (M1, M2, M3, M4, and M5) have just completed question two (presented with the example in Table 3) and just now reading question three (see Table 4).

Table 4. Team talk representative of the majority of teams as they worked to resolve Question 3.

| | | | |
|---|---|---|---|
| 1. | 00:18:34.05 | M1: | can you read the question |
| 2. | 00:18:34.07 | M2: | It just says analyze the trade offs, consider a variety of situations |
| 3. | 00:18:43.29 | M1: | [inaudible] ... you can say there is almost no way... if it happens it's going to come down to the officers of DDF [Dance Dance Fanatics] to do something |
| 4. | 00:18:59.02 | M3: | Yeah |
| 5. | 00:18:59.03 | M4: | Yeah |
| 6. | 00:19:03.00 | M3: | Like when you sign-up you should be required to like... accept--- |
| 7. | 00:19:08.13 | M1: | Like one of those... agreements [inaudible] |
| 8. | 00:19:10.29 | M3: | yeah, that you always accept and just push ok. |
| 9. | 00:19:17.18 | M4: | Something with the calendar page |
| 10. | 00:19:22.09 | M1: | Um |
| 11. | 00:19:45.16 | M2: | Members using calendar may f[**] it up. |
| 12. | 00:19:52.00 | M1: | Ha, yes! |
| 13. | 00:19:54.21 | M3: | He stole the words outta my mouth! |
| 14. | 00:20:01.21 | M2: | They... what's a better word than that?! |
| 15. | 00:20:07.22 | M1: | May not fill in all the field, or something like that. |
| 16. | 00:20:08.05 | M2: | May hinder--- |
| 17. | 00:20:10.12 | M1: | --- So their, maybe events on there but they may not have like time or place or combination of something or description just be like meeting |
| 18. | 00:20:21.17 | M2: | Like the date and time. |
| 19. | 00:20:22.05 | M1: | Might just be ambiguous as to what the person was talking about. |
| 20. | 00:20:26.10 | M4: | The date is like required. |
| 21. | 00:20:28.12 | M1: | Yeah its like, you'll know the day, but its like it might just be completely ambiguous and just say meeting... [inaudible]. |
| 22. | 00:20:50.28 | M2: | I think we're good with three. |

In turns 3, 9, and 11, Students present two problems with their design: 1) there is no simple way to monitor content, and 2) users may leave important fields in the calendar page blank. In turns four through nine, students unpack the first problem, and in turns 10-21 students unpack and discuss the second. As students speak a member writes down these problems on their team paper. There is no discussion about alternative designs or justification for why they have chosen this design even though these problems are present. In turn 22 they simply state that they have sufficiently addressed question three and move on to question 4. This was the predominant pattern of talk that ensued from 6 teams during this trade-off analysis portion of the activity: identify problem, agree/build on idea, identify another problem, agree/build on idea, write ideas down and move on. Only one team demonstrated any ability to engage in trade-off analysis, Team 6 (see Table 5 below).

Table 5: Team talk of students demonstrating ability to apply trade-off analysis concepts.

| | | | |
|---|---|---|---|
| 1. | 00: 26: 27.22 | M2: | Some others, trade-offs. |
| 2. | 00: 26: 32.11 | M4: | Cost to build or maintain, photo gallery is like it takes time for people to like |

3. 00: 26: 41.18 M3: Update their galleries because they have to send them to the administrator and then the administrator has to go and
4. 00: 26: 44.13 M1: Actually (mumble)
5. 00: 26: 47.28 M3: Yeah
6. 00: 26: 47.20 M4: (Mumble) You got a hundred members and all these photos just gonna be taking up space and all that stuff.
7. 00: 26: 55.07 M1: All, well if we get a hundred members [inaudible---all talking at once].
8. 00: 26: 59.24 M4: I don't know how restrictive the university is with all that though.

Conversation continues...

14. 00: 27: 29.03 M4: That's why it has to be each user can just login and upload their own photos
15. 00: 27: 36.09 M2: Cost to build and maintain.
16. 00: 27: 38.08 M4: So that's one of our trade offs I guess, wouldn't it be? Cause ours is like that, and after--- and not so much functional I guess, because of our own time to build something like that with our limited resources.

The patterns of talk are quite different in this team. They begin by identifying a relevant trade-off, cost to build and maintain (turn 22) and then unpack what the trade-off means as it applies to their project (turns2-8). This type of discussion continues as students build on each other's ideas. Until finally, in turn 14, an alternative design idea is proposed that would address their design problems. At which a member reminds them of the trade-off, cost to build and maintain (turn 15) and another team member summarizes their discussion by stating that this is in fact their trade-off: they are settling for a website with vey little functionality because they lack the time and resources to produce anything more complicated. The majority of teams started by identifying problems with their design and never worked their way up to how they fit into a bigger category of trade-offs or thought about how a trade-off category would play out with their project. Team 6 started with a trade-off, worked their way down by unpacking the trade-off as it applied to their system, identified related problems, alternative designs, and then weighed these designs in order to decide which would work best for their team. They did this by summarizing their discussion and defending their original design idea with concrete rationale.

## Discussion

Findings from this study have helped us to identify problematic concepts for students and provided us with insights as to how to modify the course in future iterations to address these issues. This course contained a group of seemingly engaged students, who appeared to be collaborating well on the surface. However, when their interactions were closely examined we were able to see that students were falling considerably short of what could be attained in terms of collaborative competence. Students in this course were very competent communicators, but were still lacking abilities to critically evaluate their ideas and work quality as well as plan their work and interactions. We also discovered that students' understanding and practice of the trade-off analysis process is not in keeping with the major goals of the course. Our novice usability-engineering students seem to be making mistakes analogous to Schoenfeld's (1989) novice mathematicians; they were picking solutions to problems and not stopping to evaluate if they were the best ones. Thus we should employ teaching methods similar to those used by Schoenfeld to improve students' critical thinking skills as well as their ability to step back from a problem and think about their performance as an object of thought. Our findings also suggest that we can improve team deliverables (the project score) by improving process learning (their collaborative score).

We are currently developing process-learning activities that can better meet the needs of our students for the next iteration of this course. For example, expert thinking will be made more visible for our students (Collins, Brown, & Newman, 1991) in three ways: 1) the instructor will model trade-off analysis for students with the help of colleagues and focus more on explaining his rationale behind usability decisions by weighing options, 2) students will be shown contrasting examples (such as those presented in Tables 4 and 5) of students engaging in trade-off analysis, and 3) students and instructors will work together on collaborative problem solving activities; the aim being to move to a more discussion centered methodology where evaluation of processes are common topics. We are also trying to minimize the "good enough" tendencies in our students by forcing teams to defend their design ideas during presentations to their peers, and also require peer evaluations of project deliverables throughout the semester. Thus motivating them to focus more on their work-quality and their decision-making processes.

### Closing thoughts: the importance of professional collaboration and course evaluation

It is essential for educators to ensure that the collaborative learning opportunities we provide for our students consistently accomplish what we intended them to do: give students opportunities to learn from and challenge the ideas of others, and give them an authentic context to practice applying the core concepts and techniques of a domain. Collaborations between domain experts and experts in the science of learning, such as that between the authors of this paper, are crucial to accomplishing this goal. This type of collaboration is necessary help set appropriate learning goals for students, identify learning goals that present particular problems for students, and implement changes to a curriculum to address these difficulties. Only through these types of collaborations and course evaluations we can fully develop students' learning potential and provide them with richer, more meaningful courses that prepare them to function in an increasingly team-oriented workplace. We do not pretend that these types of domain and process learning fusions do not come with extreme challenges, as we faced many. Among them was a huge push back from students who genuinely felt as though they already knew all there was to know about effective collaborative practice; our finding demonstrate that this is not the case. We contend that the only way to get past students' misconceptions of collaborative practice are to make collaborative goals and processes part of an ongoing conversation between instructors and students that begins in elementary school and continues on throughout their educational and professional careers.

# First-Year Engineering Students' Environmental Awareness and Conceptual Understanding with Participatory Game Design as Knowledge Elicitation

Melissa Dyehouse, Nicole Weber, Jun Fang, Constance Harris, Annette Tomory, Johannes Strobel,
Purdue University, 701 West Stadium Ave., West Lafayette, IN 47907
Email: mdyehous@purdue.edu, nrweber@purdue.edu, jfang@purdue.edu, harris11@purdue.edu, annette@golden-tech.com, jstrobel@purdue.edu

**Abstract:** The purpose of this paper was to investigate first-year undergraduate engineering students' awareness and conceptual understanding of environmental issues and to examine how effective a participatory game design strategy was to elicit their understanding. Respondents ($n$=1,394) completed baseline environmental awareness surveys and 24 respondents participated in the game design process consisting of four workshops and online activities. The game design component was focused on life cycle analysis (LCA) including environmental impacts of engineering design. Observations and artifacts were collected from workshops and interviews were conducted. Results showed that students had a general awareness about environmental issues but lacked awareness about LCA, pollution, and wetlands. Additionally, the participatory game design process showed that students struggled with applying the newly gained understandings of LCA in the game designs. The participatory game design provided a wealth of information on students' understanding and also served as an effective platform for knowledge elicitation.

## Introduction

According to the Accreditation Board for Engineering and Technology (ABET) criteria for accrediting engineering programs, engineering graduates must have the "broad education necessary to understand the impact of engineering solutions in a global, economic, environmental, and societal context" (ABET, 2009; p. 2). One implication of this is that engineers need to be able to recognize the importance of environmental and ecological issues in engineering and to gain an understanding of what this means to them as an engineer. For example, life-cycle analysis (LCA) is a means by which to quantify the environmental impacts of a product (Blanchard & Reppe, 1998). The issues embedded within LCA are central to the design, manufacturing, use, and disposal of engineered products.

Sustainability issues play a role in all disciplines of engineering, from the consequences of the products' design to the manufacture and eventual use and disposal of the product. For this reason sustainability concepts need to be incorporated into all engineering disciplines (Boyle, 2004). Apart from programs in environmental engineering however, sustainability concepts are not well-integrated into the engineering curriculum (Crofton, 2000; Azapagic, Perdan, & Shallcross, 2005). There is also a lack of knowledge about how much first-year undergraduates in engineering programs actually know about environmental issues and how they obtained their knowledge.

The purpose of this study is to investigate first-year undergraduate engineering students' awareness of the concept of LCA and environmental issues, and examine how students' understanding can be understood within a participatory co-design of an educational game. Additionally, baseline data will provide information on (a) how influential previous educational and demographic factors are for students' environmental awareness, and (b) which environmental issues still need attention within the first year engineering undergraduate curriculum.

It is necessary that engineering students of all engineering disciplines be aware of environmental issues and that they understand the relevance of environmental issues in engineering design. For this reason, our study focused on the participatory design process as a means of increasing students' awareness and understanding of environmental issues particularly in regards to the engineering design process as well as the assessment of its effectiveness as a knowledge elicitation strategy.

*Research questions*

The core research was guided by the following questions:

- What is the environmental issues awareness of first-year engineering students?
- What are the predictors of students' environmental awareness?
- How does the game design process enhance students' awareness and understanding of life cycle assessment and sustainable engineering?

The secondary research was guided by the question: How effective is the participatory game design as a knowledge elicitation strategy to shed more light on students' understanding of environmental and sustainability issues with engineering?

## Literature and Theoretical Framework

*Participatory Design*

Participatory design (PD) was deployed in this study as a design and knowledge elicitation feature. Rooted in the Scandinavian workplace movement, "participatory design of computer applications is about the direct participation of those who will be affected by the development of a particular computer application in the decision-making, design and/or development process" (Törpel, 2005, p. 177). PD is particularly focused on the exchange of skills, values and perspectives during the development on potential working settings (Greenbaum & Kyng, 1991; Kensing & Blomberg, 1998). In this study, students are collaborative co-designers of an educational game from which other students can both give feedback in the design and benefit from the process.

The concept of PD, used primarily in product design, has long roots in educational design (Strobel, 2006) and research practice as well: Jonassen, Wilson, Wang, & Grabinger (1993) reported that instructional designers learned far more by designing CAI (computer-assisted instruction) than the target audience will probably ever learn by using the designed CAI. Additionally, the rich teach-back literature (Johnson & Johnson, 1987) shows learners are especially successful when teaching newly acquired knowledge and skills to other learners. Nevertheless, there are few research studies and reports discussing how participatory design helps shape the educational process, benefiting students when engaged as designers and end-users. In addition, the authors are only aware of a few studies utilizing participatory design as a strategy for knowledge elicitation (e.g., Kafai, Franke, Ching, & Shih, 1998).

*Environmental Education and Stewardship*

Public education on environmental issues is essential, as public opinion plays a major role in the development and implementation of environmental policy. Popular perceptions and misconceptions surrounding environmental problems must be understood in order to make educational efforts most effective (Holl, Dailey, and Ehrlich 1995). According to Holl et al. (1999), educational effectiveness requires teaching the links between different issues, the relationship between individual actions and environmental quality, and tailoring the information on these environmental problems and solutions to a more local or individual context.

Ecological literacy and more broadly environmental literacy consists of three interrelated components: knowledge, affect, and behavior (Bruyere, 2008). That is, one must know about ecology, show concern for the natural environment, and act in a way that is consistent with this knowledge and concern. It follows then, that for students to have sustainable engineering literacy they must have knowledge about the subject, show concern for the natural environment, and show behavior consistent with this knowledge and concern, for example by developing technology with the ecological footprint in mind. Several studies on environmental behavior have found links between awareness, attitudes, and behavior or behavioral intentions, suggesting that as awareness about an issue increases, so will subsequent attitudes or behaviors (Cottrell, 2003).

*Game Design as an Educational Tool*

Computer games are an emerging and popular area of development (Danielsson & Wiberg, 2006) and seen as "an important teaching tool because they can provide a compelling context via interactive, engaging and immersive activities" (Gunter et al., 2008, p. 511). Despite the hype, whether games actually help learning remains a controversial topic (Gunter et al., 2008; Rieber, 2005; Shaffer, 2006). Becker (2007) observed that "design of games for learning is one of the biggest challenges that instructional designers have had to face" (p. 43). Other research studies have shown that few games have demonstrated that they can successfully teach academic content in a classroom teaching (Gunter et al., 2008; Rieber & Noah, 1997). Frietas (2008) reported that commercial games, which focus on fun and entertainment, often lacked the principles of good learning design. Educational games, which were created as collaborative efforts between educators and instructional designers, often resulted in boring play (Lim, 2008; Prensky, 2001). Other research studies, however, began to highlight the use of students as potential educational game designers and the positive effect this experience would have on student learning (Danielsson & Wiberg, 2006; Lim, 2008). Lim (2008) argued that students would be more likely to engage in the learning process, because they would be empowered to make decisions and take action by designing or co-designing their learning experience.

## Methodology

*Research Design and Data Analysis*

In the study's research design, participants are asked to co-design an educational game with the researchers in a process called participatory design, with both quantitative and qualitative research methods employed. Quantitative methods were used to measure baseline data about participants' knowledge and understanding of environmental and ecological issues. The baseline survey was combined with academic data obtained from the University's Registrar Offices (i.e., semesters of high school math courses) and demographic data (permanent residence zip code). Students' permanent zip code data were matched to average household income data in the U.S. Census bureau from the most recent census year (2000). Qualitative methods were used as a formative measure of participants' changes in understanding through the game design process. To analyze qualitative data, two raters used the method of content and constant comparison analysis (Glaser & Strauss, 1967) to group common themes and reveal discrepancies among participants' responses.

*Procedures and Project Implementation*

Participants were 1,394 first-year engineering students who were enrolled in the ENGR100 course and who completed and returned the initial baseline survey. The sample consisted of 1,109 males and 285 females. Of those students, 1,250 were U.S. citizens and 144 were international students. The survey was administered in August 2008 and encompassed student demographic information, as students' initial understanding of ecological and environmental engineering (return rate = 82%).

For the game design component of the study, all of the ENGR100 students that participated in this survey were sent an email recruitment letter in October 2008. For the purpose of avoiding bias and increasing reliability and validity in the data collection process, participants were selected based on a stratified sampling strategy, so each participant team had a mix of demographic background. Twenty-four students participated in the game design component, developed by the research team and consisted of four workshops, an online wikispace environment, and two online activities (Figure 1). The game design workshops provided a venue in which study participants could interact amongst themselves and be observed by research team members, the wikispaces facilitated team member communication, and the online activities supplemented information presented in the workshops. Research team members also used the workshops to develop observation data, collect team artifacts, such as drawings, reflections, and provide teams with assistance when needed.

The themes of the workshops varied within the game design process. The first workshop lasted approximately one hour, and focused on Life Cycle Assessment (LCA) content knowledge, including introductions/assessment (10-15 minutes), a presentation by LCA content experts (30-40 m.), and a group activity (10-15 m.). The second workshop lasted approximately 70 minutes and consisted of a review of LCA (5-10 m.), a presentation of game design concepts (30-45 m.), and small group discussions (20-30 m.). The design of the third and fourth workshops were structured as "working sessions." Each team used their workshop time to develop game prototypes and provide one another with peer evaluation.

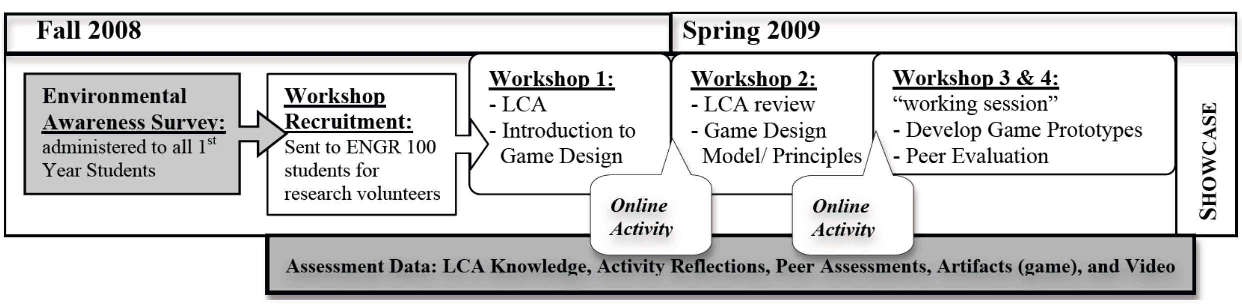

Figure 1. Workshop Activities and Timeline

*Data Collection*

Prior to the game design workshops, the research team administered a baseline survey, which consisted of several components: (a) demographic information, (b) an environmental survey (Azapagic et al., 2005) assessing students' level of awareness and understanding of sustainable development in general and about specific environmental topics, consisting of four subscales: environmental issues (14 items), environmental legislation, policy and standards (7 items), environmental tools, technologies and approaches (12 items), and sustainable development (13 items), (c) asking students to rate the importance of sustainable development, and (d) a survey about environmental knowledge from the National Environmental Education & Training Foundation (NEETF)/Roper Questions, 1997-2000 (Coyle, 2005).

Data collection for the game design process was centered on a series of game design workshops, which consisted of four face-to-face workshops and two online activities. Six teams of four students participated in the workshops and the following instruments were utilized to collect data and to triangulate the results of qualitative analyses.

- *Check-In Assessment:* Participants' reflection on their basic understanding of LCA concepts.
- *Activity Handouts:* Students reflected on activities, such as discussions and brainstorming that occurred during the workshop.
- *Artifacts:* The artifacts include the game prototypes and instructions.
- *Peer Assessments:* Each group evaluated the game paper prototypes developed by the other teams based upon a rubric developed by the research team.
- *Audio:* Includes discussion of workshop activities and final interview data.
- *Video Data:* These videos contain research team debriefing discussions held upon workshop completion.

## Quantitative Results

In the results, we will first look at the findings of the baseline survey, describing specifics of the following: self reported perspectives concerning sustainable development and environmental awareness, cultural and previous research comparisons, and predictors of environmental knowledge. Then we will discuss the effects of the game design process on environmental and life cycle analysis understanding, and the way that students integrated environmental knowledge into the game design itself.

In the baseline survey, one of the questions asked students to rate the importance of sustainable development for themselves, as an engineer, for the country, for society, for population growth, and for future generations. The percentage of students who responded "important" or "very important" was calculated for each of the categories (Table 1).

Table 1: Percentage of students' ratings of the importance of sustainable development for each category

| Category | Percentage of "Important" or "Very Important" Ratings |
|---|---|
| Future generations | 68.5% |
| Your country | 68.2% |
| Population growth | 67.1% |
| You as an engineer | 66.2% |
| The society world-wide | 65.8% |
| You personally | 61.8% |

One finding was that that approximately 35% of students did not rate sustainable development as important for any category. This indicates that engineering students may not fully grasp the importance or applicability of sustainable development in engineering or the broader society.

*Environmental Awareness*

Within the baseline survey, 12 multiple-choice items were analyzed to determine students' awareness of environmental issues and to find any gaps that may need attention within the curriculum. Table 2 displays the percentage of students who responded correctly for each question. It appears that students are most familiar with the definition of biodiversity because 92.5% of students answered this item correctly. Five other items with percentages of correct responses in the 80-89% range indicates that students are mostly familiar with the concepts assessed in these items as well, which include electricity, renewable resources, ozone, household waste, and extinction. The item that students had the least knowledge about was "What is the most common cause of pollution for streams, rivers, and oceans," with only 30.3% of students answering correctly. In addition, only half of the students responded correctly for items asking about the source of carbon monoxide pollution and the benefit of wetlands (55.2% and 55.7%, respectively). It is puzzling that environmental knowledge is particularly low when it comes to the impact of everyday behavior of end users (question 2 and 4). This knowledge assessment indicates that although students may be familiar with or have a good understanding of some environmental concepts, that there are still some important concepts they have little knowledge about.

Table 2: Percentage of students responding correctly for each item

| Item | Correct Response | % Correct Responses |
|---|---|---|

| | | |
|---|---|---|
| 1. There are many different kinds of animals and plants, and they live in many different types of environments. What is the word used to describe this idea? | Biodiversity | 92.5% |
| 2. Carbon monoxide is a major contributor to air pollution in the U.S. Which of the following is the biggest source of carbon monoxide? | Motor vehicles | 55.2% |
| 3. How is most of the electricity in the U.S. generated? | Burning oil, coal, and wood | 80.9% |
| 4. What is the most common cause of pollution of streams, rivers, and oceans? | Surface water running off yards, city streets, paved lots, and farm fields | 30.3% |
| 5. Which of the following is a renewable resource? | Trees | 82.1% |
| 6. Ozone forms a protective layer in the earth's upper atmosphere. What does ozone protect us from? | Harmful, cancer-causing sunlight | 85.4% |
| 7. Where does most of the garbage in the U.S. end up? | Landfills | 78.4% |
| 8. What is the name of the primary federal agency that works to protect the environment? | Environmental Protection Agency (the EPA) | 79.9% |
| 9. Which of the following household wastes is considered hazardous waste? | Batteries | 84.1% |
| 10. What is the most common reason that an animal species becomes extinct? | Their habitats are being destroyed by humans | 82.7% |
| 11. Scientists have not determined the best solution for disposing of nuclear waste. In the U.S., what is done with it now? | Stored and monitored | 69.2% |
| 12. What is the primary benefit of wetlands? | Help clean the water before it enters lakes, streams, rivers, or oceans | 55.7% |

Next, the self-reported levels of knowledge for four environmental subscales were analyzed. Students reported the highest level of knowledge on the Environmental Issues subscale (mean = 1.73). The Environmental Issues subscale consists of general environmental issues, such as global warming and air pollution. Students reported the lowest self-reported knowledge on the Environmental Legislation, Policy and Standards subscale (mean = 0.30); the subscale consists of specific policy and legislation questions. Finally, students still scored lower than average on the Environmental Tools, Technologies and Approaches subscale and the Sustainable Development subscale (mean = 1.16 and 1.07, respectively).

*Comparison of Self-Report and Objective Knowledge*

Previous research found that "most Americans believe they know more about the environment than they actually do" (Coyle, 2005; p. vi). To test this concept, Pearson's *r* correlation coefficient was calculated for the total awareness test score and the average self-reported awareness about environmental issues score (from environmental issues subscale questions). A significant ($p < .001$) correlation was found between the two variables. The higher a students' reported knowledge about environmental issues, the higher their actual knowledge as measured by a test of environmental issues; however the correlation was low to moderate ($r = 0.202$), indicating that strength of the correlation is weak.

*Predictors of Environmental Knowledge*

To determine what variables best predict the average awareness score of environmental sustainability, a regression analysis was performed. Standard multiple regression was considered the optimal method for answering the research question because (a) the independent variables (IVs) are correlated and there are unequal numbers of cases in cells and (b) regression can use several continuous and dichotomous IVs to represent the best prediction of the dependent variable (DV). Hypothesized variables thought to predict environmental knowledge included gender, income, previous environmental education, environmental issues subscale score, environmental policy/legislation subscale score, environmental tools/applications subscale score, sustainable development subscale score, number of semesters high school math, and number of semesters high school science.

Two variables were recoded into binary variables for better interpretation: income (low/high) and previous environmental education (none/some). The variable national/international students was omitted due to the low number of international students ($n$=144) as compared to national students ($n$=1,250). Additionally, the variable for income, although included in the model, only includes national students. Only four of the independent variables contributed significantly to prediction of environmental knowledge. These significant predictors are: (a) average self-reported knowledge of environmental issues ($\beta$=0.22, $p < .001$), (b) average self-reported knowledge of environmental tools/applications ($\beta$=0.14, $p < .01$), (c) gender ($\beta$=0.16, $p < .001$), and (d) number of semesters of HS math classes ($\beta$=0.08, $p < .01$), where $\beta$ indicates the strength of the relationship between the dependent and independent variable.

## Qualitative Results

*Students' Environmental Understanding in the Context of Participatory Game Design*

To determine what environmental awareness students gained while participating in the game design process, a content analysis was performed on the qualitative data, particularly the design artifacts, workshop observations, and follow-up interviews. The main finding that emerged was that all of the respondents ($n$ = 14) appeared to have an understanding of what LCA is, the uses of LCA, and the types of factors to consider in LCA calculations when responding to open-ended questions. It appeared that students understood the complexity of LCA and that many variables must be considered in calculating the environmental impacts of a product. For example, the most common theme that was found in the analysis of open-ended questions was *consideration of the different factors involved in LCA*. For example, typical comments were, "Deciding which factors are most/least important" and "…they [LCAs] are multifaceted [and] there is not one factor alone that determines whether one product or method is better." In contrast, all of the observers noted that of the participant teams, little to no knowledge of LCA was demonstrated at the beginning of the workshop.

At the end of the workshop, participants were asked to provide their main understanding of LCA. Out of the ten respondents, all provided either a general descriptive definition or an explicit definition of LCA. The following are examples of the two types of descriptions that participants provided.

- *Explicit (n* = 7*)*. A definition was considered explicit if a student specifically defined LCA. An example of a participant's explicit definition is, "The effect manufacturing of products has on the environment, and how to change the environmental impact of products by redesigning them."
- *General descriptive (n* = 3*)*. A definition was considered general descriptive if a student described some uses of LCA but did not specifically define the term. An example of a participant's general descriptive definition is, "My main understanding is that it is to show how you can save energy by using and building more energy proficient items."

*Integration of Environmental Information into the Game Design*

Another focus of the qualitative analysis was to determine which teams embedded to what extent LCA information into the game design. The results show that only one of the three teams explicitly embedded LCA information into the game design while the other two games had a vague reference to "improving the environment."

For example, team 4 was one of the teams that did not integrate LCA information within the game. The only decision the player must make is whether to build/expand a business or take a mission card, which could possibly be a response to the LCA criteria embedded. The mission cards allow the players to help the environment. However, this is unclear; for this team, content dissemination in the game was not consistent with the comments made by the individual group members. For example, team members made comments regarding having the player choose different options that have different LCA emphases the game reflects more about luck than choices.

Another example of a team that did not integrate LCA into the game design is team 1. In this case, players are supposed to make choices for their character with the goal of "saving the environment" and "choosing the better option," yet there are only two statements regarding environmental issues: "Player will be presented with an option based on their role…the player has to choose between improving his/ her business or saving the environment. Each decision has pros and cons that the player must weigh before choosing the 'better' option." Because Team 1 does not have data regarding personal definitions of LCA it is not clear whether the situation is similar to that of team 4, where the method of content dissemination in the game does not match what the individuals in the team articulated. The incorporation of LCA into the game became difficult to assess, and should be kept in mind for future research.

In contrast, team 2 embedded the LCA thought process into the game while developing the game, merging the concepts well. Team 2 members discussed how the game would incorporate decisions that must be made regarding the raw materials found in the environment. Although participants used the vague term "eco-index" it appears that they were thinking about the principles of LCA, as they determined the process of the game by discussing how the player will need to make choices regarding the building of the community while considering the environmental impact such as raw materials and "eco- index."

One of the reasons that students may have refrained from adding LCA into their game design was because they found the complexity of the LCA process difficult to incorporate into a game. Although a major theme that emerged from the students' written responses was the importance of taking into account the wide variety of factors in calculating LCA, this also appeared to be one of the main difficulties that students expressed. For example, several students listed the most difficult knowledge of LCA as the need to take into account many different factors and environmental impacts. For example, typical student responses to an open-ended question asking about the most difficult aspects of LCA are: "Considering the wide range of impacts that a product can have," and "…[taking] into account all that affects the environment."

## Conclusions and Implications

The purpose of this study was to investigate first-year engineering students' awareness of environmental issues and to examine how students' understanding of Life Cycle Analysis changed after participating in the process of co-designing an educational game. Results revealed that students show a lack of awareness about several aspects of environmental issues, and that all of the students who responded to the open-ended questions gained an understanding of LCA and the majority were able to define the term accurately and in detail.

Although participants responded correctly to the majority of environmental awareness questions, there were still some issues where students exhibited misunderstandings. For example, only 30% of students knew the most common cause of pollution of streams, rivers, and oceans. On a national survey, a majority of the sample of Americans also answered this question incorrectly (Coyle, 2005), indicating that there is a need to promote greater awareness about water pollution. Additional areas of concern are items relating to carbon monoxide pollution, benefits of wetlands, and nuclear waste disposal, as these issues might have implications for distributing or manufacturing certain products, and engineers should develop an awareness and understanding about these issues.

Additional results showed that there are four predictors of environmental awareness: (1) the level of awareness about environmental issues, (2) the level of awareness about environmental tools, technologies and approaches, (3) gender, and (4) the number of semesters of high school math courses. Not surprisingly, the largest predictor of environmental awareness is a students' self-reported awareness of environmental issues. Next, gender was the second largest predictor of environmental knowledge, followed by students' self-reported knowledge on the environmental tools, technologies and approaches subscale. Finally, the smallest predictor was the number of high school math courses taken, which was unexpected given that the number of semesters of high school science courses taken was not a significant predictor of environmental awareness. Thus, there may be a variable correlated with the number of semesters of high school math that was not measured and serves to predict students' environmental awareness. In addition, future research with non-U.S. citizens should use additional measures of environmental awareness because the survey used in this study may not be appropriate for international students. Lastly, students reported the lowest levels of awareness on the environmental legislation, policy and standards subscale especially as compared to the more general Environmental Issues subscale.

This study also examined how students' environmental awareness and understanding of the LCA concept changed following the game design process. Although individual participants demonstrated an understanding of the factors involved in LCA, they often did not fully incorporate their understanding into the game design. Only one of three teams explicitly embedded LCA information into the game design. Although participants showed an understanding of environmental issues as they pertain to engineering, they may have perceived LCA as too complex or lacked the time to successfully incorporate LCA into the game, indicating that additional planning time for game development is needed.

These results contribute to the research on first-year engineering students' environmental awareness. The participatory game design provided rich data about students' understanding of LCA and served as an effective platform for knowledge elicitation. It is apparent that first-year undergraduates in engineering lack awareness about many environmental issues. Because of the increased importance of sustainability in engineering, the need for engineers in all disciplines to understand sustainability issues in engineering is necessary. The game design process was a method that warrants additional research to determine the effects on students' understanding of LCA and the importance of sustainability in engineering. Future research is needed to focus more on the group processes within teams as well as how to moderate the game design process so as to better lead to participants' understanding of environmental issues in engineering and an educational game that can be used to teach others.

# "I Don't Know—I'm Just Genius!": Distinguishing Between the Process and the Product of Student Algebraic Reasoning

Jose Francisco Gutierrez, Graduate School of Education,
University of California—Berkeley, Berkeley, CA 94720-1670, josefrancisco@berkeley.edu

**Abstract:** This paper reports on a semiotic-cultural analysis of two high-school minority seniors' participation in a mathematics instructional intervention conducted at a school for academically at-risk students. Focusing on the students' speech acts, gestures, and artifact production during their successful collaborative engagement in an algebraic pattern-finding task, I adopt and adapt Radford's (2003) framework to evaluate the quality of each student's actual learning as implicated by their discursive contributions. By analyzing each student's utterances as either "to" a semiotic mode (generalization) or just "in" the mode, and then overlaying these coded utterances, I show how one student's participation, which appears to mark a developing algebraic command, in fact blinds the teachers to underlying discontinuity in the student's meaning construction. The study illuminates critical tradeoffs in the design and facilitation of collaborative problem solving.

## Introduction: The Story of Be'zhawn and Deana

We join Be'zhawn and Deana, two high school seniors classified by their mathematics teacher as low-achieving students, in the midst of a tutoring session involving a collaborative algebraic problem-solving activity. Be'zhawn and Deana are at the board, working together on a sequence of several geometric figures in an attempt to formulate its pattern algebraically (see Figure 1 below). For twenty-five minutes, the students have been bandying mathematical ideas about: some ideas are taken up and built upon, while others are ignored or proven inefficacious. Throughout this duration, both students sustain a high level of engagement and, to all appearances, contribute equally to the problem-solving process. Eventually, Be'zhawn is the first to verbally express a correct solution. And yet, when asked to explain his reasoning, he replies, "I don't know—I'm just genius!"

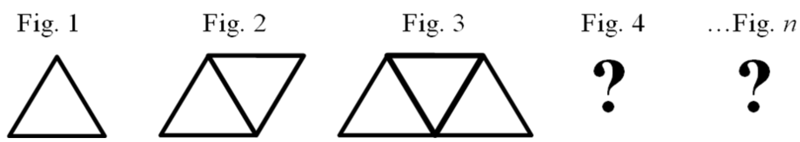

Figure 1. The triangle sequence—a paradigmatic reform-based algebra problem. The task objective is to express $U_n$, the total number of line segments in the $n^{th}$ figure. For example, "Fig. 1" consists of 3 line segments, "Fig. 2" consists of 5, "Fig. 3" consists of 7, etc., so that the $n^{th}$ figure consists of $2n+1$ line segments.

Back in our laboratory, all three teachers—the author included—discussed the students' behaviors during this activity and the nature of their mathematical contributions. We all agreed that this particular tutoring session was unique, as compared to previous sessions, in terms of the quality of students' mathematical reasoning. Also, as this was the first time they had collaborated on a pattern-finding problem, we attributed the students' engagement to the problem type's unique task structure. Be'zhawn, in particular, had exhibited much difficulty with algebraic concepts in prior sessions, where the problem items had been more routine. The pattern-finding problem was not the only item Be'zhawn solved quicker than his peers; however, this was the first time he had ever indicated that he held a positive perception of himself as a mathematics doer, when he confidently declared that he was "genius."

This particular tutoring episode was part of a larger mathematics-education research project conducted at a small alternative high school in the San Francisco Bay area. Broadly, we sought to identify and respond to learning challenges faced by academically at-risk mathematics students with respect to both reform and traditional algebra curricula. The pattern-finding episode appeared to demonstrate success and not only challenge, and so I selected this episode in an attempt to articulate principles of design and facilitation that contributed to its apparent success. That said, my enthusiasm was tempered by acknowledging that Be'zhawn's inability to explain his correct solution might implicate his solution strategies as problematic. What might it mean for a student to solve an algebraic pattern-finding problem yet not be able to explain his solution? What methodological tools could address this puzzle?

## Objectives of the Study

Researchers of mathematics education constantly develop theoretical frameworks for articulating what students struggle with as they attempt to solve algebraic problems. At the same time, though, the national achievement gap is constantly increasing. This, despite constant calls for equity in mathematics education and, in particular, for increasing the accessibility of algebra content for students from minority groups and economically disadvantaged backgrounds (for a review see DiME, 2007). The current study embarks from a conjecture that some recent theoretical frameworks developed particularly for tackling algebraic reasoning (for a review see Kieran, 2007) harbor the potential to illuminate new directions for broadening diverse participation in mathematics and, in particular, to support general success in this "gatekeeper" content. The objective of this paper is to build upon some delimited empirical data so as to illustrate what we may need to attend to as we pave new paths through the gate.

Central to the theoretical argument of this paper is Luis Radford's (2003, 2008) *semiotic-cultural approach* to theorizing the process and content of students' algebraic reasoning. This powerful approach views learning as an evolving process co-constrained by both cognitive and socio-cultural factors. Specifically, mathematics learning is conceptualized as constructing personal meaning for canonical semiotic artifacts (e.g., algebraic symbols such as the variable "*x*"). Through consolidation and iteration of such constructions, students appropriate these notations and, reciprocally, build personal meaning for mathematical content as well as fluency with the disciplinary procedures. That is, individuals who build mathematical signs upon personal meaning develop more than fluency with procedures—they develop substantive and articulated understanding of the targeted content. Radford's approach takes into account a vast arsenal of personal and interpersonal resources that students bring to bear in solving mathematical situations, including linguistic devices and mathematical tools. Most relevant to our current study, Radford has demonstrated that critical steps within individual learning trajectories can be explained by noting subtle shifts in the subjective function and status of the semiotic artifacts (Abrahamson, 2009; Sfard, 2007).

I here propose Radford's approach as a powerful tool for untangling the compound challenges faced by students who are attempting to develop a mathematical register even as they are learning new content. Specifically, I propose, the semiotic-cultural approach enables researchers to delve into the cognitive/semiotic plane below external discursive manifestations. That is, students may manifest discursive productions in a proper mathematical register, yet these "correct" utterances may belie the absence of underlying personal meaning. The semiotic-cultural approach, I submit, could be leveraged so as to expose tension between students' overt mathematical speech contributions and their covert, (dis)connected reasoning.

A potential theoretical contribution of this paper is the qualification I propose for Radford's approach, as I adapt the approach to the particular needs of at-risk students. These students' disposition toward the classroom "leading discourse" (Sfard, 2007) is complex, because for them, "talking the mathematical talk" is at once enabling and threatening. We therefore may witness gaps between these students' overt expression and covert meaning. This tension bore out in the analysis. Namely, Whereas Radford's approach was pivotal to making initial sense of these students' utterances, I gradually realized, however, that the approach was not enabling me to unwrap students' covert meanings. As the paper will demonstrate, I was thus impelled to revisit some of the implicit assumptions of Radford's semiotic-cultural framework and then make a pivotal amendment. Namely, whereas Radford's interpretation of collaborative problem solving may imply that all team members are party to critical semiotic transitions inherent to generalization acts, I submit that some students manifest productions *in* milestones of this procedure without having partook in advancing *to* these semiotic modes. Distinguishing the within-vs.-between semiotic nature of students' discursive productions is important, because, as Radford claims, it is the *transitions* from one semiotic mode to the next—not discursive acts per se—that are crucial to building meaning (Radford, 2003). Equipped with this qualification, the semiotic-cultural approach helps me characterize weaknesses in some students' learning processes during collaborative problem solving as resulting from an impetus to participate within a particular semiotic mode without necessarily having personally made the careful transition to that mode.

## Theoretical Background

From the semiotic-cultural perspective, mathematics learning is viewed as a mediated, distributed, and dynamically reciprocal process in which students' emerging presymbolic knowledge is iteratively objectified in progressively sophisticated forms of historically and culturally endowed semiotic systems. One such semiotic system—which is prevalent in the mainstream of school mathematics programs—is algebra. Viewed from the semiotic-cultural perspective, "algebraic thinking is a particular form of reflecting mathematically" (Radford, 2003), that is, algebra is about "using signs to think in a distinctive way" (Radford, 2008, p. 87).

To illuminate the content and process of this distinctive way of thinking characteristic of algebra, Radford elaborates a theoretical framework for describing and analyzing students' reasoning during collaborative engagement with pattern-generalization algebraic activities such as the triangle sequence (see Figure 1, above). I now use this problem as a context to elaborate on Radford's framework, which is central to my data analysis, and then outline a potential shortcoming with its extant formulation and finally propose a solution to this problem.

A key construct in Radford's framework is *knowledge objectification*, which is defined as the process of making the objects of knowledge apparent (Radford, 2003). For example, a mathematics learner, in an attempt to convey a certain aspect of a concrete object, such as its shape or size, will tap a variety of semiotic artifacts such as mathematical symbols and inscriptions, words, gestures, calculators, and so forth. In patterning activities, however, some of the objects of knowledge are general and therefore "cannot be fully exhibited in the concrete world" (Radford, 2008, p. 87). More generally, mathematical notions may not be cognitively accessible, because they do not exist in the world for empirical investigation (Duval, 2006),that is, these notions are never apparent to direct perception. Therefore, in order to instantiate (objectify) these ephemeral notions, students must resort instead to personally and culturally available forms such as linguistic, diagrammatic, symbolic, and substantive artifacts as well as the body, which Radford (2003; 2008) collectively terms *semiotic means of objectification*.

In patterning activities, students often resort to using one of two strategies when they attempt to construct generalizations from an initial set of numeric and/or figural cues (Radford, 2008) such as in the triangles sequence.

1. The first strategy, *naïve induction* is characterized by a process of disconnected or minimally principled "guess and check." For example, a student might propose a simple rule such as "the figure-number times two" and check its validity on a few cases. Finding that the proposed rule does not satisfy one or more cases, the student might then modify her rule or propose an entirely different rule, for example, "the figure-number times two, plus one" and check its validity as well, and so on.
2. The second and more sophisticated strategy, *generalizing*, is expressed as an active search for recurrent relationship structures and/or pattern commonalities among constituent elements in the problem space. This latter strategy, in turn, typically produces two types of generalization, *arithmetic* and/or *algebraic*.
   2.1. Arithmetic generalizations typically take the form of a *recursive solution* that only indirectly expresses any term in the sequence. In the triangle sequence, the number of line segments required to construct each consecutive figure always increases by a factor of two with respect to the previous figure, an observation expressible as the arithmetic generalization $U_n = U_{n-1} + 2$. The commensurate *explicit solution* $U_n = 2n + 1$, however, is more powerful, because it determines directly any item along the infinite sequence.
   2.2. Making the leap from recursive to explicit solutions involves generalizing a pattern *algebraically*, which requires grasping and objectifying recurrent $n$-to-$U_n$ relations along the sequence, then elaborating this objectification into a generalization that would *directly* express any term in the projected sequence.
   2.3. Finally, algebraic generalizations are subdivided into three types in accordance with their level of generality: *factual, contextual,* and *symbolic* (see Figure 2, below, for a summary as well as examples).

| | | | | | |
|---|---|---|---|---|---|
| **Solution Strategies** | Naïve Induction<br>• Characterized by "guess and check"<br>• E.g., "It's '2*n*+2'… No. Try '2*n*+1'. YES!" | Generalizing<br>• Active search for recurrent relationships/commonalities among constituent elements in the problem space | | | |
| **Generali-zation Types** | | Arithmetic Generalization<br>• Recursive (*U* is expressed in terms of previous figure)<br>• E.g., $U_n = U_{n-1} + 2$ | Algebraic Generalization<br>• Explicit formula (*U* is expressed in terms of the figure's ordinal position)<br>• E.g., $U_n = 2n + 1$ | | |
| **Levels of Generality** | | | Factual<br>• Objects and operations are bound to concrete level<br>• E.g., "1 plus 2, 2 plus 3, 3 plus 4…" | Contextual<br>• Objects and operations are abstracted and generalized<br>• E.g., "The figure plus the next figure." | Symbolic<br>• Objects and operations are expressed through formal symbolism<br>• E.g., "$n + (n+1)$" |

Figure 2. Semiotic-cultural taxonomy of algebraic pattern-finding solution processes (adapted, Radford, 2003; 2008)

## A Proposed Qualification

When I first applied the semiotic-cultural framework to the data (see Analysis Techniques, below), it indeed revealed disconnection between the students' utterances and their underlying meaning making. Namely, Deana's utterances reflected generalizing acts, whereas Be'zhawn's did not. Essentially, applying Radford's framework revealed that one student 'got it' while the other did not 'get it.' However, what the extant framework did not explain was why it appeared to the instructors in situ that *both* students 'got it.'

A second analysis of the data was conducted so as to provide an alternative description of the students' behaviors—a description that would explain how the researcher-as-analyst could see what the researcher-as-teacher could not. So doing, I realized that inherent to Radford's framework were what might be called three *semiotic modes* of action, in which both Deana and Be'zhawn were participating. By "mode" I am offering an analytic construct that is linguistic but not psychological; that is, by "mode" I am referring to the surface features of student utterances, temporarily putting aside the question of the student's subjective semiotic grounding. I could now conjecture that students' utterances *within* each of these semiotic modes were similar, thus giving the teachers the impression that both students shared similar learning experiences toward those utterance.

By introducing "modes" as an elaboration to the framework, I differentiate two meanings of "generalization": the *process* of generalizing (i.e., the way that students engage with the problem), and the *product* that results from this process. This distinction is important, because it suggests that researchers and teachers may attribute understanding to students when such attribution is not warranted. In particular, a student's utterance *within* a semiotic mode may be interpreted as marking the production of a semiotic generalization *to* that mode, when in fact the student is only appropriating and elaborating on the product of another student's generalization to the mode.

The proposed process-vs.-product distinction reflects a pedagogical position that the generalizing activity is not merely to create opportunities for students to operate *in* each of the modes, but rather to support them as they progress *along* the desired chain of signification from the factual through to the symbolic mode, thus ensuring that each and every student performs the cognitive work necessary to personally ground the target signs.

Having presented a semiotic–cultural framework and outlined a potential problem with its extant formulation as well as a proposed solution to this problem, I am now in a position to restate my research questions in light of Radford's seminal theory. Namely:

- Can a mathematics learner be *in* a particular semiotic mode without having generalized *to* that mode?
- What are the consequences of such superficial semiotic production for learning?

Next I describe the methods used to address these questions.

## Methods

For this preliminary empirical study, the research team, which included the author as well as two undergraduate apprentice researchers, conducted an instructional intervention—*The Mathematics Workshop*—at a small high-school for academically at-risk students. The intervention, which was designed to prepare a small cohort of senior students (N=5) for a state exit exam, provided one-to-one and small-group tutoring sessions with a focus on algebra content. The research team all shared in the design, facilitation, and preliminary study of the workshop. For this paper I focus on two case studies, Be'zhawn (male) and Deana (female; both pseudonyms), and conduct my data analysis from the semiotic-cultural perspective. To address my research questions (see above), I examined students' speech acts, gestures, and artifact production during collaborative engagement with the "triangle sequence." I analyzed each of these students' reasoning processes during the focus episode in terms of its semiotic trajectory and then juxtaposed these two trajectories. This juxtaposition reveals "hidden" dyad dynamics in the joint activity of interpreting the sequence and constructing its algebraic reformulation.

*Data Sources*: The entire data corpus from the intervention includes students' original work, a total of six hours of video footage from the implementation, and a project wiki (online collaborative archive) that we used to coordinate resources, document fieldnotes and meeting minutes, and share ongoing reflections. However, the study reported in this paper focuses on a span of only 28 minutes of video footage, in which the triangle sequence was implemented. I selected this particular teaching episode for deep analysis both because this activity has been previously studied (e.g., Radford, 2003; Rivera, 2008) and because the participants' behaviors as they engaged in the solution of this problem helped me first notice the process-vs.-product of semiotic constructions.

*Materials and procedures*: The teaching episode in question begins with an utterance from the first teacher (hence "T1," the author; "T2" = the second teacher, one of the undergraduate apprentice researchers; "T3" = the third teacher, the other undergraduate apprentice researcher). T1 sketched the first three figural cues on the whiteboard and instructed Deana and Be'zhawn to search for a mathematical pattern and express it as an algebraic equation. Aside from these initial figural cues, a set of guiding questions was also written on the board: "How many lines are there in Fig. 1? Fig. 2? Fig. 3? Fig. 4? Fig. 12?" Furthermore, a key design feature for implementing the triangle sequence was to substitute increasingly larger numbers (e.g., Fig. 50, and Fig. 67) as a way to impress upon students that ultimately the arithmetic/recursive strategy is inefficient, thus motivating the need for more powerful tools and strategies such as algebraic generalizing as well as the use of explicit formulas.

## Analysis Techniques

I produced and analyzed a transcription of the 28-minute teaching episode, which captures all verbal, gestural, inscriptional, and other semiotic actions that were clearly observable in the video. The transcription was parsed into a total of 440 "Lines," where each Line is defined as a segment of speaker continuous speech. Next, I identified all student utterances involving mathematical propositions (127 out of the 440 Lines). For this study, I focus only on these Lines of the transcription, for which two main analytic questions were asked pertaining to its semiotic nature:

1. Generalization Type (generalization *to* the semiotic mode—i.e., the *products*):
   1a. Is the expression the product of naive induction or generalizing?
   1b. [If so,] Is the expression an arithmetic or algebraic generalization?
   1c. [If so,] Is the expression a factual, contextual, or symbolic generalization?
2. Semiotic Mode (operating *in* the semiotic mode, and therefore having ostensibly arrived *to* the mode and ostensibly engaging in the *process* of generalizing to the next mode):
   2a. Is the student referring to and/or expressing an action upon concrete objects (i.e., operating in the factual mode)?
   2b. Is the student referring to and/or expressing an action upon abstract yet contextually situated objects (i.e., operating in the contextual mode)?
   2c. Is the student referring to and/or expressing an action upon algebraic symbolical objects (i.e., operating in the symbolic mode)?

Working with both the video footage and the abbreviated transcription, a first pass of the data was done using analytic questions 1a-1c (see above). I initially evaluated whether or not each utterance reflected a generalization *to* a particular mode or merely a reiteration *in* the mode. This evaluation was based on a qualitative microgenetic analysis (Schoenfeld, Smith, & Arcavi, 1993) of students' behaviors during their conversation. So doing, I determined whether the students engaged in authentic generalizing acts (i.e., grasping and objectifying recurrent $n$-to-$U_n$ relations and providing a direct expression for any term along the sequence) or resorted instead to naïve induction and/or appropriating the speech forms of others. Following this qualitative analysis, a second pass through the data was done using analytic questions 2a-2c, whereby all student utterances involving mathematical propositions were coded only for their semiotic mode (factual, contextual, or symbolic). For example, the student utterance "Fig. 3 has seven lines" was coded as an assertion *in* the factual mode, because Fig. 3 was perceptually available when the utterance was verbalized (i.e., Fig. 3 was drawn on the board; it was "present"). And yet, the utterance "Fig. 5 is going to have eleven" was also coded as *in* the factual mode even though Fig. 5 was not perceptually available (i.e., Fig. 5 was not drawn on the board; it was "absent"), because the utterance "Fig. 5" refers to a specific figure along the sequence, which could be instantiated as a concrete entity. In contrast, utterances such as, "We just add a triangle to every one" were coded as assertions *in* the contextual mode because the student expressed an action upon abstract objects, whereby "one" is a pronoun referring to the general term "figure." Finally, transcript Lines containing students' inscriptional actions that involve symbolical notation were coded as assertions *in* the symbolic mode. For example, the inscription "$x2 + 1$," which a study participant wrote on the board, was coded as *in* the symbolic mode.

## Results and Discussion

The results and the discussion begin by presenting a qualitative analysis of several transcription segments, followed by further quantitative analysis of students' utterances in terms of their semiotic mode. I present the results in this order—which is atypical of social science research articles—because I wish to provide for the reader a chronological description of how my initial investigation of the data led to the need for theoretical extension. Combined, these analyses reveal that the students' contributions during their conversation occupied each of the three modes, however, Deana's but not Be'zhawn's utterances generalized *to* these semiotic modes.

## Qualitative Results

I here present qualitative data analyses of a series of selected transcript segments. Due to space constraints, these selected segments do not represent all of the students' mathematical activity during the 28-minute episode; however, these segments are representative of the students' behaviors during the episode in question. With these segments, I aim to elaborate on findings from the quantitative analysis by illustrating that: (1) both Deana and Be'zhawn's discursive production were *in* each semiotic mode; and yet by-and-large (2) Deana's manifestations ultimately generalized *to* each mode, whereas Be'zhawn's did not.

*Segment 1*: At the onset of the activity, Deana immediately noticed that the figures could be construed as a succession of accruing triangles; she also noticed that the number of line segments for each consecutive figure increased by an addend of two. Deana continued to operate both *in* the factual and contextual mode. So doing, she constructed an arithmetic generalization *to* the contextual mode in the form of $U_{n+1} = U_n + 2$. Deana thus began a process of authentic generalizing *in* the factual and contextual modes and this qualitative analysis suggests that her subsequent semiotic productions could be grounded in concrete elements from the initial problem space. [Each segment of data presented below is labeled by its Line number from the original transcription, the speaker, utterance, and its ostensible semiotic mode: "F" = factual; "C" = contextual; "S" = symbolic]

| | | | |
|---|---|---|---|
| Line 14 | Deana | "[*gazes at Fig.s 1, 2, and 3 drawn on board*] Fig. 4 is gonna have nine." | F |
| Line 16 | Deana | "We just add a triangle to every one, right?" | C |
| Line 33 | Deana | "[*Fig.*] 4 has nine. It goes up every two lines, so Fig. 5 is going to have eleven…" | C |

*Segment 2*: This segment illustrates how Be'zhawn first appropriates Deana's utterance and builds upon it, such that his speech acts are *in* (but not *to*) the factual and contextual modes. Furthermore, Be'zhawn gave no indication that he had interpreted the original problem-situation and had not noticed the patterns that Deana was verbalizing.

| | | | |
|---|---|---|---|
| Line 47 | Deana | "[*addressing no one in particular, thinking aloud, referring to Fig. 12*] Twelve and two… no… twelve and two is twenty-four." | F |
| Line 49 | Be'zhawn | "Twenty-four! That's the answer. […] What's twelve times two? Eleven times two is twenty-two. Ten times ten is twenty." | F |
| Line 57 | Be'zhawn | "They all go up by two." | C |
| Line 68 | Teacher 1 | "[*after asking Be'zhawn to draw Fig. 4 on the board*] They're just triangles, right?" | -- |
| Line 69 | Be'zhawn | "Oh, they're just triangles? What the—" | -- |

*Segment 3*: For the remainder of the activity, Be'zhawn employed naïve induction. For example, he guessed that Fig. 67 is comprised of 33 lines (i.e., $U_n \approx n / 2$), and then changed his guess to 134 (i.e., $U_n \approx n*2$).

| | | | |
|---|---|---|---|
| Line 191 | Be'zhawn | "Thirty-three... That's how many lines [*Fig.*] 67 has. Nah, that's too little. [*Fig.*] 12 is twenty-six." | F |
| Line 199 | Be'zhawn | "But it's not thirty-three though, cuz only [*Fig.*] 12 is twenty-six." | F |
| Line 254 | Be'zhawn | "I think it's one hundred and thirty-four." | F |

*Segment 4*: Interestingly, it was Be'zhawn who first produced a non-symbolic version of the correct solution procedure. Assisted by the teachers, Be'zhawn noticed that his proposed rule, $U_n = n*2$, was off mark by a difference of 1. Using this piece of new information, Be'zhawn cobbled together a correct solution procedure, namely, $U_n = n*2+1$, and he used it to articulate the solution for the case of Fig. 67.

| | | | |
|---|---|---|---|
| Line 308 | Teacher 2 | [*to Be'zhawn*] That was the guess, but these are each off a little bit so what do we think this is actually gonna be? | -- |
| Line 309 | Be'zhawn | Unless you add one to it. | C |
| Line 310 | Teacher 1 | So what do you think the actual— | -- |
| Line 311 | Be'zhawn | One-thirty-five! | F |

Even though Be'zhawn's solution is mathematically correct, I argue that his semiotic constructions were disconnected from the original problem space, because they were the result either of naïve induction or of appropriating the speech forms of others, mainly Deana's. Namely, my analysis reveals that Be'zhawn was guessing and operating on proximal numerical values in isolation from the initial set of figural cues. At least, Be'zhawn could not reconstruct how he arrived at these constructions. Indeed, when a teacher asked Be'zhawn, "What's the formula?" he responded as follows: "I don't know—I'm just genius!"

*Segment 5*: Deana, on the other hand, was able to build upon her initial arithmetic generalization (see Segment 1 above). So doing, at the end of the activity she was able to connect components of the solution procedures to elements from the original problem situation. Thus, I maintain, her inscription "*x*2 + 1," which she wrote on the board, was semioitcally grounded, from the factual through to the symbolic.

| | | | |
|---|---|---|---|
| Line 366 | Deana | "The formula. Okay. You know sixteen, right? Times two, multiply by two, is thirty-two, right? "And you add one more cuz of the extra line, [*gestures the shape of the top of a triangle* "/\"] cuz it's three lines [*referring to missing bottom line*]. And you just—since it's three lines." | F |
| Line 406 | Deana | "It's gonna work because you got the two and then you add one more line." | C |
| Line 414 | Deana | "[*writes* "*x*2 + 1 = ?" *on the board*] *x* times two plus one." [*Be'zhawn walks to the other side of the board, gazes toward Deana's inscription, then he writes "*Figure x 2 + 1*," where the "*x*" is read as a multiplication symbol*] | S |

The qualitative analyses above illustrate how Deana was able to construct both arithmetic and algebraic generalizations, whereas Be'zhawn was not. We see the subtle shifts in Deana's perception of the function and status of the semiotic artifacts—beginning with her initial grasp of a recurrent relationship between figures, "we just add a triangle to every one" (Line 16), to her arithmetic generalization expressed in terms of the line segments, "it goes up every two lines" (Line 33), to her final algebraic inscription of "*x*2 + 1 = Lines" (Line 414). Be'zhawn's semiotic productions, on the other hand, certainly manifested *within* each of the generalization modes, however, his shifts *between* the different modes are weakly connected at best, and non-existent at worst.

## Quantitative Results

Figure 3, below, represents students' semiotic-mode participation sequences—it depicts a synoptic left-to-right view of each student's participation through the lens of the semiotic mode they are *in*. Every node in the graph represents a student utterance coded as articulated in one of the three semiotic modes. By overlaying their respective semiotic sequences, it may appear that both Deana and Be'zhawn are making forward advances between modes, yet a closer analysis of their manifest productions reveals that this is not the case.

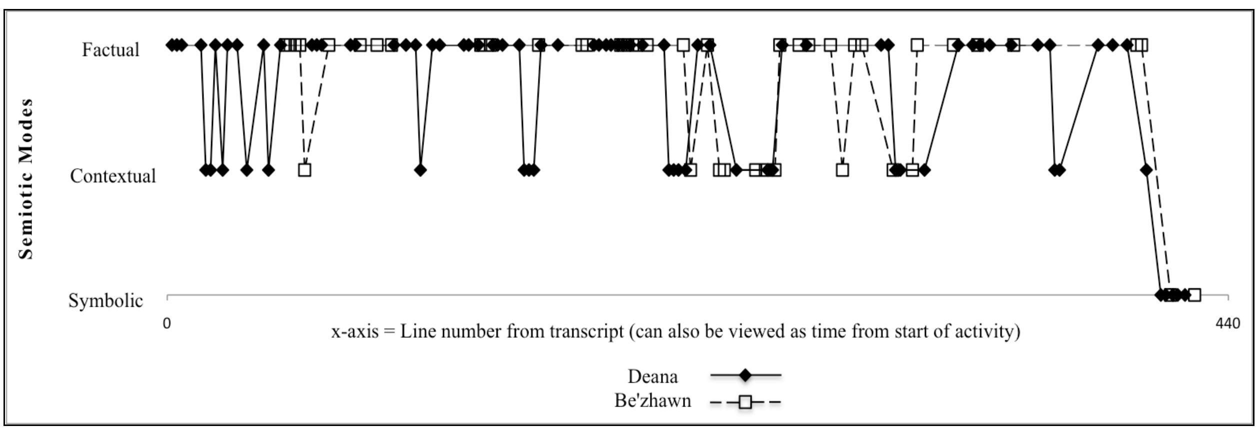

Figure 3. Representation of juxtaposed student participation sequences (ostensible semioitc trajectories)

Figure 3 clearly illustrates that Be'zhawn and Deana's respective semoitic-mode participation sequences were indeed similar, which could acccount for why the teachers, in situ, interpreted their bahaviors as indicating similar and mutually beneficial reasoning processes. And yet, in Figure 3, it is important to notice that Deanna's move from the factual to the symbolic (at the very end) occurs before Be'zhawn's move. We also see that Deanna's sequence passes through the contextual mode en route to the symbolic whereas Be'zhawn's does not, an observation supporting the hypothesis that his semiotic productions were disconnected, as apparent in his "I don't know" statement mentioned earlier in my qualitative analysis.

## Conclusions and Implications

When students participate in collaborative problem solving, their discursive productions do not necessarily reflect adequate grounding of mathematical symbols, even in the cases where these contributions are instrumental to the group's overall success. Namely, while participating in collaborative problem solving, students' individual discursive productions can occupy each of the three semiotic modes identified by Radford, yet these manifest productions might nevertheless conceal a discontinuous semiotic trajectory, resulting in suboptimal learning. Previous research has challenged the claim that mathematics learning is best done in small groups or dyads (e.g., Barron, 2003), and this paper contributes to this previous research by providing a semiotic-cultural articulation of the variability of meaning construction for individuals participating in a dyad. Notably, the paper certainly does not argue against collaboration as a mode of classroom practice. Rather, it has been my intention to provide analytic tools that problematize any assumptions that educators might harbor with respect to issues of equity that emerge when two or more students are assigned a joint problem-solving task (cf. Esmonde, 2009).

In addition to these issues of design and facilitation, the paper has also made two tentative contributions to mathematics-education research: (1) a theoretical contribution is a proposed refinement to Radford's semiotic-cultural approach; and (2) a methodological contribution is the initial development of an analytic approach to distinguishing between the process and product of students' discursive contributions to collaborative (algebraic) problem solving.

# Contingent Identification in a Biomedical Engineering Classroom

Vanessa Svihla, University of California, Berkeley, vsvihla@hotmail.com

**Abstract:** This study, set in a university biomedical engineering capstone design course, explores how students identify as engineers, finding this process to be contingent and dynamically negotiated. Biomedical engineering, as a degree program, serves as a legitimate pathway towards engineering and medical school, making identification with engineering particularly contingent. Living narratives provide glimpses into experiences students have in their design course, which aligns more closely with authentic engineering practice than their previous coursework. As a result, the design course is a significant opportunity for students to consider themselves to be engineers. Framed by changes in *accountable disciplinary knowledge* and *navigation* (Stevens, O'Connor, Garrison, Jocuns, & Amos, 2008) within the interdisciplinary context of biomedical engineering and the varied goals of students for choosing the major (engineering vs. health sciences), students' identification as engineers emerges as particularly contentious. Leadership and underrepresentation are considered in relation to identification, navigation, and accountable disciplinary knowledge.

*Everything I have learned comes into play.... All I can say is that I think like an engineer. I see things from many different angles. I calculate. I am much more realistic.*

*I mean, like a surgical procedure? I mean, that's not considered any sort of technical…? Like, a surgical procedure? And, like, taking readings in a rat's stomach? I mean, something that nobody else has* ***even*** *ventured to do in* ***this*** *course?!*

## Background

These two quotes from students express tensions between two predominant and legitimate pathways (biomedical engineering and medical school) students pursue while yet positioned as "BMEs"- students in biomedical engineering. This paper explores how students working in teams in a university capstone biomedical engineering course contingently express their identification with engineering as they learn to design. Ethnographically-collected lived narratives (Ochs & Capps, 2001) provided glimpses into student experiences during this process, highlighting tensions and dimensions of contingency in students' identification as engineers, and how this intersects with their learning. These are viewed through three *dimensions* for understanding pathways through engineering education: *accountable disciplinary knowledge* (ADK) - that is, the work and practices that *count* as engineering at a given point; *navigation* of pathways; and *identification* with and by engineering (Stevens, et al., 2008). Additionally, underrepresentation and leadership are considered in terms of how they might intersect with these dimensions of ADK, navigation, and identification.

The capstone model provides a fertile ground for observing learning and related shifts in identification, taking learning to be an "experience of identity"(Wenger, 1999, p. 215). The social process of engineering design (Bucciarelli, 1994) and learning to design in a team involves the coordination of many lenses. The capstone design course introduces new identity spaces for the students: They may form a team identity as they develop a sense of belonging in a consequential manner to their team (Guzzo, 1986). They negotiate various design decisions (Bucciarelli, 1994), learning by explaining perspectives (Webb, Troper, & Fall, 1995) and by comparing to team mates' perspectives (Phelps & Damon, 1989). Within a team, each member assumes roles such that in total, all steps are accomplished, but not by all team members (Goldschmidt, 1996). Gunther, Frankenburger, and Auer (1996) caution that though enacted roles have been noted, understanding how and why roles form is largely unexplored for design contexts. By exploring students' identifications as engineers, we may shift focus to understanding some of the dimensions students face along their paths towards or away from engineering. Additionally, understanding how individuals from underrepresented groups identify as engineers may elucidate some of the experiences that contribute to their (dis)engagement (Heyman, Martyna, & Bhatia, 2002; Seymour & Hewitt, 2000).

## Setting and Participants

The participants of this study were undergraduate senior biomedical engineering students enrolled in the capstone, year-long design class at a large public southern university. Six case study design teams were drawn from two iterations of the course (2006-07 and 2007-08). Design teams were composed of four students, organized by course instructors, and persisted across two consecutive semesters. Teaching assistants played a large role in facilitating learning, spending approximately 100 contact hours with teams. The course comprised a two-month redesign project followed by eight-month industry-sponsored project, during which teams were mentored by faculty advisors and sponsors. Course instructors used team rankings of sponsored projects to match teams to sponsors; when multiple teams ranked a project highly, the sponsors were asked to "hire" based on resumes submitted by the students. The projects came from hospitals, industry, government, and universities, and while they varied in terms of difficulty, all were real-world, complex, and ill-structured.

## Methodology

Guided initially by theories (Fetterman, 1989) related to design process (Jonassen, 2000; Schön, 1983) and learning (Hatano & Inagaki, 1986), I entered the design studio as a non-participant observer (LeCompte & Schensul, 1999) intending to study design *learning* and to model how innovative design products might arise (Svihla, 2009). As I built rapport and reconciled my etic understandings of practices in relation to these theories, I transitioned to a participant observer role (e.g., discussions of statistical analysis, assisting with presentation preparation decisions), and began co-constructing emic understandings related to the practices and experiences of specific student design teams. Adopting an ethnographic approach (LeVine, 2007) to understanding students' experiences learning to design afforded an opportunity to consider concurrent shifts in identification.

Given the diversity of projects, comparison was of primary importance, allowing me to select cases by comparison, spontaneously use comparisons as a means to understand, and comparing across cases (Vogt, 2002). For each class iteration, I collected qualitative data related to three case study teams, providing six case study teams. Teams were selected with input from the professors and teaching assistants, who listed their highest and lowest performing teams, which teams sought out resources and which did not, and were invited to suggest teams they thought might be interesting to study for other reasons. These data along with peer evaluations and a survey of interactions formed a matrix yielding three levels (high, medium, and low performing), from which teams with all or most members consenting into the study were selected.

Teams were observed as they met together and with mentors. Meetings were audio rather than video recorded due to limitations posed by the settings: much of the design activity took place in a room with only one available electrical outlet, and this was commonly in use by a student; additionally, not all sponsors were comfortable with video recording of materials covered by Intellectual Property. Informal interviews/discussions emerged during observation, either instigated by myself or by the students. Such conversations were used for member checking and clarification, though the latter was rarely needed as the students tended to assume that I had insufficient understanding of their projects, and would often teach me and ask if I had questions.

Field notes and transcriptions of interactions were reviewed multiple times and initially analyzed as team narratives of designerly solutions (Cross, 2001) to impasses in design process (Svihla, 2009; Svihla, Petrosino, & Diller, 2009). Initial analysis of transcripts involved grounded coding, allowing themes related to initial research goals to emerge, then seeking counterexamples. This process uncovered other persistent themes related to leadership and underrepresentation in relation to the adoption of designerly perspectives. Transcripts were re-analyzed using the framework presented by Stevens and colleagues (2008), framing students' experiences by accountable disciplinary knowledge (ADK), navigation, and identification.

## Navigation

Though the focus of this study is on how students identify during their capstone design experience, it is useful to consider both unofficial and programmatic aspects of navigation preceding the capstone course. The majority of students are admitted to the degree as freshmen when they are admitted to the university, and therefore recognized as "BMEs" from their first day at the university. The program is competitive even within engineering, with the 100 highest ranking students admitted each fall. This ranking is articulated as follows: "To be competitive for admission to the Biomedical Engineering program a student needs to be very strong in the following areas: 1) Class Rank and 2) SAT composite score. Incoming First Year students are ranked based on their scores in these areas and then the students at the top of this list are offered admittance to the Biomedical Engineering degree program." Reflecting on this rather general process that selects them for membership as BMEs, one student expresses a matched generality: "When I joined BME I just picked it out of a list. It wasn't until three years into the program that I realized it was exactly what I wanted to do with my life."

After two years of core curriculum, students select a track: Biomedical Imaging & Instrumentation, Cell & Bio-molecular Engineering, Computational Biomedical Engineering, and Pre-medical Engineering. Most students opt for Cell & Bio-molecular Engineering track. These official pathways mask the unofficial navigation students undertake, which comprise myriad experiences: internships of varying relevance, engineering clubs and camps in high school, and participation in social (formal and informal) aspects of being a BME.

## Identity, Identification

Wortham (2004) describes the process of social identification as possessing characteristics or behaviors that allow others to classify an individual according to a socially agreed-upon category. This process is interactional (Gee, Staff, & Paul, 1999) and contextualized by metadiscourses (in this case, biomedical engineering students and their various mentors), but also backgrounded by other social identifications that become relevant. I employ an understanding of identity that is social, negotiated, and *double-sided*, meaning that an individual may position herself or himself in a certain manner, but this occurs within social contexts such that the individual may or may not be recognized or be positioned by institutions, organizations, or others (Holland, Lachicotte, Skinner, & Cain, 1998; Skinner, Valsiner, & Holland, 2001). Considering practices of identification (Becker & Carper, 1956) affords a focus on the actions and behaviors related to positioning. I adopt this double-sided understanding of identification to explore how students negotiate and coordinate multiple identities as they transition from problem-set engineering to engineering design.

## Accountable Disciplinary Knowledge

In their framework for understanding pathways through engineering education, Stevens and colleagues (2008) refer to *accountable disciplinary knowledge* (ADK) as one of three dimensions. This term encompasses that which is counted as engineering knowledge relative to the context. As the context shifts, the ADK shifts. Reflecting on the core coursework, one student describes a burgeoning awareness both of his chosen discipline and a sense that some of the ADK of the core coursework was of less relevance for his future:

> "What do you need to know that's actually going to be useful in the future? Because, I mean, some classes, you kind of – especially when in the first couple of semesters for BME, we kind of got to see what we were going to be doing in the future. See, I mean, and I didn't do it as much at first, but then I kind of realized, like, you know, there's certain classes that we have to take as part of the core curriculum that really aren't – parts of it I don't think matter as much. So some stuff you just learn for the test and then there's some stuff you learn for life."

In core engineering coursework, ADK includes problem sets, whereas in the design courses, which reflect the professional engineering design studio, this includes actions that reside within the educational context despite originating from the professional context, as well as actions recognizable as professional. This semi-professional setting is captured is a student's description of the design class as "working more in the 'real world' environment, and getting the chance to apply what we've been studying in the classroom." The design projects were punctuated by tools (e.g., Gantt charts, Pugh charts) borrowed from the design studio but used such that the timing may not have highlighted their relevance, as evidenced by statements that the tools "detracted from the progress of the project," and "have actually hindered us." Other tasks, such as meetings with industry sponsors and progress reports for sponsors greatly reflected the professional design studio, requiring students to negotiate professional relationships, and sometimes choose between a professional goal and a classroom goal. Such professional connections, which sometimes deviate from the course structure, can be motivating (Magleby, Sorensen, & Todd, 1991), as expressed by a student: "We were very motivated in this project by our sponsors, who both impressed on us the potential for our device and made many valuable contributions to its design." These relationships may offer points of entre to engineering or provide students with examples of professional practice, allowing them to focus on what lies beyond their coursework (Stevens, et al., 2008).

Lectures given during the capstone design course touched on the nature of BME: In one lecture the course professor, Dr. Davies (a pseudonym) described his role in helping to define this relatively young discipline ("BME is a new breed"), and encouraged the students to "be a part of the definition." These lectures served as touchstones for students to decide whether they fit with this definition, ("You are probably motivated by the practical") and to highlight the shift in ADK that accompanies the transition to capstone design:

- "Engineering is doing"
- "Solving new problems in new ways"
- "Engineering is opportunity to be creative and come up with new ideas"

These lectures included discussions about differences between science and engineering, and positioned engineers as "doers." Students were told that "engineering is design" and that as mathematics is used as a tool by scientists, science is a tool of engineering. The nature of science was represented as unproblematic (e.g., "In science, there is always a right answer") and this was reflected in the engineering science courses completed previously, filled with problem sets with right answers. In an engineering program in which approximately 30% of the students plan to go on to medical school, this divide between ADK for college and for their professional futures may lie along multiple dimensions.

## Leadership and Underrepresentation

Within the design teams, students negotiated their roles. Some teams appointed leadership roles, some leaders delegated further roles, and some teams allowed leadership to be an emergent property. In some teams, emergent leadership subsumed prior leadership roles: in each case, this occurred in conjunction with shifts in relevant expertise: leaders appointed during the preliminary project initially maintained their roles in the sponsored project, but as the ADK within the team changed, leadership shifted. In one team, this shift was explicitly recognized by the team as a whole; in the other two teams, no one claimed new leadership roles, yet in both specific individuals came to be recognized within the team as the person to check with on major decisions, though in one case (expanded upon in the second case study below, team 3.4) this role was contested.

In all case study teams, underrepresented groups, specifically women and Latinos, served in non-leadership roles. In several case study teams students from underrepresented groups were the first to promote designerly ADK. Two case studies highlight how leadership and identification with engineering or health sciences promoted types of ADK and intensified or mitigated a sense of underrepresentation. Data presented here are brief due to page limitations, however, analysis of the fuller corpus of data supports these findings.

## Team 3.2: Shifts towards Designerly Accountable Disciplinary Knowledge

In team 3.2, Tom, Greg and Cynthia all planned to become biomedical engineers at the beginning of the design class, whereas Addai explained his interest as "consulting or energy policy … Of course I might wind up working in BME, although I would be a little surprised at that." The design project involved creating a way to measure movements in a patient's limb, and was sponsored by a physical therapist who described himself as "naïve" to the nuances of the project and "not an engineer!"

Tom led his teammates by deliberately not "micromanaging" so as not to risk ending "up doing almost nothing as far as my real contributions to the engineering." Tom identified strongly with engineering, and expressed this as part of his past, both in high school and in an undergraduate internship, as well as in his future plans to get a PhD in biomedical engineering:

> "I feel the senior design is sort of just one in a series of such projects. So like in high school, I did these robotics competitions that every year […] My friend and I started this club, so we tried to recruit as many of the nerdy kids [as] we could, and there was like 30 of us, 50 of us, at various levels of involvement, different schools."

Tom's identification with engineering, beyond "nerdy" was tied to a deeper understanding of design process than many of the students expressed: **"**There's all these different solution paths, right? There's all these different ways that I can come to a solution. And then there's not even one ending. There's a lot of different places to go and then even more ways to get there. And so you're trying to choose a path." Although Tom embraced the complexity of the design space, he struggled to lead his team towards choosing "a path" because of a theoretical/engineering science framing initially adopted. Tom invited his team mates into this problem space by offering an exemplar that was accessible, as evidenced by many conversations following it, an example of which is presented below:

> Cynthia: I seriously just learned more than I did in my *entire semester* of physics.
> Tom: Very difficult.
> Addai: It's such a weird notion that you can be moving-
> Cynthia: *Yeah.*
> Addai: -and have the same vector sum as *not* moving.
> Tom: Right.
> Cynthia: That is a weird thing.
> Tom: That's, that's the whole problem with these accelerometers.

Overcoming this "problem with these accelerometers" required creativity, as Tom explained and "one of the things that spawns creativity and innovation is having so many different perspectives work at once." Not every team member can productively be a leader, and it is important to explore the experiences of the less vocal team members. Cynthia, who rarely spoke during team meetings, explained mid-way through the project that she felt she had less to contribute than her team mates. Cynthia contributions, which helped to steer the team in designerly directions by invoking the customer needs and practical requirements of the sponsor, did not reflect the ADK associated with their prior coursework, but her team mates recognized that her contributions did reflect the ADK of the design course. Tom, in particular, valued Cynthia's contributions, though this was not apparent to Cynthia until later in the design project, when the shifts in team ADK meant that her design perspectives were of particular relevance. These shifts were brought on, to some extent, by the need to generate a prototype that would help them convey to their sponsor some of the theoretically challenging aspects of the design goals (Svihla, et al., 2009). Their sponsor expressed satisfaction with their final project: "I really see even more clearly that it's a viable possibility to create this thing and before, it was, before, I had a dream list of three things or four things that I would like to see become three dimensional and I think this is phenomenal! Because it really is- they're bringing a lot more data to this than has ever even been questioned." All members of team

3.2 expressed satisfaction with the design experience, including Cynthia ("I had a great experience!") and decided to pursue graduate degrees in engineering, even Addai, who explained "It is a shame that this class is the first course I've ever taken in my almost 5 years here where I have thought I know what a biomedical engineer is, and I wouldn't mind being one."

## Team 3.4: Tensions between Pathways

Team 3.4 was led by Steve, who completed an internship working with medical testing studies on animals, a connection he leveraged to position the project as more of a medical project. Steve and Dillon both planned to attend medical school, whereas Daniela and Bob planned to become engineers. This divide was a significant one for the team, particularly given that what their sponsor desired was for the team to demonstrate, through animal testing, the feasibility of placing an existing externally-used sensor internally to monitor chemical changes related to a medical condition. During their weekly team meetings with their teaching assistant, Michelle, it became increasingly apparent that the team was not designing anything. Michelle urged them to adopt a design/engineering perspective, and tensions emerged across these disciplinary identifications. Several interactions highlight these tensions, as Daniela struggled to interject a design perspective. In the first example, Daniela posed the question to Michelle, turning to face her and speaking to her as she interjected this dissonant perspective:

Daniela: I just, um, something bothers me. The fact that we are putting the sensor on the stomach during surgery, but then we're gonna, the surgery only lasts one to two hours and we're gonna take it off and the patient is gonna be, well, the surgery is gonna be over and there's not gonna be any monitoring afterwards, and I'm thinking well, there's higher chance of sepsis, I mean shock, afterwards, right? So, should we think about leaving the sensor, or… cause I don't really?
Dillon: Seriously, that could be, like, the next project.
Steve: Yeah, I think that, like are you talking about in real life? Like…?
Daniela: Yeah, like, so using it.

Steve's question about how the device would be used ("Are you talking about in real life?) not only challenged the design perspective Daniela attempted to adopt, but also demonstrated a disconnect in perspective; Steve framed this as a school problem even though they were asked to solve a real-world problem. The response Daniela received from her team mates seemed like an attack, but Daniela did not appear to take it personally, though whenever she posed these dissenting design ideas, she tended turn her body towards Michelle and to speak facing Michelle, as if this was how she gained voice. As they continued this conversation, it became increasingly clear that there was a lack of agreement about what they were doing. They retreated into an explanation of what they were "supposed" to be doing, also highlighting a lack of design perspective:

Bob: I thought the project was to do an internal sensor that you left in?
Daniela: So we are gonna?
Steve: I think that that's, be-
Daniela: How long are we gonna leave…?
Bob: I'm not sure, uh.
Steve: I think that would be something left up to surgeon or something, honestly, likelikelike, our project, I think it's kinda outside the scope of our project.
Bob: If we left it up to the surgeon and whoever actually designs the sensor?
Steve: Yeah, whoever is *really* doing this.
Bob: 'cause we're not supposed to be designing anything.
Steve: Yeah, we're just seeing if you can do it. We just have two types of sensors and we're gonna see if we can do it- we're gonna see if a [specific type of] patient- whether or not the [chemical] levels can be measured or change to a degree that we, they show up, or the…
Bob: Using currently available sensors.
Daniela: I don't even know if it's okay to just leave it there.
Steve: It's all right.
Daniela: These are, I mean, sort of? *Days?*
Dillon: They're not gonna want to cut them open again and just take it out.

Bob and Daniela's comments express, to varying degrees, dissatisfaction with the direction their project was headed, but these practical, engineering perspectives were quashed by Dillon and Steve who together, positioned these questions as peripheral or irrelevant. Later, Bob and Daniela discussed their project and the lack of design or even engineering focus:

Bob: Well, this project is definitely nothing like the hard-core engineering I thought engineering would be like, where you go, and designing a machine, to go through those, or doing material analysis? But this is a lot more like a bioinformatics problem with the evaluation method, doing statistical analysis of various sensors, correlating how they work.
Daniela: It's not really- we're not designing it, I mean, *anything*. It would be more design if we had to design the sensor, which I thought we were gonna have to do, but he didn't want, the company doesn't want us to.

Michelle leveraged this dissatisfaction to challenge Steve again to adopt an engineering perspective:

Michelle: You have to remember how you talked about all the technical aspects. I mean, most groups are having that problem anyway, and I think, like, that would be a good project for this class.
Steve: A grade.
Michelle: I mean, if that's not what he wants-
Bob: The sponsor said 'no.' He doesn't even want us to try.

This exchange highlights tensions between the ADK of the design course/perspective, and the ADK in the project Steve thought would satisfy the sponsor. Steve identified with his prior animal studies experiences, denigrating the designerly perspective as "a grade." He enthusiastically valued the opportunity to position the design project as a continuance of his prior experiences: "The whole senior design course was worth it to me because we went through this process where something, I'm gonna be doing time and time and time again." This is starkly contrasted with his frustration with the designerly ADK:

Steve: It's just my biggest, my biggest frustration with this is just, like this, like this is the project, like *this is the project we were given*. I mean if, if like Dr. Davies, and I don't mean to be disrespectful, I mean, if somebody didn't want us to do this project it shouldn't have been accepted. It shouldn't have been given to us.

Steve constructed a science problem space and phrases such as "project we were given" indicate that a lack of flexibility with regard to that problem space. That statement in particular is troubling because it is the designers' job to define that problem space. Whether he recognized it or not, they did, in fact, create a problem space, but one that was framed as a science rather than engineering problem.

Steve brought the focus back to the novelty of their project's science goals, at least in terms of the course. The novelty that excited Steve, troubled Michelle and Dr. Davies because it was effectively a substitute for a design project. As Steve expressed this, Daniela once again turned to Michelle and expressed a dissenting designerly perspective:

Steve: I mean, like a surgical procedure? I mean, that's not considered any sort of technical…? Like, a surgical procedure? And, like, taking readings in a rat's stomach? I mean, something that nobody else has *even* ventured to do in *this* course?!
Daniela: Well, we're not *designing* anything.

Because of concerns Dr. Davies met with the team. He explained to them:

> "Now, in BME, we have to be careful a little bit. It's really easy to get off and to, uh, do life sciences kind of things that are not engineering, and nearly any project can, uh, have identified some appropriate engineering dimensions for it and, uh, I think this is an important part of your education experience. […] I encounter this in my own research and can identify all sorts of neat medical things to work on. The question is, *What can you really uniquely contribute as an engineer?* Somebody across the street, this brilliant life scientist, is not gonna be able to put on the table?"

Though the sponsor was very impressed with what the team accomplished, not all team mates felt enthusiastic about the experience: "There was no design portion to the sponsored project. The design portion was assigned by Dr. Davies halfway through the project," and furthermore, this aspect was "created to fulfill graduation requirements."

## Discussion

Viewing these cases of design team lived narratives through the dimensions of accountable disciplinary knowledge, navigation, and identification provides ways to understand how differing pathways create tensions in capstone design, but not earlier. When the ADK is no longer the domain of problem sets, but instead reflects the professional design studio, students who have no intention of becoming engineers have opportunity to exploit the lack of designerly perspective brought on by having an official pathway containing no previous design experiences (Figure 1). Given that many students, as part of their unofficial navigation, have worked in laboratories doing what Dr. Davies termed "life sciences kind of things that are not engineering" it is unsurprising that a team leader might consider such activities to be the ADK of the design studio, and to see them as valuable in the future. This is expressed by Steve, reflecting on the animal testing his team undertook: It "was worth it to me because we went through this process where something, I'm gonna be doing time and time and time again." Steve expected to find the ADK of medical school to have more in common with his prior coursework ADK than that of the design course, and this made the design aspects very artificial ("A grade.").

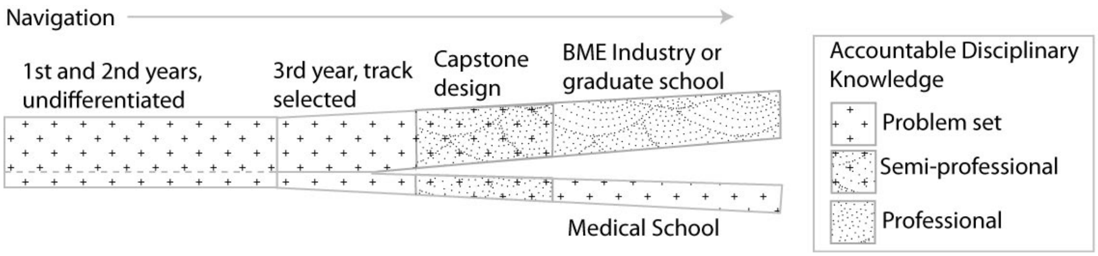

Figure 1. Changes in accountable disciplinary knowledge along pathways towards engineering and medicine.

In contrast, Tom, whose unofficial navigation included very different experiences, desired to adopt designerly ADK, though he struggled to do so. That it was such a challenge even given his desire and his team's desire to engage with design highlights what an opportunity Steve had to steer his team towards a "life sciences kind of thing." Given that official navigation pathways lack early design experiences, it is left to those with design experience from unofficial navigation to be the *chauffeurs* of designerly perspectives. In these case study teams, this role was filled by women. Thus gender emerged as a complex dimension because these women who helped to shift their teams from problem-set ADK to designerly ADK, viewed these designerly perspectives as somehow weaker than problem-set ADK. This perspective is warranted by their prior experiences in courses that emphasize engineering science. Though women were not the *chauffeurs* of designerly ADK in all case studies, gender is an important aspect to consider, given that problem-set ADK holds a privileged position garnered through prior experiences; this, taken with the degree to which team mates, especially those in leadership roles recognize the need to make such a shift, may explain, in part, why Daniela's repeated appeals for designerly perspectives were left largely unheard, whereas Cynthia's were adopted.

The official navigation creates a space in which those who champion designerly ADK may be positioned within a design team as having productive, disruptive, or irrelevant perspectives. When the chauffeurs of designerly ADK are from groups underrepresented in engineering, there is the potential to widen or narrow gaps, depending on whether those perspectives are treated as productive, disruptive, or irrelevant.

Institutional identification of students as BMEs from the first day has been noted as beneficial elsewhere (Stevens, et al., 2008). Taking identification as double-sided, it is relevant to consider students may identify themselves as engineers or as pre-medical, and that for those who identify themselves as engineers prior to the capstone design, official navigation offers few opportunities to reconcile what this means. Adoption of designerly ADK depends much, therefore, on endorsement by team leaders and unofficial navigation.

## Implications

The focus on engineering science in prior coursework and accompanying accountable disciplinary knowledge places much of the burden of becoming an engineer upon the capstone design course. The open-ended nature of the design projects, the lack of prior design experience, and the legitimacy of BME as pathways to both engineering and medical school means that students may steer their projects towards or away from engineering design projects. If students so not see design as relevant to the pathway they have selected, they are unlikely to engage with a project as designers, and may even discourage their team mates from adopting designerly perspectives. For these students, identification as engineers is contingent indeed.

# An Overview of CSCL Methodologies

Heisawn Jeong, Hallym University, Chuncheon, Korea (South), heis@hallym.ac.kr
Cindy E. Hmelo-Silver, Rutgers University, New Brunswick, US, cindy.hmelo-silver@gse.rutgers.edu

**Abstract:** This study surveyed empirical CSCL papers published in seven leading journals of the field during 2005-2007 and analyzed methodologies of a random sample of 33 studies. The dominant features of CSCL research methodologies were descriptive studies in classroom settings with self-report/questionnaire that were quantitatively analyzed. Yet, studies were quite eclectic in their research method, adopting a variety of research design, data sources and analysis methods, leading to cross-over or hybrid methodologies. Studies of collaborative learning were carried out frequently both in experimental and descriptive studies in lab and classroom settings. Diverse data sources were collected and analyzed both quantitatively and qualitatively. New techniques for analyzing collaborative processes were also emerging. Still, it appears that the field needs to be more principled in its applications of design-based research. In addition, the field is in need of more diverse and systematic ways to analyze qualitative data in order to take a full advantage of the rich data afforded in CSCL research.

## Introduction

There has been an increasing interest in collaborative knowledge construction for some time. With the advent of information technology, collaboration is also increasingly mediated by various technologies. Computer-Supported Collaborative Learning (CSCL) is an interdisciplinary research field that are concerned with how people can learn together with the help of computers (Myake, 2006; Stahl, Koschmann, & Suthers, 2006). In any field including CSCL, methodology is of utmost importance in advancing the field. Methodologies are constrained by the current level of understanding and available analysis tools in the field, and yet advancements in methodology can also open up new conceptual spaces and allow researchers to examine phenomena and questions that were not previously possible. Reflecting its interdisciplinary mission, diverse methodologies co-exist in CSCL. Traditional methods initially developed in the context of studying individuals (e.g., questionnaires, study of individual problem solving protocols) have been actively used by CSCL researchers. CSCL researchers also have reached out to methodologies in fields such as linguistics and anthropologies. The infusion of these methodologies has helped to advance the field a great deal. Currently, however, it is difficult to understand what the current state of research methodologies is in CSCL. Numerous methodologies co-exist without a clear understanding of what they are and how they are related to each other.

Recently, several meta-analyses have been conducted in related fields of CSCL. Hrastinski and Keller (2007) examined research approaches (e.g., empirical versus conceptual studies, quantitative or qualitative methods, etc.) of papers published in four leading journals of *educational technology* during 2000-2004 period. They found that about two thirds of the studies were empirical investigations, about half of which (51%) used quantitative methods, 25% used qualitative methods, and 24% used mixed methodologies (Hrastinski & Keller, 2007). Hew, Kale, and Kim (2007) also conducted similar meta-analysis on research topics and methodologies in the field of *instructional technology* based on publications in three journals also during 2000-2004. They focused on empirical articles and found that descriptive and/or correlational studies were the dominant research methods in educational technology, being used in more than half of the studies published. Methodologies varied somewhat depending on research topics; experimental method was more commonly used in studying the topic of psychology of learning and teaching, while correlational method was most frequently used with the topic of research and evaluation methodology. In addition, the studies most commonly collected survey/questionnaire data in higher education and K-12 settings (Hew et al., 2007).

Distinctions such as quantitative and qualitative methodologies have long existed in many fields. Quantitative methods were typically associated with experimental and survey studies where numerical data are collected. Analysis aimed to uncover 'general' trends that are true to the population at large, which lead to the focus on large sample sizes and quantitative analyses using inferential statistics. Qualitative methods, on the other hand, were associated with descriptive research such as case or ethnographic studies where qualitative data such as video-tapes, verbal transcripts, and artifacts are collected. Analysis aimed at uncovering 'meaningful' patterns and in-depth look at a small set of data was emphasized. While specific methodological traditions in qualitative research may focus on different aspects of the data and may take different routes to arrive at their interpretations, data were mostly analyzed qualitatively. Such a distinction, however, no longer seems appropriate. As qualitative methods become more popular, more attempts are made to triangulate data collection and analyses. Traditional descriptions of qualitative or quantitative research no longer adequately describe some of the research being carried out in the field. There is a need to develop a more sophisticated understanding of what quantitative and qualitative methods mean and how they can be better integrated to inform CSCL research at large. In addition, we need to examine and evaluate how the current CSCL methodology is addressing some of the unique challenges that CSCL faces. With its emphasis on social construction of knowledge mediated through technological tools, CSCL has been in need of methodologies to study learning as it happens in the process of interacting with learning partners and tools. Interaction is a complex phenomenon where traditional methodologies developed to study individual learning are not necessarily readily applicable. Moreover, interaction in CSCL environments is unique in that there exist diverse forms of interaction such as distributed as well as face-to-face interaction and that interaction is often mediated by technological tools (Lehtinen, Hakkarainen, Lipponen, Rahikainen, & Muukkonen, 1999). Because thinking often develops and is made observable through dialogues and discourse, research efforts have been directed to the analyses of dialogue and discourse both in face-to-face distributed interaction. Analysis methods such as content analysis, discourse analysis, and conversation analysis have thus become commonplace in CSCL literature. Combining methodologies from different research traditions has been useful for revealing ambiguities and contradictions, which in turn have led to new conceptual developments. However, it have increased the risk of confusion in different epistemological perspectives (Naidu & Jarvela, 2006). Individual researchers are confused about how different methodologies can be used to inform their research. It is equally unclear whether CSCL methodologies have been adequately addressing the key issues of CSCL.

In response to these concerns, this study attempted to provide an overview of current methodologies used in empirical investigations of CSCL. We first carried out a comprehensive examination of empirical CSCL studies, analyzing research methodology at the following four dimensions: (1) research designs (e.g., descriptive or experimental design), (2) study settings (e.g., classroom or laboratory), (3) data collected (e.g., survey data, log data, or synchronous or asynchronous text data), and (4) analyses carried out with the data (e.g., content analysis, social network analysis, multi-level analyses). Based on this analysis, we also examined how collaboration is studied in CSCL research.

## Methods

### Journal Selection

*International Journal of Computer Supported Collaborative Learning* (ijCSCL) is the flagship journal of the CSCL community. In addition to ijCSCL, there are numerous other research journals where CSCL research is published. We asked the leaders of CSCL community, CSCL committee of ICLS and the editorial board members of ijCSCL to nominate five leading journals of the field other than ijCSCL. Based on the responses from 16 community leaders, the following seven journals were selected: (1) *ijCSCL*, (2) *Journal of the Learning Sciences,* (3) *Learning and Instruction*, (4) *Computers and Education*, (5) *Journal of Computer Assisted Learning*, (6) *International Journal of Artificial Intelligence in Education*, and (7) *Computers in Human Behavior.* They are all peer-reviewed journals published by well-known publishers with international authorship and readership.

### Paper Selection

From the papers published in the seven journals, we identified *empirical CSCL* papers to be used for the content meta-analysis. By *empirical*, we mean that the study collected and analyzed primary data. Secondary data analysis, simulated results, theoretical papers and meta-analyses were not included. The data may have been collected as part of a larger project, but the analysis and finding had to be new. Papers that described the design process were included if they reported on empirical data. By *CSCL* research, we mean studies where students learned collaboratively using computers or other technological tools. Learning needed to be collaborative, but it does not mean that all phases of learning needed to be collaborative. As long as parts of the learning process involve interaction (e.g., collaborative discussion after individual study), it was considered collaborative. We focused on small group peer collaboration, that is, collaboration among learners who are similar in knowledge and status. This means that studies that examined student-teacher interaction or whole class discussions were not included unless they included small group peer collaboration. The applied technologies do not necessarily have to be collaboration technology such as e-mails or discussion boards, but need to be specific. Interaction with computerized agents were included if it involved learning. Studies about motivation or attitudes were included if they were studied in relation to learning. In addition to empirical CSCL papers, we included methodological papers that addressed various methodological issues related to CSCL (e.g., introduction of new methods such as Social Network Analysis, development of specific rating schemes).

Excluding non-research articles (e.g., editorials, book reviews, or obituaries), 868 articles published in the 2005-2007 period were screened, which means three years of publication (two years of publication in the case of *ijCSCL*). The total numbers of selected papers is currently 175, indicating that 20% of the papers published in the seven journals during 2005-2007 were empirical or methodological investigations of CSCL.

## Content Analyses

The following aspects were coded for each paper: (1) Design, (2) Study setting, (3) Data, (4) Analysis, and (5) Interaction. In this paper, we report on the analyses carried out on a random sample of 33 papers. This set constituted 21% of the total empirical CSCL paper (and 19% of the total CSCL papers including methodology papers; percentages did not come out even due to the ongoing nature of paper selection process) and were marked with * in the reference list. A combination of inductive and deductive approaches was used to develop coding categories for each code. Coding categories were initially generated top-down (e.g., using categories drawn from the submission descriptors of the 2005 CSCL conference) and then later refined bottom-up through multiple iterations of coding. Jeong and Hmelo-Silver (2010) reported on a different set of analyses (with the exception of the collaboration coding) carried out on the same sample. Specific codes for each category are described below.

### Research design

Research design refers to whether the study is (1) Experimental, (2) Descriptive, or (3) Design-based method. Experimental design refers to studies where variables are manipulated and was further divided into (a) randomized, (b) quasi-experimental, and (c) pre-post design. Descriptive studies do not manipulate variable and assign study participants to different conditions. They study the variables and phenomena as is and include studies such as case studies, surveys, and ethnographic investigations. Design-based method refers to research strategy where CSCL designs and interventions are theoretically-driven and are refined progressively over several iterations. In order to be coded as design-based method, the study not only needs to design CSCL systems or environments, but also the design needs to be theoretically grounded, instantiated in specific contexts, studied and refined iteratively as part of a bigger design-based research (Barab & Squire, 2004; Brown, 1992; Collins, Joseph, & Bielaczyc, 2004). Once a study was coded as design-based method, the design of individual iterations which can be either experimental and/or descriptive was not coded separately.

### Study settings

Study setting refers to the contexts in which the research was conducted, that is, whether the research was carried out in (1) Laboratory, (2) Classroom, or (3) Other settings (e.g., informal learning environments or workplaces). Laboratory means that learning occurred in lab or lab-like controlled settings where the task occurred isolated by itself outside the context of classroom or other authentic learning situations. Classroom setting means that learning occurred as part of classroom/curricular activities, which could involve not only physical classroom but also other settings (e.g., field trips).

### Data

Data refer to the types of data collected in the study and was coded into (1) Process, (2) Outcome, and (3) Miscellaneous data types. Process data were further divided into (a) text-asynchronous, (b) text-synchronous, (c) video, (d) audio, (e) log data, and (f) other. When papers reported on both video and audio data (e.g., Li et al., 2006), they were coded only as the video data unless they were analyzed separately. Outcome data were further divided into (a) multiple-choice questions, (b) open-ended questions, (c) expert ratings (e.g., experts' rating of students' work), (d) artifacts (e.g., contents of multi-media whiteboard), and (e) other (e.g., final course grades). Outcome data can be collected at the beginning of a study (e.g., pre-test) as well as at the end of a course. Miscellaneous data include (a) self-reports/questionnaires (e.g., demographic information, affects, perceived acceptance, etc.), (b) interview and/or focus groups, (c) field notes or observations, (d) individual difference measures (e.g., IQ, learning styles), and (3) other (e.g., course registration information).

### Analysis methods

Analysis methods refer to the kinds of analyses carried out on the data. There were two general categories: (1) Quantitative and (2) Qualitative. Quantitative analyses were further coded into the following sub-types: (a) simple descriptive or quantitative (e.g., simple frequencies and means, as well as simple quantitative analysis of qualitative data such as coding numbers of words in messages or scoring an open-ended answers), (b) code and count, (c) inferential statistics, (d) causal or multi-level modeling, (e) sequential analyses, (f) social network analysis, and (h) other miscellaneous quantitative analysis (e.g., comparison with simulated data). Code and count refers to what is often called "quantitative content analyses" (de Wever, Schellens, Valcke, & van Keer, 2006). Qualitative analysis refers to analysis that analyzes data in a qualitative manner. Qualitative analyses were further coded into: (a) (qualitative) content analysis, (b) conversational analysis, (c) grounded theory, (d) interaction analysis, (e) loosely defined.

### Collaboration

Collaboration refers to the types of student-to-student interaction and consisted of four categories: (1) Face-to-face, (2) Distributed synchronous, (3) Distributed asynchronous, and (4) Other. Face-to-face collaboration refers to co-located and synchronous interaction. Distributed collaboration refers to collaboration among distributed learners and can be either synchronous (e.g., through chat) or asynchronous (e.g., through e-mails and discussion boards). Other collaboration refers to miscellaneous interaction such as non-verbal interaction (e.g., interaction through argumentation map), interaction with computer agents, or indirect interaction (e.g., collaborative filtering or data sharing).

Methodological features of the studies were generally coded according to the authors' definitions. If authors call their design as 'experiment' then we coded them as such. In unclear cases where the authors did not explicitly state information relevant to the coding categories (e.g., no mention of whether the study was carried out in lab or in classrooms), we relied on contextual information presented in the paper. For example when a study did not specify its setting, if 'recruited' students performed a stand-alone activity with no connection to classroom activities, its setting was coded as laboratory (e.g., Mercier & Frederiksen, 2007). Similarly, when a study did not specify data and only stated that the number of words in asynchronous notes was analyzed, it was assumed that asynchronous text messages were collected as data (e.g., Hewitt & Brett, 2007). In a few controversial cases, we followed a more conventional approach so that 'near synchronous' interaction was coded as asynchronous interaction and that an 'experiment' without any mention of treatment conditions were coded as a descriptive study. Multiple coding was allowed when more than one coding categories were applicable. For example, if the study compared different versions of a course that was implemented in face-to-face, synchronous, and asynchronous learning situations (e.g., Kitsantas & Chow, 2007), all different types of collaboration were coded. Reliability check was completed in all code (except for the collaboration code, which is still in progress) by having two coders independently code the set while discussing unclear cases. Cohen's kappa values between the two coders were all above .75 in all coding categories.

## Results

### Methodological Features of CSCL Research

The analyses indicated that the most prevalent CSCL research design is descriptive design: 58% of the studies were descriptive, 33% were experimental, and 9% were design-based. Of the experimental studies, 45% used randomized experiments, 27% quasi-experimental method, and 27% single-group pre-post design.

As for the settings of CSCL research, studies were mostly carried out in the classroom: 82% of the studies were carried out in the classroom, 12% were in the laboratory, and 6% in other settings (e.g., workplaces and informal settings). Classroom studies are typically associated with descriptive design, whereas laboratory studies are typically associated with experimental design. While this indeed was a case with most of the descriptive studies being carried out either in classrooms or other settings, there were a sizable number of studies that 'crossed over'. The majority (70%) of the classroom studies was either descriptive or design-based studies, 30% were experimental studies. Classroom experiments were typically quasi-experiments using intact classrooms or single group pre- and post-test comparisons (e.g., Cho, Gay, Davidson, & Ingraffea, 2007), but there were a few cases of randomized classroom experiments as well. Random assignments in classroom setting were carried out by assigning different treatment groups to separate laboratory sessions (e.g., Vizcaino, 2005) or by online groupings (e.g., Cho & Schunn, 2007).

As for data collection, 73% of the CSCL studies collected process data, 61% of the studies collected outcome data, and 70% collected other data. The majority of the studies collected more than one data types: Only 15% of the studies collected a single data type, and the rest of the studies collected multiple types of data. Studies on average collected 3.0 data in a given study with some studies collecting up to six different data. Of the process data, log data were the most frequently collected (42%), asynchronous text-messages were the next (30%), followed by synchronous text (15%), video-(12%) and audio-data (9%). Of the outcome data, and other types was most popular (24%), followed by artifacts (21%), open-ended (18%), multiple-choice questions (12%) and open-ended questions (12%), and experts' rating (9%). Other outcome types include data such as final grades, students' self-ratings and evaluations. Of the miscellaneous data types, self-report/questionnaire was most popular (61%), followed by interviews (21%), field notes (12%), individual difference (6%), and other (3%). A quite diverse set of data is being collected in CSCL research. Additional sources of data can provide more information about the questions. It appears that CSCL researchers are actively attempting to examine learning from multiple perspectives.

As for the analysis method, some form of quantitative analyses was carried in all studies. The most common forms were simple descriptive and inferential statistics (58% each), followed by code and count (52%); Causal or multi-level modeling was used in 6% of the articles, and social network analysis and other analysis were used in 3% of the studies each. A notable trend was a development of new quantitative methodologies such as social network analyses (Cho et al., 2007) and multi-level analyses (de Wever et al., 2006) that aimed to analyze collaborative processes quantitatively. Qualitative analyses were also used quite frequently, being used in 42% of the studies. However, the methods in general were not well described or attributed to one of the more specific genre of qualitative research such as grounded theory (Glaser & Straus, 1967) or conversational analysis (Goodwin & Heritage, 1990). The majority of the studies (93%) adopted the "loosely defined" method in which data was qualitatively described with some examples.

## Studying Collaboration in CSCL Research

How is collaboration studied in CSCL research? In terms of the types of collaboration investigated in CSCL research, 36% of the CSCL studies examined face-to-face collaboration, 36% synchronous, 48% asynchronous, and 12% other types of collaboration. The majority of the studies (70%) implemented and studied only one type of collaboration, but there were studies that implemented either two (24%) or three (6%) different types of collaboration. It was due to the fact that CSCL environments often allow students to interact with each other not only asynchronously through e-mails, but also synchronously through chats (e.g., Yang & Liu, 2007) and also because studies compared different types of collaboration in a given study (e.g., Kitsantas & Chow, 2007).

How were these various forms of collaboration studied in CSCL research? Comparisons of the studies that examined different collaboration types (see Table 1) indicated that while face-to-face and synchronous collaboration are studied equally likely with experimental and descriptive design, asynchronous collaboration were mostly studied with descriptive design. Distributed collaborations, both synchronous and asynchronous, were studied exclusively in classroom settings, less likely to collect outcome data and carry out qualitative analyses. Other types of collaboration were more likely to be studied in experiments in laboratory setting with quantitative analysis. Further analyses on the sub-type of data showed that, not surprisingly, face-to-face collaboration studies collected either video or audio data, whereas synchronous and asynchronous collaboration studies collected synchronous and asynchronous text data, respectively. Studies of other collaboration types mainly collected log data, but also collected video or other types of process data along with the log data. While quantitative analyses were used across all collaboration types, qualitative analyses were more frequently used to study face-to-face collaboration than distributed collaboration. A number of factors such as theoretical commitments, research questions, and available study settings influenced the choice of research methodologies. More analyses are needed, but it appears that the choice of CSCL research methodology is also dependent on the type of collaboration examined.

Table 1: Studying collaboration in CSCL research

| | Research Method | | | Settings | | | Data | | | Analyses | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | Exp | Des | DB | Lab | Class | Other | Proc | Out | Misc | Quant | Qual |
| F2F | 38% | 50% | 13% | 25% | 75% | 0% | 88% | 100% | 63% | 100% | 63% |
| Synch | 40% | 40% | 20% | 0% | 100% | 0% | 80% | 40% | 80% | 100% | 40% |
| Asynch | 14% | 71% | 14% | 0% | 100% | 0% | 86% | 71% | 57% | 100% | 43% |
| Other | 100% | 0% | 0% | 67% | 33% | 0% | 67% | 67% | 33% | 100% | 0% |

Notes. *F2F* refers to face-to-face, *Synch* refers synchronous, and *asynch* refers to asynchronous collaboration. *Exp* refers to experimental, *Des* refers to descriptive, and *DB* refers to design method. *Proc* refers to process, *Out* refers to outcome data. *Quant* refers to quantitative and *Qual* refers to qualitative analyses. Note that there were studies that investigated more than one type of collaboration. In order to isolate research methodologies uniquely associated with different collaboration types, studies that investigated only one form of collaboration were included in the comparisons: There were eight studies that exclusively studied face-to-face collaboration, five such studies for synchronous collaboration, seven studies for asynchronous collaboration, and three studies for other types of collaboration.

Study of collaborative interaction in CSCL research is often accompanied by an accumulation of large amount of qualitative data such as video-data and discussion board messages. Such qualitative data were traditionally analyzed qualitatively most of the time using methods such as discourse analysis (Brown & Yule, 1983; Gee, 2005) or grounded theory (Straus & Glaser, 1967). How does recent CSCL empirical research approach the analyses of these qualitative data? With this question in mind, we examined how the six types of qualitative data coded in this study—video audio, text-synchronous, text-asynchronous, open-ended outcome, and artifacts—were analyzed in recent CSCL research (see Table 2). Additionally, we also examined how log data were analyzed in CSCL research. An ever increasing amount of log data is collected in CSCL research, and yet there is only a scant understanding as to how they can be used in the context of studying collaborative learning. The results indicated that the majority of the qualitative data was quantified. The quantification was mostly done using procedures such as code and count or scoring, but "simple descriptive" measures were also directly calculated in some cases, using quantitative indices of the qualitative data (e.g., word counts in notes). While most of the process data were quantified with code and count procedure (i.e., coding the presence of certain code and counting its frequency), open-ended outcome data was analyzed with scoring procedure (i.e., assigning a score using a criterion). In addition, qualitative data, especially video-data and synchronous and asynchronous text data were also often analyzed 'qualitatively', but specific kinds of qualitative analysis methods were seldom used. The qualitative analyses were mostly 'loosely defined' in that they provided qualitative descriptions of the data along with examples without committing to specific qualitative methods. As for the log data, not surprisingly, they were analyzed quantitatively, but the range of log data used for analysis was quite diverse. Studies examined time to post messages, length or duration of given threads, pages read, number of files in the folders, or participation rates. Lastly, the results also indicated that CSCL research may be good at collecting multiple types of data, but are not always good at analyzing them. Of the 50 pieces of data examined, one fifth (19%) was either unanalyzed or lacked sufficient detail as to how they were analyzed.

Table 2: Analyses of qualitative (& log) data in CSCL research

| | Simple descriptive | Scoring | Code & count | Qualitative analysis | Unanalyzed | Unspecified |
|---|---|---|---|---|---|---|
| Video | 0% | 0% | 75% | 75% | 25% | 0% |
| Audio | 0% | 0% | 67% | 0% | 33% | 0% |
| Text-synchronous | 0% | 0% | 60% | 40% | 20% | 20% |
| Text-asynchronous | 10% | 0% | 70% | 30% | 0% | 10% |
| Open-ended | 29% | 71% | 0% | 0% | 14% | 0% |
| Artifacts | 14% | 0% | 29% | 14% | 29% | 14% |
| Log data | 93% | 0% | 0% | 0% | 7% | 0% |

## Discussion

The analyses of this study showed that the typical methodology of CSCL research was descriptive studies carried out in classroom settings with the most frequently collected data being self-report/questionnaire data analyzed quantitatively. While these emerge as dominant features of CSCL methodologies, CSCL methodology is far from monolithic and can be characterized as multi-method. Studies often collected multitudes of data and also used both quantitative and qualitative analyses. As a result, research methodologies of a given study often do not fit the traditional quantitative and qualitative divide and/or experimental and descriptive divide. This seems to be driven both by the need to understand CSCL from multiple perspectives (Hmelo-Silver, 2003; Suthers, 2006) and also with the infusion from different methodological traditions. Learning, especially in CSCL contexts, is a complex phenomenon, understanding of which requires multiple approaches and perspectives ranging from individual learner, interactive processes, tool mediation, teacher roles, to general cultures. In order to achieve a richer and integrated understanding of learning, CSCL research is increasingly required to examine learning from multiple perspectives, using multiple data sources and analyses methods in the contexts of specific research questions and settings.

In spite of the dynamic developments in the field, it appears that there are a number of areas where more sophisticated methodological understanding and practices are needed. One is with what researchers called as design-based research. Although we did not carry out systematic analyses, it was clear in the coding process that researchers often did not distinguish design as a research goal from design as research methodology. Even in the case where design research was used to refer to the research method or strategies, its applications were often name in only. While exceptions exist, studies that reported on multiple iterations and progressive design refinements were rare. The field needs to be more principled in its applications of design-based research. In addition, there is a need for the field to develop a larger repertoire of analytical tools to deal with the large amount of qualitative data collected in CSCL research. Large amounts of online and offline messages and dialogues can be and are collected in many CSCL investigations. The advancement of the field greatly depends on how well these rich sources of data can be utilized. While existing qualitative methods have their values, they are not well suited to a large-scale analysis. In addition, epistemological commitments of some of these methodologies are often in conflict with those from more quantitative traditions emphasizing objectivity and generality of findings. Although qualitative analyses were used in close to half of the studies examined in this study, they rarely adopted a specific qualitative method and just described the data with no reference as to how the conclusions were derived. It might be the case that the researchers failed to attribute their analyses to specific methods even though their analyses belong to that category, but it might also be the case that existing methods may not adequately describe what researchers are currently doing with qualitative analysis. Qualitative analyses tend to be less explicit in its procedures and more challenging to learn and execute. Efforts are needed to systematize existing qualitative analyses procedures so that they are easy to understand and carry out and also to develop new analytical procedures to analyze them.

Given the small sample size of this study, the results and conclusions from this study should be taken as tentative at the moment. We aim to obtain more robust findings with additional analyses, but hope that an overview of CSCL research methodology even in this small scale is informative to researchers both in terms of understanding current CSCL research methodologies and guiding their future research. We also hope that the methodological issues raised in this study contribute to establishing a common conceptual framework for CSCL methodologies and integrating diverse findings from different research traditions.

**Abstract:** This paper reports our progress in using the Knowledge Space Visualizer (KSV) as a tool for formative assessment of online discourse. Whereas social network analysis has been used in research on computer-supported collaborative learning, it only examines the social structure of discourse participants, and does not provide information about the content of the discourse. We discuss two types of networks as they relate to online discourse: *structural* and *semantic*. The initial findings indicate that the KSV can be used to visualize a Knowledge Forum database, and can provide a fine-grained semantic analysis that may enable teachers and students to locate the key ideas around which collective learning may takes place.

## Introduction

Sawyer (2006) identifies knowledge building as one of five major educational models produced by the learning sciences. As an educational framework, it aims to make the processes by which experts create new knowledge more prominent and feasible in schools (Bereiter & Scardamalia, 1993; Scardamalia & Bereiter, 2006). One of the most important features of the model is that students' effort is directed at advancing the collective knowledge in a community (Scardamalia, 2002). Students are not just attempting to understand things for themselves, but aim to add something new to what is known in the community. In most implementations in schools, students use Knowledge Forum®, a software environment specifically designed to support knowledge building, to share and collaboratively improve and synthesize ideas (Scardamalia, 2003). Knowledge Forum also provides a trace of how the community's ideas develop over time.

Although considerable progress has been made in the last decade to develop innovative classroom practices based on the knowledge-creation model in a variety of school subjects (see www.ikit.org and kbtn.cite.hku.hk), advances in assessment of electronic discourse have lagged. We believe that the development of a suite of assessment tools is urgent, particularly tools that teachers and students can use to self-assess and reflect on the nature of their work on Knowledge Forum. Previous studies have used content analysis to examine a variety of issues including knowledge advancement (Hakkarainen, Lipponen, & Järvelä, 2002; van Aalst, 2009; Zhang, Scardamalia, Lamon, Messina, & Reeve, 2007), but these methods are too labor-intensive to inform how students can improve their own knowledge-creation efforts. Analysis tools have been available for the last decade which students and teachers can use to examine participation patterns, such as note writing and reading and social network analysis (Burtis, 1998; de Laat, Lally, & Lipponen, 2007). While these techniques provide information about the social structure of students' collaborative discourse, they reveal little about how ideas are developing. They do not, for example, provide insight into questions such as "are the ideas of students becoming more coherent with one another other over time?" Computer-assisted visualizations or representations that capture both social and semantic features of the online discourse appear to hold much promise tools for self-assessment and reflection on knowledge-creation efforts at the community level.

The goal of this paper was to consider the nature of such representations and to explore the use of one visualization and assessment tool, the Knowledge Space Visualizer (KSV; Teplovs and Scardamalia, 2007; Teplovs, 2010). This work is part of a larger project, which will study the formative assessment *practices* by teachers and students, and will seek to develop a theory of formative assessment that uses data embedded in online environments like Knowledge Forum. However, in the present paper we report our initial exploration into the nature of the representations and what they reveal about the extent to which knowledge creation was occurring.

## Background

### Formative Assessment

In various forms, assessment drives educational practice (Biggs, 1996). It is therefore important for innovative educational approaches from the learning sciences to demonstrate that quality outcomes are obtained. However, it is equally important to understand how collaborative processes contribute to such outcomes. For example, how do we know whether discourse in Knowledge Forum is likely to lead to collective knowledge advances? How does new knowledge diffuse in a database?

We use the concept of *formative assessment* to frame our work: assessment that is used by students and the teacher to enhance learning, while the learning process still is in progress (Scriven, 1967). Interest in formative assessment received a new boost after the major review by Black and Wiliam (1998), who showed substantial positive impacts of formative assessment on learning. However, these practices seem to focus on such the provision of feedback on student work (e.g., tests and projects) and in-class questioning. Several authors have criticized the theoretical underpinnings of formative assessment (Perrenoud, 1998; Taras, 2005), and Black and Wiliam (2009) have recently proposed a theory of formative assessment that refers to self-regulated learning and situates formative assessment in an overall pedagogical framework. Most authors treat formative assessment as something that stands apart from the learning process. We rather consider it as a form of *inquiry* and as part of knowledge creation itself. Regardless of whether students are assessing their own work or whether they are advancing community knowledge by, for example, determining if forest fires are caused by human activities, the underlying process is the same: they use available evidence to ask questions and test hypotheses. This perspective requires that students have data about their own inquiry, which they can use to reflect on their progress and plan future actions. Such data are available but very complex. Students and teachers need sufficiently simple representations that can inform their reflection.

## Latent Semantic Analysis and the KSV

In the last decade, much attention has been given to "assessing" information on the Web to improve the performance of search engines. One example is Google's use of the PageRank algorithm to analyze the structure of the Web to identify the most influential Web pages, in combination of an index of the relevance of a Web page to a query (Brin & Page, 1998; Maslov & Redner, 2008). Latent Semantic Analysis (LSA) is another approach to the problem that uncovers the underlying semantic structure (meanings) of a network of documents (Landauer, 2007).

LSA is a *vector space* approach. One constructs a matrix (a table) in which the columns are types documents (e.g., books, chapters, essays, paragraphs, or computer notes) and the rows different terms (words or phrases); the entries are the numbers of occurrences of the terms in each of the documents. This matrix generally has a very large number of dimensions (e.g. when the "documents" are all the novels written in English or the entire Web), so mathematical techniques are used to produce a matrix of more manageable dimensions that is a reasonable representation of the whole vector space. The most common technique is Singular Value Decomposition (SVD). To make an assessment, one then constructs and compares vectors in the SVD. Vectors can contain information about the terms in a document, about the documents that use a specific term, or a combination. Geometrically, vectors are "similar" if they can be said to point in the same general direction, and if their lengths are comparable. For example, if the cosine of the angle between two vectors is 0.866 (in which case the corresponding angle is 30 degrees), the vectors can be said to point in the same general direction; if the length of one is 1.45 and the other 1.52 (rather than, say, 4.45 and 0.15) that would provide another indication of their similarity.

The Knowledge Space Visualizer (KSV; Fujita & Teplovs, 2009; Teplovs, 2010) is a Java-based tool that was developed to visualize networks of Knowledge Forum notes. It uses visual representations as well as quantitative network metrics to characterize idea-based networks. Exhaustive similarity measures between notes are recorded as latent semantic links between notes. These links, and the explicit semantic links afforded through referencing, rising-above and building-on functionality of Knowledge Forum, are then made available to the KSV. The KSV is capable of recreating the two-dimensional representation of collections of notes in Knowledge Forum, but it also provides computer-assisted positioning algorithms to facilitate the visualization of networks of notes.

## Collective Knowledge Advancement

According to Bereiter and Scardamalia's knowledge creation theory (Bereiter, 2002; Scardamalia & Bereiter, 2006), students in a knowledge creation classroom work progressively and collaboratively on a number of shared topics, and their collaborative inquiries lead to the advancement of individual and collective knowledge. Knowledge advancement is treated as a community rather than individual achievement (Scardamalia & Bereiter, 2006). Collective knowledge resides in conceptual artifacts (ideas and theories) in the community's discourse rather than inside individual minds. Also, according to Stahl's (2006) notion of group cognition, collective knowledge is interactively achieved in discourse and cannot be simply attributable to any particular individual mind.

These ideas suggest that any theoretical exploration, or practical assessment, of the advancement of community knowledge depend on the degree to which researchers and teachers are able to accurately describe and evaluate the content of discourses occurring in a collaborative knowledge creation community. However, despite emphasis and progress in developing collaborative inquiry in CSCL research, little attention has been given to the assessment of collective learning (van Aalst & Chan, 2007). Thus, little is known about the nature of collective knowledge and group cognition, and in practice teachers are still limited in their ability to assess how collective knowledge actually is formulated and advanced, although CSCL researchers and classroom teachers have put great efforts to design various technology-enhanced collaborative learning environments.

## Network analyses of CSCL

There are at least two significant factors underlying the above issues. First, research on CSCL often epistemologically focuses on individual learning outcomes rather than collective knowledge growth (Stahl, Koschmann, & Suthers, 2006). Perhaps this problem can be attributed to the influence of cognitivism, which stresses individual learning and personal cognition. Second, methodological alignment with the social nature of collaborative learning has led many researchers to examine interactions and participation patterns, using social network analysis (SNA; de Laat, Lally, Lipponen & Simons, 2007; Cho, Gay, Davidson, & Ingraffea, 2007). SNA considers a CSCL community as a *network* in which individual learners are represented as nodes, and the relationships between learners are represented as edges connecting those nodes. The edges indicate collaborative actions such as note reading, building-on, and referencing other notes. Current studies on the application of SNA to CSCL research converge at two basic aspects: network properties of a CSCL community, and participatory characteristics of individual learners. The first of these is mainly concerned with the issues such as network density of a collaborative learning community, and emergent cohesive cliques. The second aspect seeks answers to the following questions (de Laat, et al, 2007): Who is involved with the collaborative learning task? Who are the active participants? And who is participating peripherally? Current SNA studies rely primarily on mathematical computations of the frequency of ties between learners, and ignore the *content* of artifacts notes and the connections in meaning between the notes (Stahl, 2006).

For formative assessment, it is necessary to locate and describe knowledge creation in collaborative discourse. In network models of cognition, knowledge is represented as a network in long-term memory, in which nodes correspond to the cognitive units (in the form of concepts or schema), and the relations between the cognitive units are represented as links (Bruning, Schraw, & Norby, 2004). By analogy, group cognition can be defined as a network of the conceptual artifacts collectively created in a collaborative learning process. As information units, conceptual artifacts (Bereiter, 2002; Scardamalia & Bereiter, 2006) are the objects of collaborative work on knowledge creation, which take the form of notes created and posted by individual learners in Knowledge Forum. This implies that collective knowledge and group cognition can be studied and assessed from the perspective of network analysis. Therefore, we differentiate two types of networks existing in a CSCL community: *networks of people* and *networks of notes*. The former can serve to assess the interactive and participatory patterns of students, the latter can function as a representation of collective knowledge and group cognition.

However, as noted earlier, most research has concentrated on the patterns of social interaction between students rather than networks of conceptual artifacts. Of course, one may argue that a social network of people in a CSCL community operationally corresponds to a profile of the network of notes created by those people. Social networks of people only capture at most two features of notes – authorship or readership. Most SNA studies in CSCL examine patterns of social interaction between the CSCL participants, rather than the relation between students' ideas embedded in the notes from the perspective of collective knowledge and group cognition. Therefore, comprehensive formative assessments of collaborative learning must entail a multi-faceted network analysis of notes generated in a CSCL discourse. Stahl (2006) pointed out that the meaning of the group-level constructs such as group cognition constitutes a network of semantic references within the group interaction, and collaborative learning can be viewed as the interactive construction of this referential network. In this sense, collective knowledge and group cognition produce a semantic network of conceptual artifacts (notes), that is, a network system based on shared meaning (Doerfel & Barnett, 1999).

We may ask what a semantic network of notes looks like, how researchers or classroom teachers can identify the semantic networks of notes that emerge in a CSCL process, and what is the role of semantic network of notes in assessing collective knowledge advancement and group cognition.

This paper introduces our preliminary attempt to address these issues related to formative assessments of CSCL. Taken together, the above analyses of the distinction between the network of people and network of notes suggest that networks of notes can be established in two manners. Furthermore, we propose two sub-types of network of notes: *structural (physical) network* and *semantic network.* A structural network of notes or people refers to a visible network of notes or people whereby the linkage between notes or people is physically established by any one of the collaboration operations, such as note reading, building-on, and referencing in a Knowledge Forum database. An inquiry thread (Zhang, et al., 2007), defined as a series of notes that share a problem and constitute a conceptual stream in a collaborative inquiry, manifests the limitations of the studies on the spatial threads of notes, as well as structural network of notes in understanding the formation and advancement of collective knowledge and group cognition in a collaborative inquiry discourse. An inquiry thread represents a semantic connection between notes by content analysis of each individual note, namely, and therefore is a semantic network of notes from a network analysis perspective. Similarly, Manca, Delfino, and Mazzoni (2009) introduced a semantic coding scheme aiming to obtain a relatively complete picture of social interactions among people in a web forum that the structural (physical) network construct cannot provide. However, these methods require manual coding of note content, which is very labor-intensive. Because of the two considerable drawbacks—the amount of labor involved and their reliability—teachers may hesitate to use them for formative assessment. Our study is an attempt to meet this challenge, and uses the KSV, an innovative visualization and assessment tool of collective knowledge, to automatically identify the emergent semantic networks of notes under a pre-set condition with reference to semantic closeness between them, and the as structural networks of notes in a CSCL discourse.

## Research Context and Methods

The KSV was used to study part of a Knowledge Forum database created by a class of 41 Form 4 (Grade 10) students taking physics at a secondary school in Hong Kong. The database had approximately 880 notes, which were distributed over several views (shared workspaces) in Knowledge Forum. The teacher had several years of prior experience with Knowledge Forum, and was attempting to align her classroom teaching more with the knowledge-creation model, particularly by encouraging student-to-student classroom talk. The students' presentations and the talk that followed appeared to break with the more typical classroom discourse in Asian classrooms in which students do not ask many questions (Li, 2009). The curriculum consisted of three units of study: heat and temperature (3 months), mechanics (6.5 months), and waves (1.5 months).

In this classroom it was difficult to integrate the use of Knowledge Forum on a daily basis. Rather, it was used during specific periods to follow up classroom learning and to support the two projects. For example, during the heat and temperature unit, the class as a whole discussed thermal questions such as how to keep a drink warm as long as possible (Linn & Hsi, 2000) and why people lived in igloos, which are made from ice and would intuitively seem cold. Students also used Knowledge Forum to discuss their solar cooker designs, and in this, they were asked to refer to physics concepts and phenomena such as the greenhouse effect and methods for focusing energy from the sun on a beaker of water at the center of their solar cooker. During the mechanics unit, students similarly used Knowledge Forum to discuss puzzlements about Newton's laws and their analysis of motion on rides at an amusement park. Although the amount of work in Knowledge Forum was not as extensive as in some published studies, the computer notes that were generally focused on the tasks at hand and contained explanations in which students used relevant science ideas, although a substantial number of notes dealt with the logistics of projects.

## Results

The Knowledge Forum database had several comprehensive views for two units of study: heat and temperature, and mechanics. Each unit had several sub-topics. For example, the students studied mechanics by discussing how the cable car works in the view called 'Cable Car'. This view was spatially separated from the 'Mechanics' view.

### Two Types of Network of Notes

Two kinds of network were generated with the KSV. Figure 1 shows structural networks, and Figure 2 semantic networks. The directional lines in the structural network represent links between notes by note building-on. The lines in the semantic networks in Figure 2 are non-directional, suggesting that the notes are linked to one another in *meaning*, which is reciprocal. The color of node denotes a participant in Knowledge Forum (electronic version of the paper).

Mathematically, semantic closeness between notes in KSV is quantified as the cosine between vectors representing their content. High cosine values denote semantically similar note content (Teplovs & Scardamalia, 2007). The KSV allows us to set a link visibility threshold. When the cosine between any two notes exceeds this threshold, the KSV joins the notes with an edge (shown in Figure 2). The lower the threshold is, the more semantic links between notes in the network are displayed. In this study, the semantic coefficient was set at 0.75. Semantic links between notes are invisible in Figure 1 because KSV allows users to choose either of the two types of network.

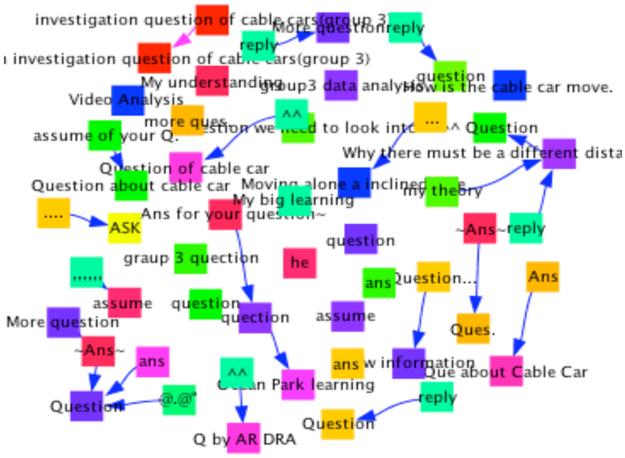

Figure 1. Obtained structural network in the Cable_car view

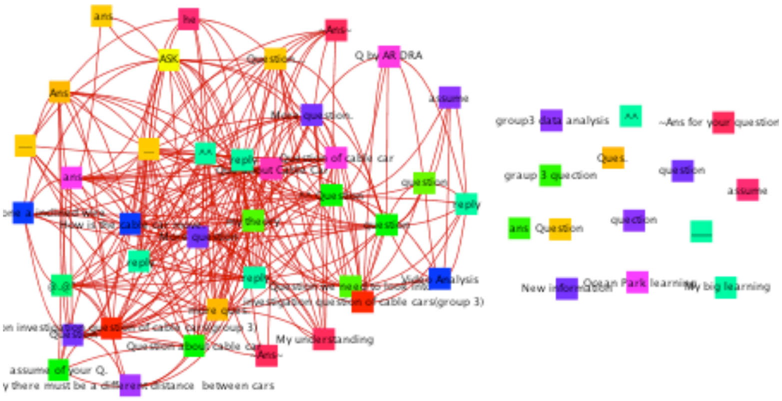

Figure 2. Obtained semantic network in the Cable_car view

Visually, the number of lines in the structural network is obviously much less than that in the semantic network, implying that many notes are linked to one another semantically but not structurally. This finding can be quantitatively reinforced by the contrast of the network properties between them. The Cable_car view contains 52 notes, 2391 words in total. The average size of note (i.e., words/notes) is 45 words. There are 22 lines (physical note links) in the structural network, which correspond to 22 physical actions (i.e., note building-on or referencing) that took place while the students collaboratively worked on that topic in Knowledge Forum. There are 281 links in the semantic network. In SNA, degree refers to the number of lines incident with each node in a graph; network density is defined as the ratio of the actual number of lines to the maximum possible lines, with a value falling within the range between 0 and 1 (Wasserman & Faust, 1994). The density of the semantic network is .212; the density of the structural network is .017, much less than the former. This finding implies that for a collection of notes in the Cable Car view, its semantic network is much cohesive than the structural network. The notes that are not linked to one another by a physical collaborative learning action are not necessarily disconnected with each other semantically.

## Visualization of Group Cognition

In the design of a KF database, the notes embedded within a view often converge at the same discussion topic. For example, the Heat view was intended to be a workspace where students collaboratively learned the concept of heat. In practice, a classroom teacher may want to examine how student online discussions in Knowledge Forum unfolded around the shared topic.

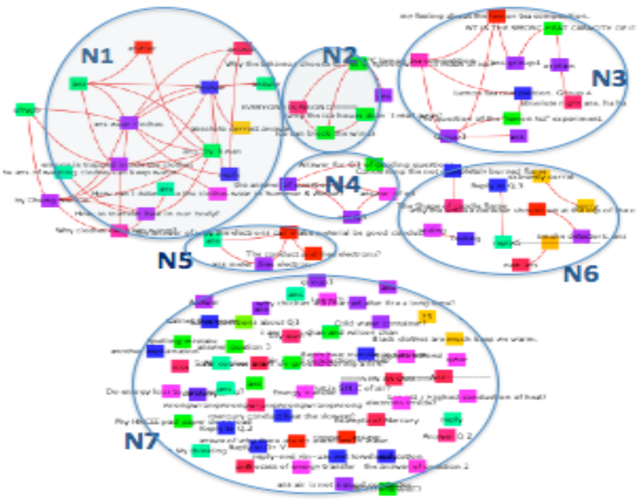

Figure 3. Obtained semantic networks within the Heat view

Table 2: The main overlapping words in each sub-semantic network

| Sub-networks | Main overlapping words |
|---|---|
| N1 | clothes (24) body (17) air (16) energy (14) warm (10) feel (6) transfer (6) cold (5) theory (5) trap (5) |
| N2 | ice (11) live (7) house (4), outside (3) |
| N3 | ice (16) energy (14) lemon (12) tea (11) loss (9) heat (8) specific (7) water (6) |
| N4 | heat (10) copper (9) water (7) specific (6) energy (5) capacity (5) conductor (3) |
| N5 | free (10) conduct (5) electrons (5) electron (5) metal (4) energy (4) shell (4) atom (3) heat (3) |
| N6 | air (17) copper (9) water (9) gravity (7) flame (6) electrons (6) |
| N7 | theory (33) air (23) energy (22) heat (20) liquid (13) ice (12) water (11) density (11 |

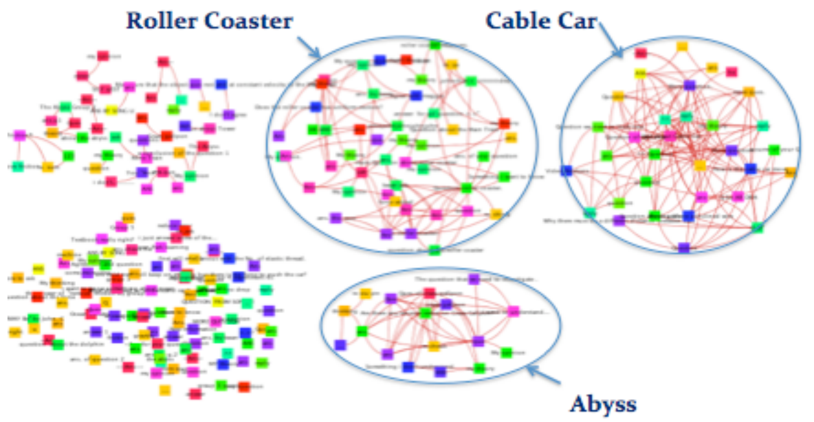

Figure 4. Sub-topics in the semantic network of notes in the Mechanics view

Figure 3 shows that the KSV revealed that there were seven clusters of notes within the general semantic network of the Heat view. These clusters can also be viewed as semantic sub-networks. Table 2 shows the major theme for each semantic sub-network. For example, the students who wrote the notes within N1 primarily were trying to understand the concept of Heat by connecting it to the daily life phenomena such as clothing from the perspective of heat transfer. Shared meaning of the notes in N3 seems to converge on heat transfer in liquids such as lemon tea, and water. Similar findings can be seen from the semantic network of another view in the same KF database shown in Figure 4 (Mechanics). Three themes in the view Mechanics can be identified by latent semantic analysis: Roller Coaster, Cable Car, and Abyss. Similarly, this finding suggests that students collectively worked on several sub-topics under the Mechanics view.

We conducted an inquiry thread analysis (Zhang et al., 2007) on the Heat view, and found seven inquiry threads (i.e., principal problems). Four themes identified in the inquiry thread analysis correspond to the first five semantic networks (i.e., sub-discussion topics) shown in Table 2. This provides some preliminary evidence that the KSV can reliably uncover sub-discussion topics that emerge in the discourse of collaborative knowledge creation.

## Conclusion

This study demonstrates a combination of computer-assisted content analysis and network analysis for formative assessments of CSCL, which is aligned with the appeal for developing innovative methodologies for analyzing participation and discourse processes in CSCL (Lipponen, Rahikainen, & Hakkarainen, 2002).

We can draw at least the following tentative conclusions. First, semantic network analysis offers an alternative approach for examining the relationship among the computer notes in a CSCL community in terms of shared meaning making, other than the traditional network analyses that mainly concentrate on the participation patterns of students. This expands the scope of formative assessments of collaborative learning by empirically revealing and conceptualizing two kinds of network of notes (i.e., structural network vs. semantic network). Second, various sub-discussion topics uncovered by latent semantic analysis in the heat view reveals the complexity of collaborative learning dynamics. This finding implies that collective learning in this class unfolded by breaking down a general concept/theory (e.g., Heat, Mechanics) into a number of sub-discussion topics (i.e., inquiry threads). Third, the notes with a certain semantic closeness may illustrate the workplace whereby collective knowledge might be forged due to the shared meaning of those notes. The overlapping words in a semantic network to some degree facilitate the visualization of the key meanings of the conceptual artifacts of group cognition. For the purpose of formative assessment of collective learning, the use of the KSV as an assessment tool provides a fine-grained semantic analysis that may enable teachers and students to locate the key ideas around which collective learning may takes place. It was found in this study that identification of the sub-topics within a view is generally aligned with inquiry thread analysis (Zhang et al., 2007). However, thread analysis used in that study was time consuming, because the theme of each thread of notes (shared topic) required labor-intensively content analysis of each Knowledge Forum note. Fourth, many current studies in assessment of CSCL use a whole CSCL community as unit of analysis, which might be appropriate when research is to assess student participation patterns by SNA throughout a CSCL process. Our study suggests that individual views as unit of analysis be appropriate as well for assessing the processes of collaborative knowledge construction and creation.

Our preliminary analyses using the KSV have yielded some findings regarding the characteristics of semantic network and the potential for further exploring the role of this kind of emergent networks in assessing how knowledge creation proceeds collaboratively in a Knowledge Forum database. Thus far, we still know little about the role of these emergent semantic networks in formative assessments of collaborative knowledge creation. The present study is just starting point along this direction. We believe that in order to have efficient and productive formative assessments of CSCL, semantic network analysis should be adopted along with other types of analysis such as content analysis of the notes within a selected semantic network.

**Abstract:** With computers becoming more ubiquitous in our daily lives and in our classrooms, questions of how students interact and learn with physical experiments and computer simulations are central in science education. We investigated how students' ideas about pulleys were influenced by the use of physical and virtual manipulatives. We found that there were advantages for each type of manipulative, and that virtual and physical manipulatives helped students develop correct understandings of different concepts. We also found that the order the manipulatives were used affected student learning, with students who used real pulleys before the simulation achieving higher scores on questions having to do with effort force, the distance the rope is pulled, and mechanical advantage.

## Introduction & Background

Laboratory experiments play a critical role in furthering scientists' understandings of how the universe works, and in light of this importance, it is no wonder that educators have historically placed high value on laboratory experiences in science classrooms. However, due to practical concerns of procuring laboratory equipment, safety concerns, and time constraints, computer simulated experiments are becoming an attractive alternative to laboratory experiments. In light of this trend, recent research in science education has explored whether computer simulations (virtual manipulatives) can be as effective for learning as experiments involving real objects (physical manipulatives) and researchers have begun looking at the circumstances in which these two alternatives may be best employed.

Finkelstein *et al.* (2005) investigated how physical versus virtual manipulatives supported students' learning about circuits. Students used either physical materials or simulations to examine combinations of resistors, build simple circuits, predict the behavior of specific elements and develop a method for measuring resistance. The simulations were similar to the set-up with physical materials, except that the simulations represented electron flow within the circuit, an aspect of the physical materials that cannot not directly be perceived. After these experiences, students who had used the virtual manipulatives were able to build physical circuits quicker than students who had previously used the physical manipulatives. In addition, the students in the virtual conditions were able to provide better explanations of circuit behavior and scored better on a related exam question. Therefore, Finkelstein *et al.* suggest properly designed simulations can be beneficial to student learning when applied in the appropriate contexts.

Triona, Klahr and Williams (2007) investigated how physical and virtual manipulatives support students' learning about the factors affecting how far a mouse trap car will travel. Students explored these factors by designing cars to be used for an experiment. Students used either physical or virtual manipulatives and were allowed to design either a certain number of cars or were allowed to design cars for a certain length of time, creating four treatment groups. All treatments were equally effective at increasing students' knowledge about causal factors for travel distance, supporting students' ability to design cars, and students' confidence in their knowledge. Based on these findings, the researchers suggest that simulations may be preferred due to their other pragmatic advantages.

Zacharia, Olympiou, & Papaevipidou (2008) studied physical and virtual manipulatives used in combination to learn about heat and temperature. Students in the control group used only physical manipulatives, while students in the experimental condition used physical manipulatives followed by virtual manipulatives. The researchers aimed to limit the differences between the physical and virtual manipulatives to speed of manipulation. On a conceptual test, students in the experimental group outperformed students in the control group. The researchers suggest this difference may be a result of virtual manipulatives being manipulated faster than physical manipulatives.

In a similar study (Zacharia & Constantinou, 2008), the researchers controlled for all differences between the physical and virtual conditions except for the mode in which experiments were performed. In particular, the simulations did not model any aspects of the phenomena that could not be perceived with the physical manipulatives (in contrast to Finkelstein, et al). In this case, the physical and virtual manipulatives equally supported students' conceptual understanding.

In our study, we also controlled for all conditions (curriculum, mode of instruction and resource capabilities) except for the mode of the activities (physical or virtual). Students spent approximately 30 minutes on each activity, although working with the real pulleys typically took a few minutes longer than working with the simulation. The design of this study replicates the study performed by Zacharia & Constantinou in a new domain (pulleys rather than heat & temperature). Furthermore, we not only looked at overall learning during these activities, but isolated particular concepts and looked at the effect of manipulative type and ordering of manipulatives on students' understandings of these concepts.

## Context and Data Collection

Students in a university-level conceptual physics lab performed two activities to learn about pulleys. One activity involved working with real pulleys (physical manipulatives) while the other activity involved an interactive computer simulation of pulleys (virtual manipulatives) (Figure 1). The activities are part of CoMPASS, a design-based curriculum that integrates concept maps and hypertext that students explore prior to performing physical or virtual experiments (Puntambekar, Stylianou & Hübscher, 2003 and Puntambekar & Stylianou, 2002). During each activity, students answered questions on a worksheet. These worksheet questions were the same for both activities. However, the temporal order of the activities was varied creating two treatment groups. Three sections (N=71) used the physical pulleys first (the Physical-Virtual treatment), while two sections (N=61) began with using the virtual pulleys (the Virtual-Physical treatment).

Students answered a set of conceptual assessment questions before the activities (pre-test), after the first activity (mid-test), and after the second activity (post-test). The assessment questions on the pre-, mid-, and post-tests were identical. The mid-test scores allowed for comparisons to be made between the effects of physical manipulatives (PM) and the effects of virtual manipulatives (VM) only, while mid-test and post-test scores indicated ordering effects.

The assessment contains 13 multiple-choice questions, with each question weighted equally in the total score. The assessment questions were developed locally to probe students' conceptual understanding of pulley concepts, including effort force, work, mechanical advantage, the distance the rope is pulled and the potential energy of the load. The assessment contained more questions about effort force and work concepts than other concepts because these are the most central to the topics of pulleys and the most applicable in other science topics. Figure 2 indicates the distribution of questions for each concept. A question was considered to be related to a concept when the concept is explicitly mentioned in the problem statement. For example, the question "If we ignore friction, what will require *less effort* (force) to lift a box to a height of 1 meter – using the pulley shown or lifting the box straight up?" is considered to be an effort force question.

A reliability analysis was conducted on effort force and work questions. For the effort force questions Cronbach's $\alpha$ = .70. For the work questions, Cronbach's $\alpha$ = .51. The lower reliability for the work questions may indicate that students have a harder time constructing correct understandings about the concept of work.

Open-ended worksheet questions were coded and analyzed using a phenomenographic approach (Marton, 1986). The conceptual assessments were analyzed statistically. For these assessments, categories of questions were created based on the physics concept probed by each question (as indicated explicitly in the question statement). The analysis included comparisons of overall scores and category scores that were made using a Repeated Measures Analysis of Variance with a between subjects factor of treatment type. P-values less than 0.05 were interpreted to indicate a statistically significant difference.

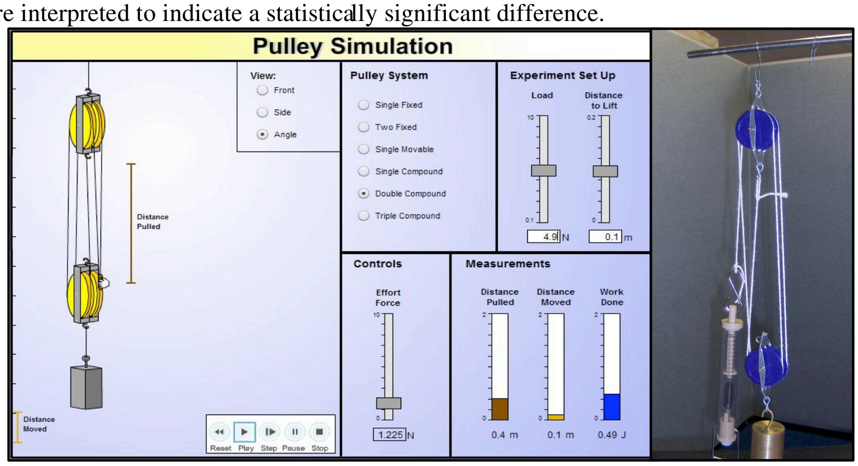

Figure 1. Virtual (left) and physical (right) manipulatives.

## Data Analysis

### Conceptual Assessment

The overall scores for the pre-, mid- and post-tests are shown in Table 1. Table 2 contains the results of a Repeated Measures Analysis of Variance for all the students. Mauchly's test indicated that the assumption of sphericity had been violated on all the comparisons made, therefore degrees of freedom were corrected using Greenhouse-Geisser estimates of sphericity. Table 2 also contains information of Mauchy's test and sphericity estimates.

Table 1: Overall pre-, mid-, and post-test scores on the conceptual assessment. Uncertainties are the standard error of the mean.

| Treatment | N | Pre-test % | Mid-test % | Post-test % |
|---|---|---|---|---|
| Physical-Virtual | 71 | **37 ± 2** | **58 ± 2** | **66 ± 3** |
| Virtual-Physical | 61 | **33 ± 2** | **60 ± 3** | **61 ± 3** |

Table 2: Mauchly's Test, Greenhouse-Gessier Estimates of Sphericity, and Repeated Measures ANOVA for Overall Score, Force Questions, and Work Questions

| Effect | Mauchly's Test | | Sphericity | Repeated Measures Analysis of Variance | |
|---|---|---|---|---|---|
| | $\chi^2(2)$ | p | ε | F | p |
| Total Score | 67.28 | <.001 | .71 | F(1.42,184.87) = 173.57 | <.001 |
| Total Score*Treatment | | | | F(1.42,184.87) = 2.33 | 0.12 |
| Effort Force Questions | 61.40 | <.001 | .73 | F(1.45,188.58) = 167.24 | <.001 |
| Effort Force*Treatment | | | | F(1.45,188.58) = 4.89 | 0.02 |
| Work Questions | 25.81 | <.001 | .85 | F(1.69, 220.09) = 27.69 | <.001 |
| Work*Treatment | | | | F(1.69, 220.09) = 15.28 | <.001 |

The Repeated Measures analysis shows that students' total scores changed significantly between tests. However, the insignificance of the interaction between total score and treatment condition indicates that the changes in scores for the two treatments were similar. The scores for the effort force questions also show a significant change between tests and a significant interaction between the effort force questions and the treatment conditions indicating that the changes in effort force score were different for the two conditions. Similarly, the scores for the work questions show a significant change between tests and a significant interaction between work score and treatment condition.

Table 3 shows the results of contrast comparisons for each effect described in Table 2. These comparisons help locate when significant changes in score occurred. Both treatment conditions resulted in a change of total score between the pre- and mid-test, but the scores of the treatment conditions changed differently between the mid- and post-test. Figure 2 shows plots of average score on each exam. The plot shows that students in the physical-virtual condition had a significantly greater change in score between the mid- and post-test. Therefore, the students who used the physical manipulatives first continued to progress on the conceptual assessment after the second activity while the students who used the virtual manipulatives for showed little further progression, although students in both treatment conditions benefitted from the activities on the whole.

On Effort Force questions, both conditions showed a change in score between the pre- and mid-test, but no change in score was observed between the mid- and post-test. The change in score for the treatment conditions was significantly different between the pre- and mid-test, with students who initially used the physical manipulatives showing a larger gain in Effort Force score than students who initially used the virtual manipulatives.

On the Work questions, an overall change in score was observed for between pre- and post-test. However, the changes were significantly different for the different treatments. Students in the virtual-physical condition show a large gain in Work score between pre- and mid-test while the students in the physical-virtual condition do not show a gain. However, this trend switches between the mid- and post-test, with the virtual-physical students showing no gain and the physical-virtual students showing a large gain. It seems that students show a large increase in score on work questions after they have used the pulley simulation.

For the other questions dealing with mechanical advantage, distance pulled, and potential energy, students in both conditions showed an increased of score between pre- and post-tests but no interaction effect was observed for these questions.

Table 3: Contrast Comparisons for Repeated Measures ANOVA

| Effect | Comparison | F(1,130) | p |
|---|---|---|---|
| Total Score | Pre-Mid | 170.94 | <.001 |
| | Mid-Post | 22.33 | <.001 |
| Total Score*Treatment | Pre-Mid | 1.71 | .19 |
| | Mid-Post | 12.04 | .001 |
| Effort Force Questions | Pre-Mid | 181.30 | <.001 |
| | Mid-Post | 1.74 | .19 |
| Effort Force*Treatment | Pre-Mid | 5.56 | .02 |
| | Mid-Post | <.001 | .98 |
| Work Questions | Pre-Mid | 10.83 | .001 |
| | Mid-Post | 26.27 | <.001 |
| Work*Treatment | Pre-Mid | 24.18 | <.001 |
| | Mid-Post | 28.14 | <.001 |

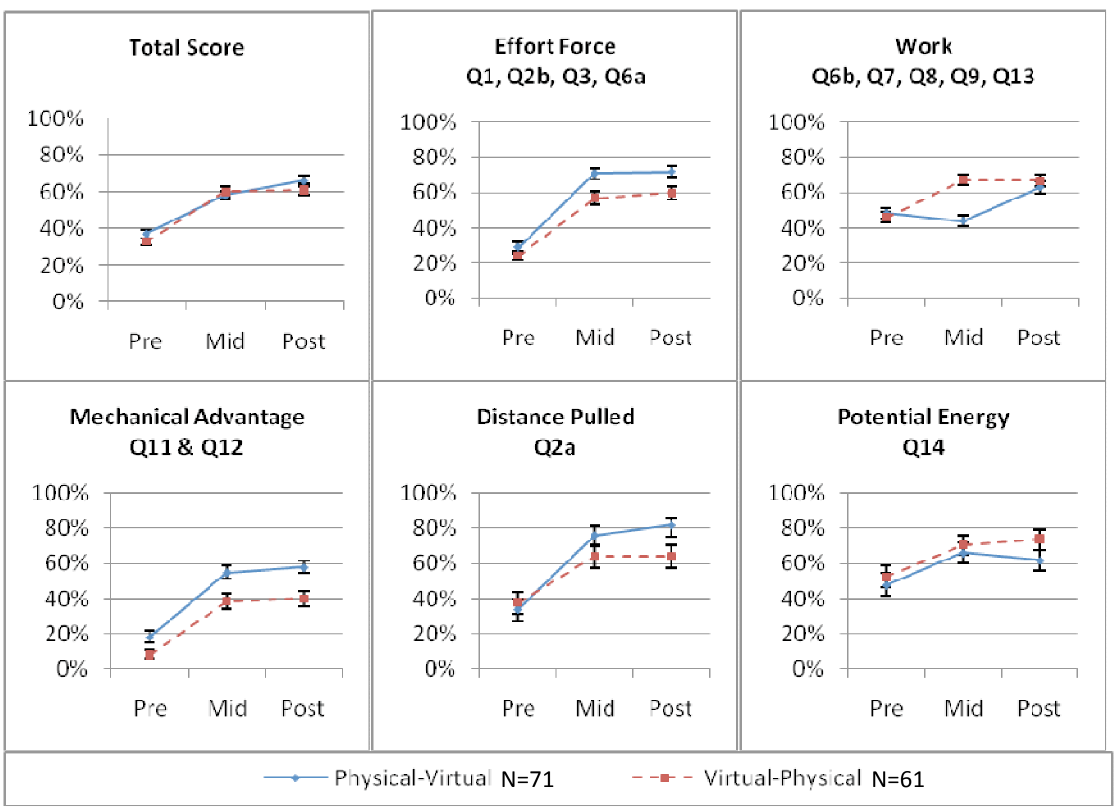

Figure 2. Average scores by category on the conceptual assessments. Error bars indicate standard error.

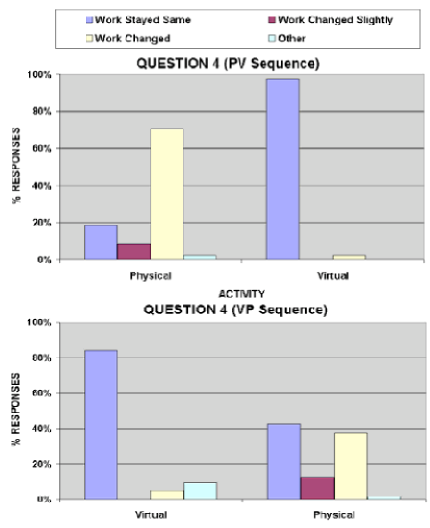
## Questions on Activity Worksheet

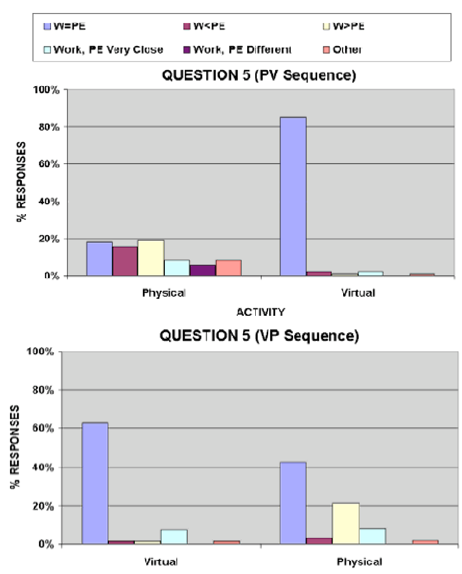
While doing the activities (with physical pulleys and virtual pulleys), students responded to questions on a worksheet. We report students' responses on some of the worksheet questions to aid interpreting the above assessment results. Question 4 on the worksheet had to do with the concept of work (Figure 3). Students in both treatments interpreted the data from the simulation as showing the work being the same for different pulley-setups. In contrast, students in the different treatments disagreed on how to interpret the data from the real pulley: students in the Physical-Virtual treatment said the work changed when you changed set-ups while students in the Virtual-Physical treatment were split, with nearly half of the students claiming the work stayed the same while the other half said the work changed across pulley set-ups.

A similar trend was seen on Question 5 on the worksheet (Figure 4). Question 5 had to do with comparing work and potential energy for a given pulley system. Students in both treatments interpreted the data from the simulation as showing the work was equal to the potential energy for a given pulley set-up. In contrast, students in the different treatments disagreed on how to interpret the data from the real pulley: students in the Physical-Virtual treatment did not come to a consensus about how the work was related to the potential energy while students in the Virtual-Physical treatment were more likely to say the work was equal to the potential energy.



Question WS4: "Based on your data, when you changed the pulley setup, how did it affect the work required to lift the object? Why do you think that is?"

Figure 3. Student responses to Question 4 on the activity worksheet.



Question WS5: "Based on your data, how does work compare to potential energy for a given pulley system? Why do you think that is?

Figure 4. Student responses to Question 5 on the activity worksheet.

## Discussion

The analysis of overall score indicates that there is no overall preferred manipulative for learning about pulleys; the students' mid-test scores (which isolate each type of manipulative) are the same. Looking at changes between the mid-test and post-test scores, however, indicates that there may be an ordering effect for using both types of manipulatives, in that the scores of students in the Physical-Virtual treatment continued to increase after the second activity, while the scores of students who used virtual pulleys first did not increase when the students switched to physical pulleys.

In looking at categories of questions, the data show that the different types of manipulative (physical or virtual) affected different pulley concepts differently. In the Effort Force category, although an increase in score was observed on mid-test for both treatments, students who used real pulleys scored higher. In contrast, students showed no increase in score on questions about work after using real pulleys, while students who used the pulley simulation showed significant improvement on work questions.

Additionally, the Effort Force category showed an ordering effect on category score, while the Work category did not. Students who used the physical pulleys first showed a greater increase in score between the pre- and mid-tests, while neither treatment group showed an increase in score between the mid- and post-tests. In contrast, students who used virtual pulleys more often answered questions about work correctly than students who only used physical pulleys, regardless of which order they encountered the manipulatives. In light of these data, it seems the ordering effect seen in the overall score may be explained by the ordering effect of questions having to do with effort force.

In short, students obtain a better understanding as measured by the conceptual assessment of the concept of work with the computer simulation and a better understanding of effort force with the real pulleys.

Why should the type of manipulative affect different pulley concepts differently? One possibility is that this result is due to a difference in the salience of the physics concepts. The concepts of effort force and distance pulled are more salient for real pulleys than with virtual pulleys. The real pulleys give students a kinesthetic experience with effort force and distance pulled; they feel the force they need to exert and how far their arms move in relation to the pulley, while students who use the virtual pulleys read-off values from a screen. On the other hand, work is less salient than effort force for real pulleys. Work depends on the combination of effort force and distance pulled, and this makes the concept of work more removed from the kinesthetic experience. In order to reason about work correctly, students need to coordinate the experiences that if less force is needed, the distance pulled is longer in exactly the right proportion so that work is constant across pulley set-ups (assuming friction is small enough to be neglected). Alternately, students might perceive the energy expended in lifting a load a certain distance with different pulley set-ups. Both of these types of reasoning are difficult to achieve through kinesthetic experience. However, all concepts are equally salient in the simulation – all quantities must be read-off the screen (Figure 1).

Capacity theories of attention suggest that people can only attend to a limited amount of information (Kahneman, 1973), and it is also known that attention can be influenced by the salience of cues, with high salience cues naturally attracting more attention (Denton & Kruschke, 2006). With physical manipulatives, effort force and distance pulled have a relatively high salience and probably dominate the attention of the learner, while less salient concepts, like work, receive less attention. This explanation is consistent with our data that Physical-Virtual students have relatively high scores on Effort Force questions and relatively low scores on Work questions. Students who use the virtual manipulatives probably divide their attention more evenly among the concepts due to their equivalence in salience, resulting in less relative attention to effort force, distance pulled and mechanical advantage concepts, resulting in lower scores in these categories and higher scores on work questions than students who used physical manipulatives. Furthermore, if the simulation is done first, the initial equivalence in salience among concepts may lessen the impact of the subsequent kinesthetic experience with the real pulleys, resulting in the continued suppression, or blocking (Kamin, 1968), observed in the Effort Force, Distance Pulled scores, and Mechanical Advantage categories.

Furthermore, the students in this study did not receive instruction on how to interpret their data in light of friction effects and experimental uncertainty. The data show that they did not interpret trends in their real pulley work data in a consistent way. This point is supported by the students' responses to Question 4 and Question 5 on the worksheet. Also, Physical-Virtual students had trouble reasoning about work in frictionless situations on the mid-test. However, after the virtual experiment, all students were much more successful in reasoning about work in frictionless environments, regardless of the order the activities.

This study suggests that curricula that include pulleys might ideally use both experiments with real pulleys and simulations. The data suggest that an ideal ordering might be to have students begin with real pulley experiments, focusing on effort force, distance pulled and mechanical advantage. Then students might perform a set of experiments with the simulation, reinforcing trends found with the real pulleys and exploring the concepts of work and potential energy in a frictionless simulated environment. Finally, students might finish with a set of experiments with real pulleys to explore how work and potential energy are related in a situation where friction is not negligible.

## Conclusion

Previous research has demonstrated that virtual manipulatives can be as effective as physical manipulatives in some circumstances. Our data extends this result to the domain of pulleys and addresses how manipulative types affect different pulley concepts. In looking at the effect of physical and virtual manipulatives on students' understandings of pulleys, we find that although there is no difference in overall score between types of manipulative, each manipulative has advantages for different pulley concepts: physical manipulatives better address the concepts of effort force, distance pulled and mechanical advantage, while virtual manipulatives better address the concept of work. The order the manipulatives are used by the students affected conceptual gains for the concepts of effort force, distance pulled and mechanical advantage. We suggest that these differences may be attributed to differences in concept salience.

## Acknowledgments

Foremost, we would like to thank the students and staff at CoMPASS Group, Wiconsin Center for Educational Research for their cooperation. We would also like to thank the students who participated in this study, particularly those who volunteered to be interviewed. Their cooperation and candor was critical to this work. Additionally, we'd like to thank the members of the Physics Education Research Group at Kansas State University for fruitful discussions and their thoughtful suggestions. This work was supported in part by the National Science Foundation under DUE grant DGE 0841414 and U.S. Department of Education IES Award R305A080507. Any opinions, findings and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect those of the National Science Foundation or the U.S Department of Education.

# Children Learning Literate Practices in Spriting

Tara Rosenberger Shankar, 22 Freeman Street, Arlington MA 02474, tara@media.mit.edu

**Abstract:** The exploratory empirical work presented here suggests that children engage in conceptual processes through a new activity called *spriting* (Shankar 2005, 2006) previously thought of as late-emerging and dependent on writing. Spriting is a new technologically-supported composition process that does not require intermediate mediation with a written form. The output of spriting is a *talkument*. In this paper, results are presented from a design research study of the impact of spriting on the literacy development of children, ages 5-10, at two different schools. In particular, composite composing and editing actions in spriting presage a reversal of some trends seen in written composition, such as older children producing longer compositions. Furthermore, this paper describes early observations of children appearing to make certain literate habits, such as pausing to plan, explicit in spriting in ways they had not learned to do yet in writing. Results suggest that spriting could offer an alternative way to explore extended forms of literacy and habits of mind before a child is able to write.

## Introduction

Learning how to write has long been seen as a precursor to developing critical cognitive skills, typically lumped under the term "literacy". For example, children who cannot read or write are not expected to understand the difference between 'meaning' and 'saying' (e.g. Olson & Torrance, 1985), understand that compositions encode purpose and make things happen in the world (e.g. Bereiter & Scardamalia, 1987), or learn to recontextualize their oral language skills for a distant and critical audience (e.g. Purcell-Gates, 1991). This article explores the idea that children are much more capable of shaping their actions and communication in a literate manner than we have been able to observe given the literate tools available. There is some evidence that composition tools impact editing practices. Word processors can positively impact more experienced writers' revision practices (Haas, 1989) and even have a weak effect on children's writing as young as kindergarten (Jones, 1998). This work introduces a new technological support for composing in order to study the impact on children with emerging literacy skills.

In order to put this work in the broad frame intended, some new terms are required. First, I introduce a new practice called *spriting* (rhymes with writing), which refers to using one's own oral productions in a writerly process of composition, supported by new technology. Pragmatically, the spriting process goes something like this: children hold or wear a microphone that plugs directly in to the computer. Using custom built software called the SpriterWriter (see the interface presented in Figure 1), the child presses a record button and speaks for as long as s/he wants, and then presses a stop button to end the recording. While the child is recording, her/his speech productions appear as graphic representations in the software. The software automatically segments the speech productions into "sausages", based on spoken phrase automatic end-point detection. These smaller sausage units are independently editable and are intended to expedite review and editing. Through simple point and click interaction with the graphic representations, the child can *aud* the work (a correlate to reading in the aural mode), and apply editing functions (e.g. rearrange by drag and drop; cut, copy, and paste; delete; insert). Theoretically, the output of a spriting process could be an oral *talkument* (e.g. an audio file) or a written *document*, if the child would transcribe his or her own spriting or was supported by a technological process such as speech recognition. In practice, children rarely transcribed their spriting to writing, more often working very hard to realize their compositions goals as talkuments.

In short, spriting does not require children to make the additional leap to using a deeply different form of composition representation such as writing itself. Yet, spriting shares important properties with writing, such as permanence and shareability, and permits extended processes of planning and editing.

The introduction of spriting helps make a new distinction in literacy between alphabetic and higher-level skills. I refer to the knowledge and skills that bridge reading and writing, and auding and spriting as *literacy.* I borrow a term from Seymour Papert, *letteracy* (Papert, 1993), to refer to the mechanical and presentational skills specific to reading and writing, including the ability to write letters, spell, punctuate, and design a page. In spriting, I observed many parallels to written mechanics in this new compositional mode. Children were as concerned with *how* they said something—and frequently edited for these new "oral mechanics"—as they were concerned with *what* they said. I have dubbed these new material concerns, *prosodacy,* referring to acoustic-phonetic features of the voice, paralinguistic features of speech, and the age-old art of poetics, composing words pleasing to the ear. This new distinction between literacy and letteracy, pushed to a radical position, means that it is possible for someone to be highly literate but not know how to read or write.

This paper presents quantitative and qualitative empirical data and observations from a study done when I was a doctoral student at the MIT Media Laboratory that show how spriting enabled children, ages 5 to 10, to compose, edit and reflect on their compositions in ways that differ in marked ways from their emergent writing practices. While the full scope of the investigation was very broad, including results on editing, collaboration, vocabulary, and singing, and technology development (Shankar 2005), my purpose here is to focus only on some very specific results in the children's editing practices.

My approach in this paper is as follows. First I describe the exploratory research method used, the three populations of children who assisted this work, and the dataset generated. Secondly, I provide a quantitative overview of composite composition and editing moves to sketch some overall trends between age groups and SES, typical predictive indicators of literacy development. Thirdly, I discuss how the introduction of a new compositional form can produce new insights into the composition process generally, as it permits comparisons where few have existed before. To do so, I present two learning stories of children spriting and how they handled the new challenge of integrating moments of pause for thinking. Finally, I conclude with a discussion

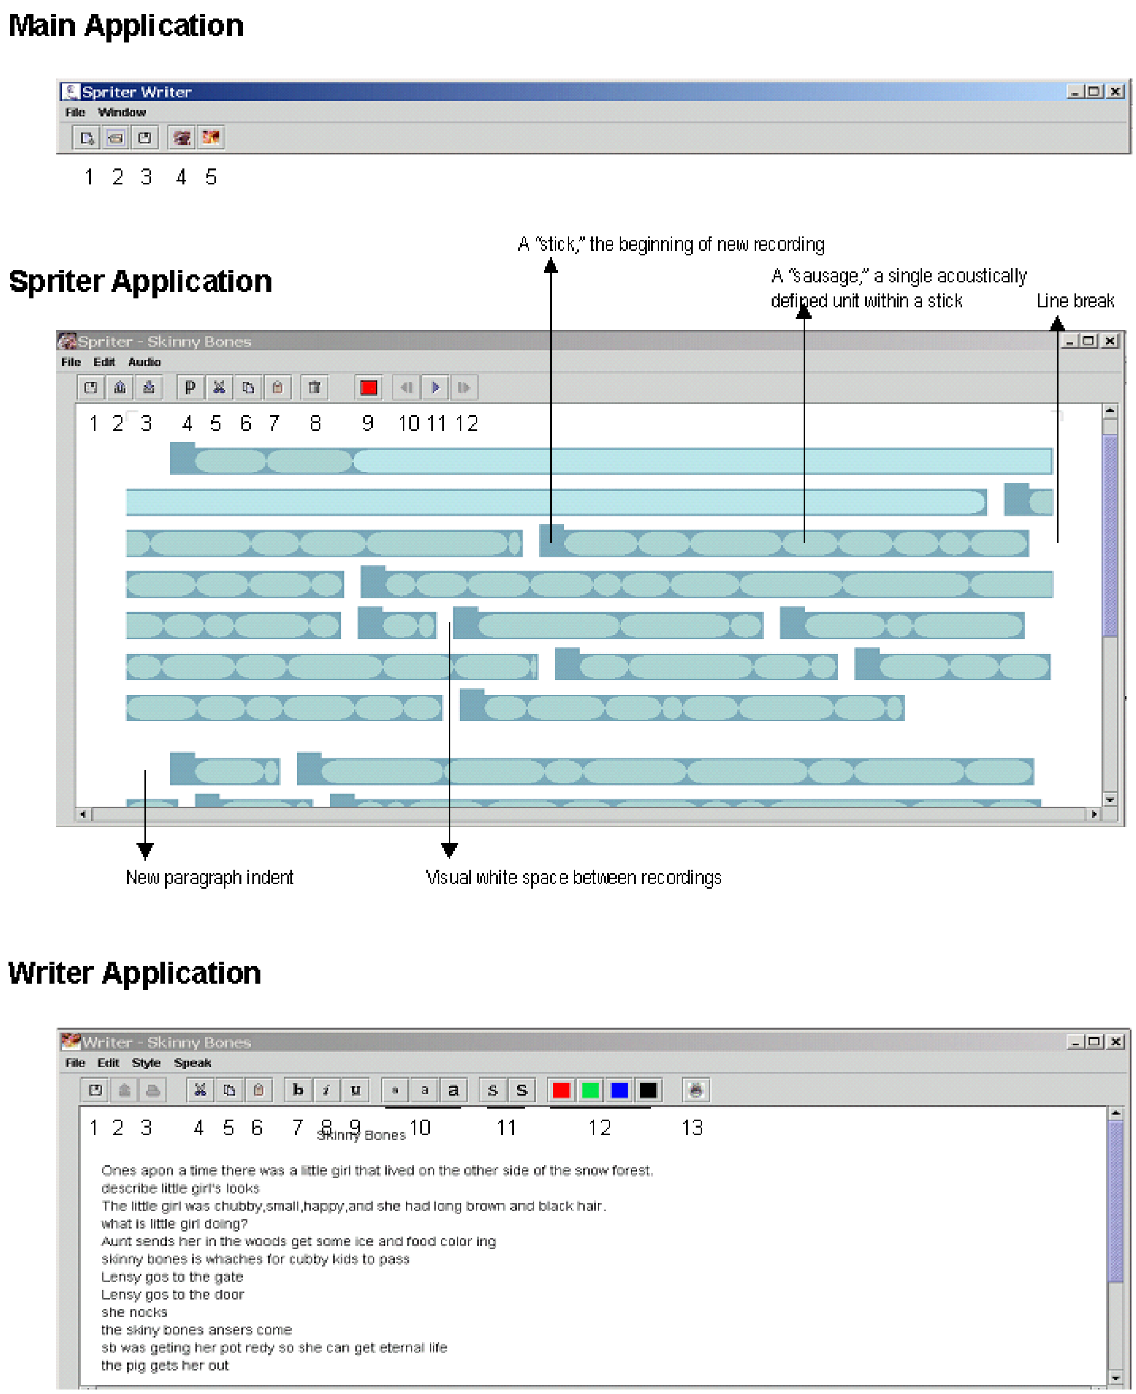

**Figure 1 The SpriterWriter interface.**

on implications for literacy learning.

## Methodology

I used a *design research* approach, inheriting from *design experiments*, which are also intended to evolve new learning technologies (Brown, 1992; Collins, 1992) and develop and refine new theories (diSessa & Cobb, 2004; Edelson, 2002) within real learning environments. Designing certain kinds of tools that challenge many dear cultural values, like writing, and require complex and sophisticated research, like spriting, might be seen as a process of evolving the ends of design as much as the means of design. While design work like this should prepare the way for many small kinds of experiments to follow, we must also allow time for design and cultural change to evolve contemporaneously. A design experiment approach was one way to allow the ends to evolve through the influence and needs of the learners themselves.

I performed initial exploratory and prototyping work with low-income adult learners in East Harlem, NYC, who were at elementary levels of letteracy learning. This research suggested that spriting can be a useful tool for supporting certain kinds of learning central to composition and editing. With particular questions and a spriting prototype, I undertook a thirteen week long study with children ages 5 to 10 at two elementary schools, here referred to as Umoja and Molière elementary schools, to explore how an improved spriting technology might contribute to their literacy and letteracy learning. I revised the software in cycles that ranged from a week to several weeks, according to my observations of its usability and the enthusiasm with which the children embraced it to do their work.

The design research experiments were conducted at two private elementary schools, both located in different urban-residential areas of a major city in the USA. The names of the schools and children referred to are pseudonyms. I call the first school Umoja Elementary, a private school founded upon African principals of community and culture (Nguzo Saba). The school functions as a one-room school house concept, not assigning children into grades per se. The students are children of color (Caribbean, African, African-American), low to middle SES, ages 5 to 10, and represented all the students in the school – not a select subset. The group ranged from 6 students when I began (referred to as the "older" Umoja students), and expanded to 11 students when the five/six year olds 'graduated up' (referred to as the 'younger' group) a few weeks later. The Umoja younger children were learning character formation rules at the time. While STEM activities were creatively realized in the Umoja curriculum, reading and writing activities were conventionally practiced with vocabulary words lists, fill-in-the-blank worksheets, some personal reflection writing prompts, and occasional stories read by the teacher. The children were invited to sprite once per week or more, and were able to decline if they didn't want to. For these children, choosing to sprite - whether or not they had the time, inspiration, and persistence to actually compose anything - must be understood as highly motivated and enthusiastic behavior.

The second school was Molière Elementary, a private French-English bilingual school. I offered an after school spriting club once a week, to which ten 3rd and 4th grade students responded (e.g. Irish, Russian, French-Canadian, French, and African families), a club which served to unintentionally self-select students from families with higher learning and research connections. The children were high SES, ranking in the top half of their classes in both French and English language exams; their school ranked in the top half of all independent schools. They had already learned to read and write in both French and English a wide variety of genres, including daily journaling activities, book reports, written poems and much more. The class was held for one hour on Thursday afternoons after regular school classes were out in the school computer lab in the basement.

The Moliere children, on the basis of their older age, longer and more extensive training in genre and composition forms often taught in schools, would be expected to make more sophisticated spriting products than both groups of relatively younger Umoja children. Differences between them cannot be attributed to their interaction with spriting. However, when certain behaviors, processes or products emerge in common between the schools—even against the predicted differences, these commonalities should be subjected to further analysis and interpreted in light of what spriting offers. In sum, how might spriting allow each child to exercise their current literacy skills, develop new abilities, and challenge themselves in powerful ways?

By acting as researcher, teacher, and technologist, I was able to exercise great flexibility in focusing and refocusing literacy activities on the fly, the technology on a weekly basis, as well as the classroom activities and forms of student participation with each other and with the computer. I judged an activity successful when the children had energy and long-term focus, spent a lot of time on editing, or requested more time. The definition of acceptable spriting work was something that the students and I continuously negotiated throughout the thirteen weeks at both schools as what could both sustain their interest and mine. However, the most unexpected results emerge from observing children's great enthusiasm for activities I did not suggest and was initially confused by. For example, although I initially framed a talkument as an intermediate product on its way to becoming a text, the children embraced talkuments as final products. Their energy and interest in making talkuments in turn encouraged me to adapt the technology to produce a better talkument product and to involve writing in ways that supported their spriting process rather than the other way around.

Data collection included video records of all spriting activities, saved daily versions of spriting work, saved records of interactions with the technology, examples of the students' writing from their regular classroom teachers, and detailed field notes. In total, the children from both schools produced a total of 197 compositions. To narrow and balance the descriptive analysis, I chose three to four solo compositions to transcribe from each child, a total of 67 compositions. Selection was based on the work's resemblance to or distinctiveness from written genres; its virtuosity relative to the child's other compositions; and the importance the child ascribed to it. The latter two factors often led to the same selection, as the work that interested them most was also the one that they worked hardest at. These 67 talkuments and all the recordings made in the process - even if ultimately deleted - were transcribed. Transcription includes notation of (filled) pauses and breathes, false starts, incomplete and unusually pronounced words using embedded XML marks, used for automated processing purposes, as well as to remind the reader that this is an imperfect and partial translation of speech, impossible to capture fully in all of its *material repleteness*. When children are trying the hardest to transform thought, feeling and intention into words is when their speech is most fragmented (Chi, 2000). The transcription attempts to draw attention to these periods of intense linguistic construction.

Since the time when I performed this work, podcasts, moblogging and other voice publication methods have emerged as legitimate and authentic purposes for real-time voice composing, making this work all the more relevant as the means of distribution of such work are emerging. Understanding the importance that children attribute to spriting and talkuments becomes even more critical for how it might inform current literacy practice and pedagogy, and how it might presage future literacy trends.

## Overview of the Composition and Editing Actions

Looking across the 67 transcribed talkuments including both individual and collaboratively composed talkuments, there is strong evidence that all children, ages 5-10, composed at length, reviewed and edited their work. Considering that at the time the youngest children were working hard to write their names, this result alone, when compared to standard letteracy development comparisons across the same ages, is a striking result. Within this general trend, there are indications of developmental differences. In order to see these developmental trends, the data is organized in to three different groups descending in average age: Molière children (ages 8-9), the older Umoja children (ages 6-8, 10), and the younger Umoja children (ages 5-6).

**Table 1 Record and Play composing moves, Recording lengths, and Total Words.**

| | | Record Actions (#) | Play Actions (#) | Record then Play Consecu. | Recording Len. Each (sec) | Talkument Len. Total (sec.) | Words Total |
|---|---|---|---|---|---|---|---|
| **Moliere** | N | 31 | 31 | 30 | 31 | 32 | 32 |
| | AVE | **18.29** | **31** | **8.7** | **37.2** | **349.3** | **359.2** |
| | SD | 17.7 | 30.3 | 7.2 | 34.4 | 216.6 | 276.4 |
| **Umoja older** | N | 25 | 22 | 21 | 25 | 25 | 24 |
| | AVE | **8.6** | **17.2** | **4.5** | **46** | **273** | **222.3** |
| | SD | 6.1 | 14.3 | 4 | 47.8 | 214 | 168.2 |
| **Umoja younger** | N | 10 | 10 | 10 | 10 | 10 | 10 |
| | AVE | **9.8** | **30.3** | **6.2** | **44.4** | **358.9** | **256.2** |
| | SD | 6.3 | 25.6 | 4.6 | 30.5 | 268.1 | 207.2 |

In Table 1, the average number of Record and Play actions per talkument are presented for each group. The Molière children, as predicted by their older average age, made an average of 18 recordings per talkument, and listened to their spriting on average 31 times per talkument. The Umoja children made more or less the same number of recordings per talkument.

While the Molière children tended to make more recordings, they also tended to make slightly shorter recordings (37 sec on average in Table 1 column "Recording Len. Each"), tending towards a more bricolage, piecemeal construction process than all the younger Umoja children. This "bits and pieces form a whole" style emerged after a few weeks in a couple of the Moliere children who desired extreme control over their talkument product. Most children at both schools tended towards long spoken expositions, with a few gross post hoc edits.

As presented in Table 1, total talkuments lengths ranged from 270 to 360 seconds for all children—with the youngest children producing the longest talkuments! This is exactly the opposite of what one would predict in writing, and an extremely important insight into what spriting can offer literacy development – composition length is no longer a bellwether indicator of literacy development. Length of talkument, however, does not predict the number of words used. Older children had more fluency with spoken language and greater grasp of compositional planning, thus averaging a little more than one word per second (359 words in 349 seconds) while the youngest averaged approximately 2/3 a word per second (256 words in 358 seconds).

Older children tend to have composition plans that exceed a single recording action. In Table 1, the 'Record then Play' column indicates the sequential relationship between recording and playing actions. The Molière children immediately listened to only 8.7 out of the average 18.29 recordings they made, while the younger Umoja children listened immediately to 6.2 out of an average 9.8 recordings—2/3 of all their recordings. I observed the older children make several recordings consecutively and then listen to a group of them, while the younger children composed in a record-listen-record-listen cycle, the next move inspired by what they have just heard. Interestingly, the youngest children also listen more often to their own recordings—in Table 1 their record-play ratio is 1:3 compared to the older children's 1:2. Thus, there are indications of a developmental trend towards making shorter, more numerous recordings that are listened together as composites (not individual recordings), in a review cycle that occurs less frequently.

**Table 2 Average editing moves per talkument.**

| | | *Delete* | *Move* | *Split* |
|---|---|---|---|---|
| **Moliere** | N | 30 | 17 | 14 |
| | AVE | **11.8** | **8.8** | **9.1** |
| | SD | 11 | 12.6 | 20.6 |
| **Umoja older** | N | 20 | 4 | 10 |
| | AVE | **8** | **4.8** | **3.2** |
| | SD | 6.6 | 4.9 | 3.2 |
| **Umoja younger** | N | 9 | 5 | 7 |
| | AVE | **9.9** | **3** | **5.1** |
| | SD | 10.5 | 2 | 4.7 |

Children engage in editing moves through spriting even before they know how to write. As they get older, they engage in even more editing moves. Table 2 shows that the younger Umoja children delete and move content, and make splits. The Molière children make on average 12 deletions and move sausages nearly 9 times *per talkument*, and they make finer edits by splitting content when necessary. The standard deviation for split edits is very high because children used splits in only certain talkuments and certain situations. The older Umoja children fit somewhere in the middle of these two groups as they begin to compose lengthy and purposeful talkuments. Spriting might be treated now as a complementary process to writing in the elementary years, both spriting and writing processes eventually to equalize in length and complexity.

## Manifestations of Planning Processes in Spriting

The spriting process affords new insights into composition generally, and might provide new insights into the general theory of composition process—heretofore examined only through the window of writing behavior. For example, planning processes in spriting are very different from what children seem to experience when writing. In spriting, several children learned that planning is a time for *pausing*.

I encouraged the children to take intentional moments for thinking. This kind of thinking activity is often called "planning" in the writing process literature, but has unfortunately been co-opted in most school settings with highly structured activities for purposes of global planning (e.g. outlines, templates, concept maps, et cetera) that should occur "first" in the composition process. Though these devices can be useful, they do not supplant the need for thinking throughout the composition process, sometimes called "local planning" in writing composition research. Ironically, the value of these kinds of global planning devices might be more recognizable, and even more necessary, in the spriting process than in the writing process, when children discover for themselves how useful broad composition plans are when writing mechanics are not the primary obstacles.

Many children become frustrated when spriting—and even frightened away from trying to sprite—by the immediacy of the task. They find that the words they expect to be there are *not* there. They fall into a silence they find uncomfortable, even unbearable. Because children talk easily when they respond to adult questions or when they converse with their friends, they seem to expect that words will always emerge to accomplish the task they have set for themselves. When they watch television, they see people who always know what to say. They see politicians answer questions no pause. We have few public models of people pausing to think before talking. Therefore, it is not surprising that children, even if they have very little experience writing or spriting literate compositions, do not expect that thinking could take time.

In writing, the time to get something down on paper or screen is much longer than speech (300% to 400% longer even for an expert typist). Therefore, the time spent thinking and planning comes for 'free' while a child struggles with mechanical production. I saw many children struggle initially with the fact that they could not say everything they wanted to in one long, synchronous recording, as they felt they did when writing. They would get frustrated at their self-perceived lack of fluency, erase everything and start over again. The idea that thinking is doing something had not seemed to occur to them before. Writing may be less conducive to cultivating the habit of mind to pause to think during composition. Spriting seemed to help students learn aspects of composition that they may have performed implicitly while writing, due to the slower mechanics, but had not realized they did so in such a way as to use this cognitive skill flexibly.

In spontaneous speech, Frieda Goldman-Eisler (1958) claims that pauses provide an external window on internal cognitive processes, and that pause lengths increase with task abstraction and 'explicitness' – a feature correlated with how familiar/unfamiliar the conversants are with each other. When I began the design research, I believed that pauses, filled (e.g. um, uh) or empty, should be reduced and minimized respectively as a feature of editing a talkument from intermediate to final product. I learned from the children that pauses – both filled with a delightful variety of sounds and empty – could be indispensably important to a talkument. Next, I tell two learning stories of how pauses were important in spriting. Neither describes the general case of learning to pause but instead complicates the notion of what pausing to think should be. These stories demonstrate that a single, global approach to pauses in spriting (pedagogically, technological support, etc.) would not only be difficult to achieve in practice, but might also be undesirable.

## Madeline Likes Her Pauses

In the fourth week of spriting class at the Molière Elementary, I devised an activity intended to focus the children on editing, and in particular to remove what I considered long and unnecessary pauses. They were to create a talkument with three short stories. If any story exceeded four spriting lines in length, they were to edit it down. They could consult with friends to figure out what might be eliminated. The best story was to be placed first in the composition (by dragging and dropping). Although complicated, the children understood these directions and produced some material that was amongst their best work for the entire spriting class.

Eight-year-old girls, Madeline and Emily, finished quickly and were the first to listen to each other's compositions. I instructed them also to point out long silences to their partner. Emily must have commented to Madeline that her composition had too many long silences. Madeline motioned me over to discuss this.

My composition has many long silences. Do I have to remove them? She said. Actually, I like the silences.

Why is that? I asked.

When I talk I often use long silences.

Well, just because your talk has long silences doesn't mean you want your composition to be exactly the same. The person listening to this will not be able to look at your face when hearing your talkument, they can only hear your voice. Sometimes when you aren't saying anything, your face says something instead. But in a talkument you can't use your face. So make sure that the silences are useful.

Clearly I didn't get her point, so she tries to restate it differently.

I also use a long pause before something scary. So, I prefer to keep them.

It hits me. She's referring to the use of pauses for dramatic effect, a performance issue an oral storyteller would be very concerned with. Using pauses for dramatic effect demonstrates a mature sense of verbal storytelling. Pauses are not always emblematic in spriting of an internal cognitive struggle to produce words. If these dramatic pauses were removed—or even shortened—automatically by the spriting technology, Madeline's mature compositional purposes would be destroyed.

Due to this and other experiences that demonstrated a usefulness and meaning to pauses that I had not considered before, I disabled the SpriterWriter's technological support for automatically shortening long pauses.

## Niesha's Beats as Pause

Niesha, an eight-year-old child at Umoja Elementary, had a gift for beats. These beats consisted of lip smacks, purses, sucks, kisses, clicks, hummed bars from songs, and more, all merged together into a drum rhythm that accompanied her spriting. Many of the Umoja children were able to create inventive, spontaneous rhythms with their voices, whereas none of the Moliere children could. Certainly a familiarity with rhythmic talk as heard in rap and hip-hop contribute to their able improvisation. But Niesha was particularly gifted amongst her classmates. She enjoyed making her compositions a continuous, unbroken weave of rhythm, talk and song. For example, here is a transcribed excerpt from one of her compositions:

> I like (.) hmm {VOC mouth sounds} (7.4) I like spaghetti, {VOC mouth sounds} I like chicken {VOC mouth sounds} spicy chicken {VOC mouth sounds} I like Chinese food, the rice the Chinese rice and the (.) red - no the orange chicken (inaudible) they are so good if you eat them your mouth bam! if you eat the orange chickens. {VOC mouth sounds}

This example is the first in a series of talkuments in which she uses descriptive and journal-like talk coupled with these drum-like mouth sounds and excerpts from songs to describe foods she likes and its effect upon her. In between each mention of a food, she made what she called a 'beat.' Beats for Niesha include sounds she makes with her mouth, song excerpts, and small bits of Americana like "Peace", "Ho Ho Ho Merry

Christmas". Her beat is nearly impossible to transcribe to text. The (inaudible) mark in particular, and the {VOC mouth sounds}, often stands for sections of spriting that simply have no textual equivalent.

One of Neisha's primary goals was to make long talkuments; she bragged about the great length of her spriting multiple times to me and to her teacher. How ridiculous our goals for mature writing, such as length, appear when they are transplanted into another media like spriting in which they are so easily achieved! Her composition approach was typical of most children at both schools. She first recorded one or two continuous recordings and then edited these by adding or deleting a few major narrative chunks. I dubbed this editing approach "chunk insertions". This composition strategy required great fluency, and children had to devise ways to plan what to say next while they were recording. Niesha appears to use beats as pausing time. Her nearly automatic ability to perform beats allowed her to time to construct her next thoughts. The effect of this strategy is a kind of stream of consciousness flood of verbal and sound images from Niesha's life experience.

## Discussion

The quantitative descriptive overview and qualitative examples are meant to suggest very different kinds of conclusions than those that have dominated literacy research, particularly with respect to the ascribed importance of writing and text in literacy development. When children are learning to speak, they explore issues both great and small simultaneously. But only a few years later when they begin school, they focus intensely on the letterate issues – the smallest units of writing composition, and neglect practice of literate concepts for several more years. The introduction of spriting at beginning levels of letterate and literate development appears to allow children practice with extended forms of literacy and habits of mind such as review and editing well before they can properly execute the full character set.

One specific issue discussed here is the importance of learning a literate habit of mind – that is, to recognize the need to make composition plans. In written discourse, planning comes for free with the longer written mechanic requirements. But spriting speeds up the composition process to a pace that resembles spontaneous speech, but lacks most if not all of the social supports. To characterize the importance of pauses in literacy development, it would be helpful to distinguish two different kinds of learning. The first is actually learning to do something; for example, learning how to sing. The second kind of learning is to be conscious of *how* one actually does that thing. This distinction might be related to Karmiloff-Smith's concepts of implicit and explicit knowledge (1992), sometimes also referred to as meta-discourse or meta-awareness. She writes that the ability to do something (implicit knowledge) can disappear for a time as the knowledge of how to do this thing shifts to making hypotheses about how one actually does this (explicit forms). Although both types of learning are not required for action (obviously, just learning how to do something is often enough), it is sometimes critical to know how one actually does it in order to deploy the ability when the usual supports are not available. Spriting allows students to discover habits of the literate mind that they may already do when writing, but do not understand or identify as actions involved in composing. Spriting forces them to think about—and potentially develop new hypothesis for— how they go about the process of composing. If children have the ability to make more aspects of the composition process explicit, they can control these skills in both their written and spoken compositions.

**Abstract:** This study examines use of knowledge space theory as a novel method of analyzing concept maps. Concept mapping is a technique for expressing relationships between ideas, using two-dimensional node-link diagrams to visually display relationships between ideas. We introduced concept mapping as a voluntary exercise in an upper-level undergraduate immunology course. The students were assigned ten concept maps (for which concept lists were provided) at intervals during the semester-long course. We utilized knowledge space theory (Folmagne & Doignon, 1988) to systematically analyze and compare concept maps drawn by students to their instructor's "expert" concept maps. Using this novel analysis method, we were able to reveal students' level of understanding of course material, changes in student knowledge across time, as well as identify students' alternative conceptions. We found knowledge space theory a productive tool for systematically analyzing and comparing students' concept maps across time and to expert's concept maps.

## Introduction

Concept mapping is a technique for externally depicting students' internal knowledge structures. Students construct concept maps by using labeled linking lines (propositions) to show relationships between ideas or objects (concepts). The process of constructing a concept map helps students build a deeper and more meaningful understanding of content material (Novak & Gowin, 1984). Concept maps are a useful pedagogical tool because they allow teachers to visualize students' knowledge structures. This allows teachers to structure lessons to expand upon students' existing knowledge structures (Edmondson, 2000; Marbach-Ad et al., 2007; Okebukola, 1990). Despite the successful instructional use of concept maps, they have proven difficult to use for assessing student knowledge.

In part this difficulty is due to the various concept map assignments, instructions and analytical techniques or scoring procedures. Some concept mapping assignments ask students to generate the important concepts for a topic, others ask students to fill in the propositional statements on the linking lines on a pre-drawn concept map, and still others ask students to construct a map from a list of important concepts. Concept mapping instructions might ask students to draw hierarchical relationships and crosslinks between concepts whereas others simply ask students to connect concepts together using propositions. Some concept map analytical techniques evaluate maps based on the degree of hierarchy and crosslinking between hierarchies, other scoring procedures are based upon the number of concepts and propositions in the map, and still other methods attempt to rate the quality of the propositions and crosslinks in the map. Ruiz-Primo and Shavelson (1996) wrote a review highlighting the myriad array of concept mapping tasks and analytical techniques or scoring procedures. In their paper, Ruiz-Primo and Shavelson call for researchers to more carefully design concept mapping assessment tasks to align with cognitive theories. They also stress the need to establish the validity and reliability of analytical techniques for concept map assessments before widespread implementation of the assessment.

Many researchers (e.g., Okebukola, 1990; Markow & Lonning, 1998; Trowbridge & Wandersee; McClure et al., 1999) have experimented with different concept mapping tasks and analytical techniques to develop concept mapping assignments that provide effective assessments of student knowledge. Novak and Gowin (1984) outlined a quantitative scoring procedure for hierarchical concept maps in their original book introducing the concept mapping technique. In this scoring method, each valid proposition was assigned 1 point, each hierarchical level of the map was assigned 5 points, and each valid and significant crosslink between branches was assigned 10 points. The sum of these points established the overall score for the concept map. Novak and Gowin's scoring technique is useful because it differentiates between simple and complex maps numerically; however, the technique depends upon the hierarchical nature of the concept map. In contrast, Kinchin, Hay, and Adams (2000) developed a qualitative method of analyzing student's concept maps. The method involves determining if the concept map's structure is best described as a spoke, chain, or net of propositions connecting concepts. This technique allows for a rapid determination of the complexity of the concept map. However, it does not account for the quality of the concept map. McClure et al. (1999) conducted a study in which they attempted to establish the reliability and validity of a relational scoring procedure for concept maps. The technique involves assigning a numerical quality rating to each proposition in a concept map.

Similar to Novak and Gowin, the sum of the numerical quality ratings for each proposition was used to represent the score for the concept map. This technique is useful because it incorporates the quality of each proposition into the concept map score. However, the relational scoring technique only provides information about a student's knowledge relative to other students. The relational scoring technique does not provide instructors with information about students' alternative conceptions or concepts that may need further instruction.

Despite the utility of each of the above analytical techniques, many questions remain about the theoretical rationale behind such techniques and the validity and reliability of each procedure. There is a need for the development of alternative procedures for systematically analyzing concept maps to reveal information about students' knowledge structures. Knowledge space theory (Folmagne & Doignon, 1988) offers one potentially useful procedure for systematically analyzing concept maps. Knowledge space theory (KST) is a mathematical theory that allows researchers to represent the state of a student's knowledge, referred to as a knowledge space, at a precise point in time using a series of assessments. The first step in determining a student's knowledge space involves carefully designing a set of questions that each measure knowledge of a discrete concept. The set of questions is administered to the student and scored for correctness. The unique combination of concepts, represented by the correctly answered questions, comprises a students' knowledge space. KST is useful to educational researchers because it allows for the systematic comparison of students' knowledge in a particular domain across time and compared to experts (Folmagne & Doignon, 1988). KST was originally designed to help researchers examine students' knowledge spaces in mathematics domains, but has also been shown to successfully represent student knowledge in science (Taagepera et al., 1997). By administering the same survey throughout a semester of chemistry, the researchers determined potential learning pathways. That is, students appeared to learn additional concepts in discrete series. Figure 1 illustrates an example critical learning pathway for chemistry students.

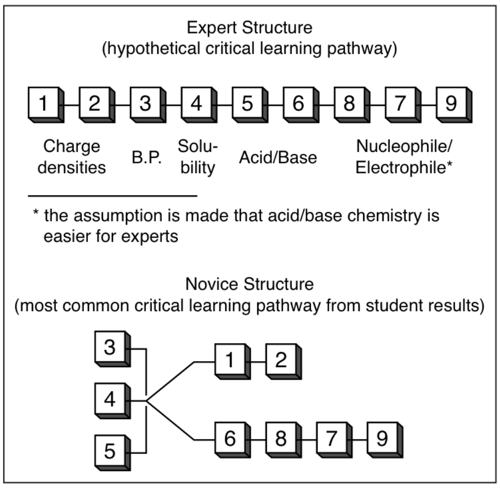

Figure 1. Critical learning pathways for novices and experts. (Taagepera & Noori, 2000).

In the present study, we applied a modified KST framework to analyze concept maps created by students enrolled in an undergraduate immunology course. We focused on examining the composite of students' knowledge spaces across time and to the instructor's knowledge spaces. In contrast to the KST approach of identifying correct answers to assessment questions, we built student knowledge spaces by identifying the presence or absence of propositions linking concept pairs on concept maps. Due to the voluntary nature of the concept mapping assignment, our data was not conducive to comparing change in individual students across time. Rather, our results indicate that analysis of concept maps with the KST framework permits the identification of the relative frequency of domain concepts in a population of students as well as notable alternative conceptions. The KST framework is also useful for highlighting similarities and differences between instructor's and students' concept maps.

## Methods

An instructor employed concept maps as instructional aids in a team-taught undergraduate introductory immunology course. The course consisted of two 1-hour lectures and one 1-hour discussion per week. Students were given a brief overview of the concept mapping technique and the instructor demonstrated construction of a sample concept map at the start of the course. On 10 separate occasions in the course, students were assigned concept maps on specific lecture topics: B Cell Development, Germinal Centers, Major Histocompatability

Complex, T Cell Development, Costimulation, Cytokines, Autoimmunity / Tolerance, Alloreactivity / Immunosuppression, Vaccines, and Immune Responses to Tumors. For each map, the instructor provided students with 11 to 17 concepts (M = 14) central to the corresponding lecture topic to use while constructing each concept map. Note that several of these concepts were present on multiple concept map assignments. Students received 1% extra credit towards their final course grade for completing 5 of the concept maps. After students submitted their concept maps, the whole class received a concept map on the same topic created by the professor. We analyzed 208 concept maps collected from 89 students enrolled in the course of 98 students. Of the 89 participants, 52 completed one or more concept maps and 37 completed five or more concept maps. Table 1 illustrates the total number of concept maps completed for each lecture topic. Due to the voluntary nature of the assignment, a different set of students completed concept maps for each lecture topic.

Table 1. Number of submitted concept maps for each lecture topic.

| **Lecture Number** | **Lecture Topic** | **Number of Submitted Concept Maps** |
|---|---|---|
| 6 | B Cell Development | 27 |
| 6 | Germinal Centers | 25 |
| 8 | Major Histocompatability Complex | 24 |
| 11 | T Cell Development | 23 |
| 13 | Costimulation | 17 |
| 15 | Cytokines | 18 |
| 21 | Autoimmunity / Tolerance | 20 |
| 22 | Alloreactivity / Immunosuppression | 27 |
| 24 | Vaccines | 17 |
| 25 | Immune Responses to Tumors | 10 |
| Total = 26 | | Total = 208 |

The concept maps constructed by the instructor and students were exclusively network concept maps that included “a semantic network with concept nodes linked directionally by labeled lines (arrows) to produce propositions” (Ruiz-Primo & Shavelson, 1996, p. 572). Unlike hierarchical concept maps, network concept maps are not arranged in a hierarchical nature (Novak & Gowin, 1984). Figure 2 illustrates an example student concept map for the B Cell Development lecture topic.

All of the concept maps were analyzed using the KST framework. We used the propositions in each concept map in place of the discrete conceptual questions used in traditional applications of KST. For each set of concept maps from a lecture topic, every unique proposition was assigned a letter or number code. All propositions generated by the instructor (those that appeared on the instructor’s map for the topic) were assigned a number; the list of numbered propositions for each topic was set by the instructor’s concept map. This list was then compared to each student’s concept map to identify the instructor-generated propositions on students’ concept maps. All propositions generated by the students (those that appeared only on students’ maps for the topic) were assigned a letter. The list of lettered propositions for each topic grew as each student’s concept map was analyzed. This list was then compared to each student’s concept map to identify the student-generated propositions. Akin to the techniques used in traditional KST, the unique combination of propositions, represented by numbered and lettered codes on each concept map, represent a student’s knowledge space for that lecture topic.

In this study, we did not focus on comparing individual student’s knowledge spaces; instead we focused on comparing a composite of students’ knowledge spaces across time and to the instructor’s knowledge spaces. The frequency of numbered (instructor-generated) and lettered (student-generated) propositions was calculated for each lecture topic. We constructed composite maps (See Figures 3 and 4) for each lecture topic to help interpret and visualize the changes across time and the differences between the students’ and the instructor’s knowledge spaces. Instructor-generated propositions were highlighted in **bold** text on the composite map if they appeared on less than 50% of student concept maps. The threshold was set at 50% indicating the potential need for instructional intervention in the classroom as opposed to individual student errors. Correct student-generated propositions that were not indicated by the instructor, were highlighted in CAPITAL text. Incorrect student-generated propositions were highlighted in *ITALICIZED CAPITAL* text if they appeared on more than 25% of student concept maps. The threshold was set at 25% indicating the possible presence of a shared alternative conception among students as opposed to an individual student's misunderstanding.

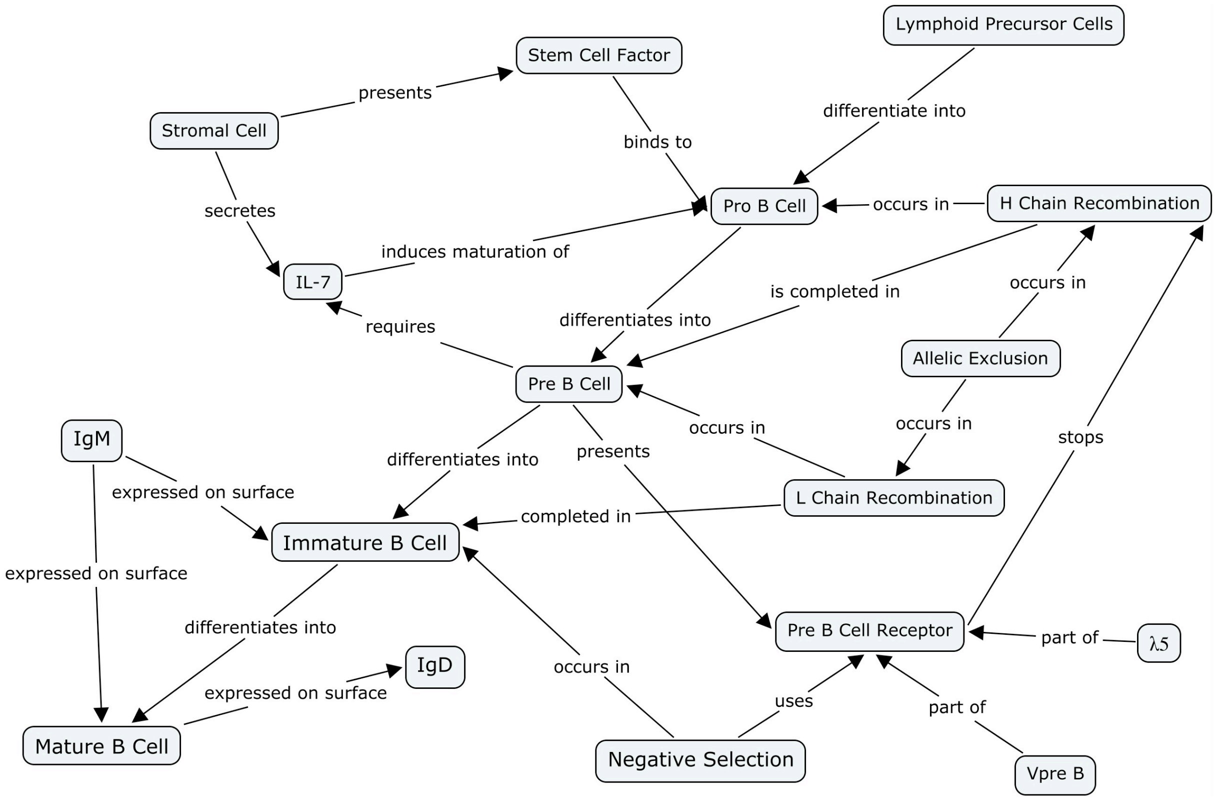

Figure 2. Example Student B Cell Development Concept Map. Concepts are the ideas enclosed in rounded boxes. Propositions are represented as directional arrows labeled with a linking phrase.

## Results

Knowledge space theory proved useful for comparing students' concept maps across time and to their instructor's "expert" concept maps. Generating the composite maps for each concept map lecture topic, systematically summarized the knowledge spaces represented by the students' concept maps in comparison to the instructor's "expert" concept map. By calculating the frequency with which the propositions from the instructor's concept map appeared on student's concept maps, the researchers were able to systematically highlight the differences in knowledge structures between the students and the instructor.

Despite the uniqueness of each concept mapping lecture topic, we were able to compare students' knowledge spaces across time, because some of the same concepts appeared in several of the assigned concept maps for different lecture topics. The B and T cell development concept maps provided a unique opportunity to compare the development of students' knowledge spaces over the course of the semester. The B cell development lecture topic concept map was the first map assigned during the semester. The T cell development lecture topic concept map was the fourth concept map assigned during the semester, after the students had taken and received feedback for an exam on B cell development. B cells and T cells both initially share similar development processes that diverge later in the developmental process. However, several of the processes that regulate the development of B cells are common to T cells as well. This unique situation allowed the researchers to analyze the change across time of students' knowledge spaces on the common processes in B and T cell development. Figures 3 and 4 illustrate the composite maps for the B and T cell development lecture topics. KST analysis of the B and T cell development concept maps revealed both positive and negative changes in students' knowledge and relatively stable student knowledge structures.

Comparison of the B and T cell development concept maps revealed an improvement in students' understanding of some concepts across time. Analysis of the B cell development composite map indicates that only 30% of the students included information about the interaction of the lymphoid precursor cells with the stromal cells. The T cell development composite map indicates that information about the interactions between the lymphoid precursors and the stromal cells appeared in 95% of the students' knowledge spaces. This dramatic change in the appearance of a proposition indicates a significant improvement in students' understanding across time.

KST was also useful for identifying positive changes in students' knowledge, such as student-generated propositions that were not emphasized by the instructor. More than a quarter of students' concept maps from the T cell development concept maps included student-generated propositions about the interactions between the lymphoid precursor cells and the stromal cell effector molecules, IL-7 and stem cell factor. These interactions were not indicated by a significant percentage (more than 25%) of students on the B cell development concept maps. Despite the accuracy of these student-generated propositions, the instructor had not included the propositions on his "expert" concept map because he was not trying to emphasize these particular relationships between the concepts. KST analysis proved useful for highlighting improvements in students' knowledge that would not necessarily have been identified using other assessment techniques.

Using KST to analyze students' concept maps also allowed researchers to show the change over time in the frequency of alternative conceptions in students' knowledge spaces. An average of 50% of students' B cell development knowledge spaces indicated a correct understanding of the role of allelic exclusion in B cell development. The appearance of the correct understanding of the role of allelic exclusion had decreased to less

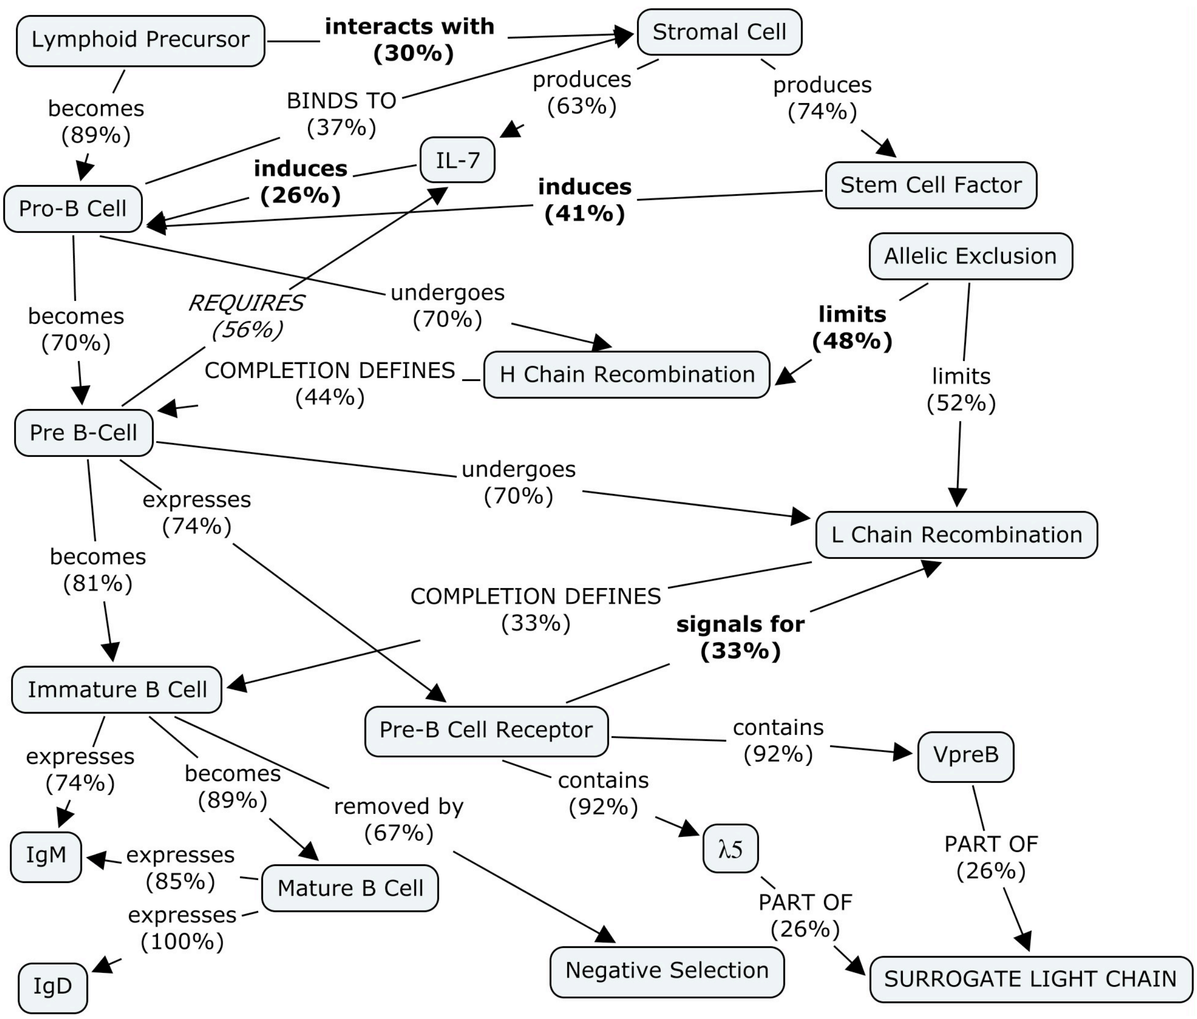

Figure 3. B Cell Development Composite Concept Map. Numbers in parentheses represent the percentage of student concept maps containing each proposition. Normal text represents concepts and propositions generated by instructor. **Bold** text represents propositions generated by the instructor that appear on less than 50% of student concept maps. CAPITAL text represents correct concepts or propositions generated by more than 25% of students. *ITALICIZED CAPITAL* text represents incorrect propositions generated by more than 25% of students.

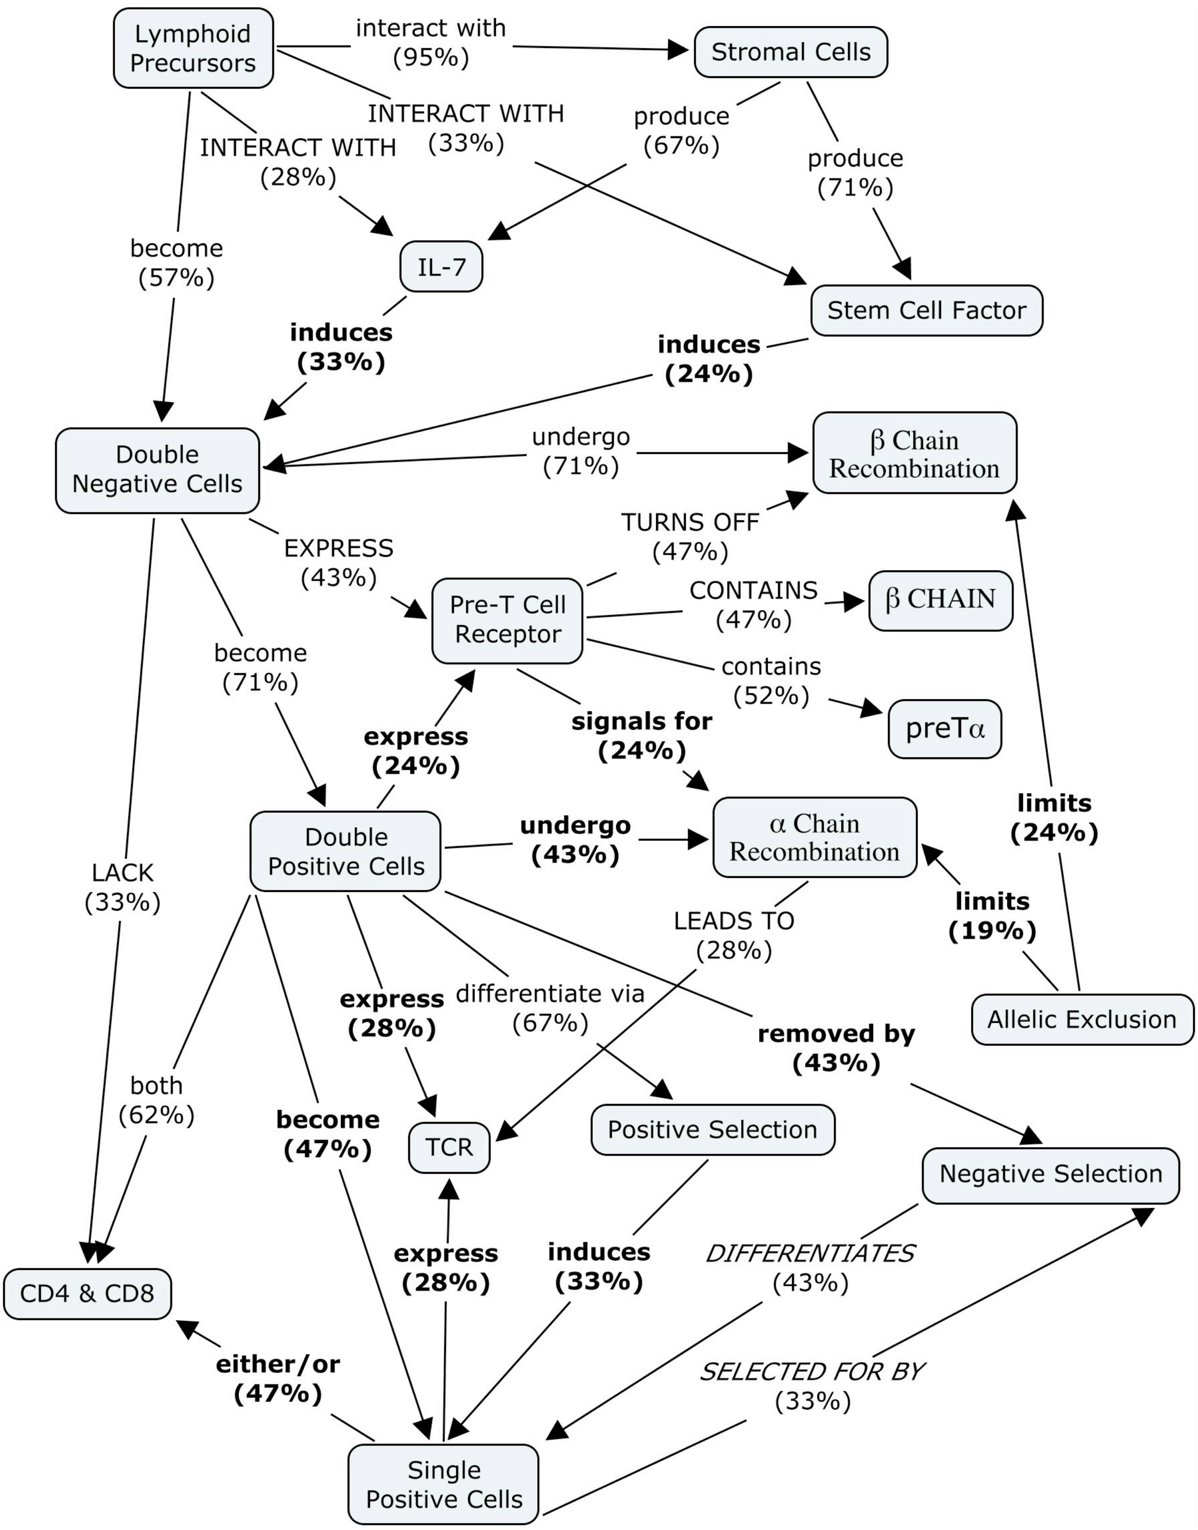

Figure 4. T Cell Development Composite Concept Map. Numbers in parentheses represent the percentage of student concept maps containing each proposition. Normal text represents concepts and propositions generated by instructor. **Bold** text represents propositions generated by the instructor that appear on less than 50% of student concept maps. CAPITAL text represents correct concepts or propositions generated by more than 25% of students. *ITALICIZED CAPITAL* text represents incorrect propositions generated by more than 25% of students.

than 25% in the students' T cell development knowledge spaces. A possible explanation for this change is that on average, students had a weak understanding of allelic exclusion in B cell development. T cell development is a more complicated process compared to B cell development and perhaps this exacerbated students' misunderstandings of allelic exclusion.

The technique of KST analysis of concept maps was limited by its ability to detect students' alternative conceptions at low frequencies. The process of negative selection was correctly indicated in less than 50% of students' T cell development knowledge spaces. Two incorrect alternative conceptions about the role of negative selection appeared in more than 25% of students' T cell development knowledge spaces. Our initial analysis did not reveal alternative conceptions about negative selection in students' B cell development knowledge spaces. Upon further analysis, 10 different alternative conceptions about negative selection were identified in student' B cell development knowledge spaces; however, all appeared at frequencies less than 25%. The thresholds set by the researchers limit KST analysis of concept maps, but these thresholds are flexible and can be adjusted as needed to detect different frequencies of students' alternative conceptions.

KST analysis of the B and T cell development concept maps also revealed concepts for which students' understanding did not improve over time. There was no significant change in the appearance of propositions about the interactions between the two stromal cell effector molecules, IL-7 and stem cell factor, with the lymphoid precursor's respective progenitor cells, the pro-B cells or double negative cells. On the B cell development composite concept map, only 26% (IL-7) and 41% (stem cell factor) of students' maps included propositions relating the stromal cell effector molecules to the pro-B cells. On the T cell development composite concept map, only 33% (IL-7) and 24% (stem cell factor) of students' maps included propositions relating the stromal cell effector molecules to the double negative cells. KST analysis revealed problematic concepts for which student knowledge remained relatively stable and did not improve over time with further instruction.

By analyzing students' concept maps with KST we were able to extract very fine detailed information about changes over time in students' knowledge spaces for lymphocyte development. KST analysis highlighted both targeted and unexpected improvements in students' knowledge across time. Analysis of students concept maps by KST revealed alternative conceptions and allowed us to track the changes in frequency of these alternative conceptions as further instruction was given about the concepts over time. KST analysis also highlighted problematic concepts for which students' knowledge was relatively resistant to instruction and remained constant over time.

The above examples have strong technical content that can obscure the critical viewpoints generated by this research. The research above used examples of immunology based concepts; however, we propose that the KST method of analyzing concepts maps can be expanded to any subject at the primary, secondary, undergraduate and even graduate levels. Using KST to analyze concept maps enhances the instructional usefulness of concept maps for both students and instructors. KST is a powerful technique for analyzing concept maps to understand a student's knowledge space at a given time, elucidate misconceptions held by a significant proportion of the students, and identify correct student-generated ideas. KST combined with concept mapping assignments has the ability to improve instructor clarity and students' perception, increase students' understanding of concepts, and assist instructors in constructively addressing students' misconceptions.

## Conclusion

Concept mapping is an effective pedagogical technique; however, concept mapping has proven challenging to use as an assessment. The KST framework is a theory driven, systematic method of analysis that can be used to evaluate the content of concept maps. We found that analysis of concept maps with the KST framework is a productive method for examining change across time in students' knowledge spaces. We also found that analysis of concept maps with the KST framework effectively highlights details of the similarities and differences between students' and instructor's knowledge spaces.

KST analysis of concept maps is productive because it is sensitive to both the omission of conceptual ideas from students' knowledge spaces and the addition of alternative conceptions to students' knowledge spaces. The technique also allows instructors to rapidly and systematically identify major themes in students' knowledge from the vast array of information contained in students' concept maps. The range of analysis times for each set of concept maps from a lecture topic was between 1 and 4 hours. The analysis time depended on the number of concepts assigned for each lecture topic and the overall similarity between the students' and instructor's concept maps. The median analysis time for the sets of concept maps was approximately 2 hours. There is the potential for computer software to assist in the analysis of concept maps using KST and shorten the analysis time. An ideal program would generate a list of all propositions linking two concepts. From this list, the researcher could easily count the number of propositions similar to the instructor's and identify frequently occurring alternative conceptions.

One limitation of using KST to analyze students' concept maps is that the researcher sets the thresholds for highlighting differences between students' and instructor's concept maps. If the threshold is set too high, it can reduce the sensitivity of the technique to subtle differences in students' knowledge spaces. The analysis time of the KST method increases as the thresholds are lowered. Lowering the thresholds also dilutes the major findings of the analysis by highlighting minor, possibly less important differences in students' knowledge structures. Despite this limitation, KST enhances the pedagogical usefulness of the concept mapping technique as a formative assessment because it provides instructors with a productive framework for systematically analyzing students' patterns of understanding and misunderstanding.

Future research can expand upon our use of KST for analyzing concept maps to include comparison of individual student's concept maps across time to identify changes in individual student's knowledge structures. In addition, more research is needed to establish the reliability and viability of using KST for analysis of concept maps from a wide variety of subject matters across a range of levels of students. KST analysis of concept maps should be compared to other established techniques of measuring students' knowledge structures, such as traditional KST applications and other standardized assessment techniques. We hope that other researchers will elaborate upon and expand the application of the KST framework for analyzing concept maps to many different disciplines of study.

# Analyzing Equality of Participation in Collaborative Inquiry: Toward a Knowledge Community

**Abstract:** This paper shares preliminary findings from a designed-based study of the Knowledge Community and Inquiry (KCI) model for secondary science curriculum. We investigate the impact of the model on students' cooperative knowledge construction and their understanding of the science of climate change. Working closely with a science teacher, we co-designed a 10-week curriculum unit with small group and whole class collaborations across two participating classrooms. We present detailed analysis of the wiki content created by two groups of students, revealing a positive correlation between students' contribution to collaborative inquiry activities and their achievements in the curriculum. This finding suggests the need for increased scaffolding to support symmetric participation in collaborative inquiry so that both high and low achieving students benefit from such collaborative science curriculum activities.

## Purpose of the Study

Typical classroom instruction in science still focuses on rote learning of content, performance of problem solving, and coverage of standards and expectations (Slotta & Linn, 2009). Several traditions in the Learning Sciences, such as inquiry-based learning (e.g. Krajcik, Blumenfeld, Marx, & Soloway, 2000) and knowledge communities (Brown & Campione, 1994; Scardamalia & Bereiter, 2006), propose pedagogical approaches that would transform teaching and learning in science classrooms. Despite its success in increasing students' understanding of topics, inquiry-based learning still seeks strategies to promote collective knowledge construction within classrooms (Linn, Clark, & Slotta, 2003). By the same token, developing knowledge communities in classrooms has proven difficult due to lack of concrete guidelines for designing collaborative activities, as well as the challenges of bridging small-group collaboration with the wider community knowledge-base, and of sustaining long-term collaborative inquiry (Lehrer & Schauble, 2006).

This study investigates the effectiveness of a new hybrid model of collaborative inquiry situated within a knowledge community that enables students and teachers to engage in inquiry activities that are designed to deeply interconnect with a classroom-constructed knowledge base. To overcome the challenges of developing inquiry-oriented knowledge communities in secondary school science classrooms, the Knowledge Community and Inquiry model (KCI) proposes utilizing collaboration scripts (Kollar, Fischer, & Hesse, 2006) scaffolded by a technology-enhanced environment – in this case, a wiki. The KCI model builds on recent research that integrates structured collaborative patterns to complement collective knowledge construction and inquiry process to alleviate aforementioned challenges and foster inquiry-oriented knowledge communities (Hmelo-Silver & Barrows, 2008).

This research extends prior studies on KCI (Slotta & Peters, 2008) by integrating the model deeply into a grade 9 science curriculum unit concerned with climate change, and by adding a scripted collaborative component to the inquiry activities. The purpose of the larger study (now entering its second year of data collection) is to investigate the effect of the refined KCI model on students' cooperative knowledge construction and deep understanding of climate change concepts. The present paper will examine the quality of knowledge objects constructed by the students and the patterns of students' engagement in collaborative inquiry.

## Theoretical Framework

### Knowledge Communities

Learning science researchers advocate the notion of "Knowledge Community" to support learning. Of special interest to this research are the conceptual frameworks of Fostering Communities of Learners (FCL; Brown & Campione, 1994) and Knowledge Building Communities (KBC; Scardamalia & Bereiter, 2003) that have been intensively researched in the context of k-12 education. Although the two frameworks differ in their guiding principles, with FCL following a cycle of "research, share and perform" KBC pursuing idea improvement as a product of students' knowledge construction efforts, they can be synthesized along three dimensions.

Distributed cognitive responsibility: Traditional forms of instruction, such as lecture, are not conducive to helping students integrate knowledge for deep understanding of concepts (Brown, 1997). In a knowledge community approach, students become involved in articulating their own learning goals and planning the learning activities. Members of a knowledge community are not only responsible for the quality of their individual learning, but also are held accountable to communicate with other community members to scrutinize the quality of collective knowledge (Bielaczyc & Collins, 1999). Metacognition and reflection serve to increase students' awareness of how they learn and thereby enable self-reflection, critical inquiry, and flexible application of knowledge in novel situations.

Community knowledge-base: In a knowledge community approach, knowledge sources are no longer limited to the teacher and curriculum materials, but include knowledge artifacts identified or created by the students (Bielaczyc & Collins, 1999). A shared knowledge base promotes a diversity of ideas and facilitates access to those ideas in order to encourage the continued growth of community knowledge (Brown & Campione, 1994; Scardamalia, 2003). Structured collaborative activities intentionally distribute expertise among students, requiring them to negotiate their individual knowledge within collaborative groups and organize their new understandings in a common community knowledge base (Brown & Campione, 1994). Students' contributions to the community knowledge base will survive and be extended only if they are deemed important to the community (Scardamalia, 2003). Thus any artifact produced during such activities should carry the potential to be improved by others.

Pedagogical and technological scaffolds: To help teachers and students achieve the nuanced flow of ideas, activities and discourse within a knowledge community, researchers often introduce specific forms of guidance or scaffolds. These include collaboration scripts technology tools that guide students' knowledge building processes or discourse. In KB, for example, technology serves as a repository of ideas as well as a tool for collaborative knowledge construction (Scardamalia & Bereiter, 1999).

### Challenges for Fostering Knowledge Communities in Classrooms

Empirical research provides inconclusive results regarding the viability of the knowledge community approach in classrooms. The few published studies conducted on FCL-inspired classrooms report major challenges regarding instructional design and implementation (Sherin, Mendez, & Louis, 2004). Knowledge community frameworks propose epistemological more than procedural changes to learning and teaching. How will these principle translate into design guidelines for classroom practice? Sustained collaboration between researchers and teachers appears to be one enabling condition. Studies on knowledge building demonstrate the need for such partnerships to focus on principles to guide their design and implantation (Zhang, Scardamalia, Reeve & Messina, 2009). Despite some empirical evidence of effectiveness, knowledge community frameworks have not received widespread popularity among researchers and practitioners. A potential explanation for this limited uptake by the wider community of learning scientists is the high demand of time and human resources that is required for the design, implementation and evaluation of any knowledge community approach.

There is an evident challenge to any application of a knowledge community model in secondary science courses. Knowledge building discourages topic-centered discussions (Bereiter, 2003) in favor of inquiry problems. It requires a long time – potentially up to 6 months – to get the community established sufficiently well that they could identify conceptually inclusive problems that connect multiple topics together Scardamalia (2003). Both of these challenges – the open-ended nature of topics and the time-intensive aspect of community development – are ill suited to secondary science where teachers must make efficient use of curricular time to target a well specified set of science topics. In one of the few published accounts of a KB approach to secondary science (Van Aalst & Chan, 2007) the authors acknowledge making several compromises and falling short of a full implementation of KB.

Considering the challenges that researchers face when studying a knowledge community approach in classrooms, one appealing approach is to develop new models that integrate Web 2.0 technologies with known collaboration scaffolds (Slotta & Peters, 2008). Web 2.0 technologies can provide increased awareness of shared knowledge and help scaffold students in collaboratively constructing new knowledge. This could facilitate the application of a knowledge community approach by researchers in a secondary science context.

## Scaffolded Collaborative Inquiry

Inquiry-based learning (IBL) approaches support students in the process of constructing, refining, and applying their understanding of scientific concepts through question-driven, evidence-based, iterative scientific inquiry processes (Krajcik et al., 2000; Linn et al., 2003).

Collaboration is valued in IBL. However, enacting collaborative inquiry within a classroom is challenging, given the longstanding knowledge transmission culture as well as practical limitations such as time and teacher to student ratio (Singer et al., 2000). The quality of collaborative work may suffer without sufficient support, as a result of students' inexperience with fundamental processes such as pooling ideas, distinguishing between valid and invalid ideas, and settling conflicts (Krajcik et al., 2000; Linn & Slotta, 2009).

Technological and pedagogical scaffolds have been used to relieve complexities of collaborative inquiry. For example, Singer et al. (2000) propose that by having small groups of students share their inquiry questions, plans and findings with the whole class, the students can improve the quality of their work.

Different forms of collaborative design patterns that support inquiry have been advanced by researchers partly driven by the increasing interest in fostering communities of inquiry in classroom. These patterns can provide detailed description of the steps required for students to complete a collaborative task, such as reciprocal teaching (Palincsar & Brown, 1984). While this approach suggests great promise, structuring collaborative inquiry in classrooms remains an important topic of research.

### Knowledge Community and Inquiry (KCI): A Hybrid Model

Knowledge Community and Inquiry (KCI) is a hybrid pedagogical model that integrates the IBL and knowledge community approaches to facilitate a culture of collective inquiry in classrooms. KCI is being developed to make knowledge communities more accessible to secondary science instruction, including a new role for scaffolded inquiry activities that put the collaborative knowledge-base to use in targeting specific learning goals.

Design principles for KCI science curricula are: (1) *Establishing a shared knowledge-base.* Students identify issues of interest related to the topic of the unit and develop knowledge artifacts—e.g. annotated resources or web pages—that embody the emerging themes to direct subsequent inquiry investigation. (2) *Collaborative inquiry.* Once teachers identify issues deemed important by the class that are suitable for inquiry, they work with researchers and technologists to co-design scripted-inquiry activities that draw upon the shared knowledge-base as a resource for the inquiry activities. Decisions about the kind of scripts to be used in the inquiry activity are made based on the topic of discussion and learning goals identified by the teacher. (3) *Continuing to develop the knowledge-base.* The class is engaged in ongoing knowledge integration, connecting their new ideas and understandings to the existing knowledge-base, which can be used in subsequent inquiry activities. (4) *Technology Scaffolds.* Technology plays an essential role in KCI to help students and teachers visualize collective knowledge, to promote every student's contribution to constructing the shared knowledge-base, and to enable students to easily find and retrieve elements from the knowledge base. (5) *Curriculum Co-design.* Designing curriculum that is accessible to teachers is of prime importance to KCI. Any curriculum design must address learning goals held by the teacher, including school district or government curriculum expectations. Moreover, the design team must accommodate the requirements of conventional assessments and must therefore design activities that yield knowledge artifacts that can be graded for content expectations and that prepare students for existing exams.

## Research Questions

The following questions guided this study:

- How will an improved KCI model that relates collaborative inquiry activities to shared knowledge-base impact students' contribution to the classroom knowledge community?
- What are the characteristics of students' contributions to the community knowledge-base?
- How do students' contributions to the knowledge-base relate to their understanding of scientific concepts?
- How do pedagogical and technological scaffolds impact students' contribution to the knowledge-base?

## Methods

Design-based methods bring researchers and classroom teachers together to create innovative approaches to problems of practical and theoretical value, allowing them to recursively examine the interactions among multiple design elements to gradually improve the design (Collins, Joseph, & Bielaczyc, 2004). Edelson (2002) identifies two different objectives for design research: Theory testing and theory development. Considering the purpose of this study, which is to understand how a KCI-inspired technology-integrated curriculum can support scientific inquiry while promoting a knowledge community in science classrooms, a design-based method, geared toward theory development, is appropriate.

### Participants and Settings

Participants of this research are one science teacher and 42 grade ten students in two classes (A and B). The participating teacher has been actively involved in previous research on the KCI model. Following a co-design approach (Penuel, Roschelle, & Shechtman, 2007), the teacher joined the research team in August 2008 for curriculum design, implementation, and evaluation. These meetings continued throughout the unit to refine materials and address unforeseen situations.

### Co-designed curriculum

The curriculum started with an initial knowledge construction activity where students identified useful resources about climate change then annotated and added them under relevant category in a designated wiki page. To promote students' metacognitive awareness of knowledge community, a discussion about "philosophy of science" was also conducted in the first stage of the curriculum. Students then identified important issues related to climate change in Canada that were used to guide small group collaborations. Collaborative inquiry activities included small-group, cross-group, and whole class collaborations. Students formed regional groups to investigate the effects of climate change within each region with regards to three Science dimensions (Greenhouse effect, Weather and wind patterns and Ocean circulation). Within the regional groups, students were assigned to one of the following "specialist roles:" primary industries, secondary industries, environmental activism and tourism industries. For the final project, specialists from all regions joined new advisory groups to synthesize the community's knowledge and provide national guidelines for reducing the adverse affects of global climate change in Canada. All groups were formed across two sessions of the class so that students collaborated with some peers asynchronously. For this iteration, technological infrastructure consisted of a password-protected wiki with sophisticated grouping and permission capabilities, in addition to a collaborative concept mapping software application. Laptops with wireless Internet connections were used for collaborative work. The teacher was highly competent in using technology for teaching.

## Data Sources

Multiple data sources were used to capture the richness and complexity of the innovation:

- Contents of student-created wiki pages provided a measure of the quality of students' ideas and their collaborative knowledge construction.
- Pre-post semi-structured interviews with the teacher and selected students provided deeper insight into the teacher's and the students' perspectives.
- Classroom observation field-notes were collected to help identify patterns of practice and to corroborate data about students' engagement in collaborative activities.
- Formal classroom assessments done by the teacher were used as one factor in examining the quality of students work.

## Analysis and coding scheme

Comprehensive analysis of data is still underway, and indeed a second iteration of the design study is presently in data collection stages. In this paper, we focus on a portion of findings that examines the effect of this co-designed unit on: a) The symmetry of students' contribution within their small groups (ie, in collaborative inquiry); and b) the quality of students' contribution to the wiki. The objective is to understand how curricular activities promote distributed cognitive responsibility and construction of cohesive and usable shared knowledge. For this purpose, we analyze the progress of two small groups: those who created the Ontario and the Prairies regional wiki pages. For any wiki page analyzed, an elaborate process of evaluating every successive version of the page supports our inferences about collaboration patterns and the growth of ideas within the page. Our unit of analysis was an independently meaningful and cohesive piece of text added to the wiki pages. A unit could vary from one sentence to a multi-sentence paragraph.

<u>Wiki development actions:</u> To measure individual group members' contribution to the wiki pages, we reviewed the actions taken by students while they were editing a page, following a constant comparative method, to identify recurring types of edit actions. This analysis sheds light on the extent to which KCI curriculum promoted distributed cognitive responsibility by revealing whether students go beyond their personal contribution to act on what has been added to their group work by other group members. The resulting categories for coding were: Initiating a new section or major idea (initiate); editing content previously added by self (edit self); editing content previously added by another group member (edit other); making link to another wiki pages (link to page); correcting grammatical mistakes or formatting (minor edits).

<u>Quality of wiki contributions:</u> individual group members' contribution to the wiki pages in progress was coded using a four-point scale: Unelaborated facts, elaborated facts, unelaborated explanations, elaborated explanations (adapted from Hakkarainen, 2003). Another category of "regulatory notes" was added subsequently to capture wiki entries concerned with planning, monitoring, or reflecting on the group's overall progress or specific developments.

# Findings and Discussion

Two regional groups, "Ontario" and "Prairies," were selected for this detailed analysis based on the teachers' assessment of their collaborative work. Groups were formed by the teacher and balanced to have both higher and lower achieving students. The mean for the two classes' final unit marking was 71.16 (SD=15.6). The Ontario and Prairies groups were selected as cases because they respectively received lowest and highest marks among seven regional groups. We hypothesized that close examination of these two groups' collaborative inquiry and knowledge construction activity could reveal challenges and advantages in our curriculum design that could guide our design of more coherent collaborative group work and further refine the KCI model.

The Ontario group consisted of six students: Cara, Cheryl, Sam, and Chris (from classroom A) and Sara and Mike (from classroom B). Of these, three scored higher than class mean and three scored lower. The Prairies group had five students: Wendy, Thomas, and Adriana (from classroom A) and Sheila and Mat (from classroom B). Adriana was absent for the final month of the curriculum, which directly affected her contribution to wiki development. We decided to disqualify her contributions from our analysis, which were generally quite minor. In this group, one student scored lower than class mean in the unit and the remaining three scored higher. On average, students in the Prairies group (mean=79.64) received higher final grades than the Ontario group (mean=72.9) in the unit.

## Collaborative Knowledge Construction

Using the "wiki development actions" scheme, we coded all versions of the main wiki page for each region, and all the pages linked to each page that had at least one author from the respective group. Each time a student clicked on the "edit" button, this was counted as one edit session. The total number of such edits was tallied as "Total Page Edit" score. Note that it was possible that during and edit session a student took several actions. Students' individual scores and group means for each item in the coding scheme were then calculated. Figure 1 shows the distribution of edit actions among students from the two groups.

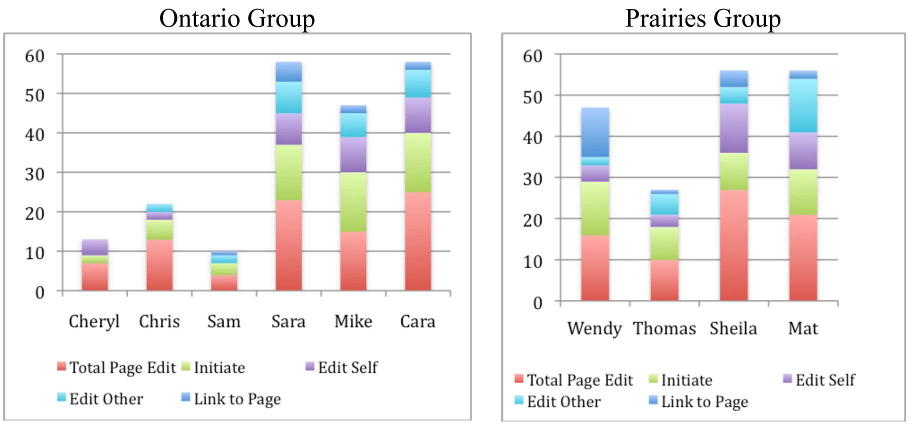

Figure 1. Students' individual scores for "wiki development actions" in Ontario and Prairies groups

The Ontario group was observed by one of the authors throughout the unit implementation. In classroom A, Cara took a leading role, dividing the work among group members. She also took on a high proportion of the work, making 25% of the edits herself (in group size of 6). In classroom B, Mike and Sara made close to the same number of edits, but unlike the classroom A students who often communicated about their collaborations, Mike and Sara only briefly discussed their collaboration in the beginning of the unit, then worked independently afterwards. Sam had the lowest "Total Page Edit" count from the Ontario group. He was present in all group work sessions, and often engaged his group members in relevant discussions. However, Sam typically only searched for information or edited the wiki when he was asked to do so by other group members.

The Prairies group, although not directly observed, demonstrated a rather more evenly distributed participation in wiki development actions. As we will discuss in the following section of Findings, this group took a more calculated approach to planning and monitoring their collaborative work.

To examine the overall performance of the two groups regarding wiki development, we compared the mean score for each action, as illustrated in Figure 2. The Prairies group showed overall higher means in all wiki development actions. Moreover, students in both groups were more likely to initiate new section of text than to edit the existing material added by other group members or linking relevant pages to their wiki page. Figure 2 shows numerical values of means for comparison. These differences were not statistically significant, presumably due to small group sizes.

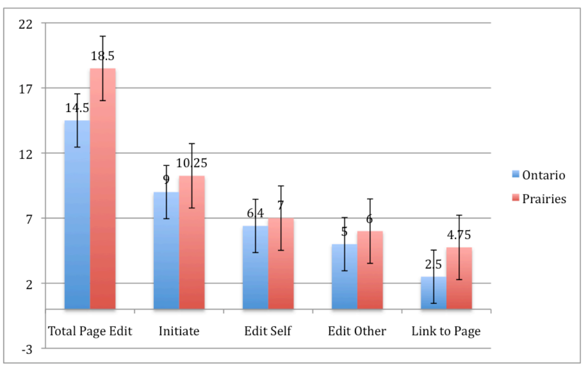

Figure 2. Comparing the means of wiki development actions for Ontario and Prairies groups

Of great interest to this research was the impact of the co-designed curriculum on students' learning. Of the four wiki development actions two provided some measure of students' progressively developing the wiki as a collectively owned artifact rather than adding independent chunks of text to it: Edit Other and Link to Page. We thus calculated a "Collaborative Knowledge Construction" score for each student by adding up her/his "Edit Other" and "Link to Page" scores. A correlation coefficient of 0.83 (Figure 3) suggested a strong positive relation between students' Collaborative Knowledge Construction score and their final grade in the climate change unit.

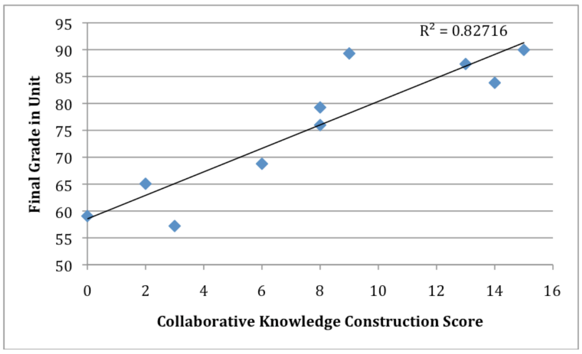

Figure 3. Relation between students' collaborative knowledge construction score in Ontario and Prairies group with their final grade in the unit

## Cohesiveness of co-constructed knowledge objects

To cover the scientific issues that needed to be addressed in the inquiry activity, students took a divide and conquer approach to group work. Since the wiki platform we used did not allow for concurrent edits, students decided to create sub-pages to elaborate on their chosen part of the activity. We were interested to know if the students finally integrated their knowledge into a cohesive final report.

Content analysis of the wiki pages revealed that students in Ontario group occasionally ignored existing wiki contents and added somewhat repetitive content to selected pages. For example Sara and Mike added the following sentences to one wiki page:

"Ontario is Canada's biggest polluter. Over half of Canada's population lives in Ontario, accounting for more waste products and pollutant." (Added by Mike on Dec 18 2008)

"Ontario has the largest population in Canada, and thus Ontario's GHG emissions will be the highest." (Added by Sara on Jan 8 2009)

Mike's entry was a standalone paragraph on top of the page about "Climate Change Issues" and by the final version of the page this paragraph was redundant. Sara's entry was an introduction into a section on "Carbon Emissions" and was well connected to the rest of the section. Nevertheless, the first entry was never deleted or merged with relevant content to make the page more cohesive and less disconnected.

We also noticed contradictory wiki entries in Ontario group. Factors that impacted the amount of released green house gases were discussed in different pages and by different students. The discussion about this issue started by Chris in the main page where initially green house gases were a sub-section of the main page"

Chris : Only about 29% of Ontario's energy is taken from fossil fuel sources- the rest is nuclear and hydroelectric (as Ontario is full of rivers that are used for hydroelectric energy)."

Meanwhile, Sara took the responsibility for developing the "Ontario Greenhouse Gases" page by turning the sub-section heading into a new page which included the following entry related to hydroelectric power:

"Sarah : "Contrary to popular belief, hydroelectric power may sometimes have more GHG emissions than the use of fossil fuels."

The link to this page was directly located above Chris' contribution on December 18 2008. Later, Chris added another entry right under his December 18 2009 entry:

Chris "Since hydroelectricity generates very little air pollution, greenhouse cases in Ontario are very rarely from power generation "

Although his contribution fell under the green houses gases topic, he did not add it to the "Ontario Greenhouse Gases" page. We assume that Chris did not read this page, otherwise he would have noticed the apparent contradiction between Sara's and his own contributions and the two of them would resolve it with more detailed evidence.

In the Prairies group, students showed higher awareness of their shared content. They often communicated with each other about their contributions through meta-comments. For example in one occasion Mat copied Thomas' contribution to its relevant sub-page, "Greenhouse Gases", edited it to decrease the redundancy, and weaved it into his own sentences previously added to that page. However he did not delete the text on the main page that was added by Thomas. Mat also left a comment on the main Prairies wiki page:

Matt: "I put it in the green house gases page and split up your points into jot note form, and got rid of some that I've already added there"

An overall comparison of the two series of wiki pages developed by Prairies and Ontario students revealed a lack of cohesiveness where contents were compartmentalized into subpages without being outlined and summarized in an introduction or a summary section. This could be a flaw of our curriculum design, as we did not require the students to synthesize their wiki work as the collaborative activity concluded. It could be inferred that students closely followed the instruction given to them, which did not directly asked for a cohesive presentation of collected information.

## Quality of contributions

Wiki pages of Ontario group contained more content than those of Prairies group. This could be attributed to the fact that there were more students in the Ontario group. Table 1 shows the quality of students' individual contributions to Prairies and Ontario wiki pages. Students in the Prairies group made extensive use of regulatory notes to communicate division of labor and state of work among themselves. In the Ontario group, on the other hand, regulatory notes were used only in one occasion to ask for all group members to work harder.

Table1. Quality of students' individual contributions to Prairies and Ontario wiki pages

| | | Unelaborated Fact | Elaborated Fact | Unelaborated Explanation | Elaborated Explanation | Regulatory Notes |
|---|---|---|---|---|---|---|
| Prairies Group | Wendy | 7 | 6 | 6 | 2 | 2 |
| | Thomas | 6 | 4 | 4 | 1 | 6 |
| | Sheila | 9 | 1 | | 1 | 2 |
| Ontario Group | Mat | 14 | 6 | 19 | 9 | 1 |
| | Sara | 12 | 10 | 9 | 6 | 3 |
| | Mike | 19 | 9 | 10 | 10 | 2 |
| | Chris | 2 | 4 | 2 | 1 | 0 |
| | Sam | 3 | 6 | 2 | 0 | 1 |
| | Cara | 7 | 8 | 11 | 9 | 0 |
| | Cheryl | 8 | 10 | 4 | 0 | 0 |

An "overall quality score" was calculated for each individual by adding the scores s/he obtained in each of the five categories of content quality. The relation between overall quality scores and final unit grades also resulted in a positive correlation with a coefficient of 0.72 suggesting that students whose wiki entries are more elaborated are likely to achieve higher marks in the unit.

## Conclusion and Significance

In this paper, we shared our interim findings regarding symmetric participation in collective inquiry from the first iteration of a design-based research that examines a hybrid KCI model. This new model encourages even distribution of cognitive responsibility towards building a deep collective understanding of science topics and aspires that students would benefit from each other's contributions to the shared knowledge. Findings shared here, will guide our curriculum design efforts for subsequent iteration of the study in 209-2010.

From the beginning, we expected to observe non-symmetric participation in the inquiry activities both in small group and in whole-class settings. It was our intention, thus, to study the patterns of participation in-situ and design appropriate technological and pedagogical scaffolds to support collaborative activities that maximize the benefits that a knowledge community can offer for all students. Using a wiki as collaboration venue allowed us to study and analyze the process of developing a shared knowledge base through inquiry by disclosing individual student's patterns of participation and their contributions to the final group product.

Careful examination of wiki development actions revealed that students in both groups were more likely to initiate semantically and conceptually new section than to edit the existing material or linking relevant pages to their wiki page (refer to figure for numerical value of means). Upon examining the assessment rubric given to students for their group work, we realized that the students were not explicitly encouraged to act on material added by their group members. A level 4 group contribution was described as "….work in class built on and extended on previous material on wiki" and "material added improved wiki". Yet known characteristics of knowledge communities require students not only to focus on the quality of their individual contributions but also monitor and act on material added by other group members. For these students it was their first experience to make a shared wiki page. "Edit Other" and "Link to Page" wiki development actions in Prairies group showed higher mean which could be due to Prairies students' self-realization that a contribution made to a shared wiki became the intellectual property of all group members. This remains only as speculation as we did not probe these students motivation for group work.

Our findings suggest that students need to be supported in understanding inquiry processes and in actively participating in a collaborative activity since uneven participation may lead to achievement differences. For our next iteration, we are proposing to include two kinds of scaffolds: A reflective self-assessment (e.g. White & Frederickson, 1998), both for small groups and for individuals, to assist students in explicitly monitoring and improving their participation in co-constructing a shared knowledge base; and a participation gauge scaffold to visualize contribution level per student.

Further analysis of the current data will look into the connections that students made between among knowledge artifacts shared by the class.

## Scientific Significance

Developing knowledge communities in classrooms has proved difficult (Lehrer & Schauble, 2006) and inquiry-based learning approaches still seek strategies to promote collective knowledge construction within classrooms (Linn, Clark, & Slotta, 2003). We build on recent research that integrates structured collaborative patterns to complement collective knowledge construction and inquiry process to alleviate these challenges (Hmelo-Silver & Barrows, 2008).

# The Construction, Refinement, and Early Validation of the Equipartitioning Learning Trajectory

Jere Confrey, Alan Maloney, North Carolina State University, Raleigh, NC 27606
jere_confrey@ncsu.edu, alan_maloney@ncsu.edu

**Abstract.** Equipartitioning, a foundational construct of rational number, is introduced in the form of a learning trajectory. Its development is linked to synthesis of research, the conduct of clinical interviews, and the development of related diagnostic assessments. Refinement and validation of a learning trajectory is described as an iterative empirical process that can serve as a prototype for design of other learning trajectories.

There is perhaps no more important conceptual area in mathematics education than rational number reasoning. The basis of the multiplicative conceptual field (Vergnaud 1983, 1996), rational number reasoning underpins algebra, higher mathematical reasoning, and the quantitative competence required in science. Failure to develop robust rational number construct reasoning and skills in elementary and middle school continues to plague American students. Rational number reasoning is complex, and mastery represents cognitive synthesis—understanding, distinguishing among, modeling, and interweaving a remarkable assortment of distinct yet closely related concepts over many years.

More than four decades of research in rational number topics have provided us with a robust outline of the concepts that comprise rational number reasoning. As described over years of research in the Rational Number Project, and recently outlined by Confrey and colleagues (Confrey 2008; Confrey et al. 2009), rational number reasoning encompasses the constructs of equipartitioning, multiplication and division, ratio, rate and proportion, scaling, length and area measurement, fractions, decimals and percents. That research and summary of rational number strongly suggests that while Rational Number Reasoning is complex, it will yield to a Learning Trajectories analysis (Confrey et al. 2009).

Once learning trajectories are developed, it is assumed that they can be deployed as a framework for curricular innovations and for strengthening teachers' understanding of and instruction in rational number. When coupled with innovative cognitive diagnostic psychometric approaches, learning trajectories may provide a robust means for teachers to assess students' cognitive progress.

"Learning trajectory" is a term with roots in Simon's (1995) definition of "hypothetical learning trajectory," a teacher-conjectured path of student learning from beginning to end of an instructional episode. Learning trajectories are also described in the research literature as predictable sequences of constructs that capture how knowledge progresses from novice to more sophisticated levels of understanding. Clements and Sarama (2004) suggested somewhat more predictable, larger-scale structures, "descriptions of children's thinking as they learn to achieve specific goals in a mathematical domain, and a related, conjectured route through a set of instructional tasks designed to engender those mental processes or actions hypothesized to move children through a developmental progression of levels of thinking" (p. 83). Science educators define *learning progressions* as "empirically-grounded and testable hypotheses about how students' understanding of, and ability to use, core scientific concepts and explanations and related scientific practices grow and become more sophisticated over time, with appropriate instruction" (Corcoran et al. 2009, p. 8). Other views of learning trajectories include the process of developing key conceptual structures (Catley et al. 2004) and that instruction should trace a prospective *developmental* (Brown & Campione 1996) or *conceptual*, *corridor* (Confrey 2006; Lehrer & Schauble 2006), spanning grades and ages, with central concepts introduced early in the school experience and progressively refined, elaborated, and extended. We use a refined definition of "learning trajectory" (or "learning progression"):

> Learning Trajectory: A researcher-conjectured, empirically supported description of the ordered network of constructs a student encounters through instruction (i.e. activities, tasks, tools, forms of interaction and methods of evaluation), in order to move from informal ideas, through successive refinements of representation, articulation, and reflection, towards increasingly complex concepts over time. (Confrey 2008; Confrey, Maloney, Nguyen et al. 2008; Confrey et al. 2009).

While learning trajectories do not dictate a hard-and-fast order in which topics must be learned for students to be successful, they permit specification, at an appropriate and actionable level of detail, of ideas students need to know during the development and evolution of a given concept over time. This information can be embedded systematically in state curricular standards (Confrey & Maloney in press), can underlie curricular interventions with varying degrees of explicitness, and guide teachers in responding to and anticipating student thinking. Learning trajectories may form the backbone of an assessment strategy that can both document

p. 1/1

 

student progress and identify individual and subgroup weaknesses that can be specifically and efficiently addressed by teachers.

The DELTA project (Diagnostic E-Learning Trajectories Approach to Rational Number Reasoning) at North Carolina State University has the multiple objectives of creating learning trajectories for up to seven distinct strands of rational number constructs, validating them through empirical study, and then designing diagnostic assessments, to assist teachers in targeting their instruction to more effectively support students' cognitive progression through the key rational number constructs across grades K-8.

## Methodology for construction, refinement, and early validation of Equipartitioning learning trajectory.

To construct a learning trajectory, an exhaustive collection, review, and synthesis is conducted of mathematics education and cognitive psychology research literature pertaining to topics in rational number. Synthesis demands careful attention to making sense of related studies, explain higher order relations in complex cumulative findings, or explain old findings by postulating new concepts (Cooper 1998). Once the initial learning trajectory is identified, additional open-ended semi-structured clinical interviews (Piaget 1976; Opper 1977) are conducted. In the case of equipartitioning, these interviews were conducted with 42 urban and suburban students in grades pre-K to 6, and lasted 30 to 60 minutes each. Interviews presented participants with various sequences of specific tasks (varying the numbers of items and people in the fair sharing activities) and followed up with particular questions designed to elicit children's explanation of strategies they used to accomplish the tasks, their justification for their solutions to the tasks, and to probe for multiple strategies for accomplishing each particular version of each equipartitioning task. The interviews permit filling in gaps in the learning trajectory.

The next step in the process[1] is to develop paper-and-pencil assessment items, which requires further clarification of the levels of the trajectory, and piloting of the items. Simultaneously, think-alouds are conducted to determine the extent to which student responses on paper express the range of student thinking elicited by the item. In the DELTA research, 14 items were piloted with 95 2$^{nd}$-grade students, and 14 think-aloud interviews were conducted (Wilson 2009). Based on the synthesis work and the interviews, outcome spaces--the range of observed cognitive behaviors--are summarized for each level of the learning trajectory.

Field-testing follows the development of items corresponding to each level of the learning trajectory. In the equipartitioning research, 125 items were created and administered to approximately 5000 students, grades K-7, across 4 North Carolina school districts. All the students in these grades in 7 elementary and 3 middle schools completed the field tests.

Item-scoring rubrics are then developed in a two-stage process: a) small teams examine all responses to an item, draft a rubric, and identify a range of student response exemplars; b) the team presents the rubric and exemplars to the entire research team, at which time the correspondence of the responses to the learning trajectory levels is evaluated. For the equipartitioning LT, rubrics comprised a 3- to 6-level scale, depending on item format, that accommodated the range of sophistication of item responses, from non-response (or unintelligible) to unequivocally correct or complete. Responses lacking sufficient evidence to be categorized were also coded. Other codes were created to facilitate collection of data on particular strategies and misconceptions.

## Defining Equipartitioning. Using cases to build an initial learning trajectory.

A broad variety of mathematics education and cognitive psychology literature bearing on as many readily identifiable aspects of rational number reasoning as possible was assembled into a comprehensive database (approximately 650 publications). The intent was to assemble an exhaustive collection of peer-reviewed journals, edited books and chapters, and conference proceedings (http://gismo.fi.ncsu.edu/database) (Confrey 2008; Confrey, Maloney, & Nguyen 2008). In examining this diverse database for studies of children's early understanding of multiplication and division, fraction, and ratio, to identify evidence of common or earliest cognitive roots of the concepts in rational number reasoning, it was noted that investigators across a diverse range of differently-oriented studies had asked participants in their studies to solve fair sharing activities. These authors had investigated a variety of mathematical and cognitive topics, including one-to-one correspondence (Frydman & Bryant 1988), partitioning (Pothier & Sawada 1983), early fraction understanding (ref), unitizing (Lamon 1996), the partitive fraction quotient construct (Charles & Nason 2000) (Toluk & Middleton 2003), early ratio understanding (Streefland 1991; Confrey & Scarano 1995; Confrey & Lachance 2000), and aspects of fair sharing itself (Hunting & Davis 1991), and the cognitive relationship between fair sharing and counting competency in young children (Pepper 1991; Pepper & Hunting 1998). Many of the authors had observed that children's reasoning in fair sharing activities followed predictable pathways of increasing sophistication. Early on, Pothier and Sawada (1983) explicitly recognized connections between partitioning and rational number ideas, and identified number theoretic properties and properties of particular simple geometric shapes as important components of children's developing reasoning. Students performing

p. 2/2

these fair sharing activities often gave evidence of reasoning about phenomena predicted by the splitting conjecture (Confrey 1988; Confrey & Scarano 1995).

These fair sharing activities possessed the common feature of generating equal-sized groups or parts, an objective initially named by the research team as "partitioning." The partitioning in these cases, however, is distinct from the kind of partitioning identified in part-part-whole number sense. *Equipartitioning,* as it has been named is partitioning with the specific objective of generating equal-sized groups. We explicitly distinguish the term "equipartitioning" from "breaking," "fracturing" or "segmenting" in which the goal is not necessarily the creation of equal-sized groups, and from the general mathematical term "partitioning." The definition of equipartitioning is as follows:

> Equipartitioning: cognitive behaviors that have the goal of producing equal-sized groups (from collections) or equal-sized parts (from continuous wholes), or equal-sized combinations of wholes and parts, such as is typically encountered by children initially in constructing "fair shares" for each of a set of individuals (Confrey et al. 2009).

Four distinct cases of fair sharing activities were identified as a means to unify equipartitioning (Confrey, Maloney, Nguyen et al. 2008). These four cases comprised the original framework of the Equipartitioning learning trajectory (EqPart LT). The cases are listed here, each with an example of one of the familiar contexts:

Case A: sharing a collection of $m$ objects fairly among $p$ people, where $p$ is a factor of $m$. Example: 15 coins of treasure shared fairly among 3 pirates;

Case B: sharing a single (dissectible) whole fairly among $p$ people. Example: 1 rectangular birthday cake shared fairly among 4 people.

Case C: sharing multiple continuous wholes ($m$) fairly among $p$ people, where $m < p$, and producing $m/p$ as a proper fraction. Example: 3 circular cakes shared fairly among 4 people.

Case D: sharing multiple continuous wholes ($m$) fairly among $p$ people, where $m > p$, and producing $m/p$ as an improper fraction or a mixed number. Example: 9 pizzas shared fairly among 4 people.

The initial learning trajectory was essentially a simple-to-complex ordering of the cases A-B-C-D, and accounted for a number of previous findings. For instance, studies of one-to-one correspondence had established that dealing was a fundamental strategy for fair sharing of collections. Studies of partitioning and splitting had already shown that 2-splits of collections or of single continuous whole objects were readily accomplished by very young (3-4 years old) pre-literate children (Hunting & Sharpley 1991). It had also been established that students mastered different levels of splits in a distinct order, but that the order of mastery did not follow a counting sequence: students consistently accomplish 2- then 4- and commonly 8-splits before accomplishing other split-values, and that 3-splits are very difficult, especially on circular shapes. It was also clear that non-even splits of circles presented far more difficulty for students than splits based on powers of 2 (Pothier & Sawada 1983; Confrey 1997).

### Iterative development of the Equipartitioning learning trajectory.

Articulating and refining the EqPart LT is an iterative process of research synthesis and empirical investigation involving clinical and think-aloud interviews, assessment item response analysis, and rubric development. Previous studies used activities of fair sharing collections of discrete items or single wholes with younger children (pre-K through grade 3), and the more complex tasks of fair sharing multiple continuous items with older elementary and middle school-aged children. However, no systematic examination of the progression of children's reasoning across a wide range of ages and across the entire set of four equipartitioning cases had been conducted. To systematically investigate children's mathematical reasoning in the context of fair sharing across all four cases, semi-structured clinical interviews were conducted with children grades pre-K through 6.

The clinical interviews were designed to elicit a range of student reasoning, including strategies, representations, mathematical practices, emergent properties, and misconceptions. Each interview probed a variety of task parameters, i.e. evaluating students' ability to accomplish tasks of fairly sharing various numbers of items for various numbers of people, and to describe the results of reversing the activity, i.e. reassembling the shares. For each combination of items and people among whom the item(s) were to be shared, students were also asked to verify that each person had received a fair share, justify how s/he knew this, to name the fair share, to identify how much of the collection or item(s) each person received, to share the collection or item(s) in at least one other way, and to identify one $n^{th}$ of the total collection or item(s). Additional questions, designed to elicit student reasoning about the consequences of, for instance, changing the numbers of persons or items at the conclusion of one task, were also employed. A typical interview task, for instance Case A, involves providing a child with a set of plastic "gold" coins, telling her that two pirates have discovered a treasure, and they want to share the treasure fairly. The interviewer then proceeds to ask the child several questions as described above. Once the child had worked through the entire interview for the first number of pirates (2), the interviewer then repeated the questions with a different number of pirates (for example, 3, then 4, or vice versa). Through analysis of these interviews, the EqPart LT was further specified into a more-or-less linear progression of levels, systematically moving through the cases. The interviews were intentionally open-ended: interviewers probed student reasoning when the students' responses or comments presented the opportunity, in order to take note of unexpected, original, or elaborated student behaviors and reasoning.

A critical development was the growing recognition of the importance of properties in explaining how students' cognitive reasoning progressed. While each of the cases required its own variety of strategies, across the cases particular properties concerning sets of tasks emerged, such as compensation (the recognition that increases/decreases in the number of persons sharing results in decreases/increases in share size), composition of splits (acting both vertically and horizontally on rectangles to produce multiplicative numbers of shares), transitivity (the recognition of equivalence of non-congruent fair shares generated from equal-sized wholes), distributivity of equipartitioning over breaking or fracturing of multiple wholes, etc. Developing proficiency in these "emergent properties" led to a re-design of the learning trajectory into a two-dimensional matrix.

Thus, early on in the development of the EqPart LT, the iterative process employed to refine it highlighted the need to differentiate between variations in the task parameters and the increased cognitive sophistication for the levels of the learning trajectory. By this phase of the work, it was clear that the learning trajectory could not be characterized as a simple linear progression of levels of behaviors. The EqPart LT was at this point represented in two dimensions: the "proficiency levels" of the concepts and behaviors on the vertical dimension, and the task parameters on the horizontal dimension. Not all task parameters were applicable to each concept level (for instance, "equipartitioning collections" only pertained to collections of discrete items, not whole dissectible shapes), nor was every concept or behavior relevant to every task parameter (for instance, composing splits on multiple wholes does not apply to single wholes).

In spring 2009, approximately 120 assessment items with individually narrowed focus, covering all relevant combinations of concepts or behavior level and task parameter, were composed and organized into 33 distinct overlapping forms for 4 grade bands: 10 forms of 6 items each for grades K-1 and 2-3, 8 forms of 8 items each for grades 4-5, and 5 forms of 8 items each for grades 6-7. Individual forms were designed for completion within a single class period, to minimally disrupt teachers' normal instructional schedules. The tests were administered to the entire student populations of 7 elementary and 3 middle schools in a rural, an urban, and two mixed suburban/rural North Carolina school districts. The research group examined all responses to each field-tested item in developing the rubrics. An example of an item and its associated rubric is shown in Figures 1 and 2.

Eight family members want to share a whole blueberry pie fairly. This is a drawing of the blueberry pie. Use your pencil to show how the family can share the whole pie fairly.

The blueberry pie

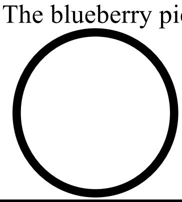

Figure 1. Item (Row 3, Task Class D) of Equipartitioning LT matrix (size reduced from original)

| Level | Descriptions and Exemplars | | |
|---|---|---|---|
| 2 | 2A. Exhausts whole and creates 8 fair shares.   | | 2B. Creates $8k$ equal-sized parts and allocates $k$ parts to each person. Description: Creates 16 equal sized parts and allocates 2 parts to each person. [No exemplar in field test data] |
| 1 | 1C. Creates $8k$ equal-sized parts but does not clearly allocate $k$ parts to each person.  | 1D. Creates 8 unequal-sized parts and exhausts whole.  | 1E. Creates more/fewer than 8 equal-sized parts that exhaust the whole.  |

| | | | | |
|---|---|---|---|---|
| 0 | Incorrect or unintelligible. |  | | |
| | 0I. Insufficient evidence. |  | | |
| | Special Code O: Creates *n+1* parts instead of *n* parts (# of cuts versus # of parts) (Here, makes 8 cuts (9 parts) when sharing among 8 people |  | Special Code P: Creates parallel cuts to try to fairly split a circle (shape misconception). |  |

Figure 2. Rubric, based on student responses, for the item in Figure 1.

This phase moves the work closer to the aim of deploying diagnostic assessments aligned with the progression of concepts in the learning trajectory. Each item's responses are examined in detail to determine whether the item elicits a consistent and interpretable range of student responses that justifies its continued usefulness for inferring student cognitive understanding. Items needing revision to improve clarity or specificity are identified at this point, as are those that should be redesigned or even discarded.

Table 1. Equipartitioning Learning Trajectory Matrix. Proficiency levels form the vertical dimension, in the left column of the table. Task classes, listed along the top row, form the horizontal dimension.

| **Equipartitioning Learning Trajectory Matrix (Grades K-8)** | | **A** | **B** | **C** | **D** | **E** | **F** | **G** | **H** | **I** | **J** | **K** | **L** | **M** |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Task Classes→ Proficiency Levels | | Collections | 2-split (Rect/Circle) | $2^n$ split (Rect) | $2^n$ split (Circle) | Even split (Rect) | Odd split (Rect) | Even split (Circle) | Odd split (Circle) | Arbitrary integer split | $p = n + 1$; $p = n-1$ | $p$ is odd, and $n = 2^i$ | $p >> n$, $p$ close to $n$ | all $p$, all $n$ (integers) |
| 16 | *Generalize*: $a$ among $b = a/b$ | | | | | | | | | | | | | |
| 15 | *Distributive property,* multiple wholes | | | | | | | | | | | | | |
| 14 | *Direct-, Inverse- and Co-variation* | | | | | | | | | | | | | |
| 13 | *Compositions* of splits, multiple wholes | | | | | | | | | | | | | |
| 12 | Equipartition *multiple wholes* | | | | | | | | | | | | | |
| 11 | Assert *Continuity principle* | | | | | | | | | | | | | |
| 10 | *Transitivity* arguments | | | | | | | | | | | | | |
| 9 | Redistribution of shares (*quantitative*) | | | | | | | | | | | | | |
| 8 | Factor-based changes (*quantitative*) | | | | | | | | | | | | | |
| 7 | *Compositions* of splits; *factor-pairs* | | | | | | | | | | | | | |
| 6 | *Qualitative compensation* | | | | | | | | | | | | | |
| 5 | *Re-assemble*: $n$ times as much | | | | | | | | | | | | | |
| 4 | *Name* a share with respect to referent unit | | | | | | | | | | | | | |
| 3 | *Justify* the results of equipartitioning | | | | | | | | | | | | | |
| 2 | *Equipartition single wholes* | | | | | | | | | | | | | |
| 1 | *Equipartition Collections* | | | | | | | | | | | | | |

p. 5/5

Item analysis and rubric development also serve a bidirectional role in the empirical process of refining and validating the learning trajectory. The outcome spaces for individual items help the research group determine whether individual items are consistent with and likely to be useful in inferring student progress with respect to the conceptual level from which the items were originally designed, and whether the item should be assigned to a different conceptual level. Conversely, and perhaps more important, the analysis of outcome spaces provides a form of test of the learning trajectory itself. The outcome spaces for different items of different cognitive levels are closely examined to ascertain whether the relative complexity and sophistication of reasoning evidenced by the students across items of different levels are consistent with the hypothesis represented by the levels of the EqPart LT, that of progression of student cognition from less sophisticated to more sophisticated.

## Levels and Task Parameters of the Equipartitioning Learning Trajectory

The Equipartitioning Learning Trajectory is represented in a two-dimensional matrix (Table 1) comprised of the progression of proficiency levels along the vertical axis (listed from bottom to top), and the task classes along the horizontal axis (listed from left to right, roughly in order of case A to case C/D tasks). The proficiency levels and task classes are organized to accommodate the following behavioral and cognitive components of student reasoning for each equipartitioning case.

- The extent to which students successfully accomplish equipartitioning.
- Strategies and representations students use to accomplish the tasks, including multiple approaches
- Evidence of mathematical reasoning practices, including naming and justifying
- Emergent mathematical properties
- Predictable patterns of errors: misconceptions and critical barriers

## Discussion

The analysis to date of clinical interviews and assessment item responses permit us to further support several major conclusions identified previously by Confrey and colleagues (Confrey 2008; Confrey et al. 2009):

- The EqPart LT is robust for children across the entire age range K-7. Older children in this age range, by and large, exhibit the same progression of reasoning about the tasks, strategies, and emergent properties as do younger children.
- Pothier and Sawada's (1983) conclusion, that number theoretic properties and geometric qualities are important in (equi)partitioning activities, is strongly supported.
- These foundations of rational number concepts do not require addition or subtraction operations, and can be developed in school in parallel to the development of those operations, rather than subsequent to them.
- Through Equipartitioning, (partitive) division cognitively precedes multiplication.
- Multiplication as re-assembly of equipartitioned collections or wholes can readily be conceptually developed instead of and earlier than it is typically developed as repeated addition, and that this would greatly strengthen children's subsequent multiplicative reasoning. We believe that deriving multiplication from repeated addition, as currently done in most curriculum, limits the development of children's multiplicative reasoning, constraining it inappropriately to additive reasoning, when it should be developed as a distinct but parallel conceptual reasoning field;
- Equipartitioning of multiple whole items leads in the higher levels of the EqPart LT to the distribution of equipartitioning over breaking or fracturing of sets or items, offering a foundation for the distributive property that can precede the numeric and algorithmic treatment of the property, and thus strengthen student flexibility with this critical concept that is essential for algebra, and which bridges additive and multiplicative reasoning.
- Behaviors, mathematical reasoning practices, and emergent mathematical properties that are elicited through equipartitioning of collections and continuous wholes, by children as young as 5 years old, anticipate the following rational number concepts:
  - Ratio, through two-dimensional 'many-to-one' numerical relationships, unit ratios, and ratio units;
  - Fraction-as-number, through the re-unitizing of fair shares to a many-as-one definition of the resulting fair share, unit fraction (students readily identify a single share of $n$ fair shares as "$1/n^{th}$ of the whole), and possibly the partitive fraction quotient construct;
  - $a/b$-as-Operator, through the development of "$1/n^{th}$ of" and "$n$ (times) as many" in naming fair shares and identifying the referent units for the fair shares resulting from equipartitioning.

## Conclusions

The contributions of the current work include the definition and elaboration of a learning trajectory for Equipartitioning, a rational number construct that integrates previously disparate cases. This was done through a rigorous and systematic process of research synthesis, clinical interviews, and extensive analysis of student item responses from a large body of assessment items developed to align with the case-based analysis of fair sharing activities.

The development of assessment items and analysis of student item responses with respect to the learning trajectory levels is an empirical process that serves to validate the ordering and specific content of levels of the learning trajectory, on the one hand, and the opportunity to correct and re-align those levels with student responses.

Our work on learning trajectories in rational number reasoning represents a large-scale design problem. The work to date on the Equipartitioning learning trajectory provides a prototype for operationalizing the design of rational number learning trajectories as frameworks for instruction and assessment. Additional study of equipartitioning is underway, directed at development of corresponding diagnostic assessments. Further validation steps include the field testing of additional items, further elaboration of the EqPart LT proficiency levels, and the application of different statistical measurement models to prototype assessments.

A significant opportunity for further work is the construction of supplemental curriculum materials based on the Equipartitioning learning trajectory. We recall that we define learning trajectories as specifically involving an "ordered network of constructs a student encounters *through instruction*…" We note that Equipartitioning is not part of any curriculum of which we are aware. It is notable that older students who have not become proficient in equipartitioning exhibit misconceptions that could be remedied by systematic introduction to equipartitioning. This suggests that if equipartitioning were embedded in elementary mathematics curriculum, understanding of rational number could be accelerated in major ways.

## Endnotes

(1) The process outlined here is informed by the "BEAR method" (Wilson 2005), adapted to link to our synthesis and interview protocols.

# Finding Transactive Contributions in Whole Group Classroom Discussions

Hua Ai, Marietta Sionti, Yi-Chia Wang, Carolyn Penstein Rosé, Carnegie Mellon University, 5000 Forbes Avenue, Pittsburgh, PA 15213, {iamhuaai,marietsionti}@gmail.com, {yichiaw,cprose}@cs.cmu.edu

**Abstract:** Automatic analysis of discussion logs from studies of computer supported collaborative learning has become more prevalent as technology for machine learning and text mining have become more powerful and usable. We extend this effort to analysis of transcripts of whole group classroom discussions. We argue in favor of adapting a transactivity based framework developed for analysis of collaborative learning discussions for use in the context of whole class discussions. Results from an evaluation of this technology applied to transcripts from 3 class periods of middle school math demonstrate promising results, specifically Cohen's Kappa of .69 in comparison with human annotators for identifying transactive contributions and .68 for identifying which prior utterance a transactive contribution relates to. Potential applications for teacher professional development, automatic assessment of learning processes, and real time support for classroom discussion facilitators is discussed. Implications for theory building related to learning in classroom discussions is also addressed.

**Keywords:** Corpus analysis, classroom discourse, automatic text processing techniques, argumentation

## Introduction

In recent years the learning sciences community has seen a growing body of work towards automatic analysis of conversational interactions in learning contexts (Soller & Lesgold, 2000; Cakir et al., 2005; Erkins & Janssen, 2006; Rosé et al., 2008). Much of this work has taken place within the computer supported collaborative learning community (Wang et al., 2007; Kumar et al., 2007; Kumar et al., 2009), as part of an effort to develop dynamic support for collaborative learning that is capable of triggering interventions in a way that is responsive to what is happening within the conversation. In this paper we present an extension of automatic conversation analysis technology into a new area, specifically analysis of whole class group discussions. Our automatic analysis involves a construct referred to as Transactivity (Teasley, 1997; Weinberger & Fischer, 2006; Berkowitz & Gibbs, 1983), which is well studied in the domain of educational psychology and computer supported collaborative learning. Transactive contributions are arguments constructed in such as way as to reference, sometimes described as "operating on", the previously expressed reasoning of self or others.

Transactivity is an important construct to target for automatic analysis technology because of the extent of its prevalence within the literature on collaborative learning process analysis and the body of work that supports its value as a property of discussions for learning (Azimita &Montgomery, 1993; Joshi & Rosé, 2007). The body of work already demonstrating the feasibility of using machine learning technologies to identify transactive conversational moves in small group discussions (Rosé et al., 2008; Joshi & Rosé, 2007) offers hope that it can be extended into this new context. Ideas related to effective patterns of discussion in classroom contexts have evolved within their own separate history from that of the community of researchers studying analysis of collaborative learning interactions. Nevertheless, a growing subcommunity of the classroom discourse community has focused on facilitation strategies for group discussions that have very similar motivations relating to encouraging children to articulate their reasoning and to listen to and respond to the reasoning of others (Chapin & O'Connor, 2004; Resnick et al., 1992; Resnick, Michaels, & O'Connor, in press; Michaels, O'Connor, & Resnick, 2007). Similarly, within the problem based learning community, where discussion groups are smaller, but similarly lead by skilled facilitators, again similar ideas have emerged (Hmelo-Silver & Barrows, 2006). Thus, it is reasonable to expect that similar technology would be capable of identifying transactive moves in whole class discussions. Nevertheless, large group discussions are more complex than those that take place within small groups of two or three participants. Thus, extension of earlier automatic analysis technology to whole group discussion data is a research contribution in its own right.

In the remainder of the paper we describe our adaptation of the Berkowitz and Gibbs transactivity coding scheme for classroom discussion. We then describe experiments towards automatic analysis of transactivity from transcripts of classroom discussions. We then discuss potential applications of this technology for teacher professional development, automatic assessment of learning processes, and real time support for classroom discussion facilitators. Implications for theory building related to learning in classroom discussions is also addressed. We conclude with a discussion of remaining challenges for producing automatic transactivity analyses from classroom discussions.

## Theoretical Framework

This paper presents our preliminary study on automatically analyzing transactivity in a classroom setting. This study is part of a larger effort related to building conversational agents that can assess the level of transactivity in ongoing discussions on the fly and respond accordingly. This work is based on the assumption that an assessment of level of transactivity in an in-progress discussion would be valuable information for facilitators to use in deciding what is needed from them to keep the conversation on a productive path in their role as orchestrators of group talk. This assumption is based on investigations of valuable conversational contributions in learning contexts that have been conducted both within communities exploring the cognitive foundations of group learning as well as the sociocultural community. Regardless of the theoretical framework, the same ideas have surfaced pointing to the value of transactivity or other very similar constructs as properties of conversation for learning. It should be noted that we are not arguing that this transactivity assessment is sufficient for facilitators to decide how to proceed, only that it provides useful insight into the level of productive engagement each student in the group is or has been exhibiting over the course of the conversation. Our work focuses on discussions involving young children, specifically middle school children learning math, although transactivity as a construct is not specific to math, and thus its definition does not refer to any specific math knowledge. Nevertheless, in order for the construct to be applied in its most valid sense, as we will see below, knowledge of math would be required in order to fully identify all of the connections between reasoning displays that students are making. Because of this, the approach we describe in the next section of this paper will be seen as necessarily a simplification of this construct. Nevertheless, the results show promise that although the annotations are being applied through automatic means, the reliability in comparison with human coding is high. Methodological implications of such simplifications are discussed at length by Rosé and colleagues (2008) in connection with automatic analysis of small group collaborative learning discussions.

The purpose of this section is to argue for the value of this transactivity analysis in connection with prior work in the learning sciences. For example, one cognitive justification for the value of transactive conversational behavior is its connection with cognitive conflict (Piaget, 1985). While we do not argue that transactivity is synonymous with cognitive conflict, we do argue that where transactive conversational moves highlight differences between the mental models of collaborating students, these moves provide opportunities for students to reflect on differences in their own mental models, which may then lead to cognitive conflict. One can argue that a major cognitive benefit of collaborative learning is that when students bring differing perspectives to a problem-solving situation, the interaction causes the participants to consider questions that might not have occurred to them otherwise. This stimulus could cause them to identify gaps in their understanding, which they would then be in a position to address. This type of cognitive conflict has the potential to lead to productive shifts in student understanding. It has the potential to elicit elaborate explanations from students that are associated with learning (Webb, Nemer, & Zuniga 2002). While transactivity has been valued previously for its role in consensus building discussions (Weinberger & Fischer, 2006), it should be noted that conversations exhibiting transactivity need not end in a common understanding or belief about an issue, and its value for learning can be seen as independent of whether this occurs or not. Furthermore, the value of transactivity is not limited to its potential cognitive benefits. From the sociocultural perspective, based on Vygotsky's seminal work (Vygotsky 1978), we can similarly argue that when students who have different strengths and weaknesses work together, they can provide support for each other that allows them to solve problems that would be just beyond their reach if they were working alone.

The most popular formalization of the construct of transactivity (Berkowitz and Gibbs, 1983) has 18 types of transactive categories, which characterize each child's conversational turn, as long as it is considered an explicit reasoning display. Before considering which of these codes, if any, is appropriate for a contribution, one must first determine whether that contribution constitutes an explicit articulation of reasoning, or at least a reasoning attempt. Beyond this, transacts have been divided in three types: elicitational, representational and operational, which ultimately were reduced to two, incorporating the elicitational in representational (R), which is considered a lower level transact, since it elicits or re-presents another's reasoning. On the contrary operational transacts (O) present a person's new argumentation, which is formed by building on another's contribution. A transact may also combine both types (R/O), because the boarders might be vague in some cases. The other two dimensions of transactive moves are focus and mode. Depending on the primary focus, a transact might be self-oriented (ego, operates on the speaker's own reasoning) or other-oriented (alter, operates on the reasoning of a partner, dyad shared opinion). Mode indicates if the transact was expressed competitively (i.e., the two expressions of reasoning are not consistent with one another) or non-competitively (i.e., the two displays of reasoning are consistent with one another). We have simplified the formulation considerably in this work and simply identify utterances according to whether they do not count as an articulation of reasoning, count as reasoning but not transactive, and transactive reasoning. In the case of transactive utterances, we identify which previous utterance is being related to.

In our formulation, articulation of reasoning by students is the goal, and thus we define what "counts" as a reasoning move. Our formulation of what counts as a reasoning display comes from the Weinberger &

Fischer (2006) notion of what counts as an "epistemic unit", where what they look for is a connection between some detail from a scenario (which in their case is the object of the case study analyses their students are producing in their studies) with a theoretical concept (which in their case comes from the attribution theory framework, which the students are applying to the case studies). When they have seen enough text that they can see in it mention of a case study detail, a theoretical concept, and a connection between the two, they place a segment boundary. Occasionally, a detail from a case study is described, but not in connection with a theoretical concept. Or, a theoretical concept may be mentioned, but not tied to a case study detail. In these cases, the units of text are considered degenerate, not quite counting as an epistemic unit.

We have adapted the notion of an epistemic unit from Weinberger & Fischer, rather than using it the same way Weinberger et al. did in their work, both because the topic of our conversations is very different in nature and because we're working with a much younger group of students. We consider that the basic requirements for a unit of talk to count as a reasoning display is that it has to contain evidence of a connection between some detail from the problem the students are trying to solve and some mathematical idea, which could be a theorem or an idea from an earlier problem they solved that they explicitly mentioned (because it shows evidence of making an abstraction), or some idea from a book that they explicitly mentioned. We would like to distinguish this from just parroting what they have heard. While teachers may use repetition to keep an idea salient within a discussion, which may be a very valuable facilitation move, we would rather not count places where students simply repeat what they have heard as evidence of reasoning. In our current formulation, we are considering the problem that the teacher has set up as what is given. We would like to make a distinction between what is given and what the students contribute beyond that.

So far we have located the instructor somewhat outside of the discussion the students are having, seeing the instructor as stimulus and support for the discussion and not actually part of the discussion. Note that we consider this scaffolding by the instructor as extremely valuable, and even necessary. However, we see it as distinct from the effect that teachers are attempting to achieve in the conversation between the students. Thus, in our current formulation, we are making a distinction between moves that facilitate the drawing out and refining of the kids' reasoning from the actual reasoning attempts. Thus, this paper only focuses on the analysis of the student utterances. As an additional caveat, while it was true also for analyses of adult discussions, it is even more true of these child discussions that we need to allow for displays of incorrect, incomplete, and incoherent reasoning to count as reasoning, as long as in our judgment we can believe an attempt at reasoning was going on. That will necessarily be quite subjective – especially in the case of incoherent explanations. However, we have achieved a human agreement of .68 Kappa using the definitions of articulation of reasoning and what it means to be a transactive utterance.

## Machine Learning Technology

Machine-learning algorithms can learn mappings between a set of input features and a set of output categories. They do this by using statistical techniques to find characteristics of hand-coded "training examples" that exemplify each of the output categories. The goal of the algorithm is to learn rules by generalizing from these examples in such a way that the rules can be applied effectively to new examples. The goal is to replace this low level coding effort by humans rather than to perform an analysis over human coded data as has been done frequently in other work (e.g., Nathan, Kim, and Grant, 2009). In order for the machine learning process to work well, the set of input features provided must be sufficiently expressive, and the training examples must be representative. Typically, machine-learning researchers design a set of input features that they suspect will be expressive enough. At the most superficial level, these input features are simply the words in a document. But many other features are routinely used in a wide range of text-processing applications, such as word collocations and simple patterns involving part of speech tags and lexical features; we will draw from this prior work.

Once candidate input features have been identified, analysts typically hand code a large number of training examples. For example, tools such as the publically available TagHelper tool set (Rosé et al., 2008) have the capability of allowing users to define how texts will be represented and processed by making selections on the GUI interface. In addition to basic text-processing tools such as part-of-speech taggers and stemmers that are used to construct a representation of the text that machine-learning algorithms can work with, a variety of algorithms from toolkits such as Weka (Witten & Frank, 2005) are included in order to provide the means to learn mappings between the input features and the output categories.

## Evaluation

We evaluated the use of machine learning technology for the analysis of transactive conversational moves in three classroom sessions where a teacher worked with a group of kids to elicit their reasoning about integers. Altogether the corpus covers 185 minutes of discussion involving the teacher and the students. The sessions have been transcribed. Altogether, the transcripts contain 707 student turns and 646 teacher turns. In this corpus, the students and the teacher contribute about equally.

## Predicting Student Moves

Student moves were coded as Not Reasoning (NR), Externalization (E), or Transactive (T). Not reasoning is a large category that includes all student utterances that are off task, are related to management (e.g., responds to announcements), are plain answers to a teacher's question, or are simply repeating what had already been articulated. A detailed discussion can be found in (Sionti et al., 2010). Reasoning utterances are grouped into two categories. Externalization refers to students' reasoning that does not connect with any previously displayed reasoning. Transactive utterances are student utterances that display reasoning that connects with previous reasoning displays in some way. For example, in this dialog exerpt below, the first student utterance is tagged as Externalization while the second student utterance is tagged as Transactive.

> Student: I sort of agree but I also disagree. I wanted to say maybe the weight line shows you more because it shows like the materials and it also showed how much they weighed by how far apart they are...
> Teacher: Can you say a bit more about that?
> Student: Like the mineral oil is way heavier than the whatsit [looks at chart], the organic materials, but the mineral oil and the water, the fresh water are way closer. Like you could fit the length of 2 mineral oils in the length of 1 gravel.

Table 1: Student Moves in three classroom sessions

| | T | E | NR |
|---|---|---|---|
| session1 | 75 | 41 | 112 |
| session2 | 77 | 25 | 126 |
| session3 | 90 | 25 | 136 |

In the case of transactive contributions, the prior utterance that the transactive utterance refers to, or operates on, is identified. Table 1 displays counts of student moves (**stuMov**) in each of the classroom sessions. We observe that students produced turns identified as articulations of reasoning (T or E) 47.1% of the time. Thus, a trivial classifier that simply assigns the category of NR, which was the most frequent category, would achieve a percent accuracy of 52.9%, although this corresponds to a Cohen's kappa of 0, which we will treat as our baseline for comparison. In the case of identifying which utterance a transactive utterance is responding to, again a simple heuristic achieves a moderate accuracy. Specifically, when predicting responding student utterance ID (**respondUtt**), we can achieve and accuracy of 54.3% by always predicting the current student turn refers to one utterance back. So again, we will treat this as our baseline, and our experiments will evaluate how much improvement we can achieve with a more sophisticated approach in comparison to these simple baselines.

Table 2: Summary of features used in machine learning experiments.

| Category | Features | Definition |
|---|---|---|
| Lexical | Utt | the string of words appearing in the current student utterance |
| Length | Len | the length of the current student utterance |
| Topic | chageOfTopic | a binary feature that indicates whether the main topic of discussion has shifted in last utterance |
| speaker Info | speaker | a binary feature that indicates whether the current speaker is one student or a group of students |
| | lastSpeaker | A binary features that indicates whether the last speaker is a student, a teacher, or a group of students |
| | changeOfSpeake r | a binary feature that indicates whether the student is also the speaker in the previous student turn |
| LSA scores | LSA1 | the LSA score representing the comparison between the current student turn and the last previous turn |
| | LSA2 | the LSA score representing the comparison between the current student turn and the turn that is two turns back |
| | LSA3 | the LSA score representing the comparison between the current student turn and the turn that is three turns back |

In our work, we built two separate classifiers to predict stuMov and respondUtt. In both cases, we first evaluated different classification algorithms by exploring combinations of different supervised learning algorithms and different sets of features on the session 1 data. Then, to test the generality of the approach we identified as best on this data, we evaluated the best performing approach on the whole corpus.

We used three standard supervised classification algorithms that have shown promising performance in previous work (Rosé et al., 2008), namely Naïve Bayes (NB), support vector machines (SMO), and decision trees (DT). For each classifier, we explored a variety of combinations of features, many of which are made available very simply through TagHelper tools. Table 2 defines the features we used and organizes them into 5 categories. Note that what is identified as the LSA score is calculated using Latent Semantic Analysis (Foltz et al., 1998), in which we calculate the semantic similarity between two utterances using LSA's latent factor approach based on patterns of co-occurrences between words. ChangeOfTopic is the only manual feature that is tagged by a human annotator. Prior work has shown that automatic topic segmentation of conversational data is feasible (Arguello & Rosé, 2006).

In our first set of experiments, we evaluated the alternative machine learning algorithms with different sets of features. The first set of features contained only the lexical features. The next set of features included that in addition to the length feature. The next set included all of those features in addition to the topic feature. The next set included all of those features in addition to the speaker information features. The next set included those plus the LSA features. The final set included all except for the lexical features.

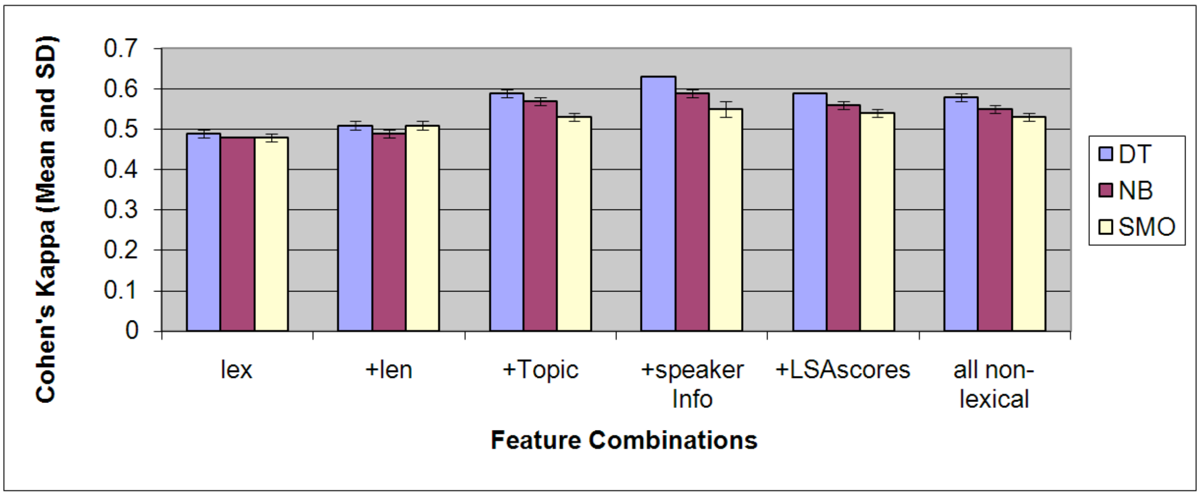

Figure 1. Classification results on predicting stuMov.

Figure 1 presents our results on predicting stuMov in the session 1 data. The bars show the Cohen's kappa and the error bars show the standard error. "+ Feature Category" stands for adding the new category of features in addition to the features that have already been used in the feature sets on its left. In the last set of feature "all non-lexical", we use all non-lexical features. We observe that the decision tree classifier trained on lex+len+changeOfTopic+speakerinfo features give us the best kappa of 0.63. Decision tree learning is also the best classifier across all feature combinations. Thus, it is reasonable to expect that this is a stable finding.

We were not satisfied with the result we were able to achieve with these combinations of features and algorithms. Thus, we conducted an error analysis in order to identify ways in which we could improve our performance. We began by looking for common confusions the best performing approach made between categories. Table 3 displays what is referred to as a confusion matrix, with allows us to see where these common confusions are occurring.

Table 3: confusion matrix of best performing classifier on predicting stuMov

| | predicted NR | predicted E | predicted T |
|---|---|---|---|
| target NR | 99 | 3 | 10 |
| target E | 7 | 19 | 15 |
| target T | 3 | 13 | 59 |

.

We can see that most of the misclassified cases are between "E" and "T". The difference between "E" and "T" is whether a student is expressing his own reasoning or relating to some previously articulated reasoning, which would have typically been contributed by a different speaker. We hypothesized that we can reduce this type of error by taking into account more information about previous contributions where reasoning was articulated. In other words, we want to utilize the predicted student moves on previous turns. As an approximation of this type of approach, we first assign first pass categories to utterances using our three category coding scheme, and then we use these assigned categories as features in order to apply the rules found in Figure 2, which describes a heuristic post-processes stage.

| Rule | Definition |
|---|---|
| 1 | After the teacher changing to a new topic, there shouldn't be T before E (if there is T, change it to an E) |
| 2 | After changing to a new topic, if the same student gives an NR, then teacher asks "why", the next utterance from this student is likely be E, not T |
| 3 | If a student's utterance is an E, teacher ask students to explain, then the next student utterance should be a T |

Figure 2. Heuristic rules for post-processing stuMov predictions.

We implemented theses heuristic rules so that they only apply in cases where the machine learning classifiers make a prediction with low confidence. We define low confidence as confidence scores which are lower than the average confidence scores over all student utterances. Note that although the heuristic rules are manually authored, they can be executed automatically by a computer program to assign stuMov. Also, these rules only reinforce the definition of the three stuMov tags that are not captured by the classifier. Therefore, these rules are not aimed to tailor the automatically predicted stuMovs to a specific training corpus.

With the post-processing, the kappa between the predicted stuMov and the human gold standard on the first session is improved to 0.71 (SD=0.01). We further apply the best classifier and the heuristic rules on the whole corpus of all three sessions and get a kappa of 0.69 (SD=0.01), which shows our approach can be generalized to a larger corpus. This result is encouraging, but we consider it preliminary until more extensive testing on a wider variety of transcripts is conducted to ensure generalizability.

## Predicting the Utterance Responded To

We employed a similar methodology in automating the analysis of which utterance a transactive utterance is responding to. We refer to this categorization as respondUtt. The target prediction is a numerical value. However, the classifiers we are using can only handle target predictions which belong to a finite set of values. Therefore, we define the class value for our prediction task to be 0, 1, 2, 4, and other. 0 stands for the current utterance, in other words, it refers to 0 utterances back, which means the current utterance is an Externalization. In contrast, values such as "1", "2", and "4" stand for Transactive moves that refer to the associated number of contributions back. If the utterance that the current utterance refers to is not 1, 2, or 4 utterances back, it is labeled as "other". We will assign a number to "other" cases in a post-processing stage using heuristic rules.

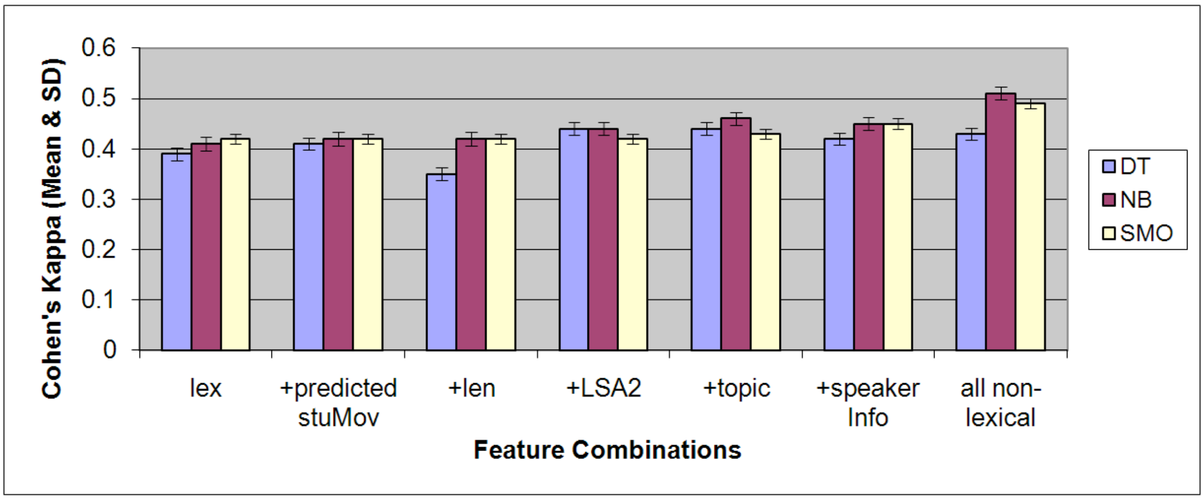

Figure 3. Classification Results on predicting respondUtt

Figure 3 shows the results on predicting respondUtt by the three classifiers in combination with the same sets of features used for predicting the stuMov. We observe that NB using all non-lexical features performs the best in this task, with a kappa of 0.51. Similarly, we add a post-processing step based on heuristic rules shown in Figure 4 using a similar methodology to what we reported in the previous section. By implementing these heuristic rules, the kappa score is improved to 0.69 (SD=0.01). Again, we apply the best performing model with the post-processing step to the whole corpus of all three sessions and get a kappa score of 0.68 (SD=0.01), which offers some verification of the generalizability of our approach.

| Rule | Definition |
|---|---|
| 1 | A student turn with transacMov=T shouldn't point to a student turn with transacMov=NR |
| 2 | A student turn with transacMov=E, respondUtt=0 |
| 3 | A student turn with transacMov=NR, respondUtt=current utterance Num-1 |

Figure 4. Heuristic rules for post-processing respondUtt predictions.

## Discussion

Much work has already been invested in fruitful applications of automatic analysis technology in the area of computer supported collaborative learning (Wang et al., 2007; Kumar et al., 2007). The work presented in this paper points towards a new line of research applying this technology in a classroom context. One potential application of this technology could be for use in teacher professional development, by supporting instructors in reflecting on how their classroom interactions with students have proceeded and how the students are progressing in terms of striving towards articulations of transactive expressions of their reasoning. In support of the students themselves, such technology could be used to track development of a student's argumentation and articulation skills over time. Finally, eventually it may be possible for such technology to provide real time feedback to instructors or students during group discussions in order to stimulate higher levels of transactivity within the discussions. In addition to these practical applications, one can imagine that such technology also holds the potential to speed up the science of investigating the role of patterns of conversational behavior in stimulating valuable social and cognitive processes within classroom contexts. Such arguments have previously been elaborated in connection to research in computer supported collaborative learning (Rosé et al., 2008).

## Conclusions and Current Directions

In this paper we have presented work to date on adapting a transactivity based analysis framework for analysis of classroom discussions and have explored the use of automatic analysis technology in this context. We demonstrated how we used an iterative development methodology to apply and extend available technology to a new analysis task, namely that of analysis of transcripts of whole group classroom discussions. Specifically, we have employed text mining techniques to analysis of transcripts from 3 classroom discussions, and have presented promising results, and positive implications both for practical applications and theory building.

Much work remains to extend this technology before real time analysis of classroom discussions will be practical. Most notably, the work presented in this paper depends upon the availability of transcripts of the classroom interaction. Thus, a considerable effort to record and automatically transcribe classroom discussions in real time using speech recognition technology still requires a substantial and targeted research effort. While advances in the field of speech recognition will undoubtedly be required in order to bring this within practical reach, prior work related to automatic assessment of group processes from speech offers hope that such an effort could be feasible (Gweon et al., 2009).

# Magnetism as a Size Dependent Property: A Cognitive Sequence for Learning about Magnetism as an Introduction to Nanoscale Science for Middle and High School Students

David Sederberg, Lynn A. Bryan, Purdue University, 525 Northwestern Avenue, West Lafayette, IN, 47906.
Email: dsederbe@purdue.edu, labryan@purdue.edu

**Abstract:** In this study, we use evidence from students in grades 10-12 (N = 148) to document the ways in which children learn about and model their conceptual understanding of magnetism. Our model-based design capitalizes on phenomena that are engaging to students, to describe the behavior of magnetic materials across scale, from the familiar to the nanoscale. Data are drawn from written responses to pre- and post-questionnaires, embedded assessments, activity journal pages, and informal interviews, to describe a progression of students' mental models of magnetism. Our goal is to integrate multiple related concepts to describe possible pathways for learning. An implication of this work is that it may be used to inform level-appropriate strategies for both instruction and assessment for the study of magnetism across scale.

## Introduction

Magnetism is long standing staple of science curricula from grades K-12 and beyond. It is a phenomenon that fascinates and interests students of all ages. Yet we know surprisingly little about people's conceptions of magnetism (Hickey & Schibeci, 1999; Maloney, 1985), nor have conceptions of magnetic phenomena been investigated as intensively as other physical phenomena such as electricity, force and heat (Borges & Gilbert, 1998; Erikson, 1994; Hickey & Schibeci, 1999).

Researchers have previously documented students' conceptions related to magnetism such as (a) models of magnetism (Borges & Gilbert, 1998; Constantinou, Raftopoulos, & Spanoudis, 2001; Erikson, 1994); (b) the confusion between magnetism and charge (Borges & Gilbert, 1998; Hickey & Schibeci, 1999; Maloney, 1985); (c) action at a distance (Bar, Zinn, & Rubin, 1997); and (d) the concept of field (Bradamante & Viennot, 2007; Guisasola, Almudi, & Zubimendi, 2004; Guth & Pegg, 1994). Less study has been devoted to the exploration of how students' conceptions about magnetism progress or to document the transitional nature of students' conceptions and mental abstractions as they learn. Nor have students' conceptions of magnetism across scale been investigated. Learning about nanomagnetism, for example, provides a means of not only introducing concepts of nanoscale science to children, but it is a vehicle to reinforce and apply science concepts already existing in the curriculum.

The concepts of magnetism pose a challenge for learners; they require higher levels of cognition and mental imagery than more concrete and tangible concepts (Barrow, 1987; Borges & Gilbert, 1998; Guisasola, et al., 2004). The idea of an object causing a force to be exerted on another without touching, or reasons why an object could be attracted toward either end of a magnet are counterintuitive for children (Constantinou, et al., 2001). Children commonly believe that magnets are electrically charged, and that electrostatic and magnetic interactions are the same (Borges & Gilbert, 1998; Haupt, 1952; Maloney, 1985). Many students may also believe that the magnetic field has a finite boundary (Bar, et al., 1997), or that the field lines are a concrete entity (Guisasola, et al., 2004; Guth & Pegg, 1994). Understanding these concepts requires the ability to construct mental models of abstract concepts, such as spatial orientation, noncontact forces and the particle nature of matter.

The goal of our research is to describe the increasingly sophisticated ways in which students construct mental models about magnetism. We will show how a limited number of key benchmark concepts, through guided inquiry, mental imagery, and metacognitive reflection, can enable students to develop a deeper and more intuitive understanding of magnetism and magnetic phenomena, both in the realm of the familiar, as well as at the nanoscale.

## Theoretical Framework

This work is based on a developmental view of learning "developing relations among a (relatively few) set of core concepts throughout schooling" (Catley, Lehrer & Reiser, 2005, p, 8). These concepts provide targets for learning, accessible to younger students yet still a challenge for in-depth understanding at later grades (Lehrer & Schauble, 2004). Wiggins & McTighe (2006) characterize these core concepts as linchpin ideas - those concepts within a content domain that have enduring value throughout and at multiple levels with the domain, providing conceptual anchors for construction of knowledge and a basis for assessment.

We also draw from the literature on mental models and model-based learning. As a representation of something in the absence of the real thing (Greca & Moriera, 1997) mental models provide a lens through which levels of understanding and cognitive sophistication, relative to a target concept, may be approximated. Model-based learning presumes that through the process of generating, critiquing and revising our mental models we can approach a more coherent and normative understanding (Clement & Steinberg, 2002; Coll, France, & Taylor, 2005; Lehrer & Schauble, 2006; White & Frederiksen, 1998). Models are the dominant form of explanation in science and learning science is to make, revise and justify self-constructed models, not simply to use models posed by others and taken for granted (Lehrer, 2009).

Mental models provide the learner a means to organize concepts in a way to help understand the world or to explain it to others (Harrison & Treagust, 1996). In order to construct a coherent conceptual understanding of scientific principles, learners must be able to formalize, assess and reflect upon, and justify their understanding of scientific concepts as they develop them (Cavicchi, 1997; Clement, 1989; Clement & Steinberg, 2002). In the process of constructing a mental model the learner reduces a phenomenon to the elements most meaningful, selecting "only some parts of the entity and relations between them" to create a personally meaningful representation (Gilbert & Boulter, 1995).

The use of mental models generated and revised by the student while learning and revealed through multiple inscriptions (Latour, 1990) will provide a lens through which both the researcher and learner will be able to access the evolutionary nature and coherence of that cognitive process. The invention and revision of models, as an expression of a form of knowing is characteristic to the natural sciences and "are the defining features of scientific thinking" (Lehrer & Schauble, 2006). Yet, it has been shown that changes in mental models and conceptions do not occur quickly and often require repeated challenges, metacognitive reflection, and multiple mixed models along the way (Nussbaum & Novick, 1982).

One of the impediments to understanding magnetism, especially magnetism at the nanoscale, is the concept of the atom and the particle nature of matter. At the nanoscale the effect that thermal energy has on particle motion is manifested in the behavior of the material. The behavior of these materials is not only relevant to the realm nanoscale science, but serves as a tool for connecting to and learning about the nature of magnetism in general.

Children are aware of the terms atom and molecule and references to both of them as "particles" and yet still believe that matter is continuous or that substances contain molecules rather than substances are composed of molecules (Harrison & Treagust, 2002). A scientific understanding magnetism requires an understanding of the particle nature of matter and the implications of thermal energy and applied forces on the appropriate hierarchy of single or aggregate groups of particles (e.g. atom, domain, magnet).

The overarching goal of this research is to provide an in-depth look at the progression and coherence of students' mental models in learning about magnetism. An important part of our work is the belief that nanoscience and nanotechnology offer an exciting impetus for learning, empowering student learning in the context of new and exciting concepts of emerging s discovery. Furthermore, the introduction of nanoscience into the existing curriculum helps to provide a big picture view of science and conceptual coherence of scientific concepts for students. The specific goals for this study will be to answer the following questions.

1) What is the nature and range of sophistication of grade 10-12 students' initial models of magnetism and magnetic interactions?
2) What common patterns emerge as students critique and revise their mental models of magnetism during the learning process?
3) What themes among students' developing mental models provide coherent explanatory power across scale?

## Method

This study was guided by an orientation in interpretive research (Creswell, 2009), to document the generation and iterative revision of students' mental models of magnetism. We used a quasi-experimental design to compare the construction and progression of mental models of selected concepts of magnetism. Emphasis was placed on students' construction and revision of models, coordinated across multiple magnetic phenomena and scale. Iterative cycles of investigation, reflection and revision were used to provide students the opportunity to revise their models for coherence and explanatory power. The two teachers participating in this study each taught their own magnetism unit, following the lesson format provided by the researchers and, with minor modifications, used the same assessment instruments.

## Participants

The grade 10-12 high school students (N = 148) in this study comprised a non-random sample, solicited from two high schools with which researchers had previously worked as constituents in a nanoscience teacher professional development program. The classes were all high school physics classes; the majority (approximately 95%) of the students in the classes were in the 11th grade (see Table 1).

Table 1: Student Groups Comprising the Sample

| Sample | Description of students | N | Intervention | Code |
|---|---|---|---|---|
| 1 | High school physics (17-18 years) | 66 | Yes | MC |
| 2 | High school physics (17-18 years) | 72 | Yes | PL |

## Intervention

The series of lessons for the intervention will follow a cycle of model-based inquiry in which students will make predictions, conduct investigations, interpret results and apply their revised mental models to new situations. During the cycle of lessons, students will be provided multiple opportunities to reflect on and revise their mental models, and to defend or revise them in light of new and possibly conflicting evidence. The series of lessons which will be employed were designed by the researcher and are based on those concepts believed to be most salient to students constructing a coherent understanding of magnetism and the behavior of magnetic materials across scale.

## Data Sources

The data collected consisted of student responses to pre- and posttest tests, inscriptions from embedded assessments, activity journal pages, collaborative group artifacts and informal interviews. Our goal was not the assessment of effectiveness of an intervention. Rather, we aimed to document the status and growth of students' mental models and explanations of magnetic phenomena through the normal course of classroom instruction by the classroom teacher. Our lessons and assessments for this study consisted of items in the areas of: the concept of magnet; magnetic interactions, magnetic versus electrostatic interactions, magnetic fields, domains, magnetizing and demagnetizing, and magnetism at the nanoscale. The assessment items were paper and pencil open ended response and graphic format.

## Data Analysis

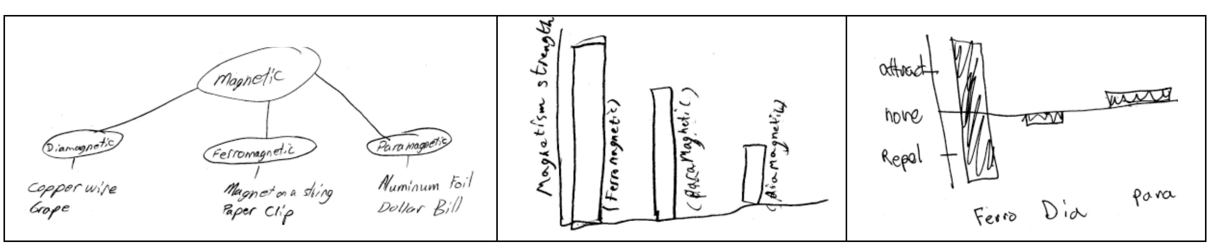
Written responses were transcribed into a spreadsheet for comparison and analysis. Drawings and graphics were coded to fit students' conceptions into categories representing levels of sophistication based on the depth of understanding exhibited, relative to target concepts

# Findings and Discussion

We describe our findings for the following categories: (a) magnetic materials and interactions; (b) magnetic fields; (c) models of magnetization and magnetic domains; and (d) magnetism at the nanoscale.

## Magnetic Materials and Interactions

Students initially conducted an inquiry designed to elicit their models of magnetic interactions and then made a drawing of their own design to interpret their findings. Interactions were typically classified as attractive, but not necessarily repulsive, in various combinations of weak or strong (see Figure 1). Some students focused on the nature of interactions, others by the materials involved.



PL-17 PL-38 PL-6

Figure 1. Classification of Magnetic Interactions

While some students' drawings depict more than one level of interpretation, many lacked the degree of sophistication that would indicate a broad understanding of concepts. Few students included repulsion, for example in their model, despite having used two magnets and despite observing the diamagnetic behavior of a grape. Very few students included the possibility that there could be no magnetic interaction even though some of the materials used were not magnetic (plastic ruler, paper, wood), and students frequently did not make a distinction between strong versus weak interactions. Some students' models indicated common non-normative beliefs, for example that all metals will be attracted to a magnet Table 2 lists categories of responses that might be used to differentiate levels of students' conceptions of magnetic interactions based on their observations with these materials.

Table 2: Concepts of Magnetic Interactions.

| Level | Key features of drawings |
|---|---|
| More sophisticated | Includes magnetic and non-magnetic, attraction and repulsion, strong and weak, includes magnet-magnet interactions; defines types of magnetism |
| | Includes magnetic and non-magnetic, strong and weak, types of magnetism |
| Less sophisticated | Little or no predictive value; reflects only materials used |

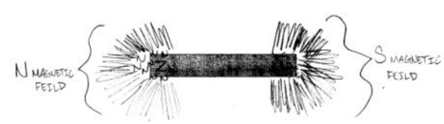
The purpose of this initial lesson was to help students develop an awareness of degrees of magnetic attraction and/or repulsion, how these interactions are observed, and what common materials exhibit these properties. Students re-visited categories of magnetic materials, the degree of response and the ability of some materials to remain magnetized or not, in subsequent lessons.

## Magnetic Fields

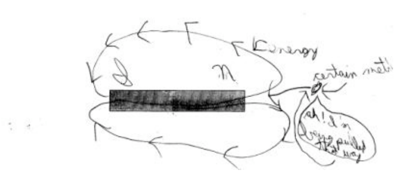
The detection of magnetic fields was an integral part of our lessons, both for investigation and as a tool for detection. The drawing of an iron filing diagram identified a change in the space surrounding a magnet and provided an overall concept of the both the geometry of the field and areas of more and less density. Students also discovered during this activity the three dimensional nature of the field. Mapping the field with a compass provided students access to the directional orientation of the field and identified the compass as a field "detector" for subsequent inquiries, the magnetization and cutting of a wire, and magnet consisting of iron filings in a straw.

The pre- and posttest assessments asked students to draw or write all of the "characteristics" that they think might help to explain how magnets work (see Figure 2.)

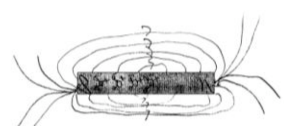
PL-22 Pretest



PL-22 Posttest



PL-50 Pretest



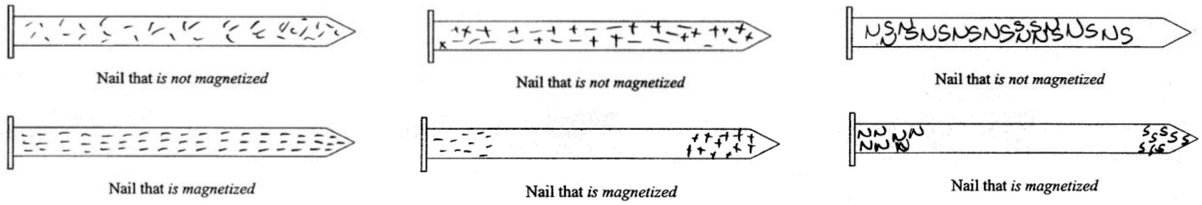
PL-50 Posttest

Figure 2. Pre- and Posttest Drawing of "Characteristics" of a Magnet.

In previous iterations we framed this question more to elicit conceptions specific to magnetic fields. However, we found that leaving the item more open for interpretation produced a broader range of responses. Additionally, we found that the degree to which students might elaborate on their conception of the field helped provide a means for categorizing understanding. The most sophisticated models included enough field lines to convey a greater density at the poles, the symmetric nature of the field, identification of poles and an indication of direction. The role of the field in the alignment of the domains of a ferromagnetic object is a key concept that recurred in subsequent lessons.

## Magnetization and Magnetic Domains

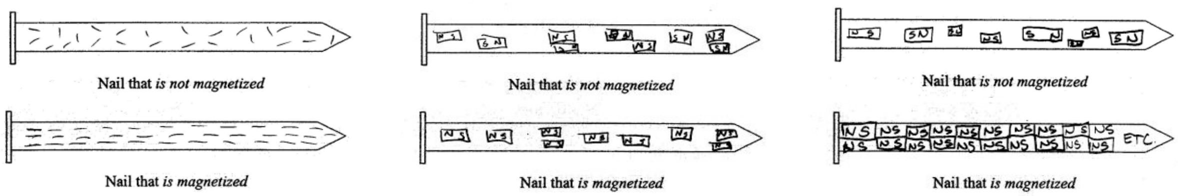
We approached the concept of domains with a stepwise progression of investigations to help students construct, and provide us access to, increasingly sophisticated mental models. At the end of the first investigation, categories of magnetism, we asked students to speculate how a magnetized nail might differ from a non-magnetized nail if they were able to "see inside." These models provide a means of eliciting students' mental models of how magnetized and non-magnetized materials might differ (see Figure 3).



PL-62 PL-14 PL-22

Figure 3. Pre-instruction Models of Magnetized and Non-magnetized Nails

These models provided a beginning for the development of the concept of domains, fundamental in providing the conceptual framework to understand how a nail, for example, can be attracted to either end of a magnet, why an object can be magnetized, or why nanoscale materials do not stay magnetized. At key times throughout the lessons, students referred to their initial models, confronting and revising them based on new evidence and their changing conceptions. Posttest responses for the same students are shown in Figure 4.

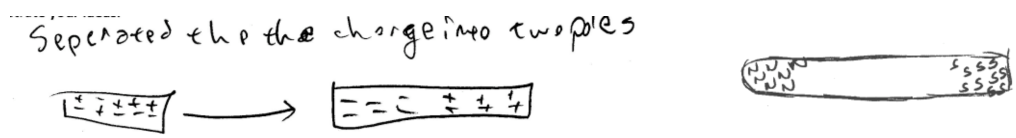


PL-62 PL-14 PL-22

Figure 4. Post-instruction Models of Magnetized and Non-magnetized Nails

These inscriptions demonstrate that while PL-22 and PL-14 had begun to incorporate the concept of domains into their conceptual framework, PL-62's mental model had not changed. PL-22's model would also indicate that the entire nail was comprised of domains, while PL-14's model gives the impression of domains embedded in another material.

One of the several ways in which we made the concept of domain accessible to students was through a "straw magnet." Student made their own magnet by filling a soda straw with iron filings and then magnetizing and de-magnetizing their magnet, observing the change in field with a compass. While students generally began to associate being magnetized with a state of conditional alignment, we found that many still held on to their concept of charge (see figure 5).



PL-14 PL-22

Figure 5. Magnetizing a Straw Magnet

The two inscriptions in Figure 5 are good examples of models between the pre- and post-instructional models in Figures 3 and 4. Both of these models show an increased sophistication from the initial model, yet are refined further during the remainder of the lessons, as the inscriptions in Figure 4 demonstrate.

After the straw magnet lesson, students from one group create a drawing for what they believed would happen when a nail is approached by either end of a magnet (see Figure 6). The other group responded to a similar question with a written response (see Table 3).

Figure 6. How a Nail is Attracted to Either Side of a Magnet (MC-21).

The drawings by student MC-21 are a reasonable model of the alignment and reverse alignment of the domains in the nail, subject to the field of the magnet. This student aligns the domains in the nail relative to the magnet and indicates the action of the field.

Table 3: How a Paper Clip is Attracted to Either Side of a Magnet

| Level | Key concepts |
|---|---|
| More sophisticated | The magnet magnetizes the paper clip, which means it causes the domains within it to be lines up. The paper clip can be attracted to both ends of the magnet because both ends will line up the domains. Therefore, one end of the magnet will line up the domains in one direction and the other end will line them up in the other direction. (MC-66). |
| Less sophisticated | The domains of the paper clip will shift according to what side of the magnet is presented allowing it to pick up the paper clip (MC-67). |

The more sophisticated of the responses alluded to the alignment of domains, yet none of the students in our sample referred to the concept the field in the action; the level of sophistication appeared to stall with the magnet causing the effect. This is however neither surprising nor discouraging, given the limited time frame for instruction and the abstract nature of the interaction.

## Magnetism at the Nanoscale

The magnetic properties of nanoscale materials is grounded in two key concepts: (1) the dominance of the behavior of a particle by the larger number of atoms on the surface of the particle relative to atoms in the interior compared to microscale and macroscale objects, and (2) thermal effects which exceed the tendency for nanoscale domains to remain aligned in the absence of a magnetic field. The investigation and explanation of the behavior exhibited by a magnetic fluid (ferrofluid), ties together all of the concepts presented in the preceding lessons. Figure 7 shows two student inscriptions, representative of two levels of sophistication, applying observations from the nanoscale material investigation with the concepts they learned.

PL-1 PL-47

Figure 7. Response of a Magnetic Fluid to a Magnet.

Inscription PL-1 correctly shows the gathering of the magnetic fluid near the pole of the magnet underneath, but lacks the conceptual detail of the field lines and the corresponding "lining up" of the magnetic particles. The second inscription shows correctly oriented field lines with the magnetic particles conforming to a pattern similar to what students had observed with iron filings.

Students were also asked to explain why nanomagnetic particles do not remain magnetized when larger samples of the same materials do. The rationale behind the question is to elicit students' ability to translate their mental models of magnetization, field, domains, and the effect of thermal energy and particle size, to the behavior of the magnetic fluid (See table 4). We found that, even at the end of the series of lessons, there remained a continued perception of electrostatic charge being a factor in the magnetic behavior of the nanoscale particles among some students' conceptions. The two following responses illustrate, "There is too much surface to keep the charges magnetized and therefore tend to lose charge quickly" (MC-52); "The charges have a bunch of space to move around and don't want to stay in one spot to stay magnetized" (MC-6).

Table 4: Why Nanosize Particles Do Not Stay Magnetized

| Level | Examples of student responses |
|---|---|
| Most sophisticated | These nanoscale particles are constantly moving around, causing the domains to become unaligned at any moment. If the domains are unaligned, the particle cannot stay magnetized (MC-4). |
| Less sophisticated | They don't have enough atoms on the inside to make up domains to stay lined up to keep magnetized (MC-15). |

While the responses in Table 4 hint at aspects of thermal energy and the impact of surface, relative to volume, students may remain "captured" by their intuitive knowledge (Cheng & Brown, 2007), reverting back to that intuition rather than using a still undeveloped but more sophisticated model.

## Conclusion

This research represents a pilot study. Our goal was to begin to document a range and progression of sophistication of students' mental models of magnetism, revealed through multiple and frequent inscriptions. We believe that through model-based learning, mentoring students to construct, metacognitively reflect on, and reform their mental models, learners will approach a more coherent and normative understanding of concepts of science. This study serves as a starting point for further research that aims to develop cognitively grounded and research-based cohesive physical science curricula organized around key theoretical principles

While we are encouraged by our results, we also recognize that learning about the nature of magnetic interactions presents many cognitive challenges. In the case of domains, for example, we found that students associate an element of alignment to a magnetized object, but that their understanding of that alignment might just as likely reside at the atomic level, involve an electrical polarization, or may consist of an alignment which, while similar to the concept of domains, appears more to be an artifact of composition. Students created multiple inscriptions based on the concept of domains, yet appear to not have significantly grasped the concept that each domain is in effect its own little magnet with its own magnetic field.

The nature of nanomagnetic materials poses challenges in learning, both in terms of magnetic fields and domains, but with the added layer of complexity of the particle nature of mater and kinetic molecular theory. We found, for example, that some students believe that atoms in a nanometer size piece of iron are smaller and closer together than in a larger piece. That notwithstanding, the impact of thermal vibrations on the alignment of the atoms in a single (nanoscale) domain was accurately described by a large portion of students. A kinesthetic activity in which students in a group each modeled an atom proved a tangible way to compare surface to volume and the effect of thermal vibrations.

Similar to the findings of Cheng and Brown (2007), we also found that students reverted to prior models in the abeyance of newer more fruitful ones and the tendency to rely too heavily on concrete interpretations of models used for explanatory purposes. Effects of thermal energy or mechanical shock, or dropping a nail to demagnetize it, are often believed by students to physically translate the atoms in the material, rather than to disorient their magnetic alignment. The distinction is confounded, however, with the observation of a magnetic fluid in which the domain particles actually do translate in the absence of a field.

We believe that the study of magnetism provides as meaningful framework and engaging segue for the introduction of nanoscience and of the size dependent nature of materials at the nanoscale. Further study of the ways in which students conceptualize magnetic phenomena across scale, and the cognitive pathways by which those conceptions are able to progress toward greater levels of sophistication will not only provide a descriptive account of learning, but may also inform instruction. In addition, we believe that evidence suggests that magnetism is a meaningful and authentic way in which nanoscience can be introduced to serve existing standards and curricula.

# From Show, To Room, To World: A Cross-Context Investigation of How Children Learn from Media Programming

**Abstract:** We conducted a year-long, naturalistic study that investigated what actually happens when children watch television. We video-recorded children's actions and interactions while watching television and simultaneously recorded the video stream from the television screen; these data were supported with parent diaries and interviews with parents and children. This paper describes two case studies, in which we consider children's interactions with others while watching television and the ways in which their television viewing influences other parts of their everyday lives. We find that both children actively applied knowledge they obtained from visual media to other contexts. In addition, they both shared their media viewing experiences with others, either by directly teaching others about what they had viewed or by creating new content based on what they had viewed.

Television viewing remains an activity that consumes a great deal of young people's time (Kaiser Family Foundation, 2010). Television programming has been criticized for many reasons, including its potential to influence children's behavior and absorb time that might otherwise have been used more productively (Buckingham, 1993; Fisch, 2004; Kirkorian, Wartella, & Anderson, 2008; Maccoby, 1952). Zimmerman, Christakis, and Meltzoff (2007) found that viewing television was associated with slower vocabulary development in children under three years of age. Another recent study (Christakis et al., 2009) found that audible television in a child's environment is associated with lower levels of adult and child interaction. Additionally, Christakis, Zimmerman, Di Giuseppe, and McCarty (2004) suggest that young children's television viewing may have some relationship to attention problems. In response to studies like these, France banned educational television for children under three (France bans broadcast of TV shows for babies, 2008) despite the existence of other research that found benefits of children's viewing (Fisch, 2004; Fisch & Truglio, 2001; Kirkorian et al., 2008; Pecora, Murray, & Wartella, 2006).

This project is informed by studies of how people learn in informal environments and situates itself among similar research studies investigating social interaction and learning (Stevens & Hall, 1998; Stevens, 2000; Stevens, Satwicz, & McCarthy, 2007). Our study directly examines what happens when children watch television in order to understand what types of learning may occur.

In this paper we describe how two children in our study watch and respond to television and YouTube videos, and how their viewing affects other aspects of their everyday lives. We employ an "in show/in room/in world" framework (adapted from Stevens et al., 2007) for the description of children's media viewing and learning. "In show" refers to the television, structure, and conventions of a specific television show. For example, some educational children's shows use conventions, such as dialogue in which TV characters directly address viewers with questions or requests (e.g., to "help" them solve a problem or complete a task), in order to achieve their learning goals. These characters elicit viewer actions by "talking" directly to viewers and leaving time for viewers to respond. Typical prompts include asking viewers to repeat words, actions, and phrases, or to sing along. However, unlike the "in game" designation from Stevens et al. (2007), which was a study of digital games, the viewers of television shows cannot change the action on screen. All interaction occurs entirely in the room. "In room" refers to the social and material characteristics of the environment in which the viewing takes place, particularly the interactions with others that occur there. Finally, "in world" refers to the ways in which the show and viewer responses elicited by the show or by others viewing in the room manifest in other aspects of a child's everyday life.

## Methods

We collected data for 6 months, followed by 6 months of analysis and follow-up interviews. The study included 16 children, 8 boys and 8 girls, aged between 9 months and 6 years. Children were observed and videotaped in their homes for 1-2 hours approximately once each week as they watched different types of media (such as television programming, DVDs, movies, and YouTube videos), and interacted with parents, friends, siblings, toys, and pets. During each session, a videotape record was created and ethnographic field notes were written.

A goal in this study was to record as accurately and completely as possible children's actual experience of watching television in their homes. In order to do this, we scheduled sessions at times when the children were most likely to be watching television in order to avoid interfering with their schedules and routines. We simultaneously recorded the in-show video stream from the television and the in-room activity of children and others in the viewing space (Stevens et al., 2007). We employed a device that synchronized the two streams at the time of recording in the field. In the early stages of the study, we set up the dual-recording equipment and then stepped out of the room while the children were watching. As the study progressed, we were able to further minimize our intrusion by leaving the equipment with the families for a week or more, during which periods the parents turned on the equipment as often as possible when the children watched television. In order to record children when they watched video on a computer, we also used a software program (Screenium) that simultaneously recorded the computer screen and the video stream from the computer's internal camera.

Figure 1: Split-screen image illustrating Harrison "in room" showing his brother Max how to follow the "blast-off" sequence from Leo, and the "in show" *Little Einsteins* program on the television.

We also interviewed or provided written questionnaires to the parents of the children about their child's viewing habits, television learning experiences, and their own feelings about television, movies, and online media usage in their homes. We asked parents to informally interview their children (these interviews were recorded) and we asked specific follow-up questions in a separate questionnaire distributed to parents via email. Finally, parents used journals to record instances of learning and discovery in their children's everyday lives when researchers were not present. These journals were critical with regard to determining whether and how children's viewing habits and interactions when watching visual media affected their everyday activities "in world."

### Data Analysis

All of the video-recorded data were logged and tagged to locate examples of children's responses to television and interactions in the room. Next, we analyzed the actions taking place within each individual clip in greater detail (Stevens et al., 2007), looking specifically at highlighted moments of activity using interaction and conversational analysis techniques (Erickson, 2004; Schegloff, 1998). We devised a transcription method (illustrated in the next section) to distinguish between activities in the show and in the room, and to display activities simultaneously. We used these techniques to illustrate how each viewer action began, what happened during the action, and how long each action lasted. Case studies were created that tied together our video analyses with interviews and diary reports in order to tell the story of an individual child's television viewing experience and relevant learning.

## Case Studies

This section is organized around the case studies of Harrison (age 3 at the beginning of the study and age 4 at the end) and Owen (age 5 at the beginning of the study and age 6 at the end), starting with the television shows they viewed and then examining their in-room interactions and in-world connections to their media viewing behavior. Both children live in the Pacific Northwest, each with a mother and father. Harrison has 1 younger brother and 1 older sister, and attends pre-school every day for a half day. Owen has 1 younger sister and attends kindergarten each day for a full day.

### Harrison

#### Show Viewing Habits

Harrison mainly watched television shows on DVD. In a pre-study questionnaire (April 2008) his mother stated that he usually watched about "*four to six hours of television a week*," including "*Dora and Diego; Super Why? … movies about animals, non-fiction; some Disney movies; basically anything he can get his hands on; no Sesame Street ([he]doesn't like [it]), [and] age-appropriate videos*." Many of the shows he watched were animated shows designed to elicit viewer actions, like *Dora the Explorer*, *Little Einsteins*, and *Go Diego Go*.

In addition to the shows mentioned above that are designed to elicit viewer actions, Harrison also watched non-fiction nature programs such as *Eyewitness Amphibians* and *Henry's Amazing Animals*. These shows employ a narrator and use video footage along with animation to explore animals, their habitats, and their behaviors. In a post-study interview (February 2009), Harrison said he liked "*nature shows the best*" and would watch them over anything else because they "*were real*."

## In Room

Harrison was a very social television viewer in terms of the level of interaction he maintained with other people while watching television shows. He watched shows in his living room, typically with one or more people, who might include his older sister Leanne (aged 5 to 6 during the study), his mother, and his younger brother Max (aged 9 to 21 months during the study). His mother closely monitored what he viewed on television because he did not like to watch shows he had not already seen and because he would get scared easily: "*[he] tends to distrust any show if it has new characters*" (May 2009). Harrison's mother also stated that Harrison usually watched shows that allowed him to learn new facts he could share with her and his other family members. "*[Harrison] enjoys yelling out facts he learns [from shows that] engage him*" (May 2009). When watching television with his sister, his mother said that "*they usually sit by each other and talk about the show. If they get scared, they work together to turn the volume down, hide under a blanket, etc. If they are learning something, they shout out to me. Once in a while they correct each other or bicker a little about a show*" (May 2009).

While viewing shows, Harrison tended to speak to and about the show, regardless of whether the show elicited viewer responses. He responded to shows that prompted him to repeat words, answer questions, repeat actions, and sing songs. Even while viewing shows that lacked prompts for response, Harrison responded to them. Tables 1 and 2 illustrate a sequence of two transcripts, several seconds apart, that exemplify Harrison's response to an episode of a nature show. The top part of the transcript records what is happening sequentially in the show and the bottom of the transcript describes what is happening in the room. The picture in the middle is a frame from the split-screen image from which the segment was taken. Actions on screen are represented in parentheses, while actions in the room are represented in italics.

Table 1: Harrison imitating the movements of the frog's mouth as its froglets jump out (October 30, 2008).

***(frog baby lands on the ground)*** ***(slow motion shot of baby frog jumping out of larger frogs mouth)***

*InShow*
*In Room*
**Harrison: (*laying on rocking chair leaning on arm rest gaze towards show*)** **(opens mouth slightly like frog)**

Harrison responds to the nature show both verbally and physically by simulating the movements, actions, and sounds of a frog on the screen. In Table 1, Harrison, while seated on a chair, imitates the mouth movements of a male frog shown on television (which stores its young in its mouth until they jump out fully formed). In Table 2, several moments later, Harrison explains the frog gestation information he just learned to his mother while continuing to watch the show.

Table 2: Harrison explaining the frog's unique gestational practice to his mother (October, 30, 2008).

|---|---|---|---|---|---|---|---|---|---|---|

Narrator: After twelve weeks the frog leaves the pond one small hop for the frog one giant leap for evolution
Screen: (*frog leaves pond and hops onto land*) (*frog jumps*)

*InShow*
*In Room*
Harrison: they they grow in its mouth he opens it and then he closes and the frog when its ready jumps out
(*sits up and looks into camera*) (*looks back at show imitates the frog by opening and shutting his mouth*)
(*moves arm to show motion of froglets coming out of mouth*)
(*sits back in chair*)
Mom: wow

These transcripts reflect Harrison's desire to perform actions along with the show and invite his mother to share in his newfound knowledge about frog gestation. It follows that television shows provide children with information they can learn and teach to others, and that young children who view a television show sometimes imitate and simulate an experience presented in the show, such as how a frog stores its babies in its mouth until they are mature enough to survive on their own. In Harrison's case, he uses his body and voice as he actively responds to the content of the show.

Furthermore, Harrison and his sister are quite familiar with the conventions of certain shows (such as the "blast-off" sequence from shows like *Little Einsteins*), which is the result of "*years of viewing*" according to their mother (March, 2009). Given this familiarity, they are able to coach their younger brother Max (17 months) to share in the experience of responding to prompts from a television show. They demonstrate this by performing the "blast-off" sequence from *Little Einsteins* for Max and he learns to participate appropriately (see Table 3 below). After a few viewings, Max was able to also perform the sequence on his own. Their mother stated that Harrison and Leanne "*encourage him to do actions or sing along*" to shows that elicit viewer responses and in other contexts. They also like to support Max "*…and teach him new words. He's their little prodigy. I think they are excited at the prospect of being able to share their knowledge with him"* (May, 2009).

Table 3: Harrison teaches Max the "blast-off" sequence from *Little Einsteins* (November 25, 2008).

Leanne: Max remember? pat, pat, pat , pat, pat, pat, pat Max likes it
(*leans forward and stretches out arm and sits up on knees and begins patting her lap*)
Harrison: pat, pat, pat hee hee hee
(*camera pans to Harrison who is patting and looking at Max*)
Max: pa
(*camera pans to Max patting lap*)

In sum, Harrison was an active viewer who responded verbally and physically to television shows that were designed to elicit responses, and to shows that were not designed to elicit any responses. According to his mother's journal, as well as our interviews and observations with him and his family, as Harrison viewed specific television programs designed to elicit viewer responses he developed techniques for how to act while watching those programs. He passed along these techniques by encouraging his younger brother to also share in the experience of responding to a show that elicited viewer responses. He also liked to share facts and information he learned from watching nature shows with his family, and applied these skills in his interactions with his family while watching television and in other contexts.

### In World

During the study, Harrison also began applying information learned while watching one show to other experiences, including other shows that did not elicit viewer responses. For example, his family went on a trip to Arizona to visit his grandparents. While there, they all viewed *Disney's Planet Earth* as a family. Harrison's mother said she was stunned when Harrison began to name the locations of certain waterfalls and demonstrate knowledge about many of the caves, animals, and rock formations in the show. She stated that Harrison and Leanne said they "*learned*" about them from *Dora the Explorer*, *Go Diego Go*, and *Little Einsteins* (March 2009). "*This instance was unusual because it crossed the bridge between cartoons and non-fiction videos,*" She thought it was interesting that Harrison was discussing information he saw and learned about in an animated fictional show and was relating that information while watching a documentary about nature (May 2009).

In addition, Harrison's mother stated that television viewing helped him make learning connections away from the television set. In her viewing journal and interview, Harrison's mother stated that "*about twice a month [Harrison] will randomly say something that he 'learned' from TV.*" For example, "*if we go to the zoo, he will say facts about the animals*" (May 2009). Furthermore, in her parent journal she wrote that Harrison asked to watch shows such as *Reading Rainbow* because *"they helped him learn to read*" (December 2008). She also said in a post-study interview, "*we did get some Diego phonics readers…because he asked for them"* (May 2009). She believed that, when Harrison asked for a Diego book for Christmas, he thought it would help him learn to read. So Harrison connected the shows he viewed to other aspects of his life.

## Owen

### Show Viewing Habits

Owen, who turned 6 years old during the study, did not watch any shows that elicited viewer responses in our study observations, yet he frequently responded to the shows he watched. His mother indicated in her journal and interviews that Owen previously watched shows such as *SuperWhy* and *Little Einsteins* that elicited viewer responses when he was a bit younger (April 2008). In a pre-study questionnaire (April 2008) his mother stated that Owen usually watched about "*fifteen to sixteen*" hours of media each week, including television shows on PBS such as "*Curious George; Dragon Tales; whatever is on when he comes home*," as well as videos on YouTube about "*Bionicles movies; commercials; vintage tv ads for toys; reviews of toys (home movies), for example Bionicles (showing how to put toys together)*," and movies such as "*…Pokemon, Digimon movies; The Black Stallion; [and the] Marx Brothers*." We observed Owen mainly watching shows on the afternoon block of PBS Kids (*Curious George*, *Arthur*, *Dragon Tails*, *Word Girl*, and *Fetch with Ruff Ruffman)*; we also observed him watching toy reviews on YouTube for Lego Bionicles as well as Hot Wheels cars and Transformers. Furthermore, we observed Owen viewing the live-action nature documentary series *Nature: The Beauty of Ugly* and the animated DVD series *Avatar the Airbender.*

In a post-study interview (May 2009), Owen stated that his favorite shows were "*Curious George because he can do things we can't*," "*Fetch with Ruffman because it's funny,*" and "*…Nature…because…my favorite thing [is] the rat-tailed scorpion… they, they were – they're not…insects like scorpions, but they're not, they're not like spiders but they're a different species… and they look weird.*" The nature shows were generally more realistic than the other types of programming that Owen viewed in terms of their settings (real life vs. cartoon fantasies).

### In Room

On an average day, Owen watched media for up to 4 hours in his basement. He was usually unaccompanied when he watched video, although he sometimes watched shows with a friend, with his mother and younger sister Mia (who was 1 year old) in the afternoon, or with his father before bedtime.

Owen often displayed sensitivity to what he saw on the screen. On several occasions Owen became upset when he viewed show characters in embarrassing or suspenseful situations. His responses to these kinds of situations included running away screaming, hiding his head under a pillow or in his hands, or shouting that he hated it or that it made him scared. With regard to these observations, Owen's mother stated that "*he seems to be frightened when something 'bad' is about to happen, whether that be someone getting angry or someone getting hurt. It does confuse me. The best answer I can give right now would be that he takes things very literally. He doesn't do a lot of 'pretending to be a character'. He gets frustrated and confused when his friends claim something that is just not true. Also, he has an explosive personality himself, and so maybe he is afraid that the characters in the show would react the same way he would, and that scares him. [Owen] feels things very deeply, so if there are scary things happening he will feel very scared!*" (May 2009).

Owen developed coping mechanisms that he employed as he watched television, even as he watched programs that were designed for children his age and that did not contain purposefully frightening content. Table 4 illustrates how Owen coped with a segment from *Curious George* that scared him.

Table 4: Owen copes with an unsettling situation in Curious George (January 12, 2009).

| Participants | 11th sec. | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20th sec. |
|---|---|---|---|---|---|---|---|---|---|---|

1. Narrator: George didn't want to get in trouble but he
2. George: (looks up) (stands with hands clutched)
3. MWYH: just tell the truth no one will be upset
4. Dog: (ooks displeased and frowns)

5.
6. *InShow*
7. *In Room*
8. Owen: tiss huhh I can just see it I can't do this ok I'll look again
9. (covers eyes with hands) (kicks up leg and lunges towards couch)
10. (sighs; uncovers eyes)

While watching *All New Hundley*, an episode of *Curious George*, in which Hundley the dog messes up the room and George is accused of making the mess, Owen was visibly upset by the fact that George was accused of something he did not do. Owen got through the unsetting situation by telling himself (out loud) that he could not look, but then decided to make himself start viewing again to see whether George would be exonerated (line 8). This behavior matches his mother's observation that Owen disliked scary and misleading situations.

According to the PBS Parents Web site, the educational objective for this episode was to "demonstrate inquiry about the world and solving problems," a process that "includes a variety of skills," and to "model positive attitudes toward learning like persistence and curiosity" (All New Hundley). Owen's reaction suggests that he missed the show's intended message because of the context in which that message was presented. Rather than reflecting an interest in persistence and curiosity, Owen relied on his technique for coping with the emotionally challenging content of the show, and engaged with the show again after George had been cleared of wrongdoing. Therefore, the way in which Owen shared George's experience was, most likely, not what the producers of the show intended.

Other forms of media also have a powerful impact on Owen, such as the toy review videos that he watched on YouTube. Owen viewed toy reviews because he found them interesting and wanted to learn about specific toys and their differences to aid his decision-making process for purchasing new toys. As Table 5 illustrates, Owen used the computer in his living room to watch a YouTube toy review about a Transformer.

Table 5: Owen manipulates Transformer toy when watching YouTube toy review (July 23, 2008).

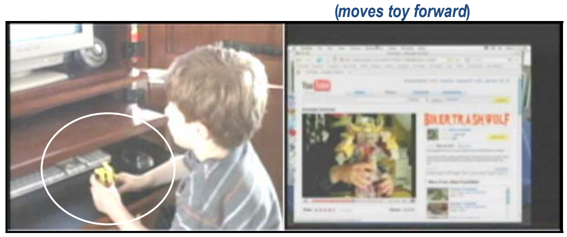
2. Turn them around to expose the orange cuz I like the orange better than the purple
3. (touches head of toy) (adjusts plate on transformer leg) (adjusts plate on other leg)
4. (moves toy forward)



5.
6. *InShow*
7. *In Room*
8. Owen: (holding transformer and watching video) (turns his transformer to the right) (moves transformer back to face video)

As the video narrator discussed the toy he was reviewing, Owen (line 8) manipulated his own similar but smaller toy along with the narrator's description. The narrator did not ask viewers to have a similar toy handy during his review, yet Owen had his toy with him anyway. Owen said he always tried to have a toy or object similar to the one being reviewed so he could more carefully inspect his own toys and see how they compared to those being reviewed (May 2009). He told us he considered these reviews useful because '*you know what to expect*' before buying something (May 2009), which could indicate that Owen was making a judgment about whether a given toy was different enough from his current toys to warrant a purchase.

The notable difference between Owen's behavior in these two examples is the level of emotional arousal he exhibits while viewing *Curious George* and the toy review. The *Curious George* show elicited a highly-charged emotional, empathetic reaction that seemed quite visceral and difficult for Owen to control. He reacted in a way that, according to his mother, mirrored several other outbursts, many of which resulted in a temporary cessation of viewing. By contrast, his viewing of the YouTube toy review was steady and controlled from an emotional perspective, and Owen's activity was limited to his manipulation of a similar toy. Instead of responding reactively, Owen ultimately responded proactively to the toy reviews he watched.

### In World

As Owen viewed more toy reviews on YouTube, he engaged directly with this form of media by becoming a toy reviewer. He came to the conclusion that other toy reviewers did not always provide helpful reviews, and he began to examine more closely how people reviewed products and how good and bad toys were differentiated. After a while, according to his mother, Owen wanted to let people know what he learned, so he recorded his own review of Jazz, a Transformers toy that he enjoyed playing with, and posted his review on YouTube. He stated that he wanted to create a review that would give viewers a more honest assessment of the product they were researching compared to some of the other reviews (May 2009). After posting the video, a few people left complimentary and encouraging comments for Owen on his YouTube page that stated how helpful his review had been for them (see Figure 2).

Figure 2: Owen's YouTube Toy Review

In this context, Owen developed proactive viewing skills that were not reflected in his highly reactive style of viewing television shows such as *Curious George*. Owen learned to watch toy reviews with a critical eye and he chose to apply that learning in practice by becoming a producer of reviews for others to watch. As stated earlier, television shows and YouTube videos provide children with information they can learn and, subsequently, teach to others. In Owen's case, the YouTube toy reviews that he watched filled in gaps in his desired knowledge about a toy that he owned, gaps that neither his parents nor his teachers could fill. His viewing of these videos also triggered an interest in producing a video review of his own with distinctive features, a video that generated enough interest to accumulate over 1,000 views and a 3-star rating.

## Discussion and Implications

While current research (Christakis et al., 2004, 2009; Zimmerman et al., 2007) indicates that young children are passive viewers who should not watch television because of potential language development and attention problems, the present study provides a more nuanced perspective. This study is important in part because little is known about how young children watch television in natural settings. Our observations demonstrate that young children can be active viewers who are indeed learning from their experiences with media and who act to draw others into their viewing experiences. Our study suggests that we might want to worry less about the mere fact of whether children watch television but rather pay more attention to what they do with it and how that might be cultivated in ways that support their development as people (cf. Penuel et al., 2009).

A good assessment of learning is the ability to actively apply knowledge from one context to another. Regardless of the media formats that Harrison and Owen viewed, both boys actively applied knowledge they obtained from those media to other contexts. The similarities between these boys center around their sharing of media viewing experiences with others, either by helping others understand television shows they viewed or creating new content they considered superior to what they had watched.

Harrison and Owen both developed specific, active viewing habits while watching and responding to television shows. Furthermore, both boys seemed to engage emotionally through embodied responses when viewing these shows. After repeated viewing of children's television shows that elicited responses from young viewers, Harrison developed the skills needed to interact with television shows and he even taught his younger brother the same skills. Moreover, when viewing a show Harrison imitated and acted out the movements and actions of the animals on screen. Harrison also shared the facts he learned from shows with other members of his family, a desire to teach that resembles Owen's proactive creation of YouTube toy reviews. Owen was also an active and sensitive viewer who developed ways of exerting control in relation to visual media. He taught himself coping techniques for viewing some television content that he found disturbing, and he recorded and published on YouTube his own toy review.

# Arts and Learning: A Review of the Impact of Arts and Aesthetics on Learning and Opportunities for Further Research

Kylie A. Peppler, Heidi J. Davis, Indiana University, 201 N Rose Avenue, Bloomington, IN, 47405
Email: kpeppler@indiana.edu, hdavis2@indiana.edu

**Abstract:** Traditionally, learning scientists have paid little attention to the discipline of the arts as the more prominent focus has been on science and mathematics. Despite this, the learning sciences could benefit from further understanding how the arts offer alternative methods of inquiry, representation, and understanding. At the same time, leaders in the field of arts education are calling for more research in areas that intersect with the learning sciences, pointing to the mutually synergistic ways that the two fields could inform one another. Guided by feminist communitarian methodology, this paper brings together a review of a wide body of research in the field of arts education, spanning affective, cognitive, social, and transformative effects of the arts. Insights are shared for how the arts as a discipline can inform the study of learning and, conversely, point to ways in which learning scientists can contribute to the field of arts education research.

The arts and aesthetic traditions have long since been a crucial part of the education experience. Scholars, such as John Dewey, have written extensively on the role of the arts in education (1934/1980), conceiving of the art object, the process of engaging in art making, and the resulting aesthetic sensory experience as theoretically independent entities. According to Dewey, the activity of art making is important because it engages learners in the process of building, designing, and constructing artifacts and provides a tool by which we search for meaning. Both of these notions lie at the heart of a great deal of learning sciences research. Despite this history, learning scientists have paid little attention to the discipline of the arts as the more prominent focus has been on science and mathematics. There are few art educators found in the learning sciences literatures and there are few scholars identified with the learning sciences community who deal with the arts in an explicit way. Despite this, there are many aspects of learning that could benefit from further research into how the arts and aesthetics play a role in our current conceptions, including the study of representations (Latour, 1987; Lynch, 1988), the design of new experiences, environments and technologies (Brown, 1992), and visual research methodologies (Pink, 2001), among many other areas of learning sciences research. One example that seems particularly ripe for exploration is the study of representations, particularly how children engage in drawing, dramatic re-enactments, and role-play when representing their ideas in simulations or models (c.f., Danish, 2009). Artistic and aesthetic facets are innate in all of this work, while their role in the learning process is seldom explored.

Historically, cognitive views of learning have prevailed in arts education (Deasy, 2002; Gardner, 1991) but more recently views have expanded to take on increasingly diverse theoretical frames and areas of study related to learning (Alexander & Day, 1992; Eisner, 2002). Taken together, these bodies of research have contributed to our understanding of the role of the arts in (1) the methods of data collection and analytical techniques (Barone, 2008; Sullivan, 2005); (2) the healing, therapeutic, and restorative processes (Eisner, 2002; Malchiodi, 1999; McNiff, 2004); (3) the discovery of the self, the group, the community or diverse cultures (Greene, 1995; Dewey, 1934/1980; Heath & Soep, 1998); and (4) in expression and communication as well as the particular habits of mind that are cultivated through the arts (Hetland et. al, 2007). More recent studies point to the long-term impacts of the arts on learning and development that outweigh other extracurricular activities (Catterall, 2009). These bodies of research are summarized more fully in this article but, taken together, represent a robust body of knowledge that is rarely built upon in learning sciences research. At the same time, leaders in the field of arts education are calling for more research on learning and artistic expression as well as more research on the arts and the transfer of learning (Arts Education Partnership, 2004). This points to the mutually synergistic ways that the two fields could inform one another. With this community bond in mind, we adopt the feminist communitarian model as our guiding methodological framework. This framework celebrates community ties and conceives understanding as inseparable from community (Friedman, 1989).

The focus of this paper is to turn our attention to the arts as an understudied area and examine how the field can expand as well as open new avenues of research in the learning sciences. This paper brings together a review of a wide body of research in the field of arts education, spanning affective, cognitive, social, and transformative effects of the arts. In addition, insights are shared for how the arts as a discipline can inform the study of learning in educational settings and, conversely, point to ways in which learning scientists can contribute to the field of arts education research.

## History of Arts Education

The study of the arts in education has a long history arcing back to the Greek and Roman eras. Plato and Aristotle wrote of the importance of the arts, "for their didactic impact as instruments of cultural maintenance," (Efland, 1990, p. 8), alluding to the earliest function of the arts as visual public curricula to convey cultural values and encourage public discourse. In his influential book, *A History of Art Education*, Efland (1990) depicts the ways in which the social status of the artist contributed significantly to how art education has been conceptualized throughout time. For example, while art objects were seen as important for the education of Greek and Roman societies, the rich did not participate in art making, for artists were not deemed important in society. Conceptions changed in the Middle Ages, when learning in the arts became a form of religious penance for many monks, thus shifting the status of learning in the arts from low-status to highly esteemed. The next big shift occurred during the Renaissance, when academies were created to educate learners on the philosophy of art, which separated art making, traditionally done by lower status individuals, from theorizing about art, now part of the newly formed academies. As these two learning contexts developed, separate identities emerged: craft and fine art. No longer appropriate only for the working class and clergy, the concept of fine art brought high status to learning in the arts and opened the door to public art education.

In the United States, art education began with emphasis on drawing in Benjamin Franklin's academy in Philadelphia (1739/1931). The Industrial Revolution also encouraged drawing as a technical skill that should be included in the general education setting. Similarly, art at the university level began in other departments such as science and anthropology. For example, drawing was a subject taught in the School of Science at Yale long before the School of Fine Arts was established. At the turn of the twentieth-century, as fine art schools emerged across the country, technical skill and art history dominated learning in the arts. At the same time, Dewey's work on aesthetics entered the educational discourse, linking all learning to aesthetic experiences and aesthetic experiences to art in his seminal work, *Art as Experience* (1934/1980). As aesthetic awareness entered the stage of learning in the arts, somatic and intuitive understanding began to get the attention of much research. Research on the imagination and creative expression emerged from this pool of research, as well.

In more recent years, these discussions have been eclipsed in some of the current day educational policy imperatives that place central the role of science, math, and literacy in 21$^{st}$ century education. Often missing from these conversations is the enduring role that the arts and aesthetic knowing plays in education. Aesthetic awareness concerns the heightening of sensory perception (Greene, 1995), enabling learners to discern and demarcate something temporal as rare, unexpected, or beautiful. Arts researchers often point out that art-centered experiences are not automatically aesthetic in nature, but rather meaning is developed through the reflective and critical eye (Dewey, 1934; Freedman, 2003). Desantis and Housen (2000) developed a theory of aesthetic development that outlines patterns of thinking that correlate with the amount of art-centered experiences a learner has had. The theory presents a continuum in which lower levels of aesthetic connection align with fewer exposures to art. This work points to the importance of art education for aesthetic growth, which is of central importance to studies of arts learning, as well as in other domains.

## Methodology

What follows is a brief review of the vast body of research that has taken place in the field of arts education. At its outset, four guiding questions framed our review and helped to organize our writing, consisting of: (1) What counts as learning in the arts? (2) How has learning been historically studied in the arts? (3) As an understudied area in the learning sciences, what implications do the arts hold for future research? By contrast, (4) how can the field of learning sciences expand the efforts of arts education?

Our intent for this review is to precipitate dialogue that bridges the educational discourse in two communities of research. In that regard, we selected a methodology anchored in communitarian epistemology apropos for building community ties and mutual interest. Our research methodology emanates from the feminist communitarian model, which puts forward that "the community is ontologically and axiologically prior to persons" (Christians, 2005, p. 152). This model provides three key foundations for this paper: where to look, what is important to look at, and how to use this information. First, this model provides a sociocultural lens, which suggests that meaning is mediated through social dialogue. From this perspective, we began the literature review by looking to key portals of dialogue in the arts community. As such, we bring together several landmark studies found in books and major journals published by leading arts education organizations, including the National Arts Education Association (NAEA) and the Arts Education Partnership (AEP).

Second, our methodological framework guided the process of selecting key themes for the paper. The feminist communitarian model holds that rules situated within a community are understood by valuing the multiplicity of voices as opposed to formal consensus. Within this framework, we looked to multiple voices in the social dialogue that provided themes that are unique to the arts. Taken together, this body of research can be summarized in four unique properties of arts learning that have broader implications for learning more generally, which are summarized in Table 1. In the following sections of the paper, we go into each of these four themes in further depth, highlighting some prior landmark studies as well as pointing to ways that the work can inform our understanding in the learning sciences.

## Art as Inquiry

**Arts-based researchers** look to aesthetic response within the disciplines of art in order to develop meaning. Arts-based research is a methodology, which includes art making into any of the phases of research from inquiry and data collection to sharing findings and conclusions (Deasy, 2009). Poetry, narrative, film, drawing, collage, painting, performance, dance, music, and sculpture are a few of the mediums used in the creative research process. Arts-based research can be used to explore questions in any discipline, not just inquiries about art. Arts-based research critically investigates learning based on the belief that there are multiple ways to develop meaning. Here, we focus on arts-based research in education, though it exists in other disciplines, such as engineering (Penny, 2000), and anthropology (Pink, 2001).

Table 1: Summary of the current research organized into four key themes.

| Properties of Learning in the Arts | Definition | Implications for the Learning Sciences |
|---|---|---|
| Art as Inquiry | The methods and mediums used by artists offer tools for art as a way of research. | Qualitative research methods. |
| Art as Transformative Experience | Art-centered experiences offer therapeutic and restorative properties. | Affective understanding.<br>Self-efficacy.<br>Learner readiness.<br>Restorative experience.<br>Healing. |
| Art as a Means of Discovery | The arts provide opportunities for multiple solutions, which allow individual differences to emerge and allow individuals to be reflexive about the self, the group, the community, and diverse cultures located across space and time. | Community Building.<br>Collaboration.<br>Cross-Cultural Awareness.<br>Sociocultural Theory. |
| Art as Literacy | Engaging in the arts requires specific habits of mind and knowledge-in-action to be able to read and write the arts. | Habits of Mind.<br>Literacy.<br>Critique.<br>Representations.<br>Transfer. |

There are many definitions and labels for inquiring about the world through artistic practice. Most descriptions include the notion of viewing education through the artistic lens. But that means slightly different things to different researchers. Sullivan (2005) summarizes four ways that education research has been interpreted through the arts: 1) educational connoisseurship, 2) Arts-based Educational Research, 3) arts-informed research, and 4) a/r/tography. A fifth group is added to Sullivan's list by including the scholARTists mentioned in Cahnmann-Taylor and Siegesmund's collection of arts based research (2008).

Sullivan's first group, Eisner's educational connoisseurship, is based on *seeing* and *sensing* educational phenomenon through the expertise of an *educational critic*, modeled upon the concept of the expertise of an art critic, who makes judgments based on having exposure to many images Similarly the educational critic makes judgments based on exposure to many educational experiences. Eisner continued to push the idea of art practice informing research by creating the Arts-Based Research Institute in 1993. In 1997, with his colleague Barone, the concept and the term, Art-based Educational Research (ABER), emerged. ABER points to the unique insights and ways of expressing that can be found only in the arts..

While ABER celebrates the distinctly different approaches available through the arts, other researchers maintain the traditional research framework for using the arts in research. For example, arts-informed research seeks to integrate scientific inquiry with artful and imaginative inquiry (Cole & Knowles, 2001). From this view, the arts are relied upon to represent understanding developed through more traditional research methods. To distinguish between ABER and arts-informed research, the results of an arts-informed study might be generalizable, while ABER would not seek generalizability, but instead value *aesthetic resonance* --that is, the research is recognized as holding meaning for a specific community (Eisner, 2008). Other researchers refer to themselves as a/r/tographers, who inquire about the world within the identity of being an artist who is also a researcher and a teacher. A/r/tographers approach research through living inquiry embodied within the daily roles of an artist-researcher-teacher. As such, a/r/tographers use multiple artforms and writing to build understanding by knowing, doing, and making (Irwin, 2004). In addition to these four interpretations of art as inquiry depicted by Sullivan, another key group includes ScholARTists, practicing artists who create stand-alone artwork developed from their research. Their artwork develops from fieldwork, such as collected and analyzed data, but the final piece is relayed through art. For example, Saldana (2008) created an ethnodrama about the nature of qualitative data based on field notes and 25 years worth of experience in the theater. ScholARTists use art practices for scholarships' sake (Irwin, 2004).

All arts-based research aims to establish research questions, share findings, and mine data in evocative and meaningful ways (Cahnmann-Taylor & Siegesmund, 2008; Irwin & de Cosson, 2004). For example, Springgay's (2004) dissertation research on tactile epistemologies employs the methods of a/r/tography to examine student perceptions of *thinking through the body*. The paper version of the dissertation is accompanied by a DVD of seven videos. Aligning with the tactile epistemological content of the work, the paper version is hand stitched with fabrics and thread, and is augmented by the author's original photography and poetry.

Ultimately, research is a tool for making sense of learning in order to positively impact the lives of learners. Human understanding advances through exploration, interpretation, and representation, which are qualities of both the arts and sciences (Leavy, 2009). Arts-based research is beneficial for the learning sciences in myriad ways, but we have highlighted three of the most significant: 1) to provide the learning sciences with an expanded toolkit for developing meaning, 2) to acknowledge and clarify assumptions about what it means to know for the researcher, and 3) to include voices previously left out of the discourse on learning. In addition to the benefits of embracing aesthetic awareness as a useful component of research, arts based research also challenges other traditional notions. Embracing post-modern theories that state there is no one truth, arts-based research encourages research that opens the conversation--it is not the researcher telling the reader, but rather the researcher invites the reader to be an active part of the process in making meaning (Siegesmund & Cahnmann-Tayor, 2008). Barone also sees the wider readership potentially available through arts-based research as an opportunity to encourage social change (2008).

## Art as Transformative Experience

Throughout history, humanity has responded to tragedy with art, as represented by the 9/11 memorial, *Reflecting Absence* or Picasso's Guernica, among countless others. Just as a nation uses art to heal and move forward, art as a transformative experience is important for education, as well. As Maslow's hierarchy of needs suggests, basic needs such as feeling safe and valued must be met before learning can occur (1943). The transformative nature of learning in the arts is well poised to meet this educative need.

Long acknowledged in the fields of art, psychology, and aesthetic education, the process of creating and responding to art offers therapeutic and restorative properties (e.g., Eisner, 2002). The transformative impact of art can be seen in studies like Malchioldi's (1999) work with children, which found stress relief and healing effects when art-making was used with hospitalized children. Kaplan et al. (1993) found that visits to a museum had a restorative effect on visitors. A number of self-proclaimed transformative art experiences exist in the literature, as well. For example, Hill (1951) professes that art making was instrumental in his recovery from tuberculosis and Allen (1995) shares how art helped her confront harmful beliefs and transformed her life.

The transformative impact of art provides insight for research in the areas of affective knowledge, restorative experiences, and self-efficacy. Art therapy is a branch of psychology that has greatly contributed to this range of research. Art therapy research has shown that healing and transformation comes from a place of affect that is beyond words (Malchioldi, 1999). Research has also shown that the affective benefits of learning in the arts act as a gatekeeper for positive self-identity in adolescents (Catterall, 2004). Similarly, in *Critical Links*, several research projects found that the affective properties of the arts contributed to positive transformations in the areas of motivation, cognitive development, school culture, academic performance, and attitudes toward reading (Catterall, 2002). Self-efficacy is also strengthened through experiences with art (Catterall, 2004; Catterall & Peppler, 2007). Eisner summarizes that self-efficacy is developed during the creative act as learners engage in a medium and bring their concepts into reality (2002). Kennedy's (2002) study found that learning in the arts increased the self-efficacy of at-risk youth, promoting positive self-esteem. In this way, experiences with art enhance individual, social, and cultural health. By readying the psychological state, learning in the arts reaches across disciplines and offers unique opportunities to restore health, which clears pathways to new knowledge.

## Arts as a Means of Discovery

Another key contribution of the arts is that it provides opportunities for multiple solutions. As Eisner states, "…Standardization of solution and uniformity of response is no virtue in the arts. While the teacher of spelling is not particularly interested in promoting the student's ingenuity, the art teacher seeks it" (2002, p. 1). The diversity of solutions and the space that is afforded for creative solutions to a problem is at the heart of what it means to engage in learning in the arts. We see the valuing of multiple solutions as essential to allowing individual differences to emerge and engender a discovery learning process that engages the learner in learning about the self, the group, the community, and diverse cultures, which are outlined in the four sections below.

*Arts and Learning about the Self.* While self-discovery may happen in all disciplines, the arts seem to be a particularly fruitful context to cultivate solutions unique to the self, imagination, and creativity. Further discovering these areas in terms of their relationship to learning seems ripe for exploration into the role of creativity and imagination in learning and seems to also be an understudied area of the learning sciences. Imagination seems to play a role in self-discovery. Greene's seminal work, *Releasing the Imagination*, stresses that when a young person's imagination is not released, that young person may have difficulty situating the self as well as the role of the self in a larger community (1995). Heath and Soep expand on this to elaborate that the arts allows individuals to be reflexive about the self as they hone the ability to make things of value to their surrounding communities (Heath & Soep, 1998). Similarly, Dewey alerts us to the transformative nature of the arts and aesthetics in challenging the status quo and the dominant elite in order to meet the needs of democratic society (1934/1980). This is particularly relevant to youth in marginalized communities because they have an opportunity to write their own narratives and insert themselves into the dominant discourse through the arts. This potentially sets the stage for higher levels of engagement in other arenas, like school. Catterall and Peppler also discuss the impact that the arts have on general self-efficacy in disadvantaged groups—the positive and authentic view of one's capabilities and achievements—developed in mastering an art form, and the critical and reflective dispositions that accompany its development (2007). Taken together, these strands of research call for future investigations into the differing effects of an arts experience for the audience and the artist, which are areas of inquiry that learning scientists are particularly poised to answer.

*The Arts and Group Learning.* As aforementioned, when young people engage in art making they explore a variety of disciplines and are learning at multiple levels, including learning about the larger group or classroom community as well as their place in it. Arts experiences frequently involve more than one learner. The performing arts, in particular, are steeped in this tradition as actors find their place in the production, musicians learn about their part in the orchestral work, visual artists work on large murals together, and dancers in their role in the dance. While the arts are not the only discipline to have group learning experiences, they offer rich opportunities to gain skills in a group setting and also to display final products. Research on collaboration would benefit from exploring the arts further to better understand the role of the collective in the arts. Researchers might also inquire into the specific qualities the arts bring to group learning processes as well as the qualities of the individual art forms that contribute to efficacious group learning and contrast this with what is known more generally about group learning and collaboration. Other areas that are ripe for exploration include investigating whether arts collaborations exhibit general tendencies to enhance equity in learning for larger numbers of learners in the group and particularly whether this is inclusive of already disenfranchised groups. Preliminary observations indicate that the arts can create more equitable learning opportunities for at-risk youth (Catterall & Peppler, 2007). Additionally, it would be interesting to explore whether the arts can serve as a training ground for learning to be part of a group outside of the arts and the conditions for such group learning to occur.

In a related manner, current and historical research points to the arts as the foundations of a democratic society, including effects of the arts on positive social interactions, tolerance, and consideration to moral dilemmas. For instance, studies suggest that the arts promote empathy, tolerance, and solution finding through taking multiple perspectives (Catterall, 2002). These effects may not just extend to students involved in the arts, they may well impact participating teachers and school identity. For example, Noblit and Corbett (2001), noted in their evaluation of the A+ Schools program in North Carolina that school faculty developed a positive school culture despite typical administrative challenges and lack of resources. This work suggests that engagement in arts activities fosters democratic values. Further inquiry may advance notions of democratic public schooling.

*The Arts and Cross-Cultural Learning.* Because artifacts are a reflection of the values held by a group of people in a particular space and time, they allow us to learn about diverse cultures through their study. This type of learning happens even when we travel across space and time. Anthropologists and historians, for example, help us to understand diverse cultures through the study of their art, which is the foundation of fields like art history and music history. Moreover, the arts are rooted in cultural traditions. Engaging youth to identify more deeply with their own culture and share this understanding with others may also be a key contribution of the arts, especially as classrooms encourage this type of sharing with peers and teaching faculty. Moreover, youth from diverse backgrounds can develop deeper understandings around issues of race, culture, and class systems (Deasy, 2002). Drama, for example, has been found to engage youth in social change and build understanding among diverse groups (Rohd, 1998). This may be because drama allows youth to explore multiple roles and perspectives through role-play (Deasy, 2002). In doing so, drama helps youth to understand character motivation, complex problems and emotions, and social relationships, promotes conflict resolution, engagement, and positive self-concept (Catterall, 2002). This ongoing body of research demonstrates the efficacy of the arts of communicating meaning across cultures through complex semiotic systems.

## Arts as Literacy

Literacy is now known to be both multimodal in nature (Kress & van Leeuwen, 1996) and mediated through shared social and culturally situated activity (Vygotsky, 1935/1978). As theories of semiotics are advanced, prior work has focused on monomodal domains of the various art forms and articulated the associated grammars of each individual system of communication (i.e., visual, auditory, etc.). More recently, researchers are promoting a multimodal view of literacy that is key to understanding newer art forms (Kress & van Leeuwen, 2001). These efforts broaden our conceptions to include a theory of "multimodal literacy" and what it might mean to "make meaning" across a range of modalities. Jewitt and Kress (2003) argue for two central practices in their theory of multimodal literacy, including "design thinking" as encapsulating the intentions of a designer in absentia of the materials and the "production thinking" emanating from those ideas in the materials. In sum, artists make sense of individual modalities with the ultimate goal of making connections between several different types of modalities. Arts engagement fosters the ability to translate one type of literacy to another.

Further, current research on language and literacy point to the ways in which various modes of communication have value in the larger social and cultural context. For example, each of the major art forms (e.g., dance, drama, music, and visual arts) can be seen as its own symbolic system of language, one capable of expressing a range of emotionality and communicating a rich set of ideas and understandings that is oftentimes unattainable through speech alone. Not surprisingly, this realization allows us to view the meaning making of disenfranchised groups in new ways (Baum, Owen, & Oreck, 1997; Catterall & Waldorf, 2000), which is especially true for young children and those with disabilities that were previously seen as illiterate or pre-literate. Young children's drawings, for example, can now be seen as efforts at meaning making and expression and can be used for thinking and reflection (Kress & van Leeuwen, 1996). Through seeing these acts as art in their own right (Gardner, 1980), we begin to recognize these acts as literate activities and can begin to understand how young children as well as all learners begin to read and write the world through artistic acts.

Moreover, artists shape and convey intellectual and emotional content in their artwork as well as to evoke intellectual and emotional responses in the viewer (Greene, 2001). As such, we begin to see that learning in the arts transcends the benefits for the artists and includes the audience in the learning process as well. This is because the art object presents opportunities for the audience to engage in learning. The arts naturally afford inclusive learning opportunities because arts tradition is deeply rooted in performance, ,which is a natural culmination of dance, drama, and music. Also, displaying the final product in the visual arts is a common culmination, which positions the audience as a primary motivating force in the arts (Sefton-Green, 1998).

As theories of constructionism would explain (Papert, 1980; Kafai, 2006), the process of producing a work of art engages the artist in an iterative exploration of ideas and emotions as the work proceeds in a meta-cognitive manner. During this process, the artist learns to refine aesthetic sensibilities and build knowledge about materials, while connecting to other disciplines. For example, figurative drawing engages an artist in further understanding human anatomy. The fact that the arts give use new ways to read and write the world, has spurred a flurry of research aimed at the arts and the transfer of learning to other traditional academic areas such as mathematics, spatial reasoning, and oral and written language acquisition (Winner & Hetland, 2000; Deasy, 2002). Studies and commentaries in the publication, *Critical Links* (Deasy, 2002), have accumulated support that the arts and oral and written language share interrelated physical and symbolic processes, an area of research that could be further explored in the learning and cognitive sciences.

Relationships between the arts and literacy and language development are found across all of the visual and performing art forms, though the research is currently most robust in music and drama. For example, music features a symbol system that shares fundamental characteristics with language. At its core, music can be seen as decoding and encoding procedures that have syntactic and expressive structures (Scripp, 2002). In a similar manner, Catterall found that dramatic enactments enhance youths' abilities to comprehend texts, identify characters, and understand character motivations (2002). Studies also indicate that dramatic activities promote both writing proficiency and prolixity in generating written material. Further research is needed into other artistic forms, particular dance and the visual arts, as very little current research exists in this area. Additionally, learning scientists could help to unpack the mechanisms at work in the connections between the arts and literacy. For example, math educators call for more research on learning and aesthetics in order to develop a mathematics aesthetic, which evokes awareness of the beauty in mathematical ideas (e.g., Sinclair & Crespo, 2006). Across these studies, we see that the arts set the stage for learning a unique language and communicating with others in the world at large. Further inquiry into theorizing such literacies is needed, with the learning sciences uniquely poised to contribute knowledge on design-based research, assessment, and situated learning.

## Discussion & Conclusion

We have pointed to ways the field of arts education could benefit from research in the learning sciences as well as the ways in which the arts alert us to an understanding that is under-represented in the learning sciences. There are a range of cognitive, social, and cultural capacities engaged by learning in the arts. The following summarizes five opportunities for future research. First, research is needed to examine how youth develop such knowledge-in-action as well as the disposition to see the world through the lens of aesthetics, as we unravel how youth wrestle with ideas, materials, and meanings in the arts (Fiske, 2000). Second, there is a need to better understand how the various art forms uniquely impact the learning experience. For example, in what ways is learning in music distinct from other ways of representing ideas, such as dance or visual arts? Deasy adds that "finding alignment among the ways in which the study of different artistic forms demands and nurtures complex thinking has significance for the development of comprehensive arts programs and for our understanding of the nature of thought in arts learning" (2002, p. 6). Third, further research is needed on the design of learning environments in the arts. Better understanding of the pedagogical approaches and classroom contexts that support learning in the arts is needed (Horowitz & Webb-Dempsey, 2002). Fourth, there is also a need to define and measure "arts learning" (Catterall, 2002). Current studies do not unpack the extent and quality of the learning experience in the arts. Consequently, we know little about the specific qualities of arts learning that contribute to the gains aforementioned in this paper. As a result, it is difficult to qualitatively compare arts programs and there is an assumption that all arts education is of similar quality. This does not contribute to our understanding of how variations in learning in the arts account for variations in learning outcomes. Lastly, further research is needed in traditional areas of the learning sciences to explore the role of arts and aesthetics in our understanding of design, representations, and research methodologies, among a host of other domains in the learning sciences.

# SPACE AND TIME IN CLASSROOM NETWORKS: MAPPING CONCEPTUAL DOMAINS IN MATHEMATICS THROUGH COLLECTIVE ACTIVITY STRUCTURES

Tobin White, UC Davis
Corey Brady, University of Virginia

**Abstract:** This paper reports on a design-based research project in which we are developing collaborative activities for classroom networks. Research in generative design has explored classroom activities that analogize the many participants in a classroom with an often-infinite family of mathematical objects. By contrast, our project focuses on classroom activity structures that support interactions among two to four students, each aligned with different components of a shared mathematical object. In each case, these network-based relationships among students are intended to serve as resources to support learners' efforts to jointly navigate the conceptual territory delineated by their corresponding mathematical relationships in the space of the network. We compare the kinds of exploration of mathematical terrain respectively supported by whole-class and small group activities in classroom networks in order to examine the distinctive learning opportunities provided by each, and consider the potential of these different activity structures for providing mutually supportive instructional experiences.

## Introduction

Simultaneously accounting for the cognitive and situative dimensions of learning remains an important and persistent challenge for contemporary mathematics education (Greeno, 1997; Sfard, 1998). Prior work along these lines highlights the importance of attending to intersections between discipline-specific content and practices in mathematics on the one hand, and social norms and interactions across different classroom activity structures on the other. For example, in a seminal account of the links between classroom interactions and mathematical activity, Yackel and Cobb (1996) observed that social structures, in the form of the collective, local norms for participating in mathematical discourse, serve as resources for structuring classroom mathematical practices. Following a similar insight in the reverse direction, research on generative design (e.g., Stroup, Ares and Hurford, 2005) has pointed to ways that mathematical structures can serve as resources for structuring social activity through a classroom network of handheld calculators. The intersection between individual students' engagement with mathematical objects in the private space of their respective devices and the collectively constructed artifacts visible in classroom networks provides rich possibilities for exploring this dynamic between conceptual and social.

In a similar vein, this paper reports on a design-based project in which we develop collaborative activities for classroom networks in order to investigate intersections between conceptual and social dimensions of mathematics learning. As in generative design, our own approach uses the mapping between student participants in a classroom group and mathematical objects in a shared virtual space to make important mathematical relationships and properties of these objects salient. Generative designs analogize the many participants in a whole-class activity with an often-infinite family of mathematical objects. For example, each student might be associated with a different function in a family of functions; a different point in a locus of points; or a different expression among a class of equivalent expressions (Stroup, Ares, Hurford & Lesh, 2007). By contrast, our project focuses on network designs and classroom activity structures that support collaborative interactions and investigations among groups of two to four students. These designs align each student participant in a small group with one of a small number of components of a single shared mathematical object, such as different representations of a common function (White, 2006).

In each case, these network-based relationships among students are intended to serve as resources to support learners' efforts to jointly navigate the conceptual territory delineated by their corresponding mathematical relationships in the space of the network. We see the forms of virtual exploration of interrelated graphical and symbolic terrain afforded by these designs as offering a visual example of Greeno's (1991) proposal that knowledge of a domain is analogous to familiarity with an environment. Our aim in this paper is to consider the ways these different activity structures for classroom networks (at whole-class and small group levels) might collectively map a corresponding conceptual territory in mathematics. In other words, we compare the kinds of exploration of mathematical terrain respectively supported by whole-class and small group activities in classroom networks in order to examine the distinctive learning opportunities provided by each, and to consider the potential of these different activity structures for providing mutually supportive instructional experiences.

## Collective Activity in Classroom Networks

A rich body of prior research has explored ways of using of classroom networks to support whole-class interactions (Hegedus & Kaput, 2004; Stroup, Ares & Hurford, 2005). A major strand of this work emphasizes using the sociocultural diversity of the class group as an engine for exploring the possible variation among families and other collections of mathematical objects (Stroup, Ares, Hurford & Lesh, 2007). For instance, in studying the notion of algebraic equivalence, students might be asked to invent and contribute expressions equivalent to a given expression (e.g., 4x). The resulting collection of expressions that are the same as 4x indicates the breadth of the space of this *equivalence class* of expressions (Stroup, Ares & Hurford, 2005). Students make use of key algebraic skills as they work to populate this space, "unsimplifying" the given expression. Because of the diversity of ideas present in virtually any classroom-sized group of participants, the range of student contributions will reliably instantiate key concepts such as the distributive law and identity and inverse properties of multiplication and addition (see, e.g., Davis, 2007).

Thus, this strand of research taps into the protean sea of the classroom group, confident that it contains sufficient variability and diversity to represent the mathematical universe adequately for pedagogical purposes. The size of the classroom group appears as a critical asset in these classrooms, as it serves as the effective guarantee that the hypothesis of sufficient-diversity will hold. We interpret activities that rely on the diversity of student contributions in this way to be using the size and diversity of the classroom group to concretize the concept of one of several kinds of *infinity*. Indeed, the representative activities of this genre tend to focus on aggregate mathematical objects such as families of functions, loci of points, or instances of geometrical relationships—all consisting of an infinite set of constituent objects. In each case, a critical learning objective is the appreciation of the nature of this infinity and of structures within it. The design of the activities allows the student to grasp the infinite family, locus, or range of figures without losing contact with the specificity of the examples—her own and those of her peers—that serve to embody the infinite aggregate.

While these instances of infinity represent a rich and varied set of mathematical topics, they do not span the full array of ideas central to the discipline. Indeed, many core mathematical objects under study in the k-12 curriculum are composed of sets of just a few coordinated sub-objects: lines are uniquely determined by two points, quadratic expressions are comprised of three distinct monomial terms, equations compare two distinct algebraic expressions, functions are commonly represented through one of three modes—symbols, graphs or tables. Additionally, many of the conceptual challenges that face students as they grapple with these concepts consist of difficulties with the coordinated significance of these sub-objects: how to determine the slope of a line, to combine polynomial terms and simplify expressions, to solve equations, to interpret relations among representations.

With these concepts and challenges in mind, our own approach uses network links among student devices in order to align pairs or small groups of students with correspondingly small sets of mathematical objects. As in the case of analogizing the many students in a whole class to infinitely many related mathematical objects, these small group designs likewise seek to capitalize on network-defined social relationships to make corresponding mathematical relationships salient in learners' activity. To that end, our designs focus on collaborative learning tasks that are centered on collective mathematical objects that participants in a pair or small group must jointly manipulate through their networked devices. Such objects are collective to the extent that they or their attributes appear—and change—simultaneously on the devices of multiple students, and that they appear in a shared display as a consequence of contributions from multiple students. These designs map the students in a small group to sub-objects in a coordinated set: each learner manipulates a linked point to collectively form a curve in a Cartesian plane, or transforms a respective side of an algebraic equation, or combines different-ordered terms or enacts different binomial operations among polynomial expressions, or examines a different representation of the same function. Broadly, we aim to structure tasks around these collective mathematical objects in order to make the successful solving of problems dependent on contributions from and coordination between all participants in a small group. Below, we describe one such design in detail, and present an analysis of the kinds of student mathematical exploration supported by this environment.

## The *Graphing in Groups* Design

The collaborative mathematics activities described in this paper were created using the NetLogo modeling environment (Wilensky, 1999) and HubNet architecture (Wilensky & Stroup, 1999) in concert with classroom sets of Texas Instruments graphing calculators connected through a TI-Navigator™ network. In the activity design called

*Graphing in Groups*, teams of two or more students share collective responsibility for jointly manipulating the graph of a function (for two students, a linear function; for three students, a quadratic). Each calculator displays a graphing window and allows the student to adjust the coordinates of a point graphed within that window using directional arrow keys on the calculator (Figure 1). The coordinate points inputted through the calculators of each member in a student pair, along with the line uniquely determined by those respective points, are displayed together in a single graphing window on the classroom server, creating a shared mathematical space for the members of a group (Figure 2). A grid composed of several groups' graphing windows and projected at the front of the classroom provides a collective display of all these small group-level graphs (Figure 3).

In the activities for the present study, each student's point was paired with that of a single partner so that their respective coordinates collectively defined a line. As students moved the individual point controlled by their respective graphing calculators, they could choose to "mark" the current coordinate location of that point by pressing a calculator key. Once both students in a pair marked points, the corresponding line appeared in their group's graphing window, along with an equation for that line in slope-intercept form (i.e., y=mx+b). Students could continue to move their respective points freely, and any time either student in a pair pressed the "mark" key again, the graph and equation automatically changed accordingly in the public display. In other words, the students controlled both an individual object, in the form of their respective points, and a collective object in the form of a line.

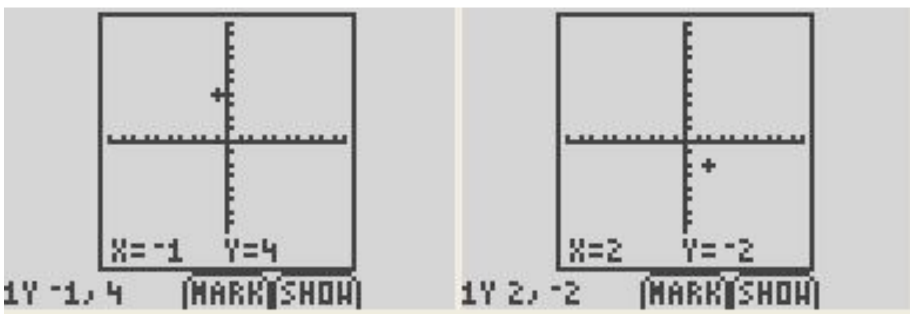

Figure 1. Two student calculator screens.

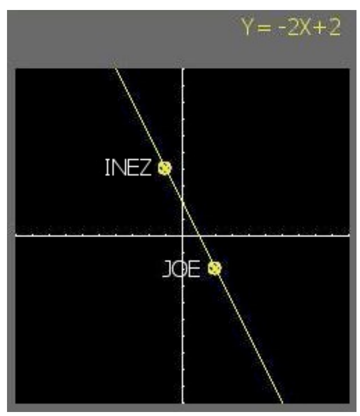

Figure 2. Two student points in a group-level graph.

## Method

The *Graphing in Groups* design served as the basis for a three-week unit on linear graphing implemented in three ninth grade Algebra I classes, each taught by a different teacher. Over a series of several class sessions, students participated in a variety of *Graphing in Groups* activities intended to complement more conventional lessons on linear equations and their graphs. The topics addressed during this unit included slope, x- and y-intercepts, the point-slope and slope-intercept forms of linear equations, and parallel and perpendicular lines. Some of the *Graphing in Groups* activities conducted during the unit were teacher-led explorations and whole-class discussions of the relations among lines generated by different pairs. Other activities were problem-solving challenges assigned to student pairs. These problem-solving tasks generally involved asking student pairs to move their respective points so as to create a line with a certain characteristic or set of characteristics: a slope of three, a y-intercept of four, a negative slope, a line parallel to a teacher-generated line, etc. Such tasks were typically closed in the sense that each pair worked toward a single solution, but open with regard to the coordinates each student might assume and the process by which they identified that solution. In each case, the instructional focus was on framing these challenges in terms of pairs' collective lines, so that completing that task required students to consider that line and its equation in relation to the coordinates of their respective points.

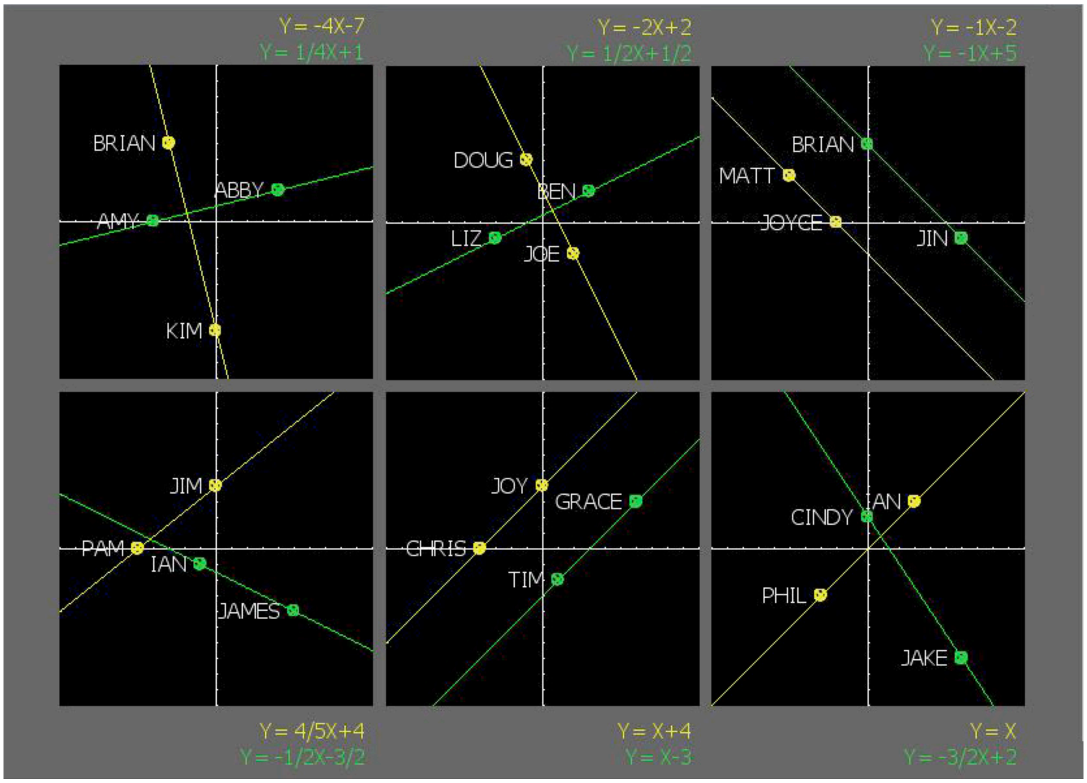

Figure 3. *Graphing in Groups* whole-class display.

Students were assigned to pairs by the teacher, and remained in the same pair throughout the unit. Two to three student pairs in each class were selected, on the basis of informed consent, as focus groups and videotaped during all collaborative activities throughout the unit. An additional camera captured the projected server display at the front of the room, as well as whole-class discussions and other instructional interactions. Server logs captured coordinates entered by the students as they manipulated their respective points to complete the collaborative tasks. Analysis of these data focused on the ways students individually and collectively interpreted the mathematical objects (i.e. points, lines and equations) and on their relations in this environment as they developed approaches to solving problem-solving tasks. Video segments of six student pairs working on between 13 and 19 tasks each were transcribed and examined alongside time-synched video of each group's shared graphing window from the server display. Students typically worked three to four minutes before completing or stopping each task; the longest sessions ran approximately 10 minutes and the shortest lasted about 30 seconds. Each transcript was then annotated with detailed descriptions of the ways students moved and marked their points. The first author and another researcher developed two different coding schemes for analyzing these annotated transcripts for each task episode: one focused on problem-solving strategies and the other on interactions between students.

Below, we analyze an episode from the video data in order to illustrate the ways learners engaged with mathematical objects and relationships in the context of this network-supported activity for student pairs. In particular, we examine the ways students explored and interpreted the relations between their respective points and a collective line, and between the graph and the equation of that line, over the course of a problem-solving task. This episode is typical of the broader data set relative to the analytic coding scheme; both the problem-solving strategies employed and kinds of student interactions occurred frequently in other tasks and among other pairs. We have selected it for presentation in the current paper because it provides a clear example of students' explorations of this mathematical domain as they undertook these problem-solving tasks, and because it features a task reminiscent of the "make expressions that are the same as 4x" example of generative whole-group activity in classroom networks.

## Analysis

This episode finds two students, Priyana and Kate, in the midst of efforts to locate their respective points at coordinates that would collectively form a line with equation y=4x-1. Just prior to the excerpt below, the students had worked for a few minutes by moving each of their respective points before realizing that they could establish a line with the correct y-intercept by having Kate position her point at -1 on the y-axis. In the moments that followed, Kate kept her point stationary at the y-intercept, watching and offering commentary and suggestions as Priyana moved her own point in a series of attempts to construct a line with slope 4. To do so, she began taking a series of paired horizontal and vertical unitary steps, marking and examining the results of each move:

1. [Kate has just marked at (0,-1) to make y=(5/3)x-1. From (3,4), Priyana moves up and right to (4,5), marks to form y=(3/2)x-1.]
2. Kate: That slope has to be the same, so…what was the slope before, a 4?
3. Priyana: [Moves up and right again to (5,6)] A negative 4. [Presses mark to form y=(7/5)x-1]. I mean a 4. Ok…[moves up and right again to (6,7)]
4. Kate: Ok, so…
5. Priyana: [Presses mark at (6,7) to form y=(4/3)x-1. Moves right and up to (7,8) and presses mark to form y=(9/7)x-1. Moves up and right again to (8,9), where the label of her point partially covers the pair's equation]
6. Kate: [Trying to read the obscured equation] What does it say? [Priyana now marks at (8,9) to form y=(5/4)x-1] Can you go down more?
7. Priyana: Yeah, maybe I should go down. [Moves down five units and left five to (3,4), then back one unit right to (4,4), presses mark. Equation does not change. Looks down at her calculator and then up at the screen again, moves down and left to (3,3) and marks to form y=(4/3)x-1. Moves down and left again to (2,2) and marks to form y=(3/2)x-1. Moves down and left again to (1,1) and marks to form y=2x-1.] Oh, there it is.

This segment illustrates the kind of incremental movements in a graphical space that students often used in order to investigate variations in a corresponding algebraic expression in this environment. Priyana began with five successive moves up one unit and over one (Figure 4a), marking and observing the resulting slope each time (lines 1-6). She used these paired unitary vertical and horizontal steps—one up and one over—to make incremental adjustments to the slope of the line, watching the resulting changes in the collective display and reacting to each with soft vocalizations (e.g. "Ok" in line 3) or pursed lips before adjusting again. In each case, she used minor adjustments to the graph as a means of gradually adjusting the value of the linear coefficient in the equation. Importantly, though, she did not simply make the smallest possible adjustment in *her position*—one unit up *or* one over. Rather, taking an incremental step in each dimension before marking to form a new line allowed her to make the smallest possible adjustment to *their line*.

The next short series of movements further highlights the students' careful efforts to alternately maintain or only minimally rotate the current line. As Priyana's point moved toward the upper right corner of the graphing window, the label on her point actually obscured part of the pair's equation (line 5). Kate, who was closely watching each move, asked Priyana to "go down more" so that she could read the equation clearly (line 6). Priyana, who was quickly running out of screen room, agreed that "maybe (she) should go down" (line 7). She retraced her steps in reverse, moving down five units and left five and then briefly pausing as though to consider returning to (3,4), the point at which she had started the sequence of moves that opened this episode. Instead, she moved one unit back to the right to position herself on the same line before marking at (4,4), and so leaving the current line unchanged. Again, these moves appeared carefully selected to make only minimal changes to the current line—to seek out the correct parameter through incremental adjustments. Priyana thus abandoned her initial sequence of similar moves only when display limitations interfered, and worked carefully to minimize changes in the line even as she adopted a new line of exploration. Continuing to display the same preference for relatively small variations in slope, Priyana began a new series of paired unitary horizontal and vertical steps, this time down and to the left from (4,4) (Figure 4b). Three such steps established a slope of two, at which point she noted the appearance of an integer slope value (line 7). At this point, Kate and Priyana briefly disagreed about how to proceed:

8. Kate: Go up like… go up a little bit. [Ignoring Kate's instruction, Priyana moves down to x-axis, left to origin, and up to (0,2), all without marking] It's supposed to be 4.
9. Priyana: [Continues circling her point around her last mark—two units right to (2,2), then back to x-axis, then left toward origin] Yeah, maybe if I keep going down, like this… [briefly brings her point to rest on the origin, as if to mark there, one unit left and one down from her last mark, but then moves down again to sit on top of

Kate's point at (0,-1) and presses mark so that the pair's line disappears]. That's not right. [moves back up to (1,1) and marks to again form y=2x-1].

10. Kate: [As Priyana moves up and over one to (2,2), but does not mark, and instead moves back to (1,2)] Go up, like, little by little.
11. Priyana: [marks at (1,2), forming y=3x-1]. There you go. Oh, hold on, I'll just do one more. [Moves up to (1,3)]
12. Kate: [reading the y-intercept from the equation] That's a negative 1 though.
13. Priyana: [Marks at (1,3) to form y=4x-1] There you go.

This excerpt highlights an important contrast between Priyana's continuing incremental exploration and Kate's recognition of a more direct path toward the desired line. Reacting to the newly established slope of two, Kate prompted Priyana to "go up a little bit" (line 8). Ignoring the instruction, Priyana wavered, appearing to consider movement in all possible directions as she traced a square path around her last mark at (1,1) (Figure 4c). Wondering aloud, "maybe if I keep going down, like this," she briefly came to a stop at the origin and directly above Kate's point, where a mark would have continued her previous pattern of paired unitary steps down and left, but also formed a line with undefined slope (line 9). While Kate now recognized that moving Priyana's point up would bring about the desired increase in the value of the slope, Priyana had to this point continued relying on incremental steps in the graphical space in order to feel her way about in search of a solution. However, the fact that she chose not to mark here at the origin indicates that she recognized she was reaching the limits of this approach. Indeed, as she instead moved down to mark on top of Kate's point and briefly erase the line, she immediately realized that her new location was "not right" and returned to her previous mark at (1,1) (line 9). Kate again urged her to "go up…little by little" (line 10). Finally acquiescing, Priyana marked one unit up at (1,2). When the slope changed from two to three, Priyana clearly recognized that they were now moving toward a line with the correct slope, and that she needed to "just do one more" similar step, quickly marking at (3,1) to form the target slope and line (Figure 4d).

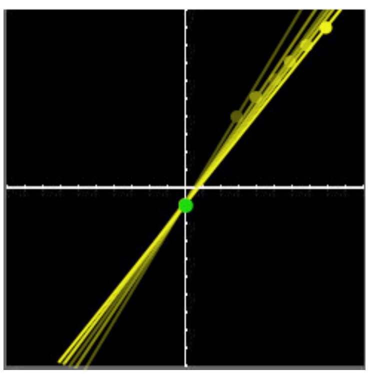

Figure 4a.

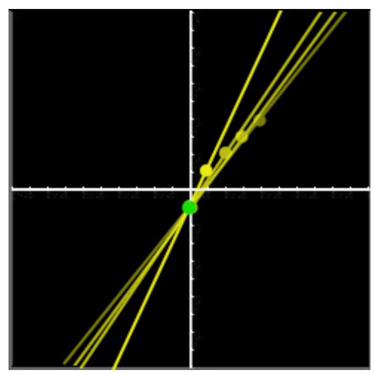

Figure 4b.

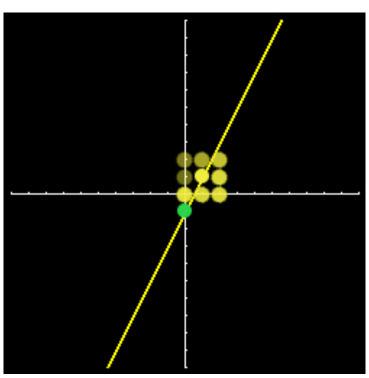

Figure 4c.

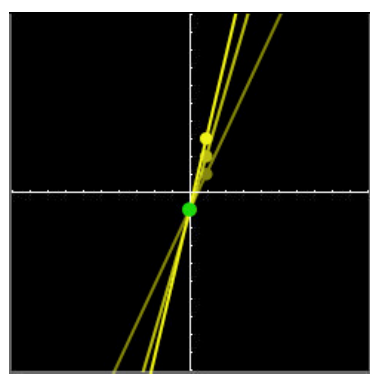

Figure 4d.

Throughout this sequence, Priyana moved from incrementally adjusting the slope downward and away from the correct value using paired unitary horizontal and vertical steps, to adjusting the slope in the same manner but upward and toward the correct value, to increasing the slope from two to the target value of four by making unitary vertical steps upward. In the first two instances, neither she nor Kate appeared to recognize the relationship between the steepness of the line and the value of the slope. In the absence of a clear target toward which to adjust the line, Priyana focused on making small and systematic changes away from the current state, first in one direction and then in another, until she established a parameter value she and Kate were better able to interpret. That moment arrived when the slope went from a series of fractions to an integer; at that point Kate urged her to “go up a little bit” because “it’s supposed to be four” (line 8), clearly associating upward vertical change in Priyana’s point location with increases in the slope. By contrast, Priyana initially appeared to interpret the achievement of an integer close to the target as an indication of the fruitfulness of her unitary moves down and left. When applying this interpretation proved unsuccessful, she instead followed Kate’s advice, and appeared to quickly come to the same insight about the relations between her vertical moves and the slope of the line.

Priyana’s transition from movements that indicate some confusion about the relationship between the graphical and the symbolic to those that reflect a clearer and more correct interpretation of that relationship suggest ways that successive, iterative movements in this space serve as resources for making meaning about slope. Both students appeared to be coming to clearer understanding of the relations between graphical movements and linear equations through real-time incremental adjustments over the course of the episode. Indeed, this episode in particular and our analysis of students’ strategic engagement with these tasks generally suggests that patterned, iterative sequences of incremental movements like Priyana’s here are particularly important resources for students’ efforts to navigate this mathematical terrain. Though these movements are sometimes exploratory and ad hoc, much of the time they indicate students’ clear expectation that these particular changes will bring about particular results. For example, students often articulated specific directions (“go up, like, little by little,” line 10) to one another or narrated their own moves (“I’ll just do one more,” line 11), suggesting that they were beginning to anticipate certain outcomes from these moves.

## Discussion

In the episode above, moving points in a graphical display allowed students to explore the mathematical space of linear functions with rational-number slopes. By systematically and incrementally varying coordinates, Priyana and Kate were able to feel their way about in the unfamiliar territory of fractionally-sloped lines, and to make use of a more familiar landmark when they encountered an integer value for slope. These kinds of exploratory movement typical of students’ engagement with the *Graphing in Groups* interface illustrate the ways that developing strategies for moving points and manipulating functions in these classroom network activities might be understood as learning to navigate a conceptual environment. In this sense, we see students’ joint exploration of virtual mathematical terrain as a productive alternative interpretation of the physical metaphor for a conceptual domain proposed by Greeno (1991).

From the standpoint of this analogy to conceptual environments, whole- and small-group activity structures may form complementary dimensions of a complex mathematical domain. The episode above suggests an illustrative contrast between the whole-class activity to “provide different expressions that are equivalent to 4x” and the *Graphing in Groups* challenge to “make a line with a slope of 4” from the raw materials of the two students’ respective coordinate locations. In the whole-class activity, the equivalent expressions are manifested as objects that fill out a conceptual *space*; in the *Graphing in Groups* activity, the small group’s solution is experienced as a process *in time* through a sequence of individual explorations and collaborative interactions. In *Graphing in Groups*, student movements of their individual points generate fluctuations and modifications of the collective graph, as the group moves incrementally towards a goal. Each student moves freely, but those movements shape and constrain the emergent activity of the group as teams explore the impact of incremental changes in their constituent sub-objects upon the nature and attributes of the collective, composite object. That collective activity is characterized not so much by attention to the family of objects that fill out a function space but rather by the manipulation over time of a single function through small perturbations—the exploration of *infinitesimal modification* rather than the unfolding of an infinite parameterization.

In generative designs for whole-group classroom network activity structures, diversity and individual expression in the classroom group serve as surrogates for infinity. In contrast, in the approach for small groups presented above, distinctive student actions take the form of infinitesimal variations in the group’s collective object. Because students are identified with complex or compound mathematical objects, with each group member given the role of a component sub-object, these variations demonstrate the dependence of the collective object on the characteristics of its components. Moreover, while the whole-class activity highlights the infinite variety of expressions equivalent to 4x, the pairs task emphasizes infinitesimal variations among linear terms increasingly close to 4x. In these ways, we see designs for whole- and small-group activity as respectively and jointly mapping spatial and temporal dimensions in a conceptual environment central to the broader curricular landscape of secondary mathematics.

## Conclusion

The relationship between the conceptual dimensions spanned by these small-group and (generative) whole-group activity structures suggests corresponding ways that they might be combined to form a complementary instructional sequence. While the analytic focus of this paper and the early phases of this design-based research project have been on mathematics learning opportunities afforded by small-group interactions, the *Graphing in Groups* collective display (Figure 3) also explicitly supports an additional layer of artifacts and instructional possibilities oriented toward the larger classroom group. For example, in a different *Graphing in Groups* task from the one depicted here, each pair of students creates a line with the same slope. While the activity at the level of each pair might unfold along the lines of the episode presented in this paper, the collection of groups in the class would typically together produce several representative members of a family of parallel lines. When the small-group phase of the activity is complete, each of the groups has produced a distinct solution to the challenge, and the aggregate begins to fill out the mathematical space of possibility defined by that challenge. This sequence aims to use the classroom network to integrate two levels of classroom activity, one in which the small group focus is on understanding the interrelations of points and lines through strategies of infinitesimal variation, and another in which the classroom group as a whole can see the infinite variety of possible lines that meet the activity's challenge criterion. Our current classroom research focus is on jointly examining these small-and whole-group levels of mathematical activity and instructional interaction in this hybrid environment. In these ways, we see small-group designs of the kind outlined in this paper as expanding the map of the social and mathematical terrain in classroom networks charted by prior research, and broadening the pedagogical modes across which those networks might support mathematics teaching and learning. Collectively, these whole and small-group activity structures highlight the rich potential of the social space of networks for mapping conceptual spaces in mathematics.

# Sequential Effects of High and Low Guidance on Children's Early Science Learning

Bryan J. Matlen & David Klahr
Department of Psychology, Carnegie Mellon University
bmatlen@cmu.edu, klahr@cmu.edu

**Abstract:** We describe a microgenetic approach aimed at examining the effect of different sequences of high vs low levels of instructional guidance on students' learning about concepts and procedures associated with simple experimental design – often called the "Control of Variables Strategy (CVS). Third-grade children were randomly assigned to one of four conditions in which CVS was taught via one of the four possible orderings of high or low instructional guidance: (High + High, High + Low, Low + High, and Low + Low). High guidance consisted of a combination of direct instruction and inquiry questions, whereas low guidance was comprised only of inquiry questions. Contrary to commonly held beliefs that high levels of guidance, and in particular, direct instruction, lead only to shallow learning, results show that repeated instances of high instructional guidance were advantageous for both learning and transfer of CVS. Moreover, the High + High group continued to demonstrate strong conceptual understanding of CVS relative to other groups five months after training. Overall the study suggests that strong amounts of instructional guidance are capable of exhibiting powerful effects on children's early science learning.

## Introduction

Effective instructional design is crucial to promoting learning and transfer. While great strides have been made within the field of instructional science over the past three decades, intense debate still exists over some fundamental issues (Kirschner, Sweller, & Clark, 2006; Klahr, 2009; Kuhn, 2007). For example, what, if any, amount of instructional guidance will maximize student learning? If there is an optimal level of guidance, where should it be placed during the course of instruction? The present study is aimed at addressing these fundamental issues facing the learning and instructional sciences in the context of elementary science education.

Of particular importance to science education is whether high levels of instructional guidance in the form of detailed, explicit instruction can produce robust learning (i.e. learning that transfers across extensive periods of time and to disparate tasks). Instruction at the extreme end of the explicitness spectrum – commonly known as "Direct Instruction" – has classically been construed as providing only short-term learning gains, leading to knowledge that is fragile and incapable of transferring to remote or "authentic" settings (Germann, Aram, & Burke, 1996; McDaniel & Schlager, 1990; Koedinger & Aleven, 2007; Kuhn & Dean, 2005). Direct instruction has also been criticized on the grounds that it allocates a passive role to learners, rather than promoting active student learning, whereas low levels of instructional guidance are more effective at inducing learners to construct knowledge on their own, thereby leading to more meaningful understanding (Kuhn & Dean, 2005). Indeed, Dean and Kuhn (2007) conclude from their investigation that, *"... direct instruction appears to be neither a necessary nor sufficient condition for robust acquisition or for maintenance over time*." (p. 394).

However, these claims are inconsistent with the results of several of our prior investigations of the effectiveness of direct instruction, in which we have repeatedly found positive learning gains in situations where we provided students with a high degree of instructional guidance: direct instruction coupled with inquiry questions. This pedagogical approach has consistently produced meaningful and significant performance gains immediately after training (Chen & Klahr, 1999; Toth, Klahr, & Chen, 2000) that have been sustained for at least a period of three years (Strand-Cary & Klahr, 2009).

In this paper we address a more nuanced version of the question about the optimal level of instructional guidance. Instead of simply asking "which is best?" we also consider the possibility that there may be an optimal temporal sequence of different levels of guidance. As Koedinger and Aleven (2007) have demonstrated in the context of cognitive tutors, each end of the high-to-low instructional guidance spectrum has its unique strengths and weaknesses. Accordingly, rather than pit one type of instruction against another, several recent studies have reframed the question in terms of how different *sequences* of high and low guidance lead to different levels of student learning. However, this research has yielded some contradictory, results. For example, Schwartz and Martin (2004) have suggested that high amounts of guidance are most effective after students attempt to invent solutions in minimally guided settings, an instructional method known as *Invention as Preparation for Future Learning* (IPL). In their study, students who invented original formulas for calculating variance benefited more from subsequent direct instruction than students who initially received instruction and then practiced applying equations of variance. The notion that students may initially fail to produce correct solutions in minimally guided settings, but that this failure can serve as a ‘productive’ learning experience when followed by instructional support (i.e. termed *productive failures*), has also been reported by Kapur (2008; In press). These studies, however, seem in contrast to research that have observed an *Expertise Reversal* effect as learners acquire knowledge (Kalyuga, 2007). According to this latter perspective, since working memory is limited, novices need high levels of guidance in order to ameliorate the strong demands of cognitive processing required of them: As learners gain expertise, however, low guidance is thought to be most beneficial because it reduces the amount of redundant information presented. In support of this, Kalyuga and colleagues have provided empirical evidence that novices benefit more from viewing modeled solution steps and that, as they gain domain expertise, they learn more from engaging in unstructured practice problems (Kalyuga, Chandler, Tuovinen, & Sweller, 2001; Kalyuga & Sweller, 2004). Overall, the implications these approaches suggest for sequencing instruction appear to be incongruous.

Given the stark disagreement in the literature surrounding not only instructional sequence, but also the utility of providing high guidance in the form of direct instruction, the present study has two inter-related goals. First, we test the claim that strongly guided instruction is insufficient for promoting robust understanding (Dean & Kuhn, 2007). To this end, we contrast the relative effectiveness of 1) High Guidance, in which students were provided inquiry questions and direct instruction, and 2) Low Guidance, in which we encouraged learning through the provision of inquiry questions, while purposefully withholding direct instruction. Our second goal is to examine the efficacy of varying sequences of these forms of instruction. Thus, while simple contrasts of high vs low guidance have been used in earlier work, in the present study, we contrast all possible orderings of these two instructional approaches across two separate training sessions, leading to four experimental conditions (i.e. High + High, High + Low, Low + High, and Low + Low). By contrasting these four conditions we are able to assess whether there indeed exist certain progressions of high and low guidance that are more effective in promoting student learning than multiple sessions of high or low guidance by themselves.

We address these issues in the context of teaching children about the Control of Variables Strategy (CVS) for scientific experimentation. CVS is the procedure used to create unconfounded experiments by keeping the values of all factors the same while changing only the variable of interest in order to determine whether or not that factor is causal with respect to the experimental outcome. The procedures and concepts associated with CVS have become increasingly influential in state standardized tests in elementary school and appear on almost all state standards as well as the National Science Standards for elementary school students (Klahr & Li, 2005; National Research Council, 1996). Despite CVS's importance, however, children throughout the elementary school years often demonstrate difficulty in applying it to relevant situations (Chen & Klahr, 1999; Kuhn, Garcia-Mila, Zohar, & Andersen, 1995), making it an ideal domain – for both theoretical and practical reasons – in which to explore these research questions.

## Method

### Participants
Forty-two third grade children (22 girls, 20 boys, $M$ = 9.03 years, $SD$ = .33 years) from three middle-class Pittsburgh elementary schools participated in the study. Children were randomly assigned to one of the four experimental conditions.

### Design
The overall design was microgenetic in nature (Siegler & Crowley, 1991), and consisted of four experimental conditions and 10 test phases. The first eight test phases were conducted approximately one week apart from each other, whereas the final two test phases occurred five months later. All phases were identical across each condition, with the exception of phases 3 and 4, where the experimental treatment varied by condition across two training sessions: (i) High Guidance followed by High Guidance (High + High), (ii) High Guidance followed by Low Guidance (High + Low), (iii) Low Guidance followed by High Guidance (Low + High), and (iv) Low Guidance followed by Low Guidance (Low + Low). Each test phase is described in detail, below.

### Procedure
#### Phase 1: Story Pre-test
The first phase consisted of a paper and pencil pre-test with six questions aimed at assessing children’s understanding of CVS. Three questions assessed children’s ability to create an unconfounded experiment (design questions), and three asked them to evaluate whether an existing experiment was unconfounded (evaluate questions). Children completed the Story pre-tests at their desks in their regular classrooms and were given as much time as they needed to finish the test. Story responses were scored as 1 if children correctly identified or designed experiments consistent with CVS, and all other responses were assigned a 0. Scores ranged from 0 to 6.

## Phase 2: Ramps Pre-test

Children were introduced to two physical ball and ramp apparatuses and were told that they would be designing experiments to test whether certain variables made a difference in how far the ball rolled. Children were told the four variables that could affect the outcome: the surface type (either fim or sif), ball type (bab or lof), steepness (steep or not steep) and starting gate (high or low) (Surface and ball type were given nonsense names to minimize children's expectations about their effect on the outcomes of their experiments). After children could identify these variables without the help of the experimenter, one of the variables was chosen at random and the child was asked to design an experiment to test whether that variable made a difference in the outcome. Children were allowed to set up an experiment and observed its outcome. No feedback was given. The procedure was repeated until all 4 of the variables were tested in a random order, and children were assigned a score of 1 if their set up varied the target variable and kept all other variables the same (CVS), and a score of 0 if the set up was of any other combination. Scores ranged from 0 to 4.

## Phase 3: Training 1

The same materials as the Ramps Pre-test (Phase 2) were used. At the start of Training 1, the child was shown the ball and ramp apparatus and asked to identify the four variables that might make a difference in how far the ball rolled. Once children had correctly identified the four variables, the child's condition determined what happened next.

(a) Children who experienced Low Guidance in Training 1 (i.e., those in the Low + High and Low + Low conditions) engaged in minimally guided discovery learning while being provided inquiry questions in order to scaffold their learning. Children were told that they would be setting up experiments to see what made a difference in how far the ball rolled down the ramps and, subsequently, they were asked to set up an experiment to test one of the four variables, chosen at random. Children were also asked two scaffolding questions to prompt their self-explanations and (minimally) guide them in the discovery process. The first question occurred after children set up their experiments, but before they viewed the experimental outcome. The experimenter asked the child why he/she had set up the experiment that way. The experimenter listened to the child's explanations and provided neutral feedback such as, "*okay*," or "*alright*" and then asked the child to roll the balls down the ramp. Upon observing the result, the child was asked whether they could tell for sure from the experiment whether the target variable made a difference in the outcome. This procedure was repeated for all four variables in a random order, and the child designed two experiments to test each variable, resulting in eight child-designed experiments.

(b) Children who experienced High Guidance in Training 1 (i.e., those in the High + High and High + Low conditions), were told that they would be evaluating experiments conducted by the experimenter and that they would be asked to evaluate the experiment on whether it was a 'smart' or 'not smart' way to test the target variable. The child observed while the experimenter set up a series of confounded and unconfounded experiments (two of each kind), and the child was asked whether the experiment was a 'smart' or 'not smart' way to test the target variable. Regardless of the child's response, the Experimenter then explained why each experiment was either smart or not smart, and provided the logical basis behind CVS. The child was then asked whether they could tell for sure from the experiment whether the target variable made a difference in how far the ball rolled, and were provided immediate feedback followed by an explanation about why one could or could not tell for sure whether the target variable was causal.

At the end of the Training 1 phase, a post-test was administered to children in all conditions. Children were asked to design an experiment to test each target variable in a procedure identical to the Ramps Pre-test. Scores ranged from 0 to 4.

## Phase 4: Training 2

This phase followed the identical procedures to the first training phase, the only difference being that children in the Low + High conditions now received a high degree of instructional guidance with the ramps apparatus and the children in the High + Low conditions now received low levels of instructional guidance. A post-test at the end Training 2 was scored identically to the post-test at the end of Training 1. The differences between the High and Low Guidance conditions are summarized in Table 1.

The remaining test phases (phases 5-10) consisted of a series of transfer tests that were meant to assess the robustness of children's ability to apply CVS to novel situations. In all transfer phases, no feedback was ever provided to children and the dependent variable was always how many experimental set ups children designed that were consistent with the logic of CVS.

Table 1: Similarities and differences between the two types of instruction

| | Amount of Instructional Guidance | |
|---|---|---|
| | High | Low |
| Goal Setting | "I'm going to design an experiment to test whether X makes a difference in how far the ball rolls." | "Can you design an experiment to test whether X makes a difference in how far the ball rolls?" |
| Number of Experiments | 4 | 8 |
| Design of Experiments | By Experimenter | By Child |
| Inquiry Questions | "Is this a smart or not smart experiment?" "Can we tell for sure from this experiment whether X made a difference?" | "Why did you set up your experiment that way?" "Can we tell for sure from this experiment whether X made a difference?" |
| Explanations | Experimenter explained why an experiment was smart or not smart, and why the child could or could not tell for sure whether X made a difference in the outcome | No Explanations |

### Phase 5: Springs Transfer Test

The materials for this phase consisted of a set of eight springs that varied across three different dimensions: length (long or short), spring width (wide or narrow), and coil width (thick or thin). A wooden centerpiece that children could hang the springs from was displayed on a table and two weights were present that could be attached to the springs in order to observe their stretching. Children were asked to design an experiment to test whether each of the variables (in a random sequence) made a difference in how far the spring stretched. Children tested all three variables and the child was assigned a 1 for CVS setups and a 0 for all other combinations. Scores ranged from 0 to 3.

### Phase 6: Car Design Transfer Test

A computer program (adapted from Klahr, Triona, & Williams, 2007) presented on a laptop computer allowed children to design cars to test what variables affected how far they traveled. Four variables – the body (long or short), the back axle (thick or thin), the front wheels (large thick, large thin, or small), and the back wheels (large thick, large thin, or small) – could affect how far the cars traveled. Children were told that they would be testing cars to figure out what made them travel farther, and that the experimenter would record the cars they made on a notepad to which they could refer back to if they forgot what cars they had constructed. Children proceeded to test each variable, which was indicated by the experimenter in a fixed sequence. In total, children had the opportunity to design 10 cars and the total possible chances of demonstrating CVS was 6. Therefore, scores ranged from 0 to 6.

### Phase 7: Ramps Transfer Test

The materials, procedure, and scoring in this phase were identical to the Ramps Pre-test.

### Phase 8: Story Transfer Test

The materials, procedure, and scoring in this phase were identical to the Story Pre-test.

### Phase 9: Remote Paper and Pencil Test

This phase took place roughly 5 months from training, when children were in the $4^{th}$ grade. Children sat at their regular classroom desks and completed a nine-question paper and pencil test that showed various experimental comparisons. Children were asked to identify which experiments were good and bad comparisons, and if the child identified an experiment as a bad test, they were asked to change the experiment to make it a good test. Three of the nine questions were good tests (CVS), whereas six questions were bad tests. Children were given a score of 1 if they correctly identified the test as either good or bad, and a score of 1 if they correctly changed the experiment. Scores ranged from 0 to 15.

### Phase 10: Remote Ramps Transfer test.

The materials, procedure, and scoring in this phase were identical to the Ramps Pre-test and Post-test, but took place 5 months after training.

## Results

Means and standard errors of the mean for each test phase by condition are displayed in Figure 1. A 4 (training condition) x 8 (test phase) mixed ANOVA on the first 8 test phases revealed a main effect of condition ($F(3, 38)$

= 6.21, $p < .005$), a main effect of test phase ($F(7, 266) = 43.64$, $p < .001$), and a significant interaction between them ($F(21, 266) = 2.05$, $p = .005$) (for the remainder of this report, statistics at each test phase will be reported for each group in the following order: 1) High + High, 2) High + Low, 3) Low + High, and 4) Low + Low) (story pre-test: $M1 = .23$, $SE1 = .06$, $M2 = .20$, $SE2 = .04$, $M3 = .28$, $SE3 = .05$, $M4 = .18$, $SE4 = .03$. For the ramps pre-test: $M1 = .25$, $SE1 = .08$, $M2 = .20$, $SE2 = .08$, $M3 = .10$, $SE3 = .06$, $M4 = .16$, $SE4 = .08$).

Post-hoc analyses (1) revealed no differences between any of the groups at the story pre-test (all $p$'s > .40) or the ramps pre-test (all $p$'s > .54). At the end of Training 1, however, the mean scores of the two groups receiving high levels of guidance improved dramatically from the ramps pre-test (all $p$'s < .001) while the groups receiving low amounts of guidance (i.e. Low + High and Low + Low) did not evidence reliable improvements (all $p$'s > .32). The groups receiving high guidance also performed at significantly superior levels when compared to the low guidance groups (all $p$'s < .01) (Training 1: $M1 = .98$, $SE1 = .03$, $M2 = .98$, $SE2 = .02$, $M3 = .50$, $SE3 = .14$, $M4 = .48$, $SE4 = .13$).

After Training 2, the Low + Low and the Low + High groups were no different from their performance after Training 1 or from their performance during the Ramps Pre-test (all $p$'s > .16), while the High + High group and the High + Low group continued to perform at ceiling levels (all one-tailed $p$'s > .21). Performance of both the High + High group and the High + Low group was significantly superior to the Low + Low group (all $p$'s < .05) (Training 2: $M1 = 1$, $SE1 = .00$, $M2 = .98$, $SE2 = .02$, $M3 = .73$, $SE3 = .14$, $M4 = .57$, $SE4 = .14$).

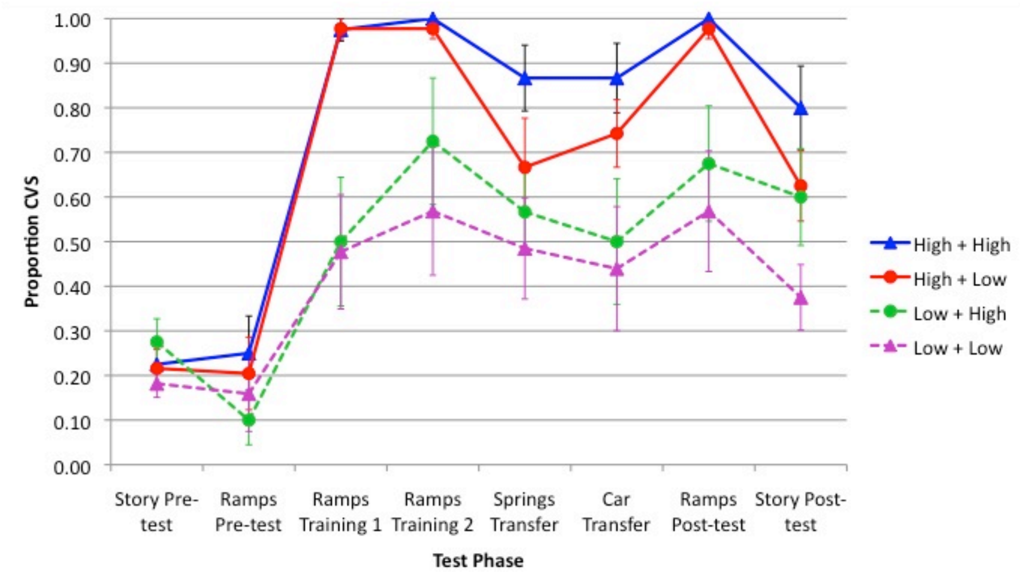

Figure 1. Means for each condition by the first 8 test phases: Error bars represent standard errors of the mean.

Of particular interest is the performance of children in the Low + High condition at the end of Training 2. Even though these children had just completed a training phase involving direct instruction, their performance was well below the ceiling levels of the High + Low group (one-tailed $p < .05$). To further examine the differences in learning gains between the High + Low and Low + High groups, a 2 (condition: High + Low vs Low + High) x 2 (phase: Ramps Pre-test vs Training 2) mixed ANOVA was conducted and this resulted in a significant interaction $F(1, 19) = 7.35$, $p = .01$, with the learning gains greater for the High + Low group. Thus, even though both groups were provided high *and* low amounts of instructional guidance during training, the order of these two types of instruction had substantial effects on learning, with the learning gains favoring the students in the High + Low group. However, since this finding might be due to low sample size, we would expect the effects to persist across a variety of transfer tests. This hypothesis was thus put to the test in the remaining transfer phases of the study.

The Springs Test was the first opportunity to demonstrate this transfer. Post-hoc analyses for this phase revealed statistically significant differences between the High + High and the Low + Low groups ($p < .05$) favoring the High + High group. All other comparisons were not statistically significant (all $p$'s > .17) (springs transfer: $M1 = .87$, $SE1 = .07$, $M2 = .67$, $SE2 = .11$, $M3 = .57$, $SE3 = .09$, $M4 = .48$, $SE4 = .11$). At the car design transfer test, significant differences were found between the High + High and the Low + Low groups ($p = .05$) with no other comparisons showing reliable differences (all $p$'s > .13) (car design transfer: $M1 = .87$, $SE1 = .08$, $M2 = .74$, $SE2 = .08$, $M3 = .50$, $SE3 = .14$, $M4 = .44$, $SE1 = .14$).

The High + High and Low + Low groups showed a significant difference at the Ramps Post-test ($p < .05$), as well as the High + Low and the Low + Low groups ($p < .05$). A marginally significant difference was found between the High + High and the Low + High groups ($p = .10$), with no other comparisons evidencing significance. Of interest was whether children performed at levels greater than Ramps Pre-test: here we found that all groups except the Low + Low groups showed a reliable improvement from the Ramps Pre-test to the Ramps Post-test (all $p$'s < .05) (ramps post-test: $M1 = 1$, $SE1 = .00$, $M2 = .98$, $SE2 = .02$, $M3 = .68$, $SE3 = .13$, $M4 = .57$, $SE1 = .14$).

The only reliable difference at phase 8 (Story Post-test) was between the High + High and the Low + Low groups ($p < .05$). No other comparisons were significant (all $p$'s > .32). We also compared children's post-test performance to their pre-test performance on the story problems and found that the High + High group evidenced a statistically significant improvement in performance ($p = .05$), the High + Low group showed a marginally significant improvement ($p = .07$), and the Low + High and Low + Low groups did not evidence any reliable improvements (all $p$'s > .16) (story post-test: $M1 = .80$, $SE1 = .09$, $M2 = .63$, $SE2 = .08$, $M3 = .60$, $SE3 = .11$, $M4 = .38$, $SE4 = .07$).

Five months after training, we assessed children's ability to apply CVS. Thirty-nine of 42 children were retained for these phases. ANOVA's for the remote paper and pencil tests evidenced no significant differences at either test phase (all $p$'s > .13) (5 month paper and pencil test: $M1 = .91$, $SE1 = .06$, $M2 = .66$, $SE2 = .09$, $M3 = .65$, $SE3 = .10$, $M4 = .61$, $SE4 = .12$. For the 5 month ramps test: $M1 = .97$, $SE1 = .03$, $M2 = .90$, $SE2 = .06$, $M3 = .77$, $SE3 = .13$, $M4 = .64$, $SE4 = .15$). However, because the null differences could be due to low sample sizes, we categorized students into CVS experts and non-experts. Experts on the remote paper and pencil test were defined as children who scored at least 13 of 15, and on the ramps post-test they were defined as children who designed at least 3 of 4 experiments as CVS. Distributions of experts and non-experts for each test are displayed in Figure 2. Chi-squared tests of independence revealed marginally significant differences in the distribution of experts at both the paper and pencil ($\chi^2(3, 39) = 7.12$, $p = .07$) and ramps tests ($\chi^2(3, 39) = 6.94$, $p = .07$). At the paper and pencil test, there was a greater proportion of experts in the High + High group compared to all other groups (all $p$'s < .05), while at the ramps test, all groups had greater proportions of experts than the Low + Low group (all $p$'s < .05).

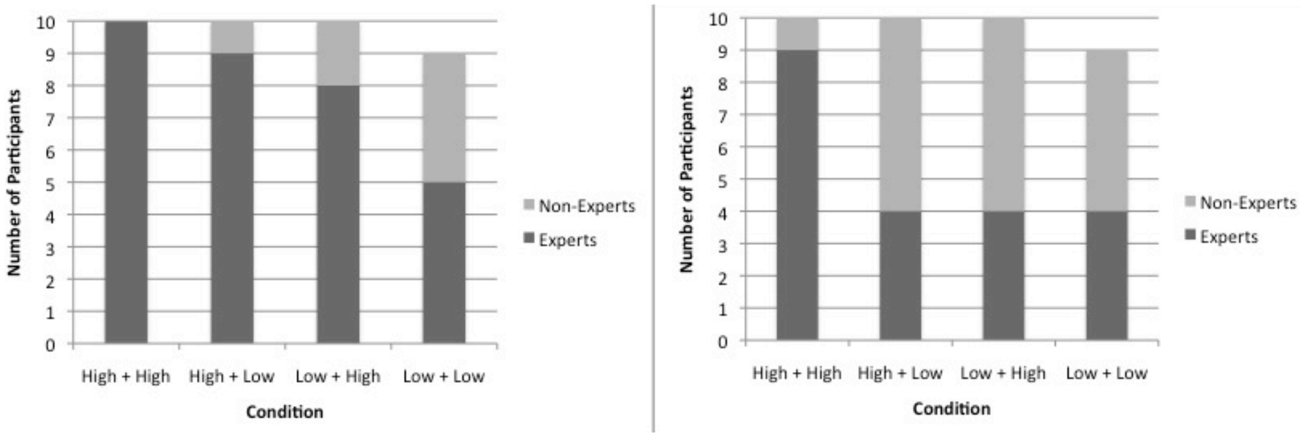

Figure 2. Left) Number of participants who were experts on the 5-month ramps transfer test by condition. Right) Number of participants who were experts at the 5-month paper and pencil transfer test by condition.

## Discussion

The most consistent finding of the present study was the superior performance of the High + High group when compared to the Low + Low group at every test phase after training. This suggests that the incorporation of direct instruction can be a powerful strategy that, coupled with inquiry teaching, is capable of promoting robust learning and transfer of scientific experimentation skill in children. Our findings also extend prior research on children's CVS learning, which has shown that a) minimally guided instruction often produces only nominal learning gains in children (Chen & Klahr, 1999; Klahr & Nigam, 2004) and b) the benefits of high amounts of guidance are not only immediate, but often continue to persist even after delayed periods of time (Chen & Klahr, 2004; Klahr & Nigam, 2004; Strand-Cary & Klahr, 2009; Klahr, Triona, & Williams, 2007).

A second goal of the present study was to examine what order of instructional guidance might prove most beneficial to student learning. While students' performance immediately after training suggested that the High + Low group may have benefited more from instruction than the Low + High group, we failed to find any differences between these groups at later points in transfer, suggesting that this initial effect after training may have been unique to that point in assessment. Moreover, in a subsequent follow-up study aimed to assess whether the differences between the High + Low and Low + High group would replicate, we divided a group of 30 third-graders ($M = 8.76$ years, $SD = .27$ years) evenly between the High + Low and Low + High groups and found no differences in learning across three separate transfer tests (averaged across all three tests, means were .69 and .63 for the High + Low and Low + High groups, respectively) independent-samples $t(28) = .15$, *ns*.

However, this follow-up study did replicate the finding that when students received high amounts of instructional guidance with ramps, they improved significantly from a ramps pre-test (for both groups, *p*'s < .05), while the Low + High group did not improve from the ramps pre-test after receiving low instructional guidance in the ramps domain (*p* = .35) (means for students ramps pre-test, ramps training 1 post-test, and ramps training 2 post-test were .14, .66, and .82 for the High + Low group, and .09, .13, and .72 for the Low + High group). Thus, it appears that, in the context of experimental design, young children learn just as well from different sequences of instructional guidance, as long as they are provided with high amounts of guidance at some point during learning.

The five-month transfer tests in the present study allowed us to assess how flexibly children could apply their CVS knowledge after extensive periods of time in 1) an identical domain to which they were trained (i.e. ramps), and 2) a domain that was removed from their original training (i.e. paper and pencil tests). Here, a large proportion of children in the High + High group evidenced flexible application of CVS to the paper and pencil post-test, whereas, only about half of the children demonstrated this proficiency in the other three groups. This result is striking when compared to the ramps transfer test, where a majority of children who had received direct instruction continued to perform at ceiling levels, and only about half of the children in the Low + Low group demonstrated this proficiency. It seems that, when transfer pertains only to time, children who receive high instructional guidance perform well on the materials on which they were trained, even after 5 months, and more so than children who do not receive high guidance. However, when transfer requires the application of knowledge over remote periods of both time *and* task, only students who received extensive amounts of direct instruction consistently applied CVS to novel situations beyond that of their training (i.e. the High + High group). Thus, results from this 5-month post-test strongly underscore the powerful effect that high levels of guidance can have on student learning.

Taken together, the present findings support the conclusion that students who are relative domain novices do not benefit more from any particular sequence of instruction, but that they do benefit – especially in the long run – from multiple lessons in which high amounts of guidance are provided. While this conclusion may, on the surface, seem conflicting with IPL and the concept of productive failures (2), it is important to note that studies reporting instructional sequence effects have often included other elements that seem key to acquiring differentiated knowledge, such as the use of contrasting cases, which we have left out of our instruction (Schwartz & Bransford, 1998). Students are also older in these studies, the youngest being 8th grade students, whereas we are investigating learning in 3rd grade students: There is little doubt that younger children differ from older children in many ways, including their working memory capacity, domain knowledge, and recruitment of metacognitive strategies. The disparity between our findings, however, prompts discussion of the circumstances that may be crucial to IPL and productive failures. One fundamental prerequisite for a failure to serve as a productive learning experience seems to be that the learner must first realize that failed solutions are indeed, failures. Without such knowledge, students may continue to practice and strengthen the use of incorrect strategies, therefore failing to acknowledge the need for more efficient solutions offered through instruction. Alternatively, if the student is aware that his/her strategies are suboptimal, the student may be more prone to recognize the value of instruction. Indeed, students in Schwartz and Martin (2004) could readily observe whether their formulas for variance accounted for the data they were trying to describe. Kapur (in press) also showed that students in less structured settings often exhibited lower confidence in their solutions, suggesting they were aware of the shortcomings of these solutions. In contrast, many of the students who designed experiments in our study gave little indication that they were aware that their strategies were incorrect, frequently responding that they *could* tell for sure whether the target variable made a difference in the outcome, even when their experiment was confounded by multiple factors. While the interactions between characteristics of individual learners, the learning domain, and instructional support are no doubt a complex issue and beyond the scope of the present study, we propose that attempting to understand the relative contributions of each of these factors, as well as how they interact, would be a productive area for future research to move towards.

What this study does contribute to our thinking about instructional design is that it refutes widely held beliefs that direct instruction is insufficient for promoting robust learning (Dean & Kuhn, 2007) and that shallow transfer is one of the hallmarks of this form of instruction. On the contrary, the present study suggests that, for domain novices, minimally guided instruction that neglects direct instruction may miss opportunities to optimize student learning. We recognize that over the course of a students' life, he/she may experience a great number of instructional events, and that this study addresses only the very earliest of these instructional experiences. We thus agree with, and emphasize that a combination of various instructional approaches may indeed prove of large value to a learner throughout the course of their education (Koedinger & Aleven, 2007). At least in early stages of learning, however, the present study suggests that providing high amounts of guidance, particularly in the form of multiple phases of direct instruction, can be a useful strategy in promoting robust understanding of scientific experimentation skill.

## Endnotes

(1) All between subject post-hoc tests are Tukey adjusted, and within subject post-hoc tests are Bonferonni adjusted.
(2) We purposefully exclude discussion of the Expertise Reversal effect here, as this view could explain the present findings by positing that, despite receiving training, children were relative domain novices at this stage in learning.

**Abstract:** This study compared three pedagogical approaches on the acquisition and robust understanding of the control of variables strategy (CVS). In Sao Pedro et al. (2009), we showed that two direct learning conditions (with and without reification) significantly outperformed the discovery learning condition for constructing unconfounded experiments starting from an initially multiply confounded experimental setup. In the study described here, we retested 57 students six months later on constructing unconfounded experiments in a virtual ramp environment, solving problems requiring CVS, and explaining CVS. Collapsing over time, we found that the direct+reify condition had more robust learning than either the direct-no reify or discovery learning conditions on constructing unconfounded experiments. At the delayed posttest, we found a strong trend favoring the direct+reify condition over the other conditions as measured by tasks designing unconfounded experiments starting from a multiply confounded state.

## Introduction

Currently, there is a debate in the science education community regarding the effectiveness of discovery vs. direct instruction. Critics of discovery learning claim that it may be less effective when compared to instructional approaches with emphasis on guidance (Kirschner, Sweller, & Clark, 2006). In particular, it has been found that during open-ended inquiry, students can have many false starts (Schauble, 1990), and have difficulty designing effective experiments, forming testable hypotheses, adequately monitoring what they do (de Jong, 2006), linking hypotheses and data, and drawing correct conclusions (Klahr & Dunbar, 1988; Kuhn, Garcia-Mila, Zohar, & Andersen, 1995). On the other hand, direct instruction, in its traditional form, has also received criticism, namely, that it can turn into rote instruction leading students to lose engagement and develop inert knowledge that cannot be flexibly applied or transferred (Bereiter & Scardamalia, 1989).

Within these approaches, researchers have begun to determine if these instructional paradigms yield successful transfer of knowledge and skills. Some have shown that explicitly teaching *strategies and skills* in one context can successfully transfer to another context (Klahr & Nigam 2004; VanLehn et al., 2005) or domain (Chi & VanLehn, 2007). More specifically and relevant to the present study, Klahr and Nigam (2004) found that students who were taught the control of variables strategy (CVS) in a direct learning condition significantly outperformed those in a discovery learning condition on a near-transfer test of CVS. Furthermore, those who mastered CVS, irrespective of learning condition, outperformed non-masters on a near-transfer test of this skill. These results suggest that the purported benefits of discovery learning, particularly the deeper learning, may not always occur. These Klahr and Nigam (2004) findings, though, are not without critique (cf., Hmelo-Silver, Duncan, & Chinn, 2007). Others such as Kuhn (2005) have criticized Klahr and Nigam because they did not test students' knowledge about when and why to use CVS.

In a similar vein, others have explored the degree to which these instructional paradigms lead to long-term robustness of skills. For example, Strand-Cary and Klahr (2008) compared the long-term effectiveness of guided and unguided approaches to teaching CVS by repeatedly testing students over a much longer period of time, up to 3 years after their initial intervention. They found significant differences in skill at constructing unconfounded experiments favoring their explicit instruction condition immediately after their intervention, but that 3 months later, those in their exploration condition caught up to the explicit instruction group on average. Furthermore, those who mastered CVS by the 3 month mark, irrespective of condition, significantly outperformed non-CVS masters on transfer tasks 3 years later. Dean and Kuhn (2006) explored the role of practice and engagement within the direct and discovery frameworks on robust acquisition of CVS. They found that direct instruction alone did not lead to robust acquisition; practice and engagement, irrespective of initially receiving instruction, produced deep, lasting learning. In our work, we explored the role that self-explanation played in long-term retention and transfer of CVS skill.

Our first study, Sao Pedro, Gobert, Heffernan, & Beck (2009), an extension to Klahr and Nigam's (2004) study, compared the effectiveness of two types of direct instruction versus discovery with regard to the acquisition and transfer of CVS. We hypothesized that the self-explanation component in Klahr and Nigam's direct instruction condition could have played a role in students' acquisition of CVS. By adding our third condition, direct no-reify, which removed prompting for student explanations, we empirically tested if the explanations in the direct+reify condition affected the acquisition of CVS. The terms "direct" and "discovery" have slightly different meanings than is reflected in our learning conditions; that is, these terms typically represent polar opposites in terms of level of *directedness* given to students. Our direct instruction conditions portray variants of guided inquiry in which students are taught the procedure of CVS in a concrete context, a virtual ramp environment. Our results showed that in an immediate posttest following the interventions, students in both direct conditions significantly outperformed students in the discovery condition on tasks involving creating unconfounded experiments starting from an initally multiply confounded setup. The direct conditions, however, did not significantly differ from each other.

In the present study, we tested the efficacy of the reification task (self-explanation) on the acquisition and robust understanding of CVS over time, 6 months after the original Sao Pedro et al. (2009) study by administering a delayed posttest on participants from our original study. We compared the conditions on the understanding of CVS as evidenced by their skills at constructing unconfounded ramp setups, explaining the CVS procedure, and solving multiple choice and open response problems requiring CVS. Self-explanation has been found to support deep learning (Chi M. T., 1996) and knowledge intgegration (Linn & Hsi, 2000). Thus, in this study, we hypothesized participants in the direct+reify group would outperform the other conditions even though the direct-no reify group showed the same performance as direct+reify for certain items at the immediate posttest (Sao Pedro et al, 2009).

## Method

### Participants

Participants were seventh-grade students from a public middle school in central Massachusetts. We chose this group because middle school may be the time to optimally learn model-based inquiry skills (Schunn, Raghavan, & Cho, 2007). Participants all had the same science teacher through the school year who taught five heterogeneously grouped sections. Students at this school typically struggle with science. For example, in 2008, 92% of eighth grade students at this school scored below proficient on the science MCAS exam, a standardized test administered by the state (Massachusetts Department of Elementary and Secondary Education (ESE), 2008).

All class sections participated in the experiment. For this paper, we concerned ourselves only with the performance of those students who completed our initial intervention and posttest (Sao Pedro et al, 2009) as well as the delayed posttest. Further, we did not include data from students on individual education programs (IEPs) and one additional student who used an incorrect web browser during the initial intervention, leaving a total of 57 students in the analyses for this study.

### Materials

We used The Science ASSISTment System (Gobert et al., 2007; Gobert et al., 2009), a web-based intelligent tutoring system, to host our materials, run randomized controlled experiments and log time-stamped student interactions with the system. We used several types of activities to assess students' acquisition of CVS. Students practiced authentic inquiry by constructing unconfounded experiments using our virtual ramp environment. The same ramp activity acted as a near-transfer performance assessment. We also developed a far transfer test involving several multiple choice and open response questions. Some were designed by us and others were obtained from a study conducted by Strand-Cary and Klahr (2008).

#### Ramp Environment

The ramp environment (Figure 1) was developed using the OpenLaszlo framework (www.openlaszlo.org). We created different kinds of questions by embedding the ramp environment within the ASSISTment System. The ramp apparatus has four variables that can be manipulated: *surface* (smooth or rough), *ball type* (golf or rubber), *steepness* (low or high), and *run length* (long or short). The objective is to set up the ramps so that the target variable is contrasted and all other variables are held constant. Pressing the "run" button causes each ball to roll down its respective ramp. Depending on each ramp's settings, the ball will roll different distances. Participants submit their final setup using the "submit" button. Pressing "reset" causes the balls to be placed back on the ramp and clears the distances rolled. On each press of the "run" or "submit" button, student information is logged. This includes a timestamp of the run or submission, the correctness of their setup in terms of CVS, and the current and previous ramp value settings.

Unlike the physical and virtual environments used in Klahr and Nigam (2004) and Strand-Cary and Klahr (2008) in which participants set up ramp conditions starting from a blank slate, our ramp setup was always initially set. There was always an initial condition students must change in order to create an unconfounded experiment. In a sense, this activity can be viewed as an experimental setup repair task since students must morph a given setup into one that follows CVS. The experiment's starting state could initially be *unconfounded* (all variables are controlled), *singly confounded* (one variable is not controlled), *multiply* *confounded* (more than one variable is not controlled), and/or *uncontrasted* (the target variable is unchanged). Our instruction and feedback format was also different from previous studies; the CVS explanations given to the direct conditions were entirely computer-based whereas the other studies both used human tutoring.

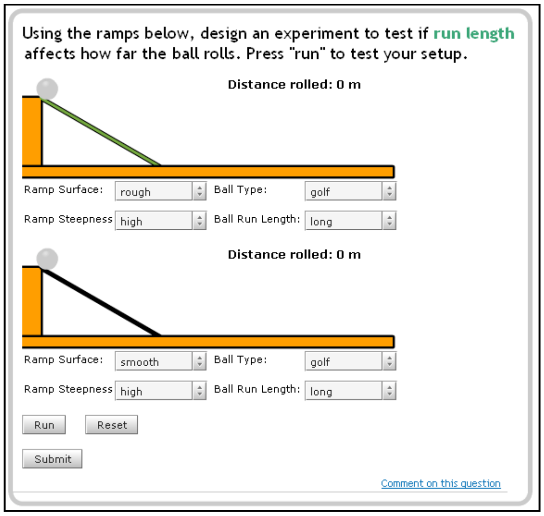

Figure 1. ASSISTment question using the ramp environment. This setup is uncontrasted and singly confounded because the target variable, run length, is the same for each setup and one extraneous variable, surface, is not controlled.

## Multiple Choice and Open Response Transfer Items

In Sao Pedro et al (2009), we developed three multiple choice and two open response items to assess students' skills in using CVS to solve problems and in communicating the procedure. We reused these exact items again for this study. The multiple choice items, referred to as the WPI CVS Inquiry items, asked students to identify an unconfounded experiment, identify a CVS procedure step, and determine an appropriate experimental setup with a valid control condition. The two open response items asked students to describe in their own words the CVS procedure. Specifically, they asked how (1) they "could determine if one particular variable affects how far the ball rolls in the ramp experiment" and (2) "when there are many variables that can be changes, explain how [they] could determine how each variable affects the distance the ball rolls." Students needed to clearly state that CVS was a procedure one could systematically repeat to find out how each variable affected the outcome.

For this study, we also added two multiple choice items and one open response item from a transfer test developed by Strand-Cary and Klahr (2008). Their multiple choice items on plant and seed growth required students to choose the correct experimental setup that contrasted a variable of interest and kept all others constant. Their open response item asked, without specific prompting for CVS usage, for students to critique a confounded experimental design that tested if beetles preferred to live in sun or shade.

## Procedure

This study determined the long-term effects of the differing interventions on CVS acquisition using both the original posttest materials and the new Strand-Cary and Klahr (2008) assessments. In our original October 2008 experiment, students were first pretested on their skillfulness at creating unconfounded experiments in the ramp environment without receiving feedback. We also tested them on the WPI CVS Inquiry items, multiple choice questions involving CVS. The ASSISTment System then randomly assigned each student to either the direct+reify, direct-no reify, or the discovery condition. In each condition, students practiced how to perform CVS in the context of the ramp environment. Following the intervention, students were tested on their skill at constructing unconfounded ramp setups, answering the same WPI CVS multiple choice questions as the pretest, and explaining in their own words the CVS procedure within the context of the ramp environment.

In both direct conditions, students were first asked to read an overview of CVS with examples of confounded and unconfounded ramp setups. In this overview, we did not explain that CVS could be used to solve problems in other domains. After reading the overview, students addressed whether a series of ramp setups had correctly controlled for variables. In the *direct+reify* condition, participants first responded if a given ramp configuration enabled them "tell for sure" if a variable affected how far a ball would roll by responding "yes" or "no". Next, they answered an open response question asking them to explain their reasoning. For the same ramp setup, students then were allowed to run the experiment as many times as desired *without changing* *the setups* and explained again if they could tell for sure that target variable affected how far the ball would roll. Finally, students read an explanation why the experiment was confounded or unconfounded for the target variable. If the setup was confounded, students were told which variables were confounded. Students in the *direct-no reify* condition followed the exact same procedure, except they were not asked the two open response questions. Students in the *discovery* condition were instructed to create experiments that tested if a particular variable affected how far the ball rolled. The discovery condition students were neither given the initial CVS explanation nor any feedback about the correctness of their experimental setups. All conditions practiced on six identical initial ramp configurations. For more details on the original experimental procedure, see Sao Pedro, Gobert, Heffernan, & Beck, (2009).

The present study took place six months later in June 2009 and acted as a delayed posttest of CVS skill. Throughout the school year, students used the ASSISTment system extensively for math class but not for science-related activities. All students in each class section took the delayed posttest irrespective of having participated in the original experiment, though we only analyze those students for whom we have posttest data from our October 2008 experiment. Students first answered the WPI CVS Inquiry multiple-choice questions developed in the previous study. Next, students answered the subset of Strand-Cary and Klahr (2008) questions, including one open response question. Students were then presented a reintroduction to the ramp environment that described the ramp variables and how to interact with the simulation. Students then constructed four unconfounded ramp setups with different target variables. The initial setups were identical to those in the previous study's posttest. Finally, students again answered the open response items in which they explained CVS in the context of the ramp experiment.

### Scoring

Multiple-choice questions were automatically scored by the ASSISTment system with a 1 if correct or 0 if incorrect. Correct ramp setups demonstrating CVS for the given target variable were awarded 1 point, 0 otherwise. All open response items were hand scored by two different graders according to a rubric. The Strand-Cary and Klahr (2008) open response question was graded out of 3 points, one point for identifying that the experimental setup was incorrect, and up to 2 points for correctly explaining the experiment's design flaws. Maximum points were only awarded if the student addressed the lack of control in the question's experimental design.

The two ramp open response items were combined into one measure to capture skill in correctly describing the CVS procedure, marked out of 3 points. Higher scores indicated deeper understanding of CVS. One point was given for identifying independent and dependent variables and the presence of some relationship between them. Two points were awarded for stating that the target variable needed to be contrasted and all other variables should be the same. Three points were given for understanding that CVS should be repeated for each variable to determine how each individually affected the outcome. For example, a student who received full credit answered as follows: "For each variable keep the others the same and change one variable at a time." When reviewing student responses, we realized a large number of students described how each specific variable affected the distance rolled instead of describing a procedure. If students answered with such evidential knowledge, they were scored according to a different rubric and were treated as missing data for this metric. Students falling into neither category, such as those responding "I don't know" received 0 points.

## Results

We analyzed 57 students' immediate and delayed posttest scores to determine which condition(s) yielded better performance on each CVS measurement: problem solving using CVS via the multiple choice items, articulation and explanation of CVS via the ramp open response items, and authentic inquiry performance with the ramp environment. In particular, we determine if self-explanation in the direct+reify condition led to better performance over time for the various near-transfer and far-transfer CVS tasks. We also analyzed if the findings favoring the direct+reify and direct-no reify groups over the discovery group on multiply confounded ramp items were robust for the delayed posttest. For each analysis of variance below, we report partial $\eta^2$ values as measurements for effect size.

### Differences between Groups on Transfer Items

In these analyses we looked for trend differences between groups at immediate and delayed posttest for the WPI CVS inquiry test and the ramp open response items. We also compared groups' performance on the Strand-Cary and Klahr (2008) items. Means and standard deviations for all transfer items are presented in Table 1. Only students who completed all the questions for a measurement were included in that measurement's analysis. We conducted a repeated measures ANCOVA to compare performance on the WPI CVS Inquiry multiple choice items over time. The WPI CVS Inquiry pretest was used as a covariate. Though time was not a significant within-subjects factor (Wilks $\lambda$=1.00, $F(1,48)=0.19$, $p$=.668, partial $\eta^2$=.004), the interaction effect between time and condition was marginally significant, Wilks $\lambda$=.907, $F(2,48)=2.47$, $p$=.095, partial $\eta^2$=.093, suggesting

* Open response items include only those who responded with procedures, not evidential statements.

there may have been performance differences between the conditions as time progressed. As Table 1 indicates, performance in the direct-no reify condition was the same for the each posttest, *M*=1.25. Students in the direct+reify condition showed better performance on average at the immediate posttest, but did not maintain those scores. The discovery condition's performance increased on average as time progressed. Condition was not a significant between-subjects factor, $F(2,48)=1.78$, $p=.179$, partial $\eta^2=.069$. This indicated no performance differences between the groups when collapsing over time.

Another repeated measures ANCOVA determined if any intervention affected students' skill in explaining CVS. In this analysis, we compared only students who explicated procedures for constructing unconfounded experiments in response to the two ramp open response questions since some students explained which variables affected how the ball rolled instead of explaining a procedure. There was neither a significant effect for time (Wilks $\lambda=.98$, $F(1,21)=0.49$, $p=.492$, partial $\eta^2=.023$) nor for the interaction between time and condition, Wilks $\lambda=.93$, $F(2,21)=0.81$, $p=.460$, partial $\eta^2=.071$. Condition was also not a significant between-subjects factor, $F(2,21)=0.23$, $p=.800$, partial $\eta^2=.021$.

Finally, we analyzed if there were differences between the groups on the Strand-Cary and Klahr (2008) items using an ANOVA. We normalized the beetles open response item in order to equally weight all items for the dependent measure. No significant difference was found between the groups on this measure, $F(2,52) = 0.39$, $p=.681$, partial $\eta^2=.015$.

Taking these transfer results as a whole, we saw no significant differences in trends and no significant differences between conditions for any of the transfer item subsets. This suggests that our different learning conditions did not enable transfer from constructing unconfounded ramp experiments to solving more complex reasoning problems requiring CVS. As for explaining CVS, we believe we would expect to see differences between learning conditions if the questions were worded such that students answered with procedures rather than evidential statements. We believe this because there were significant differences between groups' overall skills in constructing unconfounded experiments in the ramp environment as discussed next.

## Comparison of Ramp Items

We compared each condition's skill in constructing unconfounded ramp experiments over time using a repeated measures ANCOVA. Total ramp scores at each time were dependent measures and total ramp pretest score was used as a covariate. Means and standard errors for ramp performance over time are shown in Figure 2. Four students did not take the original ramp pretest and were not included in this analysis, leaving 53 students. Within-subjects tests revealed no significant main effect for time, Wilks $\lambda=.97$, $F(1,49)=1.36$, $p=.249$, partial $\eta^2=.027$, and no significant interaction between time and condition, Wilks $\lambda=.92$, $F(2,49)=2.03$, $p=.143$, partial $\eta^2=.076$. However, condition was a significant between-subjects factor, $F(2,49)=3.26$, $p=.047$, partial $\eta^2=.117$, controlling for ramp pretest score. Post hoc comparisons revealed that the direct+reify condition constructed significantly more experiments adhering to CVS than the discovery condition (*M*=0.92, *SE*=0.43, *p*=.037, 95% *CI*=[0.06, 1.79]) and the direct-no reify condition (*M*=0.98, *SE*=0.45, *p*=.033, 95% *CI*=[0.84, 1.88]). No significant difference was found between the direct-no reify and discovery conditions, *p*=.903.

Since there was a significant between-subjects effect on condition, we also analyzed group differences solely at the time-2 delayed posttest using an ANCOVA with ramp pretest score as a covariate. The analysis yielded a main effect on condition, $F(2,49)=3.36$, $p=.043$, partial $\eta^2=.121$. The ramp pretest was not a significant covariate, $F(1,49)=1.38$, $p=.247$. Post hoc tests revealed that the direct+reify condition constructed significantly more unconfounded experiments in the delayed posttest as compared to the direct-no reify condition (*M*=1.34, *SE*=0.53, *p*=.014, 95% *CI*=[0.29, 2.40]). No significant differences between direct+reify and discovery, *p*=.131, and direct-no reify and discovery, *p*=.306 were found. As shown in Figure 2, the direct+reify condition maintained its higher performance at the immediate and delayed posttest. Though the direct-no reify condition improved at the immediate posttest compared to the pretest, the improvement is lost 6 months later at the delayed posttest. Also, the discovery condition's skills on this CVS authentic inquiry task increased as time progressed.

We also compared the number of students proficient at CVS (those who scored at least 3 out of 4 on the ramp) in each condition at the delayed posttest. We used only those who did not score a perfect 4 out of 4 on the ramp pretest (49 participants). Of those remaining, 59% (10 out of 17) in the direct+reify condition, 24% (4 out of 17) in the direct-no reify condition, and 33% (5 out of 15) in the discovery condition were proficient. Though the tallies favor direct+reify over the other conditions, the differences were not significant, $\chi^2(2)=4.43$, $p=.109$. We note that in the delayed posttest, there were more than twice as many CVS-proficient students in the direct+reify condition as compared to the direct-no reify condition.

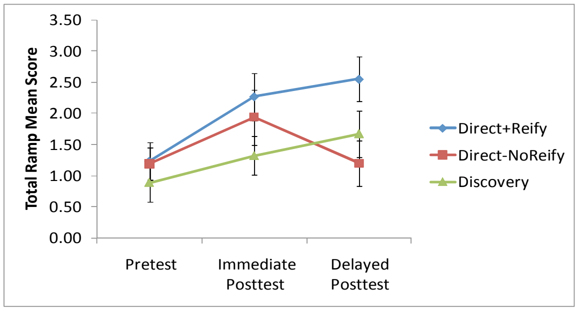

Figure 2. Means and standard errors for total ramp score by condition. The maximum score on this measure is 4.

## Comparison of Ramp Items by Level of Complexity

As in our previous 2009 study, we examined performance changes over time for ramp items of differing complexity, namely singly and multiply confounded initial setups. To determine time and condition effects we conducted a repeated measures MANCOVA using singly and multiply confounded ramp items at each time point as within subjects factors, condition as a between subjects factor, and singly confounded ramp pretest score as a covariate. This design mimics the design used in our 2009 analysis. There were neither main effects on the dependent variate for time ($p=.646$) nor for the time and condition interaction, $p = .31$. However, there was a significant between subjects effect on the dependent variate for condition, Wilks $\lambda=.73$, $F(4,96)=4.18$, $p=.004$, partial $\eta^2=.148$.

ANCOVAs on each dependent measure revealed a main effect for condition for multiply confounded ramp items, $F(2,49)=7.58$, $p=.001$, partial $\eta^2=.236$ but not for singly confounded ramp items, $F(2,49)=1.18$, $p=.156$, partial $\eta^2=.073$. Post hoc comparisons between conditions for multiply confounded items revealed that the direct+reify condition created significantly more unconfounded experiments starting from a multiply confounded state over both the discovery ($M=.62$, $SE=.19$, $p=.002$, 95% $CI=[0.25, 1.00]$) and direct-no reify conditions ($M=.64$, $SE=.20$, $p=.002$, 95% $CI=[0.24, 1.03]$). Again, no significant differences were found between direct-no reify and discovery, $p=.949$. As shown in Figures 3 and 4, the direct+reify condition maintained its performance edge over time as compared to the other two conditions. Also, though the direct+reify and direct-no reify conditions were similar at immediate posttest, the direct-no reify condition did not show long-term skill in constructing unconfounded experiments as shown by the drop in performance at the delayed posttest. Again, the discovery condition continued to increase in average performance over time.

Group differences for the time-2 delayed posttest were also analyzed using a MANCOVA with singly confounded ramp pretest items as a covariate. The dependent variate comprised of singly and multiply confounded ramp items at time 2 was marginally affected by condition, Wilks $\lambda=.84$, $F(4,96)=2.21$, $p=.074$, partial $\eta^2=.084$. The covariate was also marginally significant, Wilks $\lambda=.91$, $F(2,48)=2.41$, $p=.100$, partial $\eta^2=.091$. Observing the differences more closely with ANCOVAs on each dependent measure revealed a significant effect for condition for multiply confounded ramp items, $F(2,49)=4.23$, $p=.020$, partial $\eta^2=.147$ and a marginally significant effect for condition for singly confounded ramp items, $F(2,49)=2.82$, $p=.069$, partial $\eta^2=.103$. Pairwise comparisons revealed a significant difference in constructing experiments that followed CVS starting from a multiply confounded state favoring direct+reify over direct-no reify ($M=.73$, $SE=.26$, $p=.007$, 95% $CI=[-0.21, 1.25]$), and a marginally significant difference favoring direct+reify over discovery ($M=.48$, $SE=.25$, $p=.061$, 95% $CI=[-.02, 0.97]$). The direct-no reify condition was not significantly different than discovery learning condition, $p=.350$.

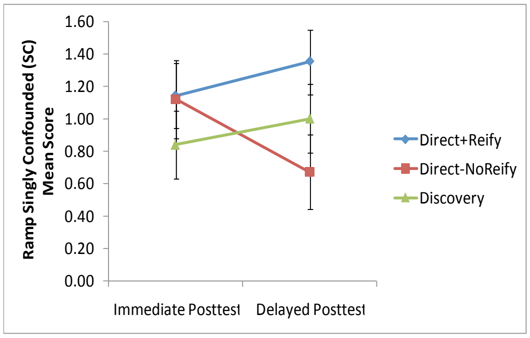

Figure 3. Means and standard errors for singly confounded ramp items (max=2). The pretest was omitted since it had only 1 singly confounded item.

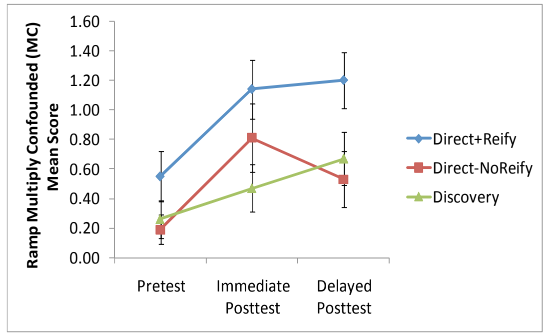

Figure 4. Means and standard errors for multiply confounded ramp items (max=2).

## Discussion and Conclusions

The primary goal of this research was to compare three pedagogical approaches in terms of their efficacy at fostering robust understanding of CVS as measured by successful application of CVS and long-term retention of this skill. Specifically, we examined if direct instruction coupled with self-explanation (direct+reify) afforded any long-term benefits on CVS acquisition over direct instruction without self-explanation (direct-no reify) and discovery learning. In Sao Pedro, et al. (2009), we found that students in each learning condition did not perform significantly better than each other on CVS problem solving and overall construction of unconfounded experiments. However, those in either direct instruction condition were better at correcting the more difficult multiply confounded setups to correctly contrast variables than the discovery condition at the immediate posttest. When incorporating the results of the delayed posttest administered six months later, direct instruction with explanation yieded a deeper understanding of CVS, collapsing over time. Looking specifically at the delayed posttest, those in the direct+reify condition significantly outperformed the direct-no reify condition on authentic inquiry items starting from a multiply confounded state. Additionally, those in the direct+reify condition outperformed those in the discovery condition, but these results were not strong enough to reach statistical significance. The instruction method did not impact long-term skill to articulate CVS nor CVS problem solving skill. The differences between our direct and discovery conditions are not as drastic as those of Klahr and Nigam (2004); this may be attributed to our choice to use text as the means to communicate instruction as opposed to audio as Klahr and Nigam did.

Our results are comparable to both Strand-Cary and Klahr (2008) and Dean Jr. and Kuhn (2006). Like us, Strand-Cary and Klahr reported that in a delayed posttest, students in their “discovery” condition, on average, rose to the levels of their explicit instruction condition at constructing unconfounded experiments. We concur with their interpretation that students’ engagement at constructing unconfounded experiments, though initially unsuccessful, may have made them more aware of the necessity to control for variables. Furthermore, it may be possible that students’ initial failure primed them for future encounters with the concept (Kapur, 2008). Further research needs to be conducted to empirically test these claims. Nonetheless, our collective findings suggest that it is possible for unguided exploration to reach levels comparable to explicit instruction with self-explanation, albeit more slowly. Additionally, Dean Jr. and Kuhn (2006) found that participants who practiced CVS regularly, irrespective of whether they received direct instruction or not, were better able to apply the strategy and make inferences when compared to those receiving direct instruction and not practicing. In their study, the practice condition dyads provided explanations to each other and entered them into the computer; these activities could have significantly affected students’ knowledge of CVS. In other words, it is difficult to ascertain whether the robustness of their findings is due to practicing the skill or providing the explanation.

In this paper, we have shown that the reification process (self-explanation), when added to direct instruction of the skill, supports both efficient acquisition and long-term retention of CVS, as measured by authentic inquiry performance. Of interest, we also found that on the same measurement, a nontrivial number of students in our unguided discovery condition were also able to perform, on average, at levels comparable to the direct+reify condition 6 months after the initial intervention. To address which behaviors within each intervention led to robust acquisition of CVS, we are looking at the quality of self-explanations, student responses, and all log files of student interactions within the ramp microworld. This will allow us to characterize the affordances of each condition for learning CVS and examine interactions with student variables such as prior knowledge of inquiry, in particular, knowledge of designing and conducting experiments. A fuller description such as this will provide important data towards our eventual goal of developing adaptive scaffolding support for CVS as it is a necessary but not sufficient skill for conducting inquiry (Gobert et al., 2007; Gobert et al., 2009).

# A critique of how learning progressions research conceptualizes sophistication and progress

Tiffany-Rose Sikorski, David Hammer, University of Maryland, College Park, MD 20742
tsikorsk@umd.edu, davidham@physics.umd.edu

**Abstract:** Researchers in science education have moved quickly to pursue "learning progressions," defined by the NRC (2007) as "descriptions of the successively more sophisticated ways of thinking about a topic" (p. 219). Given the speed of its adoption, it is not surprising there are variations in how the notion is understood, regarding how to assess sophistication as well as how to conceptualize progress. We examine learning progressions by three leading groups, to challenge assumptions that (1) ideas are "more sophisticated" insofar as they align more closely with end-state canonical knowledge, and (2) student progress can be characterized as a sequence of levels. These assumptions conflict with advances in science education research toward views of learners' knowledge and reasoning as complex, dynamic ecologies. By moving quickly to embrace learning progressions as an organizing concept for research, the community risks surrendering its own hard-won progress.

## Introduction

In the past few years science education has turned toward *learning progressions* as an organizing concept for research. Learning progressions are "descriptions of the successively more sophisticated ways of thinking about a topic" (NRC, 2007, p. 214). Already, researchers have articulated learning progressions (LPs) for many different grade levels, topics, and aspects of science. Some LPs focus narrowly, such as on celestial motion (Plummer & Slagle, 2009). Others focus broadly, such as the LP for atomic-molecular theory (Smith, Wiser, Anderson, & Krajcik, 2006). There are also LPs focusing on students' engagement in modeling (Schwarz, Reiser, Davis, Kenyon, Acher, Fortus et al., 2009) and other scientific inquiry practices. In addition to articulating these descriptions of progress, researchers have designed a variety of supporting materials for LPs, including assessment instruments, curricula, and instructional strategies.

Work on LPs has proceeded apace, as reported in a dedicated conference (Alonzo & Gotwals, 2009), a special journal issue (Hmelo-Silver & Duncan, 2009), a chapter in a National Research Council publication (NRC, 2007), and at least one literature review (Salinas, 2009). Recently, a working panel identified and discussed learning progressions from at least twenty different research projects, in part to define a common set of guidelines for future LPs (Corocoran, Mosher, & Rogat, 2009). Some researchers are even looking ahead to ways that LPs could be used to inform curricula and professional development (see for example Corrigan, Loper, Barber, Brown, & Kulikowich, 2009; Furtak, 2009).

Given the speed at which the community has adopted the notion of a learning progression, it is not surprising that there are variations in how that notion is understood. Much in particular depends on how educators understand "increasingly sophisticated," and in this there is tension over whether to focus on disciplinary knowledge or on disciplinary practices (Hodson, 1988; Hutchison & Hammer, 2009). To focus on the former, we should consider an idea more sophisticated if it comes closer to current scientific understanding. To focus on the latter, we should consider an idea more sophisticated if it was generated and defended in ways that more closely resemble scientific practices, based on the evidence and reasoning available to students. That is, in considering what constitutes increasing sophistication, what aspect of the discipline should have priority?

Much depends as well on how educators conceptualize what constitutes progress. In this there is also tension, much of it tacit, over whether to expect a linear progression from one way or level of understanding to another, or whether to expect a variety of learning paths. Most advocates of LPs explicitly endorse the latter, but in practice published LPs more typically describe a sequence of levels.

In this paper we offer a critical review of three learning progressions, in student understanding of (1) heredity (Roseman et al., 2006), (2) force and motion (Alonzo & Steedle, 2008), and (3) matter (Carraher, Smith, Wiser, Schliemann, Cayton-Hodges, 2009; Wiser, Smith, Doubler, & Asbell-Clarke, 2009). The authors in each case are prominent researchers on learning progressions, and as a set, these LPs reflect a range of approaches and perspectives with respect to assessing sophistication and conceptualizing progress. We begin with a summary of each progression with respect to its scope, development, and substance.

## Three Learning Progressions

### Roseman, Caldwell, Gogos, & Kuth (2006): Molecular Basis of Heredity

This LP aims to present the sequence of ideas that will lead to a "coherent understanding" of the two main functions of DNA: "determining the characteristics of organisms" and "passing information from one generation to the next" (Roseman et al., 2006, p. 1). The learning progression spans grades K-12, but the authors describe in more detail the sequence of ideas they propose students encounter in high school.

The authors drew on the *Benchmarks for Science Literacy*, the *Atlas of Science Literacy,* and a series of other standards documents, as well as on their own evaluation of the discipline and education research studies, to identify potential sequences of scientific ideas that could lead to an understanding of heredity. Roseman et al. (2006) propose an order of topics that deviates from the traditional textbook approach: they present "proteins before DNA" and "DNA before genes and chromosomes" (p.1).

The LP takes the form of a map and consists of two interrelated strands corresponding to the two main functions of DNA. Both strands connect to the learning goal: students' understanding that "heritable characteristics ultimately produced in the development of an organism can be observed at molecular and whole-organism levels—in structure, chemistry, or behavior" (Roseman et al., 2006, p. 6). For example, the LP has this sequence of ideas as part of the strand for learning the second function of DNA:

> Drawing mostly from benchmarks in the Heredity section of *Benchmarks'* Chapter 5: The Living Environment, the learning progression expects students in grades K-2 to learn that offspring resemble their parents (rather than other kinds of organisms). In grades 3-5 students learn that for offspring to resemble their parents, there must be a reliable way to transfer information from one generation to the next. In high school, with their prior knowledge of cells and protein molecules, students are ready to learn about the link between proteins and DNA and, hence, between DNA and traits. (Roseman et al., 2006, p. 2)

The authors provide a similar description for students' progressively more sophisticated understanding of the first function of DNA.

Roseman et al. (2006) propose to continually refine and validate their LP. First, they will reconsider "the grain size and language of the ideas" in the LP, ensuring that they align with standards, activities, and assessments (p. 3). Second, they intend to clarify the boundaries of "what specific knowledge students are and are not expected to know" (p. 3). As well, the authors will review the literature to identify common misconceptions regarding each idea. The misconceptions will inform the design of assessments and instructional activities, as well as help clarify the language of the LP itself. Finally, the authors plan to identify phenomena that will help students overcome their misconceptions and master the ideas in the LP.

### Alonzo & Steedle (2008): Force and Motion

Alonzo & Steedle (2008) are developing a learning progression to serve as an interpretive framework for assessment. This LP is designed to "diagnose" students' understanding of force and motion, particularly after an introductory unit on the topic (p. 3).

Alonzo & Steedle (2008) define LPs as "ordered descriptions of students' understanding of a given concept" (p. 1). They employ an "iterative process" of (1) hypothesizing a series of levels for student thinking, initially based on the research literature, (2) constructing and implementing related assessments to probe student thinking at each of the levels, and (3) revising the hypothesized levels based on the results of the assessments (p. 4). The goal of the revisions is to ensure that the LP captures the breadth of student thinking about force and motion, as well as to ensure that assessment items accurately diagnose students' level on the progression:

> [T]he learning progression represents a hypothesis about student thinking, rather than a description. As such, it expresses a current idea about how student understanding develops, which can—and should—be revised in response to new information about student thinking. (Alonzo, & Steedle, 2008, p. 5)

Alonzo & Steedle (2008) used the *National Science Education Standards* for eighth grade to inform their initial hypothesis, specifically to define the highest level of the LP. They also conducted a review of the literature to compile a list of "common student conceptions" about force and motion, and ordered these conceptions into levels “based upon research literature…and (occasionally) the relative difficulty of these ideas, as well as a logical consideration of proximity to the top level of the learning progression” (p. 7-8).

The current version of the LP consists of 5 levels (0-4) and describes students’ thinking at each level along four kinds of problems: force or no force, and motion or no motion. The LP also includes anticipated common errors at each level. For example:

> Level 2
> Student believes that motion implies a force in the direction of motion and that nonmotion implies no force. Conversely, student believes that force implies motion in the direction of the force.
> Force: If a force is acting upon an object, it is moving.
> 2A: The force acting on an object could be the initial force (which is carried with the object and may dissipate over time).
> No Force: If no force is acting upon an object, it is not moving.
> Motion: If an object is moving, a force is acting upon it.
> No Motion: If an object is not moving, no force is acting upon it.
> Common Errors:
> - If there is no motion, there are no forces acting.
> - When an object is moving, there is a force in the direction of its motion.
>   - 2A: This motion could be the force that put the object into motion initially.
>   - 2A: This object may come to rest because the force it carries with it has been used up. (Alonzo & Steedle, 2008, p. 16-17)

In addition to creating descriptions of each level in the LP, Alonzo & Steedle have developed associated assessment items for diagnosing students' levels on the progression.

## The Inquiry Project: Matter

The Inquiry Project is currently conducting research on 3rd-5th grade students' reasoning about matter, material, weight, volume, and density, in part to contribute to a learning progression on the nature of matter (Smith, Wiser, Anderson, & Krajcik, 2006). The group has yet to publish a complete LP for these grades. However, two recent Inquiry Project publications (Carraher, Smith, Wiser, Schliemann, Cayton-Hodges, 2009; Wiser, Smith, Doubler, & Asbell-Clarke, 2009) describe in detail the project's work on developing such a progression.

Wiser et al. (2009) frame the problem of designing a learning progression as follows:

> [G]iven a single starting point (preschoolers’ concepts and beliefs in the matter domain) and a single target point (the atomic-molecular theory taught to adolescents in a majority of countries) in how many ways can the knowledge network evolve (when characterized at the level of concepts and beliefs)? (p. 4).

In alignment with previous work (Smith et al., 2006), the Inquiry Project grounds its work on LPs in a theoretical framework of conceptual change. In this view, students’ initial understandings of matter are fundamentally different—and incompatible—with scientists’ understandings. For example, learning the atomic-molecular theory of matter (ATM) requires massive "reconceptualization" of students' ideas about material and matter (Wiser et al., p. 2). Wiser et al. (2009) predict that there are only a few possible pathways to a learning goal such as ATM, because “knowledge network[s] can only change productively in very few ways” (p. 4). Carraher et al. (2009) anticipate that 3rd-5th grade students' progression in reasoning about matter will involve two interrelated changes:

> - A gradual shift from (a) perception-centered thinking, that is, understanding and explanation closely tied to perceptual judgment and appearances, to (b) model-mediated thinking, informed by views about matter and drawing upon a set of increasingly advanced, inter-related concepts and scientific habits of mind.
> - The development of quantitative reasoning and understanding of measurement that students can use to make predictions, interpret, and explain relationships among physical quantities... (p. 3)

The Inquiry Project has undertaken a three-year longitudinal study to explore these changes. The study involves the design and implementation of a novel curriculum aimed at "fostering the development of students' knowledge about matter" (Wiser et al., 2009, p. 1). The Inquiry Project also conducts a series of clinical interviews to explore control students' (those exposed to a traditional curriculum) and treatment students' (those exposed to the Inquiry Project curriculum) ideas about matter-related concepts (see Carraher et al., 2009).

The Inquiry Project is currently in the process of gathering and analyzing data. They have confirmed some aspects of the lower anchor of their LP, for example, that "the distinction between material kind and weight are sporadic and context-dependent" (Wiser et al., 2009, p. 9). The authors are working to establish the "intermediate" levels—or "stepping stones"—of the progression (p. 1).

## Sophistication and Progress

Despite the variety of definitions of *learning progression* circulating in the literature, they all share a general sense that LPs describe how students become more sophisticated with respect to some aspect of science (Salinas, 2009). Roseman et al. (2006) design sequences of concepts in the canon based on disciplinary knowledge as mapped by Project 2061. Alonzo & Steedle (2008) hypothesize, test, and refine sequences of student conceptions using both disciplinary knowledge and research on learning. Wiser et al. (2009) are looking for sequences of student conceptions interwoven with epistemologies and practices of science. Our focus in this critical review is on how each of these LPs assesses "sophistication" and on how each conceptualizes the dynamics of progress.

### Assessing Sophistication

It may be educational common sense that what students learn should be correct knowledge, beginning with simpler, more foundational ideas and building from there to more complex, difficult material. Children learn to count, then to add, later to multiply, and so on. Roseman et al. (2006)'s work is designed around that view of knowledge and progress. In their LP, the canonical ideas themselves constitute the pathways of learning, and these pathways are therefore naturally towards more complete, correct understandings (Furtak, 2009).

Alonzo & Steedle (2008), on the other hand, create a learning progression not from canonical ideas, but from students' ideas, both correct and incorrect. In this respect, the two LPs are quite different. Roseman et al. (2006) do not include students' alternative conceptions in their LP, a difference that we explore further in the section "Conceptualizing the Dynamics of Progress." With respect to their determinations of sophistication, however, the two LPs are similar. According to Alonzo & Steedle (2008), the force and motion LP describes

> the thinking that students at that level could be expected to exhibit, including both the correct ideas that can be carried to the next level and the misconceptions that will need to be revised before students can reach the next level (p. 4).

Like Roseman et al., Alonzo & Steedle take "more sophisticated" to mean "more correct," that is more completely aligned with the target canonical understanding.

There are several reasons, however, to question the educational common sense that student learning should proceed as a sequence of conceptual attainments. First, such a sequence has not generally characterized progress within the sciences. Unlike basic ideas of arithmetic, which have been stable for millennia, basic ideas within science have gone through dramatic change. Concepts of life, matter, and energy that are foundational today were relatively recent constructions. (That life arises only from other life and the concept of energy are less than 200 years old; the idea that matter is made up of atoms is a notable exception, although the modern understanding of atoms as opposed to molecules is quite young.)

Moreover, it has happened often in science that the formation of a wrong idea has been generative for later progress. For example, the Caloric Theory treated heat as an invisible substance that is contained in hot objects and can flow into from them to cold objects. That incorrect idea was a stepping stone toward differentiating heat as an extensive quantity from temperature as an intensive quantity, as well as toward understanding energy as conserved (Chang, 2004). That is, the formation of a wrong idea may be a productive development in science. By including only correct concepts in their LP, Roseman et al. (2006) systematically omit the possibility of productive, incorrect ideas. And although their conceptualization of LPs does not necessitate it, Alonzo and Steedle (2008) do something similar by including among their hypotheses only sequences that become more correct over time.

Second, research on science learning has come to understand that progress is not entirely, or even primarily, about correct *concepts*. Indeed, the original emphasis of misconceptions research was that students' wrong ideas are often rational in ways that are constructive of scientific practices (Strike & Posner, 1985); in subsequent years Strike and Posner (1994) specifically revised their discussion of misconceptions to emphasize that "if conceptual change theory suggests anything about instruction, it is that the handles to effective instruction are to be found in persistent attention to the argument and in less attention to right answers" (p. 171). Minds, they argued, are complex, dynamic *ecologies*. To determine the sophistication of student ideas by their alignment with the canon is to overlook other aspects of those ecologies.

One outcome of a focus on “right answers” is that, in the practices of assessment and instruction it encourages, students may learn to assess ideas by their alignment with the canon rather than by fit with the evidence and reasoning they have available (Coffey, in preparation). That is to say, measures of sophistication organized around alignment with the canon are often at odds with assessments of quality by the *practices* of science. How, for example, should a teacher think about a student's progress who develops an account of inheritance based on evidence of how a mother's behavior and health during her pregnancy affects offspring characteristics? That account may differ greatly from canonical understanding, but the student's reasoning in producing it may reflect nascent scientific practices of generating ideas from evidence and reasoning.

For a number of years, the field has moved toward conceptualizing students' progress in science in ways that consider engagement in disciplinary practices (Engle & Conant, 2002; Ford, 2005). Progress in that engagement may involve students’ pursuit of non-canonical, but by other criteria sophisticated, accounts of phenomena (Hammer, 1997; Russ, Coffey, Hammer, & Hutchison, 2009).

Unlike Roseman et al. (2006) and Alonzo & Steedle (2008), Wiser et al. (2009) work explicitly from a cognitive theory in which movement along a learning progression is more than just the linear acquisition of “more elements of the expert theory" (p. 9). Instead, they define movement along the progression such that students are put “in a better position, eventually, to understand a basic version of AMT” (p. 9). In this framework, "stepping stones" need not align with the logical structure of the end-state canonical knowledge, nor are they limited to concepts:

> [T]hey are sets of concepts, beliefs, principles, models, numerical & mathematical understandings, and representational tools that provide students with coherent interpretations of a broad range of phenomena… (Wiser et al., 2009, p. 9)

The Inquiry Group acknowledges flexibility in determining stepping stones, especially for young students. For example, they considered two potential stepping stones in the fifth grade curriculum: (i) "a solid understanding, at the macroscopic level, of weight, volume, material, mass, and density, and their interrelations, consistent with the expert view", or (ii) a particulate model of matter (Wiser et al., 2009, p. 10). The researchers opted for option (ii). That is, students are permitted to continue with their non-canonical ideas about mass and weight, for example, in order to pursue melting, freezing, evaporating, and a host of other phenomena explainable by particulate models of matter. The authors predict that pursuing a particulate model for matter will be more interesting to students, align more with students’ expectations about science, and have “the most pay-off or ‘legs’ from a scientific perspective” by “introduc[ing] students to a productive new framework for thinking about matter” (p. 11).

It is unclear, however, whether the Inquiry Project will allow students' *non-canonical models* of matter to act as stepping stones in their progression. Allowing the development of non-canonical, but productive models is not prevalent in learning progressions literature, though Stevens, Shin, & Krajcik (2009) and Corcoran et al. (2009) for example suggest that non-canonical models might help students’ move towards upper anchor understanding. Wiser et al. (2009) appear to be struggling with this aspect of the development of their LP:

> A central issue is exactly what set of elements to include in a particulate model and how to introduce them in a way that helps students understand deeper epistemological issues about models, including their tentative revisable nature and their use as tools of inquiry. (p. 11)

This is an essential challenge for research on learning progressions: Conceptual understanding is only part of a complex dynamic, and LPs that treat it as a separable component may direct educational attention in such a way as to interfere with a healthy, productive cognitive and metacognitive ecology. Understanding the mind as a complex, dynamic ecology challenges another feature of LPs as well, namely the idea that students' conceptual knowledge can be characterized by levels. We turn to that aspect of our critique now.

## Conceptualizing the Dynamics of Progress

A working panel on learning progressions recently suggested that any 'good learning progression' should contain a levels-like description of students' knowledge:

> Levels of achievement that are intermediate steps in the developmental pathway(s) traced by the learning progression. These levels may reflect levels of integration or common stages that characterize the development of student thinking. (Corcoran, Mosher, & Rogat, 2009, p. 38)

Many groups have taken levels-based approaches to constructing LPs (see for example Mohan, Chen, & Anderson, 2009; Plummer & Slagle, 2009). A levels-based LP provides an organizing structure for “grouping similar sets of ideas” about a concept together and maps a clear pathway from initial to expert understandings (Alonzo & Steedle, 2008, p. 5). For example, Alonzo & Steedle's LP consists of five levels, each describing a qualitatively distinct way that students might think about force and motion. The progression also suggests a possible pathway for "how student understanding develops"—that is, from one qualitatively distinct level to the next (Alonzo & Steedle, 2008, p. 30).

There are several reasons, however, to question a levels-based approach to characterizing students' progress in science. In their work on validating the force and motion learning progress, Alonzo & Steedle (2008) highlight one potential problem: levels may not adequately describe the state of students' knowledge.

Levels, as described by Corcoran et al. (2009), denote periods of consistency in students’ knowledge. In this view, a student who gives a Level 2 response on a Newton’s third law question, for example, should give similar responses on all Newton’s third law questions. Alonzo & Steedle (2008), however, found that students “do not respond consistently across problem contexts” (p. 29). That is, students can appear to be on two different levels simultaneously. Alonzo & Steedle attribute some of the inconsistency to ambiguities in the language of assessment items. However, the authors also acknowledge that students' reasoning may be context sensitive, and so it may not be possible to "produce a single, reliable diagnosis of a student’s level” on a learning progression (p. 29).

Steedle & Shavelson (2009) investigated whether students’ responses on the diagnostic test designed by Alonzo & Steedle (2008) do indeed “reflect the systematic application of a coherent set of ideas needed to afford valid interpretations of learning progression level diagnoses” (p. 15). They found that in general, the answer is no—students do not respond in ways that suggest systematic application of a coherent set of ideas. In other words, students’ ideas are not accurately described by coherent, qualitatively different levels. The two exceptions to this finding are students “whose understanding is (nearly) scientifically accurate and those who believe that velocity is linearly related to force” (p. 15). The phenomenology of levels-like response patterns cannot be denied in these narrow exceptions. However, both Alonzo & Steedle and Steedle & Shavelson suggest that the levels-based approach is of limited use in instances where students show evidence of “unstable, context-dependent” reasoning (Steedle & Shavelson, 2009, p. 15).

Research on learning in science has been moving toward complex, dynamic views of cognition (Strike & Posner, 1992; Thelen & Smith, 1994; diSessa, 1993; Redish, 2004; Brown & Hammer, 2008). Rather than describe students as “having” or “not having” a particular level of knowledge, this research conceptualizes students’ knowledge as manifold, context-sensitive, and coupled to and embedded in the social and physical environment. Scherr (2008) for example documented how a college student could easily distinguish mass and density in one context, but conflated them in another. Frank (2009) documented multiple stabilities in how groups of students reason about motion. Smith (2005) found that she could alter infants’ performance on the Piagetian A-not-B task by changing their body positions or adding weights to their wrists. These and other results challenge the view that students possess a static “level” of knowledge, skill, or understanding.

Evidence that student knowledge is generally not well characterized as level-like at any point in time, clearly, raises questions regarding LPs composed of a succession of qualitatively different levels of knowledge or understanding. According to Corcoran, Mosher, & Rogat (2009), the levels approach

> stems from a structural view of cognitive development which suggests that the development of student thinking may not be purely incremental but may proceed as a series of increasingly complex schemes for organizing understanding of the world which may be rather stable for periods of time, but which eventually are modified or even broken down and rebuilt to take account of new evidence and new perceptions... (p. 18)

That structural view is at odds with evidence of contextual sensitivity in student reasoning. Identifying levels of conceptual understanding becomes even more problematic when we consider views of how different aspects of learners’ cognition interact (Perkins & Simmons, 1988). Consider the challenge of describing students' progress along two just dimensions: i) content knowledge of biodiversity and ii) generating evidence-based explanations. Songer, Kelcey, & Gotwals (2009) present one solution: create an LP for concepts in biodiversity, create a separate LP for generating explanations, and then measure students’ location on each. This approach, we suggest, misses the complexity of the interaction. Lehrer & Schauble (2009) make this point succinctly in their commentary:

> We hope that Songer et al. will elaborate the meaning of complexity of explanation...We suspect that complexity interacts with the nature of the knowledge of biodiversity being assessed, and a syntactic definition may miss this interaction. (p. 732)

For an example from physics, understanding the Newtonian concept of *force* (or *mass*, or *energy*) is in close interaction with understanding the disciplinary practices of positing universal "laws" of nature, of expecting and working to construct underlying principles that govern *all* experience within a domain. Learning the concept *involves* participating in that practice; and for many students coming to a first appreciation of that practice happens in learning Newtonian mechanics. The inquiry practices and the conceptual understanding are inseparable.

## Concluding Remarks

Our purpose in this presentation has been to lay on critical brakes to the adoption of learning progressions as the organizing concept and language for research on learning. By reviewing LPs constructed by several prominent groups, we hope to have illustrated how at least some LPs assume progress occurs as a sequence of conceptual attainments, monotonically increasing toward the end-state disciplinary view. Research in science education has slowly made progress toward views of learners' knowledge and reasoning in a complex conceptual, metaconceptual, motivational and social ecology. The field should take care that the quick adoption of "learning progressions" as a construct for organizing work does not set that progress aside.

**Abstract**: This paper presents case studies of three elementary teacher candidates in a one-year master's certification program, focusing on their participation in science and mathematics methods courses. Through one primary case and two contrasting cases, we examine the interplay among a teacher candidate's orientation to each discipline (math and science), orientation towards discipline-specific teaching, and emerging practices of attending to student thinking in disciplinary domains. This study is of interest because it reveals significant differences between learning to teach science and math, suggesting that practices of attending have disciplinary grounding and therefore do not necessarily transfer across disciplinary contexts. We argue that better understanding these dynamics becomes important for teacher education, particularly for elementary teachers, who are responsible for teaching across disciplines.

## Background & Motivation

High quality teacher education programs emphasize student-centered curriculum and instruction (Darling-Hammond, Hammerness, et al, 2007). The importance of attending to the substance of student thinking is grounded in research on how people learn and construct understanding (National Research Council, 1999) and in the role practices of attending can play in shaping teachers' instructional moves and supporting students' learning (Ball, 1993; Black & Wiliam, 1998; Hammer, 1997). Little research addresses the role teacher education can play in facilitating the development of teachers' practices of attending to student thinking.

A recurring theme in elementary teacher education research literature concerns teachers' subject matter background and preparation; in math and science, specifically, research shows that prospective elementary school teachers often lack a strong disciplinary foundation (Ball, 1990; Lewis, Parsad, et al, 1999; National Research Council, 2007). While we know that the subject matters for instruction (Stodolsky, 1988), and that content knowledge plays a role in effective teaching practices (Hill, Rowan & Ball, 2005), the ways in which a subject matters for learning to teach is less clear. Since student thinking occurs in discipline-based contexts, better understanding how practices of attending to student thinking across the disciplines develop is a pressing issue for elementary teacher education. To that end, this study asks: How do elementary pre-service teachers (learn to) attend to student thinking and how is that process similar or different across disciplines, specifically mathematics and science?

We situate this study in elementary teacher education because of the dynamics that arise in elementary classrooms: the same teacher is typically responsible for teaching the same group of students all of the school subject areas. This poses a unique challenge for teacher education, as elementary teacher candidates must learn about content, pedagogy, student thinking and student learning in multiple disciplines. Furthermore, we specifically chose to study elementary mathematics and science teacher preparation for two reasons. First, as pressure for improving mathematics and science achievement and calls for accelerating coverage reaches into the elementary grades, high quality elementary mathematics and science teaching is critical. Second, elementary teacher candidates often have had difficult experiences with mathematics and science and come to teacher preparation with negative orientations to the two disciplines and anxiety about teaching them (Sowder, 2007). Therefore, coming to understand the ways in which their discipline-relevant experiences and backgrounds interplay with learning to be responsive to student thinking are key considerations in effective elementary teacher preparation (Kilpatrick, Swafford, & Findell, 2001).

## Our Study

Our study took place during the 2008-09 school year in the context of a one-year elementary master's certification program at a large public university located in the mid-Atlantic United States. The study specifically focuses on the math and science methods courses and associated field experiences. Two of the authors were course instructors.

Both courses framed teaching as responsiveness to students' ideas and reasoning. With this emphasis, the courses foregrounded everyday assessment as a driver for instructional decision-making (Atkin & Coffey, 2003; Erickson, 2007; Levin, Hammer & Coffey, 2009). Coursework reflected this orientation: Both courses asked students to engage in case studies of student thinking, and individual and collaborative reflection on student work, among other field-based assignments. Both courses regularly engaged students in disciplinary reasoning and problem solving; in other words, the pre-service teachers did math and science, and reflected on what that doing entailed. Each course met weekly for three hours during the Fall semester. In addition to university coursework, the pre-service teachers spent three days each week in field placements in large public school districts with uniform curricular demands and diverse student populations.

## Subjects

Our analysis draws on data from three of the 25 consenting pre-service teachers in the cohort. All three were interning in 3rd grade classrooms. Brief profiles of the case study teachers are presented here; additional information relevant to their teaching is provided below in the analysis and discussion. Together the cases capture the variation along the axes of disciplinary orientation and attending practices explored in this paper. Kim, who serves as the primary case for this paper, is a white female in her mid-20s, with an undergraduate degree in Communications. Natalia is a white, female in her mid-30s who received dual undergraduate degrees in International Studies and Russian Studies. She is a former attorney, and, just prior to the program, was a stay-at-home mother. Barbara, a white female in her late 40s, received an undergraduate degree in Psychology, with a minor in Physics.

## Data Collection & Analysis

Data is drawn from the semester-long math and science methods courses, taken concurrently, including artifacts generated in participants' field placements. Specifically, we analyzed audio and video records of course meetings as well as the course assignments, which include: written reflections and activities involving analyses of students' scientific and mathematical thinking; field-based assignments involving instructional design and implementation; an analytic case of their students' disciplinary thinking and leaning (for math and science); and observations of teaching.

Initial analysis entailed iterative coding and comparative review of pre-service candidates' work and the nature and patterns of their class participation in both methods courses. An interplay of three dimensions emerged that are particularly salient for understanding how the pre-service teachers were learning to teach in math and science:

1. **Orientation to the discipline**: Beliefs about nature of each discipline (math and science), discipline-related experiences, epistemological issues, attitudes and dispositions, content area competency (self-described and demonstrated).
2. **Orientation towards discipline-specific teaching**: Visions of discipline-specific teaching, role of the teacher, ideas about student learning, goals and priorities within the discipline.
3. **Practices of attending to student thinking**: The aspects of student thinking that participants notice, what sense they make of that, how they take that up in their analyses and recommendations for next steps for teaching and learning.

Our analysis in this paper reflects case study methods used to capture variation in dynamics among these dimensions. We selected three cases that illuminate important distinctions across individuals as they learned to teach science and math and reflect patterns of variation that we observed among the broader group of 25. Kim serves as a primary case study to organize data and discussion. The other two cases presented here–Barbara and Natalia–offer interesting contrasts, which we discuss at the end of this paper. We are not arguing that these are the only dynamics at play; however, across the pre-service teachers, these dimensions emerged as fundamental to understanding the variation in learning to teach in discipline domains. Of course, school context played a role in shaping teachers' expectations and what they did in the classroom. While all three taught the same grade in large public school systems in the same state (thus sharing state standards), Kim and Natalia taught in a district that, overall, was higher performing than the district where Barbara taught.

# A case study of elementary pre-service teachers' engagement in attending to student thinking in math and science – a closer look at Kim

Like many of her peers, Kim demonstrated differences in her practices of attending to student thinking across her math and science methods courses. In her science methods class, attending to student thinking afforded Kim opportunities for deep engagement in disciplinary practices and in student reasoning. In math, while she clearly demonstrated personal engagement in mathematical inquiry and problem-solving, the purposes Kim ascribed to attending to student thinking—to assess students' progress toward successful problem solving—constrained how she inquired into student thinking and what that attention made available for her. We found that Kim's differing views of the disciplines, as well as the differing ways in which the presses (e.g. curricular, external testing demands) manifested in math and science teaching in her field placement setting, contributed to marked differences in her abilities to attend to students' thinking in mathematics as opposed to in science. Before we take a closer look at the ways in which she attended to student thinking, we briefly describe her orientations to the disciplines of math and science and towards teaching in these disciplines.

## Orientation to the discipline

In science methods, Kim initially portrayed science as wonderment and exploration on one hand and "knowledge" on the other, without a clear articulation of the relationship. Her work over the semester in attending to students triggered her own episodes of engagement in scientific reasoning. Kim began to appreciate scientific reasoning as a way to get from wonderment and exploration to knowledge. Scientific reasoning took on dimensions of instrumentality—she began to see it as a useful "tool" for asking questions about the world.

During the semester in her math methods class, Kim's orientation to mathematics shifted from a belief that mathematics is primarily about getting a "right answer" and a focus on its instrumentality to the centrality of conceptual understanding and sense-making. At the start of the semester, Kim reflected that her experiences learning mathematics fostered a view of school mathematics as concrete, straightforward exercises that "are either right or wrong" and a view of mathematics learning as primarily mastery through repetition and memorization. She recognized the instrumentality of mathematics outside of school and felt that the usefulness of mathematics was a key motivation for students, including herself, to learn mathematics. Through the course of the semester, doing math became about achieving deep conceptual understanding and the satisfaction of "getting it" through "successful" problem solving. She approached mathematical explorations and problematic tasks in the methods class as puzzles to be pursued. Despite her clear enthusiasm and competency in pursuing these personal mathematical challenges, her central goal, however, remained "getting" or mastering them as opposed to the processes of conjecturing or inquiry.

In both disciplinary areas, Kim demonstrated a curiosity toward puzzling situations and problems (including self-initiated questions) that support deep engagement in disciplinary practices. However, in math her primary focus was on understanding achieved through successful problem-solving, whereas in science she demonstrated a value on the processes of questioning and reasoning unto themselves.

## Orientation to discipline-specific teaching

During the science methods course, Kim's focus shifted from student ownership through topic relevance to creating opportunities for students to articulate and question their scientific reasoning. Her primary goal involved helping students engage in questioning and sustained reasoning of everyday phenomena to which they may or may not bring prior knowledge, or even see as relevant. To help students engage with each other's ideas, Kim regularly asked, "Do you understand what he is saying?" and "Does that make sense?" Science content goals became secondary in practice to her facilitation of and responsiveness to reasoning, although she did not drop them all together. For her, one would lead to the other.

Teaching math for Kim involved providing students with opportunities to explore and make sense of rich problems in order to achieve "success" on the problem and, thus, develop understandings of mathematical concepts. Her role was to reveal students' strategies and reasoning by asking questions and then use that information to pose guiding questions to support students' movement toward successful solutions. During the math methods course, she also began to value students' sharing of their strategies with one another to make multiple solutions available to students.

## Practices of attending to disciplinary thinking: Kim's science teaching

Over the course of the semester in her science methods coursework, the focus of Kim's analysis of classroom activity was on the substance (beyond canonical correctness) of students' ideas and reasoning. In her classroom teaching experiences, attending to student thinking served as a way for Kim to help her students clarify their reasoning and engage with each other's ideas. Kim's written analyses show that she began to see her role as a science teacher as one of facilitating students' articulation of reasoning as a bridge to scientific understanding. The analysis below helps illuminate this positioning.

The following excerpt comes from Kim's transcript of her 3rd grade class discussing why days were longer in summer than in winter. This segment begins with an explanation set forth by one of the students, that "the sun goes around the Earth slower and the Earth spins faster." On first consideration, what may jump out in the student's statement are the inaccuracies of the students' ideas. Kim's treatment of those ideas–both in her subsequent moves in the classroom and her written reflection—demonstrates a commitment to helping students clarify their reasoning and engage with each other's ideas. Despite the fact that Kurt's and Rye's ideas were wrong, Kim sought clarification, in a way that indicates she was trying to understand the reasoning behind the explanations.

Kurt: I was thinking that the sun…that the sun goes around the Earth slower and the Earth spins faster. So, so, it's um, so the sun goes to the other side of the Earth, um it goes to the other side of the Earth cause because the Earth is rotating around…(trying to show what he is saying with his hands)

Kim: Can you draw me a picture of what you mean up here? Can you draw a picture? I'll erase some space. Can you draw a picture you think?
Kurt: Yup.
Kim: Ok draw us a picture. Let's see if we agree on understanding Kurt.
Kurt: So this (*drawing suns orbit around Earth*), so the sun is going around and this the Earth is spinning fast. So this is the, hold on, this is the Northern Hemisphere and this is the Southern. So now it's so, so, and then it turns like it turns really fast like, and if you, its night time and the sun is here and…
Kim: Ok. Guys, look up here at what Kurt did. He said, here's the sun, he said the sun is going around the Earth like this. And the Earth is spinning like that. Does anyone agree or disagree with what Kurt is saying. Think about what we know about the Earth, and day and night, and the sun…Rye?
Rye: I agree.
Kim: You agree with him? Why do you agree with him?
Rye: Because the sun does go around fast, and the Earth, but I disagree a little bit because the Earth goes slow around.
Kim: Explain it, say it again. What do you mean the Earth goes faster and what do you mean it goes slower?
Rye: It goes slower because if it went faster it would be the year 3000 tomorrow.
Kim: So you're saying if it went too fast then time would pass?

In her analysis of this conversation Kim wrote, "Some students said that the Earth can speed up and slow down, and that's why we have longer or shorter days…They do get that the Earth rotates on its axis and that is what causes day and night. So it must seem natural that the speed of the rotation must change to explain the change in the length of day. We can't feel the Earth moving anyway, so we probably wouldn't feel a change in speed…Looking back I could have followed up with asking them what causes the Earth to spin slower or faster." We see her pushing students to consider the ideas in light of other things they "know" – "think about what we already know about the Earth, and day, and night, and the sun." Her analysis indicated that she was also able to identify instances where she could have pressed students on their reasoning, and in particular push for a causal explanation.

Kim appeared to allow the specifics of her conceptual understanding goals to emerge from the discussion. For example, although she is expressed concern about the inaccuracy of the statement that "the sun goes around the Earth slower and the Earth spins faster," Kim addressed students' conceptual understandings not by "correcting" their statements but by encouraging students to examine the logic of their reasoning. In any given moment of interaction, she primarily attended to students' clarity of articulation and reasoning, allowing students to engage meaningfully with each other ideas.

Following the exchange in the transcript above, Kim offered students a globe and differently sized balls "to allow them to model what they knew." She explained, "I had hoped that if we established some things we all agreed to be true, we would be able to reason that the Earth always rotates on its axis at a constant speed once every twenty-four hours." A student then challenged the idea that the sun orbits the Earth, offering as explanation that "the Earth spins so slow that the side facing the sun is in the summer and it stays that way until it moves out of the light, and then it becomes winter." Kim noted, "Her response was right in so many ways…she knew that the Earth orbits around the sun and that the relationship somehow caused the different seasons to happen on different sides of the earth. She also knew that the Earth was rotating on its axis while it was orbiting. However, it was hard for me to let it go there because we just established that the day/night cycle happens every twenty-four hours…"

Kim held students accountable for their scientific reasoning. Recognizing the inconsistency in the student's reasoning, Kim explained: "I brought the discussion back to that idea and sure enough a student was able to challenge her on her idea. Dan responded, 'I have to disagree with Verna because…if it was summer over here, if it was summer over here, then like how could it move because its summer over here and its winter over here. I don't get it. Because if it was summer over here, it would have to be summer there for, like, a season and if was, um, winter over here it would have to be winter for a season. And then they would never have day, well it would never be night.'" As this brief snippet exemplifies, over the semester Kim began to see reasoning as the bridge to scientific knowledge, and her role as teacher as one of facilitating this connection. For Kim, the end point of any particular science lesson was less important than the process by which students got there, which she came to see as the primary work for learners doing science. While this was the case within a particular lesson, at the end of a several lessons, Kim expected to see conceptual progress towards canonically accepted explanations. Yet, she was able to let this end goal go in most moments of interaction.

## Practices of attending to disciplinary thinking: Kim's mathematics teaching

Kim's attending practices looked different in the math methods course. Her analyses of students' mathematical thinking addressed conceptual and procedural understandings as she attended to the details of students' talk, inscription and gesture to make her judgments. She increasingly saw the value of revealing student thinking, but viewed attention to student thinking in math as a teaching strategy for assessment of student understanding and readiness. In her practice, Kim questioned her students primarily to determine their problem-solving strategies and, if necessary, to steer them toward a successful solution (while honoring and building upon the particular direction each student had attempted to take).

The following example comes from Kim's instruction with a small group on the task: "Greg climbed 2,600 meters up the side of a mountain. His brother Harry climbed half as far. How far did Harry climb?" Before starting the task, Kim focused the students on problem-solving strategies ("What are some important steps when you are problem solving?" "What are some possibilities for solving problems that maybe you've tried before, some strategies you used?") as well as the multiplicity of strategies that could be used to solve a problem ("Are there different ways to solve problems?" "Do you agree that there are multiple ways to solve a problem not just one correct way?"). Her interactions with the students on this task reflected how she uses questions to reveal students' understandings and then "guide" students to "success" on the problem. The following excerpt is typical of the kind of revealing and guiding questions she asks as well as her emphasis on "making sense."

Kim: What if we separate these two numbers [2000 and 600], Mish. What if we separate them by what their place value is?
Mish: What do you mean separate them?
Kim: What does the two really mean there?
Mish: Two thousand.
Kim: Ok, so if we do 2000, then what's the rest? Do you remember when we did expanded notation?
Mish: Yes…
Kim: So, how can we divide all these numbers in half? What is half of zero?
Mish: Zero.
Kim: Yup, half of zero is zero. What is half of 600?
Mish: 300.
Kim: You're right. How do you know that it's half of 600?
Mish: Because 300 plus 300 is 600…[Mish completes the problem.]
Kim: You're right, now tell me why.
Mish: Because that's in the thousands, that's in the hundreds, that's in the tens and ones, so and I don't have anything to add up to these so they stay in, these two I don't change.
Kim: And you're going to add these two numbers together?
Mish: Yes
Kim: So we've figured out half and you're going to add the halves together. Does that make sense to you?
Mish: No.
Kim: No? Well why doesn't it make sense. Think about it. You know you're right and I just want you to think about why that's true.

For Kim, teaching math involved questioning strategies that guide the students down solution paths: "By [this] task, I felt really comfortable with my questioning strategy and I think I was able to do less work and let the students do more work. Some of my favorite questions were: Where are you going next? How will you know when you have your answer? What does that mean? When I was watching video, I think that these questions turned the work back on the students and made them think about what it was that they were doing and trying to accomplish. It also helped me understand them."

Kim's analyses of her students' mathematical thinking address conceptual and procedural understanding, though not mathematical processes such as explanation and justification. In her analysis of the excerpt above, she wrote: "He was unable to come up with the correct answer, but the process he was using told me he understands a few things; what half means, how division and subtraction work together, and place value. He knew that half meant dividing something into two equal parts. He told me right away that half of 600 is 300. He also was using the division symbol and attempting to divide the large number by two. Later when I prompted him to check his answer he did so by subtraction and subtracted his answer from the whole number. When the answer was not equal after subtraction he knew it was the wrong answer…I know he understands place value because after attempting to divide 3,600 by 2, he broke the number down into 3,000 and 600. He still got confused because he kept putting the number back together before he knew he had found half of each."

Kim viewed attending to student thinking in math as a teaching strategy for assessment of student readiness: "I have learned that this [analyzing student thinking] is all a very important process in teaching. I have tried to incorporate this into each math class. I have found that I am able to assess student progress easier. I can tell what they might need more work on and when they are ready to move on. It also helps in giving me ideas for lessons."

In summary, in math, Kim focuses on students' problem-solving as a means of providing her information about progress and uses questioning to "guide" them toward the correct answer. In science, she attends to the nature and clarity of reasoning and ideas, largely so students can begin doing the same. In the moment, she does not appear to be concerned about the specific directionality of the reasoning (although in retrospective reflection, she comments on progress toward conceptual knowledge).

Overall, for Kim, teaching science was about fostering sense-making and teaching math was about guiding students in making sense. In math she valued reasoning toward a particular end--the problem solution. In science the particulars of the end depended, in large part, on the emergent lines of student reasoning. The differences we saw in her math and science attending practices with students seem to coordinate with differences we see in her orientations to, and relationships with, the disciplines of science and math, and teaching in the disciplines. Kim identified science as one of her favorite subjects growing up, in part because she said it was a "break" from other academic subject matters; she wrote of it as "a chance to explore, and have fun doing it." Not unlike some of her peers, she drew on experiences outside of the classroom to inform her views about science. When asked to describe a positive learning experience in science, she wrote of exploring the woods and streams around her house, and about excursions with her father. The theme of exploration – of things and ideas – is echoed in her own teaching. In mathematics, Kim's orientation shifted from a belief that mathematical activity entails getting right or wrong answers and a focus on its instrumentality, and she began to recognize and embrace the sense-making nature of the discipline. This was reflected in her practice and in her practices of attending, which focused on fostering sense-making with her students while still retaining a strong focus on successful problem-solving.

In both disciplines, Kim's practices of attending to student thinking further facilitated her own conceptual knowledge and exploration. For example, in the science methods course, discussion of video clips of elementary students doing science presented opportunities for engagement in disciplinary reasoning practices. An example occurred during a conversation the pre-service teacher candidates were having about a transcript of 2nd graders were talking about whether a cup full of water and ice will overflow when the ice melts. Two competing ideas were under consideration by the elementary-aged students: "Ice gets smaller when it melts so it would be less water;" and "So the water holds the ice up and then when it melts it sinks to the bottom and pushes the water out." (Restated as, "It sinks. It melts. And makes more water…and pushes the rest out."). Kim asked her classmates, "Why does ice expand when it freezes? What's happening?" She made several moves similar in nature over the semester. In both methods courses, she took up opportunities to analyze student thinking as invitations to engage deeply in the conceptual content. As she attends to and explores student thinking, she is making sense of student ideas *and* the phenomena about which they are reasoning, as though they are part and parcel of the same thing.

## Learning From Other Cases – Barbara and Natalia

Kim's trajectories in learning to teach math and learning to teach science were different than some of her peers. Broadly speaking, Barbara's orientation to teaching math was a strong response to her own negative experiences as a student in "traditional" math. She articulated that math teaching should be engaging and hands-on in order to motivate students and support understanding. Barbara also articulated the importance of students learning that there is more than one way to solve a problem. In her own mathematical activity, she was willing to engage the tasks and discussions about the mathematics, but displayed a lack of confidence, deferring to others and joking about her competence. Her analyses of students' mathematical thinking attended to both conceptual and procedural understandings in a detailed manner, and her lessons provided opportunities for students to cooperatively engage in tasks. However, in practice, she focused on getting students to a "right answer" through leading questioning (which she described as "guided invention"); also, her teaching reflection revealed that she was primarily concerned with students being "on-task" and enthusiastic and their arriving at correct answers.

On the other hand, Barbara reported to "love science" and to want to "inspire" that same sentiment in her students. Barbara minored in physics as an undergraduate and was the only student in the program who had significant undergraduate education in science or math. In her methods class, she positioned herself, and was positioned by others, as an expert in science. Peers often (physically) looked to her for explanations or to confirm the (in)correctness of an idea. Her disciplinary view of science revolved around canonical knowledge. Barbara believed background knowledge was a precursor to doing the work of science, which entailed controlled experimentation. She saw science as a difficult subject to learn because students "often lack background knowledge" and were coming from homes where "parents are not comfortable with their level of knowledge." On multiple occasions in the methods class, Barbara chose not to engage in scientific activity – in the sense making - because she didn't "know enough about people's background knowledge" and didn't want "to give away answers". In attending to student thinking in her field placement, she focused on correctness of knowledge, as articulated through use of appropriate terminology.

The case of Barbara highlights that disciplinary background – and confidence - alone is not enough to precipitate robust practices of attending to the substance of student thinking. Unlike many elementary school teachers, Barbara was neither math nor science phobic. In science, her academic background and self-proclaimed expertise influenced her (dis)engagement in scientific sense making and her focus in attending to student thinking, or more aptly stated, student knowledge; knowledge was paramount to reasoning. In contrast, in math, while comfortable, Barbara was not as confident. While she aspired to reform-based teaching and learning, her teaching looked more traditional, with a focus on correctness.

Natalia, our final case presented here, articulated that math should be taught "as inquiry not as conclusion" and that "discussion and experimentation are essential with each student exploring different strategies and sharing..." Rich tasks and appropriate manipulatives are also important for "helping students to understand and conceptualize abstract math concepts." She demonstrated strong mathematical competence and a disposition toward inquiry in her own math activity. During the course, she began to situate her understandings of math teaching and learning in her developing role as a teacher in a real school context, accountable to and for her students' learning. She was concerned with allowing students to harbor misconceptions and felt that exploration should be followed by "closure" in which concepts are made explicit through a teacher-led discussion of student-generated problem solutions. She was explicit about the need to address "efficiency" in a climate of accountability and strived to find "balance" between exploration and direct instruction.

Natalia wrote of science as "a process of discovery and developing knowledge and understanding about the world," which entailed systematic observation and exploration. At the start of the semester, she highlighted as a hurdle that "students are not used to following the scientific method to create their own answers." Initially, teacher content knowledge was important for "answering questions", fostering "intelligent debate", and identifying appropriate content goals. Substantive analyses of student thinking came easy to her. While her analysis foregrounded students' conceptual ideas, she also noticed reasoning that strung the ideas together. She viewed her responsiveness to student thinking as a necessary means to help students reason in order to appropriate conceptual knowledge and achieve conceptual understanding. She valued ambiguity and "wrong ideas" for information she could glean and as opportunities for students to reconcile competing ideas. Student reasoning, thus, served as a pedagogical role to inform her teaching, and not necessary as a vehicle for her students to do science.

This case highlights the dynamics for a candidate who entered the teacher preparation program with sophisticated notions of disciplinary teaching and strong analytic skills. Natalia saw immediate benefits of attending to student thinking to further align disciplines and disciplinary teaching. This initial position allowed her to meaningfully tackle both understanding and negotiating how these threads come together in the broader context of schooling. Over the semester, the alignment between her orientation towards the discipline and disciplinary teaching became more refined. Contrasts in science and math teaching that emerged were rooted in different contextual presses, such as high-stakes testing and degrees of prescription of the county curriculum.

## Conclusions

This work has begun to explore the role of disciplines (i.e., disciplinary understandings, beliefs about the disciplines, dispositions toward the disciplines) in learning to teach within and across the disciplines at the elementary grade levels. As the cases of Kim, Barbara and Natalia reveal, practices of attending to student thinking have disciplinary grounding and therefore should not be expected to share generic characteristics across disciplinary contexts. The role that discipline plays in learning to attend to student thinking, and thus, learning to teach, is important to understand, particularly for work with elementary school teachers. To support prospective teachers' learning to conceptualize and enact attending to student thinking as central to teaching, we need to better understand how their disciplinary understandings and orientations toward teaching specific to those disciplines interact with practices of attending to student thinking, including how, to what, and for what ends. We have begun to identify dimensions that seem salient and dynamic. Our work suggests that teacher education, particularly for elementary teacher candidates, should consider how the interactions amongst these dimensions of teacher knowledge and practice can be leveraged to foster deep reconsideration of discipline and disciplinary teaching. We see promise in better understanding these dynamics for informing teacher education.

This work also closely relates to notions of teacher identity and problematizes the uni-dimensional treatments of teacher identity, particularly with respect to elementary teachers. While, on some level, prospective teachers are constructing identities as 'teacher', as discussed in literature (Cohen, 2008), our work suggests that elementary school teachers may be navigating multiple identities as 'teacher' (Smith, 2007), specifically ones that reflect the disciplinary groundings of school subject matters. Policies geared to math and science teaching and common "wisdom" (i.e., constructs of "science and math" person or strong analytic thinker) often assume close alignment between notions of mathematics and science; however, experiences with and analyses of our cohort of pre-service teachers challenge this assumption, as the cases above demonstrate significant differences across these disciplinary contexts.

We situate this work in elementary teacher education and learning practices of attending to disciplinary thinking. A criticism of elementary school teaching is that teachers often lack disciplinary expertise (Ball, 2000; NRC, 2007; Seaman & Szydlik, 2007), which in the case of math and science, is often judged by the number of completed math and science courses. We do not intend to argue – even implicitly – for subject matter specialists at the elementary grade levels. While we agree that teachers often come into teaching with negative views and varied success, we question the metric of course completion as an indicator of the depth and usefulness of knowledge that can be reworked for understanding and supporting students' thinking (Ma, 1999). Moreover, we see promise in teacher education helping prospective teachers establish a stance towards practices of disciplinary attending that could contribute to more robust notions of disciplinary learning and understanding and deeper conceptual understandings – for themselves as well as for their students. We see value in teaching across multiple school matters and contexts. Knowing the student in multiple contexts, including across subject areas, could provide useful insights for identifying resources students' bring to their subject matter learning. We hope to pursue these connections in the future.

**Abstract:** Understanding teacher cognition – and in particular teacher noticing - poses significant challenges to researchers because of the ongoing nature of teaching. To overcome those challenges learning science researchers have used a variety of methods to help them understand how teachers reason and make decisions while teaching. In this symposium we describe a new digital technology that allows teachers to capture short video clips of classroom activity as they are teaching. The three papers explore different aspects of what we have learned about teacher noticing using this new technology. The first paper describes the potential of the camera to serve as a window into teachers' in-the-moment noticing. The second examines teacher noticing of their students' thinking. The third paper investigates our efforts to use clips captured using this methodology as the basis for video clubs in which teachers watch and discuss excerpts of one another's classrooms.

## Introduction

Learning science researchers have, for many years, had a strong interest in teacher cognition. In particular, we would like to understand how teachers reason and make decisions in the act of teaching. Yet studying teacher thinking during instruction poses challenges for researchers. Because of the ongoing nature of teaching, it is not feasible to interrupt and ask teachers what they are thinking, what decisions they are considering, or what questions they have at the moment. Instead, researchers generally use other, less intrusive, approaches. For example, some researchers draw on observations of teaching to make inferences about a teacher's thinking (e.g., Schoenfeld, 1998). In this approach, researchers may try to construct a plausible chain of reasoning events that aligns with the teacher's actions and utterances during a lesson. Another approach involves asking teachers to reflect, after-the-fact, on their teaching. Using retrospective interviews, for instance, researchers may ask teachers to recall how they came to a particular decision or what alternatives they were considering at the time (Peterson & Clark, 1978). A third approach is to try to simulate teaching in some manner, for example, by showing teachers videos of instruction and asking them to comment (e.g., Copeland et al., 1994).

Each of these approaches, however, has limitations. Some of what a teacher thinks may not be visible in a teacher's actions or words, making it difficult to infer how a teacher is thinking simply by watching them. Also, in retrospective interviews, there is a risk that teachers will construct new interpretations of what took place during the interview, rather than recall their thinking during instruction. Similarly, even if simulations are carefully constructed to present teachers with situations that closely resemble instruction, teachers will lack the kind of detailed background information they use to make sense of real-world situations while teaching. It seems possible then that simulations will provoke a different kind of reasoning than takes place during instruction.

Whether or not these approaches suffice will depend in part on what aspect of teacher cognition the researcher is interested in. In our work, we are particularly interested in teacher noticing — in how teachers attend to and make sense of significant interactions during instruction. The classroom is a complex environment with many things happening at once. How does a teacher decide where to focus his or her attention? This issue is particularly important in light of efforts to reform mathematics and science education in the U.S. today. Teachers are called upon to continually assess the ongoing nature of lessons and to base their instruction, at least in part, on the ideas that students raise in class. In this context, how teachers direct their attention in the act of teaching is a critical area for researchers to investigate.

Given our interest in teacher noticing, the three approaches outlined above pose methodological challenges. First, it may be particularly difficult to observe a teacher "noticing;" noticing may not align with specific utterances or actions on the part of the teacher. In addition, because noticing is likely to take place in a fleeting manner it may be hard to capture retrospectively. Furthermore, during simulations noticing may operate in a manner that is quite different than how it operates during instruction. How then, can we effectively study teacher noticing?

The purpose of this symposium is to discuss a new technology that we are using to study teacher noticing during the act of instruction. Our claim is not that this new technology should replace the methods discussed above. Rather, we believe that this new technology has the potential to add an additional, complementary, window into teacher thinking in action.

### Exploring New Technology

Recently, a new class of video cameras have been introduced, cameras that are small enough to be mounted on a hat or a pair of eyeglasses. Of particular interest are cameras that offer "selective archiving" capabilities. Selective archiving allows the user to select moments of video to capture immediately after they occur.

Two cameras were used in the studies we present here: the Deja View CamWear 100 (Reich, Goldberg, & Hudek, 2004) and the POV 1.5 (V.I.O., 2009). Both cameras include two components: a small wearable camera approximately one inch long, and a recording module about the size of a cell phone that can be attached to a belt. The cameras record in a loop mode, and record over themselves after a short time. Pressing the "save" button on the recording module interrupts this process and saves the previous "loop" of video in a digital file — 30 seconds in the case of the Camwear 100 and 3 minutes in the case of the POV 1.5. In both cameras, the digital files are stored on a video card that is housed in the recording module. The files can easily be downloaded and viewed on a computer.

We developed the following two-part methodology to support our use of the new cameras. First teachers were asked to wear the camera during instruction and to press the record button "when something interesting happens." Occasionally we used variations of this prompt, but in general we asked teachers to focus on events that they found "interesting." In order to capture a complete record of the lesson taught, we also videotaped the classroom from the back of the room using a single stand-alone video camera. Second, on the same day, a researcher met with the teacher to review the set of clips that had been captured. To do so, we developed a process intended to increase the possibility of teachers drawing on their thinking during instruction, rather than creating retrospective accounts of their noticing. Specifically, a still image of the start of the captured clip was shown to the teacher. If the teacher could recall, just from the still image, why he or she captured the clip, then the video clip was not reviewed further and the teacher explained at that point why the clip had been captured. If the teacher could not recall why the clip was captured, then the clip was played but only until the point at which the teacher was able to recall his or her reason for capturing the clip. Teachers were also asked to generally describe their experiences using the camera that day, and whether the clips represent the events that the teachers had intended to capture. All interviews were videotaped and later summarized and partially transcribed.

The three papers presented in this symposium explore different aspects of what we have learned about teacher noticing thus far using this new technology. The first paper describes what we have found about the potential of the camera to serve as a window into teacher noticing during the instruction. The second paper looks closely at those clips teachers describe as being about student thinking. The third paper investigates our efforts to use clips captured using this methodology as the basis for video clubs in which teachers watch and discuss excerpts of each others' classrooms. While all three papers share methodology for studying teacher noticing, the specific data examined are somewhat different across the papers.

The format of the symposium will be as follows. We will begin with a brief introduction of the goals of our project as well as a demonstration of the wearable video camera and illustration of the kinds of data that were collected. Following this, there will be three 12-minute presentations of the papers. Next our discussant, Rogers Hall, of Vanderbilt University will provide comments on the papers. Dr. Hall's research explores the relationship between one's perception of events and how one participates in such events in a number of contexts including teaching. Finally, we will have 30 minutes for questions and discussion with the audience.

## Freezing Time: What Mathematics and Science Teachers "See" While Teaching

Bruce L. Sherin, Miriam Gamoran Sherin

Our methodology was designed to tap directly into teachers' in-the-moment noticing in a way that has not been possible before. Specifically, the idea is that the clips themselves have the potential to reveal the kinds of events that teachers pay attention to during instruction. In addition, the hope is that teachers' comments in the interviews will provide valuable information concerning the ways in which noticing acts during instruction, for example, the extent to which noticing is a conscious process and the reasons behind teachers' attention to various kinds of events. The goal of this presentation is to summarize and illustrate the data we have collected thus far, and then discuss the ways in which the methodology achieved its potential as well as problems we faced in the process.

Over the past two years, we have worked with 12 high school mathematics and science teachers who volunteered to use one of the cameras during instruction. The teachers taught in three different school districts in the Midwestern United States, all of which have diverse student populations. Most teachers used the cameras on three separate occasions; in all we conducted 39 interviews lasting approximately 45 minutes each. Each of these interviews was conducted after a teacher had worn a camera for one class session.

Overall, we found that teachers were able to use the camera to capture moments of instruction during teaching. About one-half of the teachers initially faced logistical problems using the camera — pressing the wrong button, or not pressing the button correctly, or other malfunctions of the camera. After one or two attempts at taping, however, these issues were generally resolved. The clips themselves illustrated a range of types of classroom events — whole group discussions, small group work, individual seatwork, and student presentations. Teachers reported to us that using the camera was not overly disruptive, either for themselves or for their students. This is also evident in the fact that teachers typically captured clips throughout a lesson; thus it was not the case that teachers captured clips only during the first 10 or 15 minutes of class at which point the demands of instruction took priority and camera use fell off.

On average, teachers captured 9 clips per 50 minute class period. We see this moderate number as suggesting that teachers were somewhat selective in capturing moments of instruction. Furthermore, the distribution of clips was not evenly spaced throughout a lesson. Teachers did not simply press the button every five minutes or so without regard to the specifics of the moment. Instead, teachers seemed to be sufficiently conscious of what they viewed as interesting to be able to push the button when an event stood out to them. Mason (1998) writes of the need for teachers to be "aware of their awareness." It is this kind of conscious awareness that we believe we have accessed with this methodology. Along the same lines, in many cases, teachers were able to recall what they had captured and why from looking only at the still image or a few seconds of video. Specifically, issues of student thinking, pedagogical techniques, and organizational issues were reported to have captured the teachers' attention.

Our methodology was not without problems, however. At times, teachers stated that they did not remember why a particular moment was captured. "I don't know why I pushed the button there, but I know I actively did because I can see myself [look down to press the button.]" In such cases, our methodology failed to tap into teachers' in-the-moment thinking about the noticed moment. Another concern is that there is some evidence that the act of wearing the camera and capturing moments may alter the very noticing that we intended to access. In particular, a few teachers suggested that using the camera heightened their sensitivity to noticing events that took place during instruction. "[Using the camera] made me more aware of what I thought was important." Thus while our efforts to access teachers' in-the-moment noticing appears to have been somewhat successful, there is reason to also be cautious as we move forward with the new technology.

## Science and Mathematics Teachers' In-The-Moment Noticing: Attending to Student Thinking Within a Lesson and Beyond

Adam A. Colestock, Rosemary S. Russ

Recent reform efforts in science and mathematics education call for teachers to carefully attend and respond to their students' thinking in the classroom (Schifter, 2001; Hammer & Van Zee, 2006). To help teachers achieve this goal we must first understand their existing practices for attending to student thinking (Sherin, 2001; Levin, Hammer & Coffey, 2009). In this paper we investigate how the teachers in our sample attend to student thinking in the moments of instruction. In particular we draw on data collected with our new methodology to explore the question: "Why do particular moments of student thinking stand out as interesting to a teacher?"

For our analysis, we relied heavily on the teachers' reflections in the interviews. In particular, we used this data to explore teachers' ideas about the moments of student thinking they captured with the camera. First we reviewed the videotaped interviews and created descriptive summaries of what a teacher found interesting in each captured moment. Second, from those descriptions we identified and selected for analysis only those summaries in which the teacher discussed students' thinking as an important aspect of the reason they captured that moment. Of the 266 clip summaries we created, we identified 48% as relating to student thinking. We then looked across these summaries for evidence of why particular moments of student thinking stood out to the teacher. The four themes that emerged from the data suggest that a teacher's predictions and expectations for a particular lesson and their knowledge of their students' prior and future learning strongly influence the student thinking moments to which they attend. Below we describe these four themes, highlight how they relate to the work of teaching, and provide illustrative examples from the data.

*Theme 1: Attending to unanticipated moments of student thinking*. In planning for a lesson, teachers use their prior teaching experience, their knowledge of typical student thinking, and their understanding of this particular group of students to anticipate students' reactions to different parts of the lesson, including what students might find routine or easy and what they might find challenging or puzzling (Schoenfeld,1998). Thus teachers may have a set of expectations about what student thinking will emerge in the lesson. In our data we found that teachers often described the moments they captured as being surprising or unexpected. For example teachers sometimes focused their discussion of a moment on a particular student question or insight that they had not anticipated, but were nonetheless pleased with encountering. For example, one teacher captured a moment because a student was able to solve algebraic equations involving absolute value signs, something they had not yet learned as a class. At other times teachers described moments when students had trouble with aspects of the lesson that they had assumed would be straightforward. For example, a science teacher captured a moment in which a student has difficulty answering what she considered to be a straightforward question. In describing the moment, she explained, "I asked what the function of the cell membrane, which we've spent the last 15-20 minutes talking about… It is literally written on the slide. We've said it like ten times. And I call on Jess and she has no clue."

*Theme 2: Attending to the progress of the lesson.* Another aspect of lesson planning involves considering the pace of a lesson, the sequence of ideas, and the location of important conceptual checkpoints within the lesson (Leinhardt, 1993). When discussing why they captured particular moments of student thinking our teachers sometimes discussed the ways in which a student's idea related to the progress of the lesson. Some teachers reported specifically waiting for students to express certain ideas and capturing them because they were important benchmarks for monitoring lesson progress. For example, one science teacher captured several different moments in which her students were accomplishing her instructional goal of making the connection between the pattern recognition activity that they were engaged in and the organization of the periodic table of elements. In describing one interaction with a student she explains, "He said, 'Oh, this is just like the periodic table!' and I was like 'Ding, Ding, Ding! Yes, that is exactly what you were supposed to [figure out].'" In contrast, other teachers captured moments when the lesson was not progressing as they had hoped, such as when students struggled with a crucial part of the lesson. For example, a mathematics teacher captured a moment in which a number of students were having difficulty understanding why it wasn't necessary to write the variable $t$ as part of the answer when finding the rate of change of a parametric linear equation. She took this as evidence that she should think about doing more work to help students understand slopes and rates of change.

*Theme 3: Attending to students' prior knowledge.* In planning a lesson, teachers make assumptions about the relevant prior knowledge students possess, either from the everyday world or from previous formal teaching. In our data teachers frequently described moments as being interesting for what they revealed about a student's prior knowledge. For example, during a lecture about membrane structure one science teacher captured a moment in which a student asked what a solute was and another student provided a poor explanation. This moment of student thinking stood out to her because she was surprised that despite their previous coursework the students were unable to accurately describe a solute, "It was mind-boggling to me that they do not know what a solute is because these are kids who have come through two years of honors chemistry and physics…so I have to think about assumptions that I make about what they have learned in the past." In addition to capturing moments in which student prior knowledge was lacking or problematic, our teachers also captured moments in which students productively drew on prior knowledge by making connections with previously learned material. For example, the same science teacher captured another moment because a student applied his understanding of protein structures that he had learned in class a month and a half ago to a new context in a class research presentation about a particular disease.

*Theme 4: Attending to opportunities for future learning.* Often teachers plan to leverage the understandings that students develop in one day's lesson as starting points for future lessons in the curriculum. As a result, teachers may draw on their awareness of how ideas will be used in the future to be alert for opportunities to foreshadow or motivate future learning. Several teachers in our sample discussed the student thinking they captured in terms of its importance for future lessons. For example, one Calculus teacher captured a student question and subsequent discussion about how a particular integration technique might be similar to other methods they would encounter later in the week. He was pleased because the discussion allowed him to foreshadow upcoming lessons; he said, "it was an interesting question because we've just started talking about these solids of revolution today…but eventually we will get to what Eric was talking about." The teacher also indicated that he decided to bring the conversation to a certain point and then stop it because they would be returning to these ideas later, "If we were working on cross sections we could have spent more time with Derrick's response but as it was I thought Dylan answered the question sufficiently for today."

In this work we have examined why teachers may attend to particular aspects of student thinking in the moments of instruction and not others. In particular we discussed how their attention to events is influenced by (1) the student responses they anticipate (2) the conceptual checkpoints that help them determine when to proceed (3) the relationship of the current lesson to students' prior knowledge and (4) the opportunity of the thinking to foreshadow future learning. Furthermore, the methodology we employed to access that teacher thinking allowed us to see teachers in their own teaching situations — situations in which they have rich knowledge of the curriculum, the students' learning history, and the possible paths along which the lesson will progress. Our analysis suggested that this detailed knowledge creates expectations and predictions that substantially influence which moments stand out to teachers. Thus we suspect that other methodologies that do not allow teachers to draw on this rich set of knowledge – either because teachers are reflecting on classrooms that are not their own or because they are too far removed from the in-the-moment use of that knowledge in their own classroom – may be unable to access the kind of thinking about student thinking we describe here. In our future work we plan to continue to use this methodology to explore how teachers attend to their students' thinking during instruction and the role that this noticing plays in shaping their teaching practice.

## Supporting Video Club Conversations Using Teacher-Selected Video Clips

Melissa J. Luna, Martha Mulligan, Miriam Gamoran Sherin, Janet Walkoe

The other papers in this symposium report on the kinds of classroom moments teachers captured using wearable cameras and the reasons teachers give for capturing such moments. In this paper, we take a different approach. Specifically, we investigate using these captured moments to support conversations among teachers around their students' ideas in science and mathematics.

This work takes place in a particular context we call video clubs. A video club is a type of professional development experience in which a group of teachers watch and discuss classroom video excerpts of their instruction with a particular focus or framework in mind (Frederiksen, Sipusic, Sherin, & Wolfe, 1998). For example, discussions in a video club context can be intentionally focused on a range of issues such as discourse, student thinking, or management (Tochon, 1999). The use of video is central to the work of a video club. Video is able to capture the complexity of a classroom and meaningfully reduce that complexity by providing a record of interactions (Borko, Jacobs, Eiteljorg, & Pittman, 2008). With video, teachers do not have to respond immediately as they do when they are teaching. Therefore, watching and discussing video opens up rich opportunities for teachers to reflect upon and analyze events that occur during teaching.

Prior research on the use of video clubs demonstrated that this is an effective context for helping teachers notice and respond to students' ideas in mathematics (e.g. van Es & Sherin, 2008). This paper extends such work to include science teachers. Furthermore, the use of a new video technology—the wearable camera—inspired a slightly different video club design. Other video clubs typically ask teachers to reflect on and discuss video that researchers have selected of teachers' classrooms from footage from the back or side of the classroom (i.e., video from a researcher's point of view) (Sherin & Han, 2004). Here we instead asked teachers to reflect on and discuss classroom moments that the teachers themselves captured while wearing the Deja View or POV 1.5 camera. In doing so we had two main goals. First, we wanted to explore the ways in which clips from the wearable camera would support conversation around students' ideas. Would the fact that the video clips are exclusively from the teachers' point of view—and thus teachers are not visible—prompt consistent discussion of students' thinking? Second, we wanted to take a first step towards testing the feasibility and viability of making video clubs self-sufficient rather than relying heavily on a research team. In our experience, teachers do not usually have time to select excerpts from video of an entire class session. The wearable camera allows teachers to select the moments while they are teaching, thus removing this barrier. While we were still heavily involved in the logistics of the video clubs discussed here, we view this study as a valuable first step toward understanding what it would take for teachers to sustain a video club on their own.

The data in this study draw from our work with three separate video clubs. All video club meetings were videotaped.

(1) *High School Mathematics Video Club.* This video club consists of two experienced high school math teachers and a researcher-facilitator. Both teachers had previously participated in other video clubs to examine their students' mathematical thinking using classroom video. However, both were new users of the Deja View, which required them to capture classroom moments from their point of view for the video club discussion. Video club conversations focused on students' mathematical thinking.

(2) *Middle and High School Mathematics Video Club.* This video club consists of seven teachers with varying levels of teaching experience and a researcher-facilitator. Both the video club context and the POV 1.5 were novel for this group. At the start of the year the researcher videotaped the classroom and selected video clips for the video club discussions. Then later in the year, teacher-captured clips were used as the focus of

discussion in the video club. Video club conversations focused on classroom discourse around mathematics.

(3) *Elementary School Science Video Club.* This video club consists of four 3-5th grade teachers with varying levels of teaching experience and a researcher-facilitator. The video club context and the POV 1.5 were new for this group as well. However, this video club was different from the others in that it only used teacher-captured video clips for discussion. Video club conversations focused on students' ideas in science.

While the three video clubs reported here differed in important ways, they were similar in that they all included the use of a small wearable camera by teachers. We argue that because of its capability to capture classroom moments as they happen, this tool helped support interesting conversations in the video club as teachers reflected on and analyzed those moments. In our analysis of the video club discussions, three issues stand out as noteworthy.

First, the short time length of the videos appeared to influence the teachers' initial conversations around the video clips. Video club discussions in general focus on 5 to 10 minutes of video footage from a participating teacher's classroom. The Deja View and POV 1.5, however, capture short episodes of classroom events ranging from 30 seconds to 3 minutes. In using these shorter clips as a basis for discussion, we found that this placed greater burden on the teacher whose clip was being discussed. Essentially, these shorter clips strip away contextual details and thus require the presenting teacher to provide sufficient context in order to reconstruct the event for others. In addition, the other teachers had to articulate a range of questions as they made sense of the event. For example, after watching a 30-second clip of students from Richard's class, Richard and Nancy conversed back and forth until they arrived at a shared understanding of the moment. In the video students were discussing how they expanded the binomial $(x+5)^3$.

*Nancy:* [So] her question was, how do you multiply all three binomials at once?
*Richard:* Yeah that['s]… right.
*Nancy:* She was like… "How do you multiply three times three times three?" …
*Richard:* Right. Times three…
*Nancy:* So I think she wanted an easier way…to expand that binomial, but you haven't gotten to that. …But I don't really understand what the presenter said…
*Richard:* Well, …the first girl, her question was, … "How do you know? If you do the first and the second…or the second or the third first, which do you do?" And so what the girl in front said is that it doesn't matter because it is multiplication.

Together these two teachers carefully scrutinized the short captured clip in order to understand both what the student was asking and what the student was thinking about expanding binomials. This level of scrutiny required close attention to a classroom event on the part of both teachers.

Second, when teacher-captured clips were shown in the video club, presenting teachers had already "noticed" these moments during instruction. Thus, they typically came into the video club with an established interpretation of what had taken place in the captured moment. Perhaps using the camera during instruction heightened their noticing somewhat as well as deepened their interpretations in the moment. Interestingly, however, we found that teachers remained open to considering alternative interpretations of the events when viewed with colleagues in the video club. In fact, these new interpretations often built on the ideas the presenting teachers brought to the group. For example, upon capturing a classroom moment Nancy initially thought her students had understood the classroom talk around the equation 2x + 3:

> I think I captured it because they [the students] *did* correct it [the problem]. …the girl did say "No wouldn't that be plus 3x?" But then I think something else happened after that. I think the presenter was convinced that she didn't need to say per week, … and she did change her mind.

However, while discussing her clip in the video club she realized something different:

> Well, ...now I noticed, as I think about this a little bit more, I'm thinking how she [the student] described her situation. I think it might have been just sort of tangled in semantics. [So] is *x* the total amount of money she saved, or is *x* the amount of money she saved that week? So, right now I don't know what it was…But I think that distinction matters and so this whole conversation, I don't know that anybody was clear on that.

This differs from other video clubs because teachers in those clubs did not capture the video clips themselves, and therefore, the first explicit interpretation of the event occurred in the context of the video club. We found that having teachers bring their in-the-moment interpretations into the video club discussion, as well as their willingness to consider other interpretations, added a level of depth to unpacking the classroom event captured.

Third, at times we noted a topic of discussion that was new for video clubs. Specifically, teachers occasionally mentioned and asked each other about the reasons why they had captured particular moments with the wearable cameras. For example, in the above example, the conversation later turned to why Richard captured the clip to begin with and he responded by explaining his thinking.

> Well, it's just really about multiplying, because I was thinking…a lot of times they don't quite understand a parenthetic expression is like, you can treat it like a number. And so, in terms of applying properties, she was saying it is just multiplication, it just doesn't really matter. So I think that is probably why.

We suspect this kind of talk occurred because we asked teachers to capture specific kinds of classroom events (e.g. "Capture students' algebraic thinking." or "Capture student ideas about magnets.") while wearing the Deja View or POV 1.5. Since all teachers from one video club had the same prompt, it is not surprising they were curious of each others' reasons for capturing a particular classroom moment, and thus turned the video club discussion towards unpacking the teachers' thinking and reasoning behind the moment of capture. While we want video club discussion to focus on what students are saying and doing, we recognize that unpacking teacher thinking can be a productive focus for a video club conversation helping teachers understand their own thinking in this process.

In conclusion, video clubs that utilize clips captured by teachers in the moments of instruction do support sustainable conversations in the video club context. We have found that such conversations involve teachers in collaborative sense making often elaborating on contextual detail not apparent in the clips, being open to alternative interpretations when viewing practice, and focusing on their own thinking about why they identified a particular classroom moment as worthy of capture.

## Implications of this Methodology

Our purpose in presenting these papers as a set is to give the reader a sense of the potential of a new digital video technology – selective archiving – for the study of teacher noticing. For us, the power of these cameras lies in that they allow teachers to record particular moments of classroom interaction as the interactions unfold and without interrupting the on-going instruction. Although the full breadth of our research program with these cameras is still emerging, our use of this technology so far has provided a window into the kinds of data we might collect when working with teachers, the kinds of questions that data will allow us to answer, and the kinds of theoretical issues that data will inform.

In terms of the data we can reasonably expect to obtain with this methodology, we have seen that teachers can implement this selective archiving technology to collect moments that are meaningful to them, and that those moments can ground both personal reflections and discussions with colleagues. This process then provides us with data about the range of things that teachers notice during instruction, their own thinking about what they notice, and their colleagues' interpretations of that noticing. In terms of the questions this data can address, we see that this data may be useful for examining both population- and individual-level questions. For example, aggregating data across multiple teachers will allow us to answer questions about trends and patterns in teachers' in-the-moment noticing. In contrast, identifying moment-to-moment relationships between a single teacher's noticing as captured with the camera and that teacher's instruction may allow us to better understand the how's and why's of a successful teacher's noticing. The answers to both kinds of questions will be crucial for understanding and impacting teacher noticing. Finally, in terms of the theoretical issues our data might inform, we have found that just the possibility of capturing teachers' in-the-moment noticing has forced us to examine our underlying conceptualization of teacher noticing. For example, the methodology raises questions about whether the noticing that is conscious - and thus captured with this data - and more tacit noticing are the result of similar or distinct cognitive processes. In addition, data from teacher reflections suggests that we as researchers may need to explore the possibility that noticing is not isolated to a single event in time but is rather distributed across multiple episodes. While we do not yet have definitive answers to all these questions, our preliminary analysis of the data suggests that this new technology will allow us to make substantial contributions to the study of teacher noticing – both methodologically and theoretically - in the near future.

# Software-Based Scaffolding: Supporting the Development of Knowledge Building Discourse in Online Courses

Nobuko Fujita, Christopher Teplovs
OISE/University of Toronto, 252 Bloor Street West, Toronto, ON, M5S 1V6,
nobuko.fujita@gmail.com, christopher.teplovs@gmail.com

**Abstract:** This design-based research study investigated instructional scaffolding for knowledge building discourse among participants (n=17, n=20) in two online graduate courses. In particular, designs of software-based scaffolding as found in web-based Knowledge Forum's scaffold support feature were refined. Analyses of the student discourse data suggests that Knowledge Forum's scaffold supports offer a promising avenue for future design innovations to encourage knowledge building discourse. Results show that students increasingly used the scaffolds to focus their reading and writing of notes over iterations of the study. The proportion of scaffolds for knowledge building discourse increased during each iteration with a corresponding decrease in the proportion of scaffolds for expressing an opinion in the second iteration. Finally, notes with scaffolds contained significantly more words than notes without scaffolds, suggesting that scaffolds promoted more student reflectivity. Implications for formative assessment of student learning and knowledge building are discussed.

## Introduction

In recent years, opportunities to enroll in online courses have grown substantially. During the fall 2004 term, 2.3 million higher education students were taking at least one online course in the United States; one year later, during the fall 2005 term, this figure increased to nearly 3.2 million students (Allen & Seaman, 2006). The primary mode of online course delivery at nearly 90% of U.S. higher education institutions is asynchronous computer-mediated communication (CMC) (Greene, 2005). Asynchronous CMC typically uses a web-based computer conferencing technology (e.g., Blackboard, Drupal, Knowledge Forum, Moodle, etc.) to connect distributed participants in a networked learning environment. Like distance education, CMC frees students from time and space constraints; like face-to-face instruction, CMC affords interactivity (Kaye, 1989). Ideally, CMC is used to create a "the kind of learning community that can arise in a good graduate seminar" (Hiltz, 1998). In such educational settings, students may be able to engage in complex learning where they share, question and revise their ideas to deepen understanding and build knowledge.

Yet CMC is a lean medium for social presence crucial to perceptions of cooperation and trust necessary to build a learning community (Palloff & Pratt, 1999; Preece, 2000). Thus, widely accepted models for teaching in online learning communities focus first on establishing social connections between participants. For example, Salmon's (2000) five-stage model for "e-moderating" describes the progression of students as they move through the beginning stages of access and motivation, to online socialization, information exchange and knowledge construction, and ultimately to development. This model highlights the importance of the instructor's role in the earlier stages of creating an online learning community. Once a sense of community is established, the instructor shifts the locus of control to the students, who are then able to engage in active learning and collaboration (Palloff & Pratt, 1999).

This study departs from previous studies by focusing on higher goals for social interaction in online learning communities. Research indicates that critical thinking and knowledge construction rarely occur in these educational settings (Garrison, Anderson & Archer, 2001; Gunawardena, Lowe, & Anderson, 1997; Kanuka & Anderson, 1998). Previous studies on scaffolding dialogue for knowledge building have explored how certain critical thinking types increase or decrease the length of discussion threads (e.g., Sorenson & Takle, 2005). However this study takes an approach consistent with a knowledge building pedagogy (Scardamalia & Bereiter, 2003, 2006), rather than one informed by a critical thinking model. While many online studies have examined social interaction and collaboration, less is known about how instructors may move students to the next step and foster knowledge building discourse. Therefore, the purpose of this study is to investigate what kinds of scaffolding embedded in the software and course activity structures can support the development of knowledge building discourse in online graduate courses. As well, we argue that scaffolding is closely linked to formative assessment (c.f., Shepard, 2005) and that can activate students to take ownership over their learning (Black & Wiliam, 2009) in a way that is aligned with the knowledge building pedagogy.

## Theoretical Framework

Social constructivist pedagogy emphasizes the importance of discourse in fostering deep learning, and the importance of tools in mediating knowledge construction (Hmelo-Silver, 2003; Palincsar, 1998). Knowledge building is defined as "the production and continual improvement of ideas of value to a community" (Scardamalia & Bereiter, 2003, p. 1370). It is a constructivist approach that centers the curriculum on big ideas and accords students with high levels of agency in working with those ideas (Scardamalia & Bereiter, 2008).

Knowledge Forum, an extension of CSILE (Computer Supported Intentional Learning Environment) software, is designed to support knowledge building. Students work in virtual spaces or "views" to develop their ideas, represented as "notes." Knowledge Forum offers sophisticated features not available in other conferencing technologies including "scaffold supports" (labels of thinking types), "rise above" (summary note), and a capacity to connect ideas through links between notes in different views. These features provide means to overcome the chronological sequence of threaded discussion, in which important ideas may be lost. In addition, Knowledge Forum facilitates the collection of data that are amenable to analysis with a variety of assessment tools. These include behavioral and interaction analyses (Burtis, 1998), traces of vocabulary development (Hewitt, 1999), social network analysis (Teplovs, Donoahue, Scardamalia, & Philip, 2007), and semantic analysis (Fujita & Teplovs, 2009). Such assessments provide feedback to help students make progress in their discourse.

Many studies on knowledge building discourse have examined elementary science classrooms (e.g., Hakkarainen & Palonen, 2003; Bereiter, Scardamalia, Cassells, & Hewitt, 1997). These show that CSILE/Knowledge Forum can support improved learning and knowledge building over time (Scardamalia & Bereiter, 1994; Zhang, Scardamalia, Reeve & Messina, 2009). However, few studies have explored how to support the development of knowledge building discourse in exclusively online higher education courses where the participants are distributed across time and space and instructional scaffolding for knowledge building is not provided off-line. The knowledge building teacher's role in this setting is one that helps students move beyond the formation of social ties to the creation of knowledge. This study offers a unique perspective by refining designs of software-based scaffolding as found in Knowledge Forum's scaffold support feature to foster knowledge building discourse in online graduate courses.

## Methods

Using a design research methodology (Collins, Joseph, & Bielaczyc, 2004), modifications to the selection of Knowledge Forum's (KF) scaffolds were made within and across two 13-week online graduate courses, which comprised two iterations of the study (Table 1).

Table 1: Design Changes to Knowledge Forum's Scaffold Across Two Online Graduate Courses

| | Iteration 1 | Iteration 2 |
|---|---|---|
| Modification | Educational Applications of Computer-Mediated Communication | Constructive Learning and Design of Online Learning Environments |
| Knowledge Forum Scaffolds | Theory Building<br>Opinion<br>Idea Improvement<br>Feedback | Theory Building<br>Opinion<br>Idea Advancement |

KF scaffold supports are typically used as sentence openers that students use while composing notes in the database. They function in similar ways as prompts in social networking applications like Facebook (What's on your mind?) or Twitter (What are you doing?) by placing yellow highlights of thinking types into the text that bracket segments of body text in notes. Scaffold supports go further than just prompting users at a generic level. They are customizable by facilitators and, in some cases, students. The two sets of scaffold supports that are supplied by default ("Theory Building" and "Opinion") are more specific to knowledge building discourse and argument than the more generic prompts from Facebook and Twitter. Scaffold supports are not dissimilar to "tags" that are common in other Web 2.0 environments such as the collaborative bookmarking application known as "delicious". An important difference between the simple tagging available through such sites and the scaffold supports in Knowledge Forum is the ability to tag specific parts of posts and thereby indicate with relatively high specificity and accuracy that part of the text that is being tagged. Moreover, advanced search capabilities in Knowledge Forum allow users to search for specified text within a specified scaffold support (e.g. find all the "My Theory" supports that contain the word "constructivism").

In Iteration 1, only Theory Building and Opinion scaffolds built in to Knowledge Forum were available to students at the beginning of the course. Later, in week 9 of 13 weeks, students took on the responsibility for designing the customized Idea Improvement scaffolds as part of their discussion leadership (Table 2). These scaffolds emphasize the knowledge building principle of improvable ideas key to knowledge building discourse. In addition the researcher introduced the customized Feedback scaffolds in week 10 to help students provide constructive feedback to each other.

Changes to the scaffolds from Iteration 1 to 2 resulted from analysis of the students' learning journals. The design researcher and the instructor addressed students' concerns for the constraint scaffolds imposed on creative thinking and interpersonal relationships were addressed by combining the Idea Improvement and Feedback scaffolds into Idea Advancement scaffolds in Iteration 2.

Table 2: Knowledge Forum Scaffolds and Scaffold Supports Used in Iteration 1 and 2

| | Scaffolds | | | |
|---|---|---|---|---|
| Scaffold Supports | Theory Building | Opinion | IDEA IMPROVEMENT (all caps in original) | Idea Advancement |
| | My Theory | Opinion | IDEA ADVANCEMENT | Current statement of idea |
| | I need to understand | Different opinion | WHAT DO WE NEED THIS IDEA FOR | How idea is useful |
| | New information | Reason | PROBLEM/QUESTION | How idea could be advanced |
| | This theory cannot explain | Elaboration | | Problems/limitations |
| | A better theory | Evidence | | How could we test X? |
| | Putting our knowledge together | Example | | This idea fits with |

## Data sources

Student discourse, online questionnaire responses, pre- and post-course assignments, and learning journals were collected from participants (n=17, n=20) in two 13-week graduate courses taught entirely online using Knowledge Forum (version 4.5.3). This study focuses on findings from the analysis of KF scaffold use in the discourse data.

## Results

Using log file data accessed via the Analytic Toolkit built in to Knowledge Forum, this study found patterns in the students' use of KF scaffolds that affected the development of knowledge building discourse. First, there was an overall increase in the total number of scaffolds used from Iteration 1 to Iteration 2, as shown in Table 3:

Table 3: Frequencies of Knowledge Forum Scaffolds Used in two Online Graduate Courses

| Course | Theory Building | | Opinion | | IDEA IMPROVEMENT/ Idea Advancement | | Total Number of Scaffolds | | Total Number of Student Notes | |
|---|---|---|---|---|---|---|---|---|---|---|
| | *f* | % | *f* | % | *f* | % | *f* | % | *f* | % |
| Course 1 | 128 | 42% | 91 | 30% | 87 | 28% | 306 | 100% | 907 | 100% |
| Course 2 | 167 | 36% | 200 | 43% | 98 | 21% | 465 | 100% | 1058 | 100% |

Course 2 students used more total scaffolds than Course 1 students. Course 2 students also used more Opinion than the Theory Building or Idea Improvement scaffolds than Course 1 students. A Pearson chi square test showed a statistically significant difference between the two Iterations, $\chi^2$ (2, N=771) = 14.46, p<.001.

### Relationship Between Use of Scaffolds and Types of Scaffolds Used

To understand whether the types of scaffolds used in student notes changed over time within each course, the frequencies of different types of KF scaffolds used were calculated for the first third and last third of the course, excepting the first week and last week. These weeks were omitted because they were used as introductory and evaluation sessions. When calculated, this analysis showed that Course 1 students used all of the scaffold types more frequently in the last third of the course compared to the first third (Figure 1).

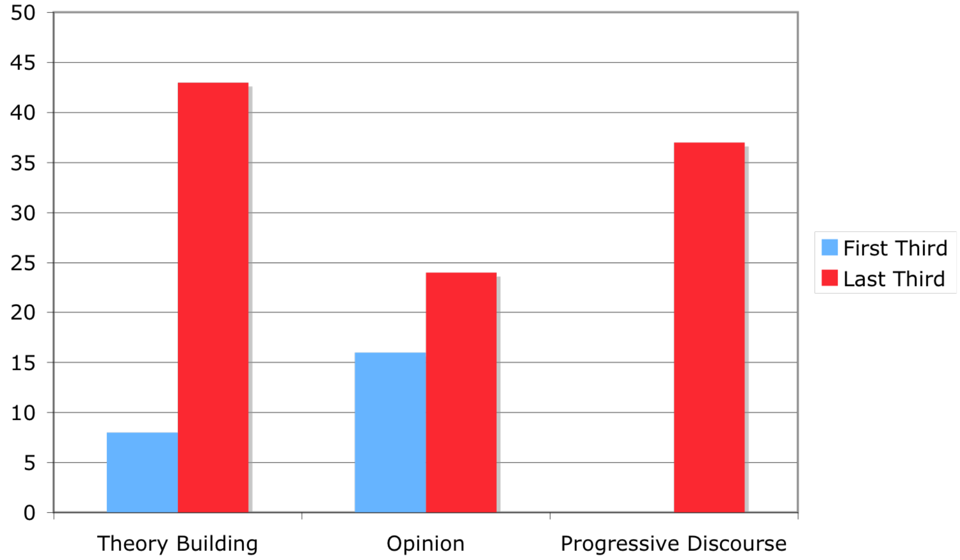

Figure 1. Types of Knowledge Forum scaffolds used by students in Course 1.

In comparison, all three types of scaffolds were available from the beginning of Course 2. Promisingly, the students' use of Theory Building and Progressive Discourse (Idea Improvement and Idea Advancement) scaffolds increased and their use of Opinion scaffolds decreased from the first third to the last third of the course (Figure 2).

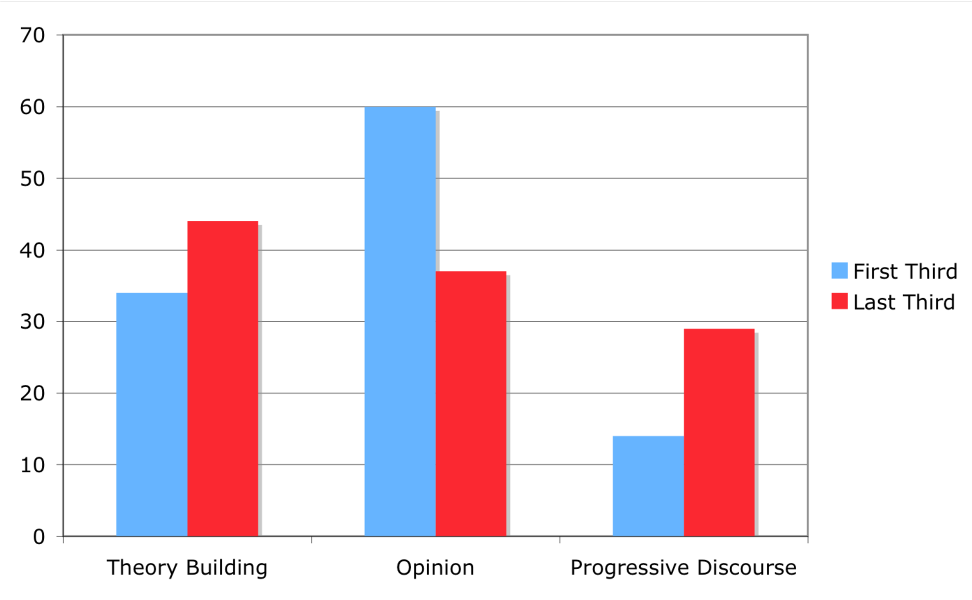

Figure 2. Types of Knowledge Forum scaffolds used by students in Course 2.

### Relationship Between Use of Scaffolds and Length of Notes

To understand the relationship between the use of KF scaffolds and length of notes, the mean word counts of student notes with scaffolds and without scaffolds were compared. A paired samples t-test found that notes with scaffolds contained significantly more words than notes without scaffolds, $t\,(33)=3.626$, $p<.001$.

## Discussion

This design-based research study refined designs of software-based scaffolding as found in Knowledge Forum's scaffold support feature to foster knowledge building discourse in two online graduate courses. KF scaffolds not only metacognitively prompt students to focus their reading and writing of notes, but also allow them to tag relevant parts of notes and search for ideas to improve them. Such a feature offers students, not just teachers, the opportunity to take responsibility for accessing support as needed, customizing supports for local needs, and obtaining some formative assessment of the progress of the unfolding discourse to deepen their learning. Analyses of the student discourse data suggest that KF scaffold supports offer a promising avenue for future design innovations to encourage knowledge building discourse.

Finding that students used scaffolds for expressing opinions aimed at argument rather than scaffolds to support knowledge building discourse aimed at explanation was disappointing, but not surprising given the challenge of engaging students in this kind of discourse to promote complex learning online. Scaffolds can guide students in complex learning by structuring tasks, but they can also problematize tasks by making them more complex in the short term (Reiser, 2005).

Over time within course discussion spaces, however, students increasingly used customized scaffolds to support development of knowledge building discourse. In Iteration 2, students not only increased their use of scaffolds for knowledge building, but they also decreased their use of scaffolds for expressing opinions. This is a positive finding since using the Theory Building and Progressive Discourse scaffolds require students to take a more active role in regulating their own learning as well as providing constructive feedback to peers.

From a knowledge building perspective, a characteristic of a mature producer of knowledge is "disciplined creativity" (Scardamalia & Bereiter, 2003). KF scaffolds help students to organize their own thinking, writing, and reading of other's notes. This may promote disciplined practices for knowledge building discourse. Unfortunately, some students in this study (35% in Iteration 1; 25% in Iteration 2) did not like the "disciplined" aspect of creative knowledge work that scaffolds were designed to support and identified constraints scaffolds posed for creative thinking and identified usability issues.

Previous researchers (e.g., Hara, Bonk, & Angeli, 2000; Schrire, 2006) have suggested that the length of messages is one sign of the depth of online student interaction and reflection on course readings. This study found that student notes with KF scaffolds are longer than notes without them. Students might be reflecting more when they compose longer notes with scaffolds and thus more effectively engage in knowledge building discourse to advance knowledge in their online learning community.

## Conclusion

In this paper, we explored designs of software-based scaffolds and course activity structures that encourage their use to support the development of knowledge building discourse in online graduate courses. Through analyses of students' scaffold use, this study found the following trends in the students' use of the Knowledge Forum's scaffold support feature:

- an increase in the use of scaffolds over iterations of the study
- the proportion of scaffolds for knowledge building discourse increased during each iteration
- the proportion of Opinion scaffolds for argument decreased during the final iteration
- notes with scaffolds contained significantly more words than notes without scaffolds

The students appear to be taking greater responsibility for their own learning by customizing and using the KF scaffolds to make their online course contributions more meaningful. Qualitative analyses reveal that the graduate students use KF scaffolds to work towards common understanding in discourse, but need encouragement to expand the factual base and to test ideas to build knowledge (Fujita, 2009). Formative assessment that is embedded in the software and tightly coupled to the learning (Collins & Halverson, 2009) may help students overcome such barriers in knowledge building discourse. To this end, Knowledge Forum's assessment tools offer ongoing and formative feedback to students as well as teachers and researchers to enable them to deepen understanding of the unfolding discourse in the online learning community (Teplovs et al., 2007).

# Seeing Algebraic Thinking in the Classroom: A Study of Teachers' Conceptualizations of Algebra

Janet Walkoe, Northwestern University, 2010 Campus Drive, Evanston, IL, 60208,
Walkoe@northwestern.edu

**Abstract:** Ideas about how students learn algebra have shifted over the years. Reform curricula have been developed to address these changes. Teachers' conceptualizations of algebra play a large role in how they view and implement reform curricula. This paper explores teachers' conceptualizations of algebra and investigates how they draw on their conceptualizations in the moments of instruction through the use of new methods that incorporate teacher-selected classroom video clips. Data revealed that teachers' verbal descriptions of student algebraic thinking did not always align with moments of instruction they selected as providing evidence of student algebraic thinking.

## Introduction

Algebra is seen as a critical subject matter for students. In particular, algebra has been identified as the "gatekeeper" to advanced mathematics. Students need to have taken algebra in order to have access to upper-level mathematics courses. Such courses can then lead to further opportunities such as admissions to colleges and universities. Despite its importance, many students struggle in algebra classes (Kieran, 1992). This has prompted inquiry into the question of how to effectively support student learning of algebra.

Ideas about how students best learn algebra have recently shifted. Up until the last decade or so, algebra classes emphasized procedural activities such as symbol manipulation over more conceptual activities. In addition, procedural activities were generally separated from the conceptual sense-making activities (Kieran, 2004). This was in line with the "symbol precedence" view of algebra that most textbooks presented. According to Nathan and Koedinger (2000a) the belief underlying this view is that "arithmetic reasoning strictly precedes algebraic reasoning, and symbolic problem-solving develops prior to verbal reasoning" (Nathan & Koedinger, 2000a, p. 209). In contrast to the symbol precedence view, more popular today is an emphasis on the conceptual nature of algebra and of the importance of connecting symbolic and conceptual learning (Kaput, 2008). In response to this shift, reform curricula have been developed that are more in line with current views of algebra and algebraic thinking. However, research has shown that it can be difficult for teachers to teach reform curricula in the ways that they were intended (Cohen, 1990). One reason is that teachers' ideas about algebra may not align with the goals of reform. In this project, I investigate new methods for exploring teachers' conceptualizations of algebra and algebraic thinking and how these conceptualizations can inform practice.

## Teachers' Conceptualizations of Algebra

There is much discussion in the literature about what constitutes algebra and algebraic activity (Battista and Borrow, 1998; Kaput, 1998; Kieran, 1996; NCTM, 1989; Usiskin, 1988). Kieran (1996) identified three forms of algebraic activity: generational, transformational, and global/meta-level. Generational activities include generating equations and expressions from data, situations, patterns of numbers, or number sequences. Transformational activity includes manipulating symbols following the rules of algebra. This includes typical classroom activities such as simplifying an expression, expanding a polynomial, and solving equations. Global/ meta-level activity includes using algebra to solve problems. This includes modeling, problem solving, providing evidence, and generalizing.

Traditionally, mathematics classes tend to give precedence to transformational activities. Such classrooms rely on highly procedural activities such as symbolic manipulation and focus little attention on more conceptual understanding that includes global/meta-level activities (Kieran, 2004). Recent shifts in the teaching of algebra recommend that transformational activities no longer be distinct from conceptual understandings. Therefore reform curricula have moved toward a balance among the forms of algebraic activity, emphasizing conceptual activities such as generalization, argumentation, and justification (Kaput, 1998; Carpenter, Franke & Levi, 2003; Kieran, 2004).

Teaching algebra from a more balanced perspective can be difficult for teachers for a number of reasons. First, while learning algebra themselves, most teachers experienced classes that emphasized procedures and symbol manipulation. As a result of this "dilemma of experience" (Doerr, 2004), teachers tend to hold on to this view and focus on procedural knowledge in their classrooms (Menzel & Clarke, 1998; Nathan & Koedinger, 2000b; Stephens, 2008). Second, because traditional methods are what we find in most algebra textbooks today, many teachers have not had the opportunity to explore a more conceptual approach to teaching algebra. Even when given reform materials, teachers are often asked to implement them without much guidance and they may end up interpreting the new materials in terms of their familiar approaches to the topic (Sherin, 2002). This is reminiscent of Cohen's (1990) description of Ms. Oublier, who interprets a reform curriculum in light of her traditional teaching methods.

## Conceptualizations of Algebra in Practice

This paper seeks to understand teachers' conceptualizations of algebra and the relationship between these conceptualizations and teachers' instructional practices. In particular, the goal is to investigate the conceptualizations that teachers draw on while teaching. This is somewhat of a challenge, however. One way to explore a teacher's conceptualizations is through interviews where teachers are asked to explain their ideas. We know, however, that a teacher's espoused beliefs do not always align with their teaching practice (Cooney, 1985; Cohen, 1990). For example, Cooney (1985) describes an example of a teacher who, when interviewed, said he believed problem solving was essential to mathematics learning yet, due to a number of factors, did not incorporate much problem solving in his instruction. In order to explore the relationship between teachers' conceptualizations of algebra and their practice, we need to look at both espoused views and views as enacted.

One way to gain information about a teacher's enacted views is to observe her class instruction. However, one problem with observing a class and making inferences is that we do not know if our interpretation is the same as the teacher's. We might interview a teacher after class to try to access her thinking during instruction, but she may not remember what she was thinking in the moment of instruction. Many times teachers recall general things about a class based simply on overall feelings about how the instruction took place (Rosean, Lundeberg, Cooper, Fritzen, Terpstra, 2008). A related approach to exploring a teacher's practice is through the use of video.

## Video to Explore Teacher Thinking in the Moments of Instruction

Video has been a valuable tool used to examine a teacher's practice (Lampert & Ball, 1998; Sherin & van Es, 2005; Sherin, 2007). Video offers the advantage of allowing observers to watch events as they took place instead of relying on memory or observation notes. This allows teachers the ability to "get back into" the moment of instruction. However, while the use of classroom video gives us valuable insights, it raises questions about whether a teacher's attention to student thinking after the fact is different from her attention in the moment of instruction. Relying on classroom video may draw a teacher's attention to things that they did not notice in the moments of instruction. Ainley and Luntley (2007) used video as a way to access teachers' in-the-moment reasoning. As they observed, however, "in some interviews, the effect of watching the video was to draw attention to aspects of the classroom that the teacher had previously been unaware of, rather than to help recall their perceptions of the lesson" (p. 9). So we cannot always be sure an interview based on classroom video taps into what a teacher was thinking while she was teaching.

To address this issue, new methods have been explored that make use of a camera that allows a teacher to record moments that catch her attention while she is teaching (Sherin, Russ, Sherin, & Colestock, 2008). This allows access to in-the-moment noticing that was not available before. Sherin, Russ, Sherin, & Colestock (2008) piloted the Camwear 100 (Reich, Goldberg, Hudek, 2004) that allows teachers to capture short video clips while they are teaching. It involves a small camera a teacher can wear on her person while she is teaching. When the teacher presses the record button, the camera captures the previous 30 seconds and saves it to a small digital video file to be viewed later. Using this technology allows me to study teachers' in-the-moment thinking in a way that has only recently become possible. By asking a teacher to press the button while teaching, I can identify moments the teacher was attending to in the midst of instruction and can save these moments to discuss later.

One question that might arise with this method is whether using this technology actually allows access to a teacher's in-the-moment noticing or whether it instead prompts an ad-hoc development of the vision of what is going on at the time. Sherin, Russ, and Colestock (in press) provide evidence that interviewing a teacher about the clips they captured using this technology can in fact bring teachers back to the moment and does help them talk about their thinking during instruction.

In this study, I make use of this methodology to create a more complete picture of how teachers' conceptualizations of algebra inform a teacher's practice. By using methods that allow access to teacher-selected classroom video, I can identify the moments a teacher notices while teaching. I use information about what teachers notice and how they reflect on these moments, in addition to classroom observations, to help better explore their ideas about algebra and how they draw on these ideas in the moments of instruction.

## Methods

This study explored high school teachers' ideas about student algebraic thinking. Four high school algebra teachers who teach in a local urban district volunteered to participate in this study. Two of the teachers, Dana and Maggie, taught from a traditional curriculum. Maggie taught ninth grade algebra and Dana taught eleventh grade algebra. Their teaching experience was four and nine years respectively. Nancy and Richard taught from a reform curriculum. Similar to the other pair, Nancy taught ninth grade algebra and Richard taught eleventh grade algebra. Their teaching experience was thirteen and seven years respectively. The traditional curriculum espoused a symbol precedence view whereas the reform curriculum placed a focus on student sense-making and emphasized the conceptual nature of algebra. The data consists of interviews, class observations, and selected excerpts of instruction chosen by the teachers.

### The study protocol and instrumentation

#### Pre-observation interview

Each teacher participated in a pre-observation interview designed to investigate his or her ideas about algebra and algebraic thinking. The pre-interview had two sections, the *general question* section and the *concrete student response* section. Each section of the interview lasted around 20 minutes. The general question section consisted of questions about the teacher's ideas about algebra. I asked direct questions to try to get a sense of the teacher's ideas about algebraic thinking. An example of a question from this phase was, "What do you mean when you say that you want to get students to think algebraically?" In the student response section, I showed the teacher sample student responses to problems and asked the teacher whether he or she thought the student was thinking algebraically based on the solution presented.

#### Classroom observation

The Camwear 100 is a small, portable camera developed by Dejaview (Reich, Goldberg, & Hudek, 2004). When the camera is on it continually records and erases footage in a loop mode until the "record" button is pushed. When the user presses the record button, the camera saves the preceding 30 seconds. These clips can be downloaded, saved and viewed on a computer. I videotaped each classroom session from the back of the room. During the session, I asked teachers to wear the camera while teaching. I asked the teachers to press the record button whenever they saw evidence that their students were thinking algebraically.

#### Post-observation interview

After the classroom observation, I interviewed the teachers and asked them about each clip they captured and why they thought their students were thinking algebraically in each clip. I wanted to understand the nature of student thinking the teachers were paying attention to while they were teaching. Although I cannot claim that the camera is a direct window into the teachers' thinking, I can use the clips the teacher captured as a slice of evidence of what they were paying attention to while they were teaching. My intention for the post-interview was to help clarify or provide additional insight into the moments the teacher captured and why those moments stood out to the teacher. Furthermore, it would permit triangulation with the pre-interviews in order to gain a better understanding of the teachers' ideas about algebraic thinking.

### Data analysis

In the first stage the type of activity the students were engaged in during the clips was coded. This was done by viewing the clip in the context of the whole class video that had been taken from the back of the room. This allowed me to see the context of each clip in the larger landscape of the class activities. There were two broad codes, procedural manipulation and conceptual. The procedural manipulation code was applied when the student or students in the clip were in the midst of solving a symbolic algebra problem or discussing how they had solved the problem. An example is when Maggie asked her students to compute the side length of a triangle using the Law of Sines. The conceptual code was applied when the student or students in the clip were involved in a larger sense-making activity. An example is when the students in Richard's class extended a problem he asked them to do and discussed whether the procedures could be generalized from two dimensions to three or more dimensions and if so, what it might look like.

Then the post interview in which each teacher discussed the reasons for capturing each clip was reviewed. In this first pass, I was able to distinguish between the clips the teachers had a reason for capturing and those they did not. It turned out that in a few cases, upon further reflection of the clip, the teacher decided that he or she would not consider the thinking the students were engaged in during the clip to be algebraic so those clips were removed from the next stage.

In the third stage the moments the teacher captured and the reasons they gave for capturing that moment were coded. The unit of analysis was the teacher's reason for capturing the clip. I was interested in why the teacher thought the student or students in the moment they captured were thinking algebraically. I engaged in the process of open coding where I looked at some of the teachers' responses and came up with some categories. I continued with these categories and the main reasons for identifying algebraic thinking that emerged were students (1) making connections, (2) generalizing, (3) justifying, articulating or testing, (4) understanding rules or properties of algebraic structures, (5) manipulating symbols or solving an equation, and (6) knowing or following rules of algebra. The first four were considered conceptual reasons and the last two were considered procedural reasons. Each teacher's response was assigned one code. After coding the teachers' reasons for capturing clips, I made a table containing a summary of the information. I looked for patterns in each teacher's responses. I also looked for patterns across teachers.

In the fourth stage I reviewed the pre-interviews. I was curious about whether or how ideas that emerged in the pre-interviews influenced the moments the teacher captured and how the teacher talked about those moments. I was interested in each teacher's ideas about algebra, goals for students, and feelings about their curriculum that emerged in the interviews. The analysis of the pre-interviews took place in three steps. In the first step, I segmented the transcripts and identified which portions dealt with ideas about algebra, goals for students, and thoughts on the curriculum. In the second phase, I looked at all the segments having to do with each of the three categories and I identified the central idea the teacher discussed in those segments. I did this iteratively and came up with a set of central themes the teacher discussed. In the last stage, I identified whether the themes corresponded with procedural or conceptual ideas about algebra.

Finally, I reviewed the class videos and created a summary. In the summary, I included three aspects of the class and the structure of the lesson. They were the way the class was organized, the mathematical topic that was covered, and the types of problems the students were asked to work on.

## Results and Discussion

I found that two teachers' espoused ideas about algebra aligned with the clips they captured in the classroom, therefore adding evidence to their conceptualizations of algebra as described in their interviews. One of the teachers, Maggie, held a symbolic view of algebra and this was consistent in her pre-interview and in the clips she captured and the way she discussed them in the post-interview. For example, in one clip, while Maggie was presenting a problem on the overhead a student volunteered a solution to the problem. Maggie captured the clip and when asked why she captured the clip in the post-interview she responded, "(the student) was doing basic problem solving equations. They were solving for x. Solving for the variable."

Another teacher, Nancy held a conceptual view of algebra and this was consistent with the way she discussed algebra in the pre-interview and in the clips she captured and discussed in the post-interview. In one of Nancy's captured clips a student was explaining why he thought the quadratic function the class was graphing would not "bounce" at zero. When asked about the clip in the post-interview said she thought the student was thinking algebraically because he understood the properties of parabolic functions and understood how the graph should look. He understood how symmetry was connected to the shape of the graph and saw how the graph related to the equation.

While Maggie and Nancy captured clips that supported the ideas that emerge in their pre-interviews, the other two teachers were less consistent in the way they talked about algebra in the pre-interview and the clips they captured while teaching.

## Dana

Dana taught eleventh grade algebra from a traditional curriculum. She talked about algebra from both a symbol manipulation and conceptual point of view in the pre- interview. When she discussed the clips she captured in class, however, she discussed 8 of the 11 clips with a focus on symbol manipulation.

The aspect of student thinking that stood out to Dana was the students' facility with the symbols and rules. Even though this would appear to be evidence that Dana's conceptualizations of algebra are dominated by algebraic procedures and symbol manipulation, her pre-interview told a different story.

The primary theme that emerged in Dana's pre-interview was that she believed there were two types of algebra, school algebra and more "sophisticated algebra" that is not taught in schools. When presented with a student's less traditional, more conceptual solution in the pre-interview, she commented, "(it's) logical reasoning. And it's algebra but it isn't the kind of thing that gets taught… explicitly taught." In response to another student's similar solution she said, "(the solution) is more logic than…official algebra. But I still think they're a thinking person's approach to the problem… yeah, I think that's algebra. It's just not the rote algebra we have taught." She continued, "We teach them algorithms so they can develop that. I think (the solution the student had is) really sophisticated. But this (pointing to a more symbolic answer) is what I teach." So Dana is capable of recognizing two types of algebraic thinking- procedural and conceptual algebraic thinking. In the classroom, however, she tends to focus on the procedural aspects of algebraic thinking. For example, she captured a moment in her class in which a couple of students were trying to explain why negative numbers are not in the domain of the log function. In the post-interview she said that she thought the students were thinking algebraically because they were "defining how you do algebra" and they were discussing the rules of the game. Instead of focusing on the conceptual aspects of the conversation, she focused on the students' knowledge of the rules. In another clip she captured a student answering a problem she posed on the overhead projector. The problem had more variables than the previous problems had. Dana said the student was thinking algebraically because she was able to manipulate the symbols to solve the more difficult type of problem. She commented:

> …(some students) may have said '… there are so many pieces here, how do I plug this into where it goes and this into where it goes? I've got four pieces and I've only got three slots, what am I going to do?' So I was relieved to see that most of (the students in this class) just looked at it and went, 'oh', and just did it. And saw that it was actually a simple problem. It's a little bit rote, I mean I've got- here's this equation and here's this equation and here's how you transform them. It may not be super meaningful, but… but it's algebra *(laughs)*.

Her focus was primarily on the students' realization that they could manipulate this problem as they had done with others in the past. She did not focus on the student's conceptual understanding of the problem. Overall, Dana tended to focus on students' knowledge and manipulation of the rules of algebra during instruction.

Dana exhibited dual views of algebraic thinking in the pre-interview. One is more conceptual and she believes is not the type they explicitly teach in schools. The other is more procedural and is emphasized in her curriculum. Even though she is capable of recognizing the more conceptual algebraic thinking she did not use that to inform the moments she captured in class or the way she discussed those moments. She could have discussed the same clips she captured in a more conceptual way. In the next case, we will see an example of a teacher who, similar to Dana, primarily captured clips where students were engaged in procedural activity but who discussed them in a more conceptual way.

## Richard

Richard taught eleventh grade algebra from a reform curriculum. The students' desks were arranged in groups and they spent a large part of the class working in their groups. The class started with a set of five problems that involved factoring and expanding polynomials, a highly symbolic type of problem. For the first 30 minutes of class the students worked on these opening problems in groups and then five students presented their solution to one of the problems to the class on a whiteboard. For the remainder of the class period, the topic shifted to probability and students discussed more open-ended problems from the curriculum in groups. Occasionally groups would present their solutions to the problems.

Richard captured a total of 10 clips in which he saw his students thinking algebraically. All but three of the clips were captured during the first 30 minutes of class when the class was working on the symbolic algebra problems. Richard's ideas about algebra and the symbolic nature of algebra prompted him to capture most of the clips where students were working through problems with symbols and manipulating expressions or equations using algebraic structures. For example, he captured one clip while listening to a groups' presentation of their solution to one of the symbolic problems he posed at the beginning of class. However, when asked why he thought he saw his students thinking algebraically in the clips, he discussed nine of the ten clips in terms of students' sense-making and only one of them was discussed from a procedural standpoint. For example, Richard captured the clip of students symbolically solving a problem, yet when he discussed the clip further, he said that the student was thinking algebraically, not because of symbol use, but because of the students' "high-level understanding of exponents". Richard's focus went beyond mere knowledge of the rules to a concern with students' understanding and sense-making. When he discussed the clip, he did not mention the symbol manipulation or procedures but focused on the depth of the student's understanding.

I found it interesting that most of the clips were captured during the very symbolic algebraic part of the lesson yet he discussed most of them from a conceptual standpoint. I would have thought that if he limited his attention to the traditional algebra problems, he might focus on the symbolic or procedural nature of the students' thinking, as Dana and Maggie did. Why did Richard discuss procedural clips differently than the other two teachers? What lead to his focus on the conceptual nature of his students' thinking? I turn to Richard's pre-interview to answer some of these questions.

The theme that emerged from Richard's pre-interview was the dual nature of his goals for students. Because his goals were influenced by both his pre-teaching experiences and his curriculum, he had two distinct goals for his students. He described one of his goals for student learning as helping students master as much of the content as they could. This idea seemed to drive many of the clips he captured. This idea of mastery of the concepts seems to me to be in line with a more procedural idea of algebra and algebraic thinking.

Richard's learning goals for students seemed to be influenced equally by his ideas about algebra and the reform curriculum he uses. When I asked him about his goals for students, he answered, "I think that I'm probably a product of this curriculum. I'm not saying I know what they were thinking but I know my opinion is highly influenced by what I taught over the past five years." His curriculum emphasizes the conceptual nature of student thinking. The dual nature of Richard's goals for students becomes apparent when he talks about his experiences.

Richard's ideas about algebra and the curriculum influenced each other, however they were also in conflict with each other. There was kind of a trade-off, back-and-forth kind of interaction between the two and how they would affect his learning goals for students. His preconceived ideas about algebra affected the way he viewed the curriculum. He appreciated the conceptual nature of the curriculum but also believed it needed to be supplemented with more procedural material. On the other hand, the curriculum affected his ideas about algebra. The dual nature of his influences was apparent again when he said, "I also think that, however…that (the curriculum) is much more on the 'it's really important to conceptualize and understand end of the spectrum' than 'let's do these equations and understand'. You know? So I feel like I'm kind of trying to bridge the two." So his ideas about algebra before he started teaching influenced how he worked with the curriculum and the curriculum he uses influenced his preconceived ideas about algebra. Both factors were influential in his goals for students. This dichotomy might explain the fact that even though Richard tended to record clips in which students were involved in procedural activities, he focused on the deeper, conceptual understanding the students exhibited.

Richard's preconceived ideas about algebra were focused on procedures and skills and he believed that the probability lesson might not provide many instances of this type of thinking. The fact that all but one of the clips he captured was from the part of class where students were engaged in manipulating symbols might illustrate his need for symbols and equations as *signifiers* of algebraic thinking. On the other hand, influenced by curriculum he teaches, when he discussed the clips he captured, he did so in a conceptual way, meaning that he did not discuss the symbol manipulation. Instead he discussed the deeper, conceptual thinking his students were engaged in. Dana also captured clips where students were engaged in manipulating symbols, but when she talked about them, she discussed symbol manipulation and following procedures as the primary reason for identifying the students' thinking as algebraic.

## Conclusion

Using a variety of methods allows us to draw a more complete picture of teachers' conceptualizations of algebra. In particular by using a video camera that allows teachers to capture footage in the moments of instruction, I was able to go beyond what is typically available through interviews and classroom video alone. Classroom activity is complex and watching video of an entire class does not necessarily give us insight into what a teacher was attending to while they were teaching. However, allowing a teacher the ability to capture and save video clips in the moments of instruction has the potential to give us this insight. Furthermore, interviewing the teacher about the clips they captured allows us access to the teacher's insight about the moment they captured and why that moment stood out to them.

I also extended prior research by exploring the relationship between teachers' professed and enacted views about algebra in particular. In line with previous research that has noted how difficult it can be to balance procedural and conceptual views I found that teachers continue to struggle with this dilemma.

In this study I showed that teachers can hold more than one idea about algebra and it is difficult to predict which aspects of their conceptualizations they will draw on from moment to moment while teaching. If we continue to explore teachers' ideas using methods described in this study we may be better able to understand their conceptualizations- where teachers' ideas come from and how they drive what a teacher notices in the classroom. This, in turn will help us facilitate teachers' transitions to a more balanced approach to algebra teaching that includes conceptual as well as procedural activity.

# Conceptual Change and Epistemic Growth through Reflective Assessment in Computer-Supported Knowledge Building

Carol K.K. Chan, Ivan C.K. Lam, University of Hong Kong, Pokfulam, Hong Kong
Email: ckkchan@hku.hk; ivanlmhk@gmail.com

**Abstract:** This study examined the design and process of how students' reflective assessment promoted collaborative metacognition for conceptual and epistemic changes, mediated by Knowledge Forum, a computer-supported environment. The design involved augmenting knowledge-building inquiry with reflective assessment – Students wrote reflective summaries to track their initial understanding and trajectories of growth toward scientific understanding in the domain of electrochemistry. Two classes of 10th grade students in Hong Kong participated in Reflective Assessment (RA) and Reflective Assessment with Scaffolds (RAS) conditions. Results indicated that both classes improved on conceptual-change and epistemic-beliefs measures; the effects were stronger for the class with scaffolds. Qualitative analyses showed how students' reflective assessment and collaboration helped them to develop metaconceptual and epistemic awareness as they examined their own and others' understanding. A path analysis indicated that students' engagement on Knowledge Forum predicted reflective collaboration that in turn exerted effects on their changes in conceptual understanding and epistemic beliefs.

## Theoretical Perspectives

Across science education and learning sciences, there are now major shifts towards theories of learning that emphasize both individual and social aspects of science learning (Duit & Treagust, 2003; Vosniadou, 2008). It is now widely accepted that science learning can be facilitated when students articulate their prior ideas and explain their understanding to each other. Conceptual change is examined emphasizing the social construction of knowledge and discursive interactions in classroom (Scott, Asoko & Leach, 2007). Furthermore, researchers now question conceptual change as a sudden change or a replacement of misconceptions with scientific ones through externally-driven conceptual conflict (Chan, Burtis & Bereiter, 1997). Instead, conceptual change involves a gradual process where science concepts are gradually restructured mediated by students' intentional-learning strategies (Sinatra & Pintrich, 2003). From a learning sciences perspective, there is a need to capture processes of conceptual change supported by collaborative discourse and to design learning environments to foster intentional conceptual change.

### Intentional Conceptual Change

Current research on intentional conceptual change emphasizes the role of learners' metacognitive strategies, epistemic beliefs and agency in knowledge restructuring (Sinatra & Pintrich, 2003). It also points to the need to designing learning environments that encourage learners to employ goal-directed, reflective strategies and to develop metaconceptual awareness. Cognitive research has shown that students' epistemic beliefs can constrain or facilitate student thinking, reasoning, and science learning (Stathopoulou, & Vosniadou, 2007). Researchers have argued that conceptual change involves not only changes in concepts; there needs to be changes in students' views about the nature of science (Duit & Treagust, 2003). Vosniadou (2008) noted that conceptual change involves metaconceptual awareness – Students will be able to learn science concepts and principles only if they are aware of their prior understanding and the shift of their initial views toward science knowledge. Increasingly the emphasis is to examine conceptual change that includes not only individual cognitive development but also social and collective aspects; socio-cognitive discourse plays a key role in facilitating conceptual change. Although there has been much progress indicating the role of metacognition and epistemic beliefs on students' conceptual change, most of the research are correlation studies. Fewer studies have examined designing for intentional conceptual change that brings about metaconceptual awareness with epistemic changes supported by social and collective discourse.

### Computer-Supported Collaborative Knowledge Building

How can current views of intentional conceptual change be integrated in instruction emphasizing collaborative discourse? Researchers have suggested how computer-supported collaborative learning (CSCL) can make important contribution to conceptual-change research (Miyake, 2007). Relating to the roles of interaction and discourse in science classroom, technological affordances can further provide a medium whereby students can articulate, communicate, represent and reconstruct their ideas for sustained inquiry. This study adopts an educational approach, knowledge building, a forerunner of CSCL, that emphasizes knowledge creation as a collective work of the community; and that knowledge is improvable by means of a discourse (Scardamalia & Bereiter, 2006). To support student discourse, knowledge Forum (KF), a multi-media database constructed by students, was designed to support collaborative knowledge building discourse. In a knowledge-building community (both face-to-face and online), students engage in scientific discourse that involves posing cutting-edge problems, generating theories and conjectures, searching for scientific information, elaborating on others' ideas, co-constructing explanations, and revising their theories. Students' pre-instructional ideas and learning pathways can be represented on the computer forum and thus become objects of inquiry for conceptual change. There is now substantial evidence on the roles of knowledge building on students' collective inquiry and scientific understanding (e.g., Zhang et al., 2007).

### Knowledge Building, Reflective Assessment and Conceptual Change

A question may then arise as to why another study is needed on knowledge building and scientific understanding. Despite major progress in two decades of research, there have been no systematic studies using this knowledge-building approach to examine conceptual change. Various principles advocated by researchers in conceptual change such as intentional goal-directed strategies, metaconceptual awareness, epistemic beliefs (Vosniadou, 2008) are well aligned with knowledge-building. However, how collaborative knowledge-building dynamics can bring about metaconceptual awareness and epistemic changes has not been examined. Further, we argue that knowledge building can enrich conceptual change studies that often emphasize small-group collaboration. There is a need to understand how conceptual change can take place in communities of learners and knowledge-builders. Knowledge building is not just a pedagogical approach but a theory of epistemology; so how students working with knowledge might change their epistemic views are fruitful lines of inquiry. Finally, knowledge-building research on science learning has mostly been conducted with elementary-school children. It would be useful to extend the scope of inquiry to investigating knowledge building for high-school science.

This study employed a design developed in research on assessment of knowledge building with students assessing their own collaboration (Lee, Chan, & van Aalst, 2006; van Aalst & Chan, 2007). Research has shown that students assessing their own scientific inquiry promoted metacognition (White & Fredericksen, 1998). Similarly, student-directed e-portfolio assessment with students documenting how they collaborated in knowledge-building discourse fostered their domain understanding (van Aalst & Chan, 2007). This study extends this line of inquiry: We designed knowledge building for conceptual change focusing on promoting metacognition in a collaborative context. Extending our earlier study (xx), we asked students to reflect on their prior conceptions and to track how they moved towards scientific understanding as they considered others' contributions and revised their ideas.

To iterate, this study aimed to design and examine how reflective assessment with collaborative dynamics would promote metaconceptual and epistemic awareness for conceptual change. Three research questions were included: (1) What was the role of the knowledge-building environment on students' conceptual and epistemic changes? (2) How did students' reflection contribute to their changes in conceptual and epistemic understanding? and (3) what were the relations among knowledge-building dynamics, conceptual change and epistemic growth?

## Methods

### Participants

Eighty 10th graders (Age ranging 15-16) in two chemistry classes in Hong Kong participated in this study. The lessons were conducted in English and students wrote notes in English on Knowledge Forum (KF). Both classes engaged in knowledge-building inquiry with reflective assessment. The first class is called Reflective Assessment (RA, n = 40) and the second Reflective Assessment with Scaffolds (RAS, n = 40). Both classes were taught by the same teacher, who had taught high-school chemistry for more than twelve years and had used knowledge-building pedagogy for over 6 years.

### Procedure

This study was conducted in the second semester of 2008-09 lasting from Feb-June (16-18 weeks). There were five chemistry lessons each week; each lesson was of 35 minute duration. In both classes, students learned electrochemistry using knowledge-building inquiry approaches and they wrote computer notes on Knowledge Forum. Due to school policy for comparable curriculum, students had similar inquiry experiences (see later section, 1-4) and both used the same instructional topics, textbooks and reference materials and conducting the same experiments. However, there were also some key differences: Primarily students in the "Reflective Assessment with Scaffolds" class (RAS) wrote reflective summaries on KF using a set of pre-designed conceptual-change "scaffolds" (e.g., *My initial ideas, What we think, What I think now).* Alternatively, students in the "Reflective Assessment" class (RA) wrote reflective summaries without the scaffolds (RA). "Scaffolds" are prompts or sentence openers on

KF; different scaffolds can be designed depending on subjects and contexts. The use of conceptual-change scaffolds were to examine further whether the use of scaffolds would enhance further students' collaborative reflection.

## Designing a Knowledge-Building Environment for Conceptual Change

We designed the learning environment based on knowledge building pedagogy aligning that with conceptual change principles (Vosniadou & Kollias, 2003). The principles and activities of the design are briefly described:

(1) *Activate prior knowledge through classroom discourse.* Students need to activate and reflect on prior knowledge and to articulate their ideas for science learning. Students worked in groups discussing science topics/problems in classroom. Students were scaffolded to present their ideas, make observations of experiments; raise questions they did not understand, elaborate and comment on others' views. Students' ideas were shared and made public using concept-maps, posters and knowledge-building walls (boards for posting ideas). When students became familiar with articulating their thinking, they then continued their inquiry and contributed their ideas and questions onto KF.

(2) *Foster metacognition through KF scaffolds and problem-centered inquiry.* Students were encouraged to raise authentic problems from prior ideas and daily life on electrochemistry that puzzled them. Extending the classroom inquiry, students wrote their ideas on the discussion views on KF (Figure 1 left): Students engaged in goal-directed inquiry- they posed problems, made conjectures/hypotheses, co-constructed explanations, compared different explanations and revised their understanding. KF scaffolds including '*I need to understand*', '*my theory'*, '*new information*', and '*a better theory'* prompted metacognitive thinking and theory revision. Teacher facilitation involved helping students integrate KF and classroom discourse and to notice conflicts, discrepancies and identifying gaps for further inquiry.

(3) *Develop deep understanding through model-based explanatory inquiry.* Students were involved in constructing models of chemical cells using everyday materials and explaining to each other how their chemical cells work.

(4) *Integrate fragmented ideas and use 'rise-above' explanation.* To tackle the problem of fragmented ideas, a common barrier to conceptual change, students deepened their understanding using KF functions of 'rise above' and 'references' to synthesize diverse and fragmented ideas from classmates as they worked towards more *coherent explanations.* Teachers integrated online discussion with classroom talk to help students deepen their inquiry.

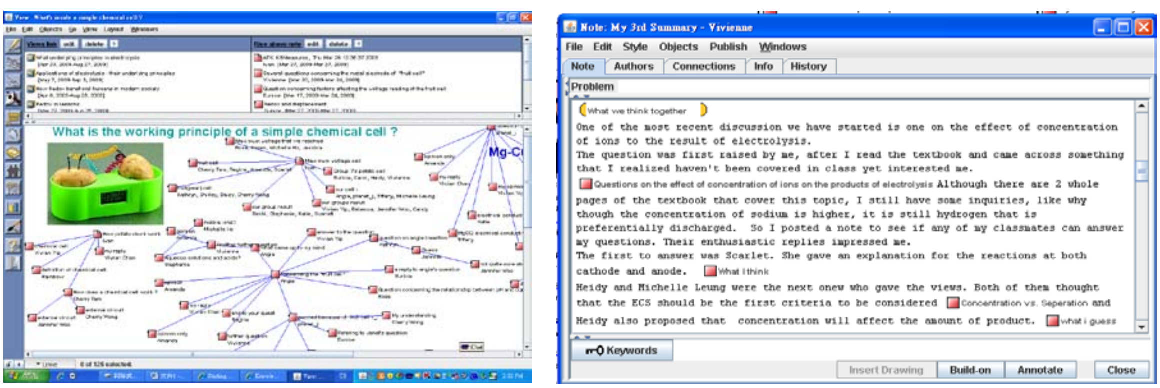

Figure 1. A Discussion View on Knowledge Forum (left) and an Example of a Reflective Summary Note (right).

(5) *Develop metaconceptual awareness through reflective assessment.* In both classes, students were asked to review the notes on KF, to reflect on their initial beliefs, and to track their changing ideas incorporating classmates' ideas (Figure 1, right): The teacher prompt written on KF included: You are encouraged to review the computer notes written by you and your classmates in the database. Write a summary note to reflect and to consolidate what you have learnt from the views of '*Batteries' &* '*Simple chemical cell*'…In writing the summary, you may select relevant computer notes (references) as evidence that support your understanding. Think about how your chemical knowledge has developed or changed. As noted above, in the Reflective Assessment with Scaffolds (RAS) class, students were further provided with conceptual-change scaffolds (e.g., "My initial idea"). Students could also use other KF scaffolds such as "a better theory" and "this theory cannot explain" and "putting our knowledge together".

To help students with their reflection, in both classroom and online discourse, the teacher would scaffold students to reflect more deeply in discussing their notes. As well, the teacher also wrote on KF making some observation: "So far I have observed some benefits of chemistry gains from your summaries: (i) You are encouraged to give more evidence (chemical knowledge) to reflect on your understanding or knowledge gains (not just say KF is good). (ii). It may be useful to tell us more of your initial thoughts and final thoughts on a particular chemistry concept. (iii) Continue to build on others' notes to deepen your ideas after reviewing these previous notes. Of course you can continue to raise other (emerging) questions or observations in everyday life."

## Analyses and Results

We first assessed student changes in conceptual and epistemic changes after the instruction; we then examined why and how such changes might take place relating to knowledge-building inquiry and reflection, and finally we investigated the relations among knowledge building activities, conceptual-change learning and epistemic changes.

### Conceptual-Change Learning in Electrochemistry

Conceptual-Change Written Tests and Explanation Written questions were designed to tap into students' understanding of electrochemistry probing into students' alternative conceptions. The written questions were designed based on studies on conceptual-change in electrochemistry in science education research. Questions included open-ended ones asking students to explain their understanding of key concepts to probe their conceptions (what is oxidation?). Responses to forced-choice questions were coded on students' explanations of their choice. The pretest and posttest percentage scores were 13.8 (7.1) and 57.3 (12.3), and 14.1 (6.4) and 49.1 (15.4) for Reflective Assessment with Scaffolds (RAS) and Reflective Assessment (RA) classes, respectively. Analyses of pre-posttests using paired t-tests showed that both classes improved on the conceptual-change tests with RAS, $t$ (39), = 20.14, $p$<.001, and RA, $t$ (39), = 14.21, $p$<.001. Analyses using ANCOVA controlling for pre-test differences indicated that higher scores were obtained for students in Reflective Assessment with Scaffolds (RAS).

Changes in Alternative Conceptions in Written Tests The number of alternative conceptions (misconceptions) for each student was identified from their responses to the written tests. The means of alternative conceptions were 6.4 (1.7) and 5.7(1.2) at pretests and 1.9 (1.5) and 3.0 (1.9) at posttests for RAS and RA classes respectively. Students in both classes decreased in the number of alternative conceptions after instruction. ANCOVA on posttest results using pretest scores as covariates indicated that there were more decreases in the number of alternative conceptions for students in the class of Reflective Assessment with scaffolds (RAS), $F$ (1, 78) = 10.08, $p$<.003.

### Changes in Epistemic Beliefs

Students were administered a questionnaire on epistemic beliefs (adapted from Conley et al., 2004) to examine the ways students think about the nature of knowledge. The questionnaire was pilot tested with over 300 students and validated in our earlier study (xx). Consistent with the earlier study, three factors were identified (1) "Certainty-Source", (2) "Development" and (3) "Justification" with scale reliabilities ranging from 0.64 to 0.83. An example of an item on Certainty is "Most questions in science have one right answer"; an example of an item on Development is "Scientific knowledge will not change over time", and an example of an item on Justification is "Ideas in science can come from your own question". Interviews were also conducted to provide more information on what students thought about these items; qualitative analyses are currently undertaken. Paired t-tests showed that students in both classes made changes towards more sophisticated epistemic beliefs based on the combined scores, for RAS, $t$ (38) = 4.73, $p$<.001 and for RA, $t$ (38) =2.27, $p$<.03. Separate analyses showed that students in RAS improved more on the subscales of "certainty-source" and "development" and students in RA improved more on "justification".

### Students' Knowledge Forum Engagement and Collaborative Reflection

Knowledge Forum Engagement (ATK) We examined students' overall participation and engagement in Knowledge Forum (KF) using a software called the Analytic Toolkit (ATK, Burtis, 1998) that uses log files to show students' participation and activity on KF. We included several ATK indices commonly used in knowledge-building research : (1) number of KF note written, (2) % of notes read, (3) % of linked notes, (4) scaffolds (thinking prompts) (5) keywords and (6) revision. Some of these indices show student collaboration (e.g., notes read/linked) and others reflect metacognition such as the use of scaffolds" and "revision" of notes for purposeful activities.

We now report results of ATK indices for RAS and RA classes: number of notes written, 21.5 and 22.60 notes; percentage of notes read, 55% & 47%; note-linked, 80% and 68%; and scaffolds, 21 and 9.0, respectively. Although there were no norms for ATK, comparison with other studies indicated that these students were engaged actively participating and collaborating on KF. Compared to the literature on online learning with fragmented contribution (Hewitt, 2003), these number indicate high level of contribution; they are also comparable to those identified in mature knowledge building communities (Zhang et al., 2007). Comparison of ATK indices also showed some advantages for the RAS class over the RA class.

Reflective Assessment and Collaborative Reflection As described above, students wrote three reflective summaries to reflect on their initial and new ideas in electrochemistry based on their discourse. These reflective summaries were scored on a 6-point scale. At the lower levels (1-2), the reflection depicts that students were just describing new information with limited reflection on what it meant for their conceptions. At the mid-levels (3-4), students demonstrated some personal thinking for identifying misconceptions or knowledge gaps in their understanding. At the highest levels (5-6), student reflected on their prior knowledge, identified gaps, considered how others' ideas supported their reflection; they demonstrated metaconceptual awareness of initial and new ideas and noted how they changed in their understanding of some concepts The summaries were coded and currently inter-rater reliability checks were being conducted. In the following, two contrastive examples of reflective summaries are provided to suggest how collaborative reflection may foster metaconceptual awareness for conceptual and epistemic growth..

Table 1: An example of a reflective summary note (low-level response).

| Restating Information | Excerpts from the Reflective Summary Note |
|---|---|
| States impartial information | In the simple chemical cell, I found out that a potato cell can actually conduct electricity and drive the calculator to work. … |
| Makes reference to one note; no reference to one's own thinking | Through Florence's note, I knew that the electromotive force within each potato makes to move electric current. And the copper wire makes the electrons move in the potato, causing energy to move into the clock. This let me know more about how a potato cell conducts electricity |
| Describes factual information and formulae; no reflection | In the redox reaction of copper, I knew that …when the copper reacts with oxygen, copper acts as the reducing agent and causes oxidation, while oxygen acts as the oxidizing agent, causes reduction : $2Cu(s) + O_2\ (g) \rightarrow 2CuO\ (s)$<br>And when hydrogen reacts with the copper oxide, hydrogen acts as the reducing agent, reduce the copper oxide : $CuO(s) + H_2(g) \rightarrow Cu(s) + H_2O(l)$… |

Table 2: An example of a reflective summary note (high-level response).

| Reflective Metacognition | Excerpts from the Reflective Summary Note |
|---|---|
| The student reflected on her understanding on state of matter and electrolysis | |
| - Identifies her prior conception; reflects on the source of difficulty<br>-Considers role of textbook information | What I think before The products of electrolysis are always the same as long as the chemical salt is the same, disregarding its state.<br>-*Because in many previous textbook chapters such as molarity, water plays no role* in the sense that it does not react.[1] What I think I thought we do not melt the salt in electrolysis just because it is too troublesome. |
| -Considers other ideas and explanations<br>-Selects relevant ideas and organizes them to show some learning pathways (e.g., further) | What we think together Jennifer provides detailed chemical equations to explain the difference[2] Agree. Candy *further* provides the significance of the difference[3] *molten and aqueous*, that metals like sodium could never be formed in electrolysis if there were no molten sodium salts…She also mentioned an interesting fact that mercury electrode can be used to extract pure sodium. This thought is *further worked* on.[4] Mercury electrode |
| -Reflects on new idea<br>–Continues to query gap of understanding | When doing work regarding electrolysis, I have to look carefully whether the chemical is *molten or aqueous* as the results are very different. *However I still do not understand* the working principles of mercury electrodes. |
| The student noted another cycle examining factors influencing electrolysis | |
| -Reflects on prior beliefs; notes prior gaps in understanding;<br>-Identifies source of confusion & difficulties<br>-Refers to textbook as conveying information not in real science | What I think before As stated above, *I thought* the products of electrolysis are always the same if chemical salt is the same. *I didn't think a* higher voltage, except speeding up the process, will produce other results. For example, in aluminum anodization, *I thought only* the quality of the original aluminum will provide different results. Moreover, although I noticed that the metal deposited on the electrode is unevenly distributed, *I always thought* it was due to our poor skills or equipment. I have not considered it a natural occurrence*, mostly because textbooks often show the electrode fully and smoothly covered with the metal.* |
| -Considers others' ideas<br>–Identifies puzzling info | What we think together …Rainbow suggested that temperature as well as acidity affects the results. *She also gave a curious suggestion that lower temperature gives* |

| | |
|---|---|
| and reflects on what she does not understand;<br>- Examine various ideas and explanations to help her move toward better Understanding | *thicker layer of aluminum oxide, which I still can't understand* as I thought a higher temperature facilitates reaction, like what angie said [6] Answer.. [7] more information Cherry Wang further told us that an unsmooth layer is resulted as the metal plated is attracted to external corners and avoids internal ones. [8] Effects and Limitations of electrolysis. Besides, a higher current can lead to the formation of other substances in the solution, as mentioned in [9] 2 substances formed? |
| Reflects on new understanding | What I think now The product of electrolysis could be affected by various [external] effects; the metal plated does not naturally spread out evenly. |
| The student included another scaffold and reflect on her beliefs and knowledge | |
| Reflects on beliefs about knowledge pointing to coherence (structure of knowledge) and evidence in justification | My belief on learning &knowledge The most useful part is it broadens our thinking by *relating one topic to another*. For example I have never considered rusting from a redox or electrolysis point of view. *I believe we could learn more if we try to search for information before writing the notes instead of guessing without any evidence* |

Note: 1. What I think – Scaffolds in reflective summaries
2. [3] Reference notes in summaries with hyper-links to students' notes in the database

Table 1 shows an example of a reflective summary in which Student A was not actually engaged in reflection – She described some impartial information; referred to only one note from a classmate, described some factual information and formulae but did not reflect on her understanding or made attempts to describe changes. Table 2 shows another example with two related episodes – In the first one, Student B identified her prior understanding (state of matter & electrolysis); it is a key concept and a common alternative conception. She reflected on why she had the problem (prior knowledge & textbook); considered various classmates' explanations and organized them; and she noted her new understanding but continued to identify areas she did not understand (mercury electrode). In the second episode (factors influencing electrolysis), Student B continued to identify her prior ideas and gaps of understanding; noted others' ideas and she puzzled over her classmate's curious information. She tracked different ideas but focused on the original problem and reflected on her new understanding. Student B employed good use of the scaffolds and demonstrated metacognition noting what she knew and what she did not understand. As well, she showed metaconceptual awareness as she became more aware of her initial conceptions and how they differed from scientific ideas. There are various instances that showed how such reflection prompted Student B to examine nature and source of knowledge. For example, she noted textbook as unauthentic science and "imperfect" source of knowledge. Furthermore, she concluded using a scaffold My belief on learning &knowledge implying some thinking about the importance of coherence (structure of knowledge) and role of evidence.

### Contribution of Knowledge Building Activity to Conceptual & Epistemic Changes

Correlation Among Measures Table 3 shows the correlation among various measures; we pooled the two classes because the key principles of reflective assessment are same. To improve the coherence for analyses, the various ATK KF indices were combined using factor analysis (see Lee et al., 2006). Two factors were extracted, Factor 1 is called **metacognition** (scaffold use, note revision and keyword) that explains 32.6% of the variance, and factor 2 is called **collaboration** (notes created, notes linked and read) that explains 30.1% of the variance. Table 3 indicates that KB reflection was significantly correlated with ATK metacognition, conceptual change and epistemic change scores. Furthermore, ATK collaboration scores were significantly correlated with conceptual-change scores.

Table 3: Correlations among ATK forum participation, KB reflection, conceptual and epistemic measures

| | 1 | 2 | 3 | 4 | 5 | 6 |
|---|---|---|---|---|---|---|
| 1.ATK Metacognition | | | | | | |
| 2 ATK Collaboration | | | | | | |
| 3. KB Reflection | .57*** | .18 | | | | |
| 4. Post-Epistemic Belief | | | | | | |
| 5. Epistemic Belief Change | | | .27* | .26* | | |
| 6. Post-Conceptual | | .38** | .44** | | | |
| 7. Conceptual-Test Change | | .31* | .40** | | | .90*** |

Note: * $p<.05$; ** $p<.01$; *** $p<.001$

Regression and Path Analyses We conducted hierarchical regression analyses on students' post-conceptual scores first using exam results and pre-conceptual scores (prior achievement) as predictors ($R^2$ =.34) When KF engagement (ATK Collaboration) was added, additional 4.6% variance was explained ($R^2$ =.38). Further, when we added reflection scores (summaries), there were additional 7.4%variances explained ($R^2$ =.46); R2 changes were all significant. These results indicated that over and above science achievement and prior knowledge, student engagement in forum and metacognitive reflection further contributed to post-test conceptual scores (Table 4)..

Table 4: Regression on post-conceptual scores with achievement, ATK collaboration & reflection as predictors.

| | R | $R^2$ | $R^2$ Change | F Change |
|---|---|---|---|---|
| Mid-year exam & pre-conceptual scores | .58 | .338 | .338 | $39.82^{***}$ |
| Forum – ATK collaboration | .62 | .384 | .046 | $5.63^{*}$ |
| Collaborative Reflection | .68 | .458 | .074 | $10.3^{**}$ |

Note: *p<.05; **p<.01; ***p<.001.

We also employed a path analysis testing a causal model to provide a more coherent picture: Student engagement in Knowledge Forum including both ATK metacognition (e.g., scaffold use; notes revision) and ATK collaboration (e.g., notes read and linked) predicted KB collaborative reflection that further exerted effects on students' epistemic belief change scores and conceptual-change scores.

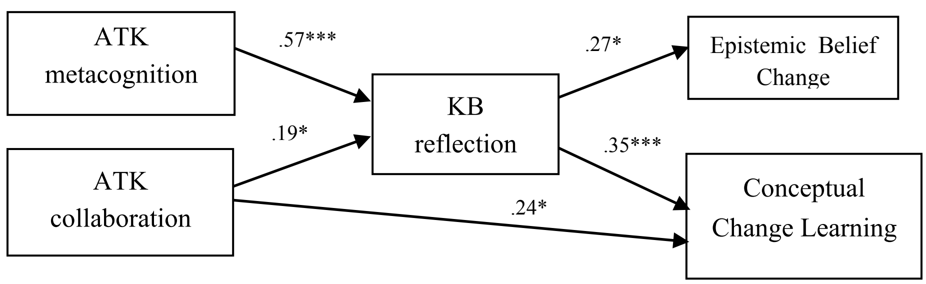

Figure 2. A Path Analysis Indicating Contributions of Knowledge-Building Activity to Conceptual and Epistemic Changes.

## Conclusions, Implications and Significance

This study developed a knowledge-building environment augmented with reflective assessment to examine and to foster conceptual change and epistemic growth. The environment was designed in ways that aligned with conceptual-change principles focusing on students' goal-directed strategies and agency elaborated with collaborative reflection. Results indicated that after the instruction, students in both classes changed towards more sophisticated scientific understanding measured by conceptual-change tests in electrochemistry. There is some evidence suggesting students also made some shifts in their epistemic beliefs. Comparing the two classes when students both had reflection, the effects were stronger for students supported with conceptual-change scaffolds for reflection.

A key question to address is to examine knowledge-building dynamics and to explain the pre-posttest gains, that is, how it may be possible for students to experience these changes. We demonstrated that asking students to engage in knowledge-building inquiry augmented with assessing their own scientific understanding in their discourse could help them activate prior knowledge, develop meta-conceptual awareness, and reconstruct fragmented views into more coherent explanations. As the excerpt shows, the student identified her prior conceptions; examined the nature of difficulties; considered others' views; puzzled over gaps of understanding; and integrated fragmented ideas into a more coherent account. The excerpt also suggests metacognitive reflection was facilitated because of the rich collaborative context with diverse ideas from classmates. Although ATK KF indices are quantitative, the extent to which students engaged in KF was a prerequisite for conceptual work – It supports the notion of how CSCL may provide the medium through which students can articulate, represent, interact and inquire into their ideas for sustained inquiry. Regression analyses provided support of this account indicating that students' engagement on KF and collective reflection predicted post-test conceptual scores *over and above* their academic achievement. A path analysis further showed that students' activity on Knowledge Forum predicted their collaborative reflection that in turn influenced students' posttest conceptual and epistemic changes.

Regarding epistemic shifts from questionnaire data, the excerpts provided some glimpses suggesting how changes were possible in collaborative inquiry and reflection. For example, Student B reflected upon the textbook as a source of 'imperfect" knowledge decontexualized from real-world science (i.e., textbook pictures always show smooth surface). She also pondered upon the importance of the connection among topics (structure of knowledge) and the need for justification using evidence. When students tackled authentic problems and reflected on their changes in understanding, they might be better able to see that knowledge is not certain and that it can be advanced.

To conclude, this study integrated two lines of research on intentional conceptual change and knowledge building examining how conceptual and epistemic changes could be fostered through collective inquiry and reflection. The study furthers research on knowledge building aligning with conceptual change augmented with student-directed assessment. Whereas many studies have demonstrated the role of metaconceptual awareness and epistemic beliefs, this is one of the few studies that illustrated how it might be possible to foster conceptual, metaconceptual and epistemic changes through collective reflection. Furthermore, the conceptual-change reflective assessment summaries provided a rich data source to examine students' alternative understanding of electrochemistry, as well as to track how students could move between individual and collective growth towards conceptual change. Instead of eradicating misconceptions, students' prior understandings could become objects of collective inquiry. Metacognition for conceptual change is not an individual accomplishment but one that can be examined and fostered in a community of knowledge builders. Turning over agency to students and asking them to reflect and to assess their own and collective understanding may help them develop conceptual and epistemic changes and provide insights into further research on collaborative conceptual change.

# Talking with your mouth full: The role of a mediating tool in shaping collective positioning

Kate T. Anderson, National Institute of Education, 1 Nanyang Walk, Singapore 637616, katherine.anderson@nie.edu.sg
Melissa S. Gresalfi, Indiana University, 1900 E. 10th St., Eigenmann 532, Bloomington, IN 47405, mgresalf@indiana.edu

**Abstract:** Research on classroom discourse has long underscored the integral role of social interaction in learning, yet designing for and supporting meaningful classroom interaction often remains a challenge. This paper examines the ways that elementary school students are positioned and position themselves during activities aimed at promoting reflexivity about small-group math discussions. We examine one student group's participation in three such activities over eight months' time and specifically highlight the role of a mediating tool that was designed to support participation-centered rather than ability-centered conceptions of learning. Our aim is to examine how one focal group's math discussions were or were not shaped by the tool in ways that were consequential for productive collaborative engagement.

## Introduction

The role of small group discussion in shaping mathematics learning has received much attention in the last decade and has been promoted as an important element of effective teaching and learning (Boaler & Staples, 2008; Gresalfi, 2009; Horn, 2005; Staples, 2008). Specifically, authors have pointed to the potential of collaborative interactions in promoting deep conceptual understanding, and more specifically, in supporting the high functioning of heterogeneous groups (Ben-Ari, 1997; Cohen & Lotan, 1995). However, *how* to foster students' learning through small group discussions that require exploring multiple perspectives, negotiating tensions, and probing disagreements continues to be studied; doing so entails changing many of the traditional practices of mathematics classrooms.

This paper considers the affordances and constraints of a particular mediating tool—conversation rubric—that was used to support small group discussions about mathematics. Specifically, we examine how the conversation rubric was taken up by one student group across multiple events in a fifth grade classroom. We analyze their discussions for evidence of whether the mediating tool a) supported collaborative engagement in math activities, and b) shaped students' reflection about their understanding and their positions in discussions in ways that might not have occurred without this particular tool. By systematically examining interactions across a suite of math activities focused on student discussion, we interrogate ways that particular activity designs can afford productive tensions between students that lead to positioning in light of math and each other. The analysis we present constitutes both evidence for how artifacts can shape the texture of learning across math discussions as well as a methodological lens by which to examine math learning discursively across cases and time.

The aim of our analysis is to examine the role of an instructional scaffold as a mediator of collaborative activity. In particular, we consider whether and how students' positioning relative to one another and relative to the subject matter, elementary mathematics, is shaped by externally structured group reflection on recently completed activities. In so doing, this study has both theoretical and pragmatic implications. With respect to theory, we seek to extend positioning theory to consider how tools can serve to mediate interaction. Thus, rather than considering positioning to be an interactive accomplishment of interlocutors alone, we demonstrate how an artifact can serve as a resource and an authority for co-positioning. With respect to practice, we demonstrate how instructional scaffolds structure interaction processes among learners (Kobbe et al., 2007), although not always in intended ways.

## Positioning Theory

Our analysis draws on positioning theory as a means of tracking changes in student collaboration. We consider positioning as moment-by-moment interaction, which involves the kinds of opportunities that interlocutors create for one another to participate in particular ways (Davies & Harré, 1999). This can be seen most easily in talk as participants speak to and about each other (van Langenhove & Harré, 1999). Positioning concerns the fluid arrangements that people make available for themselves and others through their talk and refers to participants' fluctuating status relative to one another. For example, students are positioned relative to each other as smart vs. slow, or cooperative vs. competitive. Positioning can include students' relative academic status but can also reference students' positions outside of the classroom

(Cohen & Lotan, 1995). Interpersonal positioning can also be accomplished though implicit and explicit comparisons between students. Students' ideas might be positioned as equally valuable (even if they are not both accurate, c.f. Lampert, 1990), or one idea might be positioned as less important than another—for example, in a classroom that is more competitive. In some classrooms, distinctions between who is "smart" and who is not may become a particularly dominant form of positioning, while in others such distinctions are rarely made. The effects of positioning can begin to endure as students become associated with specific ways of participating in classroom settings (e.g., Anderson, 2009; Holland, Skinner, Lachicotte, & Cain, 1998; O'Connor & Michaels, 1996; Wortham, 2004).

## The Importance of Math Talk

Significant attention has been given to the challenge of promoting robust mathematical conversation in classrooms. In particular, the goal of such initiatives has been to shift mathematics away from a procedural, didactic activity to an active process that involves strategic thinking, problem solving, decision-making, and talking about math. The challenges of organizing mathematics classrooms in this way have been well documented and include teachers' own histories and experiences with mathematics, their vision of the nature of mathematical thinking and learning, and students' previous histories with mathematics and their resulting expectations for activity in the classroom.

It is clear that classrooms cannot promote problem solving, discussion, and justification without supporting students to learn how to talk with and work with each other. Productive collaboration has been notoriously difficult to facilitate, particularly in classrooms that are organized heterogeneously. However, examples of successful collaboration in such classrooms paint a picture of the possible and a vision of what to strive for (Boaler & Staples, 2008; Staples, 2008). This research has led to recommendations for practice that are likely to support collaboration, including assigning students roles (Ben-Ari, 1997; Cohen & Lotan, 1995), structuring students' interaction (Kobbe et al., 2007), posing complex problems (Staples, 2008), and being consistent about expectations and accountability (Gresalfi, Martin, Hand, & Greeno, 2009). What is clear is that successfully supporting collaboration is no mean feat and requires facility with content and with orchestrating student practice. In this paper, we consider the role of a small intervention that targeted only student group work (as opposed to teacher practice) as a resource for organizing collaborative activity.

Our perspective on the role of discourse in mathematics classrooms aims to make visible the ways that what we say, how we say it, and how we implicate others' engagement in such interactions all shape participation in ways that affect students' opportunities to learn. Supporting productive modes of interaction and awareness of the crucial role of discursive exploration of math topics is central to views of language and learning as inherently social processes (Barwell, 2005). Implications of such sociocultural views on positioning within mathematical learning point to a need to foster and examine discourse that supports learning how to navigate both ways of being (social selves) in relation to ways of knowing (math learners) that are viewed as relevant, expected, or valued in certain classrooms.

In this paper we build on our understanding of student positioning with the goal of investigating how an external artifact mediated student interaction. Considering one group's interactions over the course of the academic year, we track students' patterns of participation over time and examine micro-interactional details of their conversations across three days spanning the ten activity days we conducted throughout the school year. We view such small-group math discourse and the meta-discourse through which students evaluate their participation as evidence of their positioning relative to each other and the math at hand. We thus consider how the tool afforded or constrained interpersonal and perhaps disciplinary positioning.

## Context of the Study

The data we consider draws from the second of a three-year, U.S. National Science Foundation-funded research project that examined the role of discourse in supporting mathematics learning in fifth grade classrooms (Hickey, Lewison, & Mewborn, 2005). The overarching project aimed to examine the impact of regularly occurring, collaborative math activities aligned to specific state and national mathematics standards on the development of student learning. The project's goals were to support teachers' facilitation of mathematics activities and to refine activities and related assessment materials to promote conversation and collaboration, which was not normative for the schools with whom we partnered. In this study, we conduct a fine-grained interactional analysis of the how certain aspects of the designed activity structure afforded participation in math discussions in ways that differ from traditional math classrooms, which are often modeled after learning-as-acquisition models (Sfard, 2001).

We partnered with four classrooms in two midwestern primary schools for the second year of this project. Teachers of these classrooms taught all subjects, including mathematics. We worked with these four classroom teachers for the duration of the school year, throughout which we participated in monthly interventions during math class time as well as monthly meetings with all four teachers in which we reviewed data, activities, and discussed and planned upcoming activities.

## Activities

The interactions that we had with the four classrooms entailed: (1) monthly, small-group math activities in which small groups of students completed and discussed pencil-and-paper problem sets that the research team designed (three to four questions each); (2) whole class discussions led by the teacher in which representatives of each group presented problem solutions on transparencies projected overhead: (3) *conversation rubric discussions* in which groups reflected on the quality of their group discussions (the focus of our analysis, discussed below); and (4) bi-yearly pre-post formative assessments that covered similar topics to the monthly problem sets and were completed individually, were not graded, and were discussed in similar fashion to the activities already described. In addition, we also administered bi-yearly pre-post tests that served as a proxy for state and nationally administered achievement tests. The design of both the monthly activities and formative assessments included small-group feedback conversations that were meant to foster discussion of math reasoning and reflection on math discourse. We focus here on an interactional analysis of one group's participation in three of the ten monthly, small-group activities.

The problem sets in the monthly activities dealt with recently covered concepts from students' regular math curriculum, such as determining the area of polygons, prime factorization, interpreting graphic representations of data, multiplication and division of fractions, and order of operations. The sets often prioritized open-ended problems with multiple solution paths and were intended to foster extended discourse within groups. These activities were not graded, but students did receive "hints" sheets (named "Dori's Hints" after a fictional cartoon sixth grader) partway through their discussions. These "hints" were intended to scaffold possible procedures to solve the problems and to move group conversation forward.

### Conversation Rubric

In addition to the problem sets themselves and "Dori's Hints," the main focus of our analysis is the role of the *Conversation Rubric* (CR) as a mediating tool that shaped students' participation in math discussions. The CR was designed to foster groups' reflection on their math discussions about the problem sets and their positions as engaged learners within those activities (see Figure 1 below for the CR). The CR (and teacher and research team's scaffolding of groups' use of it) focused students' attention on what are considered important elements of "productive" math discourse—listening, explaining, challenging, and reflecting on understanding.

Groups worked on the CR collaboratively after discussing their reasoning and completing whole-class discussion of the problem sets. Additionally, prior to completing the problem sets on each activity day, teachers organized a whole-class discussion around the prior month's CR to encourage groups' reflection on points for improvement from last time, which usually took five to ten minutes. Our interest in highlighting the CR for examining small group discourse lies in its potential for provoking reflection on students' participation in groups. In these reflections, students were no longer talking just about math, but also talking *about* their talk about math (and sometimes taking a personal stake therein). This talk effectively created a context for students to contest the accuracy and quality of their groups' math discussions, when students actually engaged the CR, which was not always the case. We argue that this affordance of the CR evoked different ways that students could orient to their own and each other's positions with regard to the math activity, their participation in it, and what social elements were relevant to distinguish "productive" and "unproductive" engagement in math talk (Gresalfi, 2009). We argue that the traditional classroom space of received mathematical learning (Boaler & Greeno, 2000) and classroom mathematical practice was mediated by this affordance of the CR in that it prompted students to think about the ways they talk about math together—not only the mathematical procedures used, reasoning employed, or their own individual understanding, but also how productively they engaged discourse and understanding as a group.

The CR was thus a pivotal artifact (Jurow, 2005) in that it provided a shifting frame that was outside that of received mathematical knowledge, which characterizes the traditional, individualistic math instruction these students were accustomed to engaging in, because it focuses on group work and discussion. The CR was also outside the frame of the group math activities themselves, because it fostered reflection on those activities. Despite both the activity's and CR's distance from "traditional" math instruction, it is not entirely separate, as it shares some features such as pencil-and-paper format and is easily adoptable by teachers without an actual change in classroom practice. The ways that interactions afford meaning making in classrooms vary widely but are never neutral. Theoretical views on classroom talk range from characterizing it as dissemination of information to a tool for problematizing understanding, creating meaning, and positioning identity. We view interaction around the CR as a reflective meta-tool for learning on two levels—understanding how to position one's self as a type of person, and understanding ways to reason about math with others.

## Methods

The small groups in which students completed and discussed the problem sets were comprised of three to five students each, which we organized with the teacher at the beginning of the school year based on mixed student math ability and parity across male and female students. In each of the four classes with whom we partnered we video-recorded two focal groups (limited due to equipment and personnel constraints), which we selected based on teachers' recommendations about likely talkativeness (a positive thing when examining discourse), consent to be video-recorded, and diversity of socioeconomic status, race, and math ability across the eight groups.

The data for this study include three, hour-long video-recorded activities of a four-student focal group comprised of two boys (Trey and Adam) and two girls (Christy and Mandy; all names are pseudonyms). We chose this group because they remained intact for all but the first activity day of the year, and they often talked at length about the CR. We chose these three activity days—day 2, day 4, and day 10—out of the total ten because they included complete video records of the CR discussion that also represents a range across the entire group trajectory throughout the year. Our analysis examines the types of positioning and learning that the CR fostered, both in the discussions around the problem sets and in the CR discussions themselves. Since the CR was discussed at the start of each activity in a whole-class discussion led by the teacher, we found that it shaped elements of discussion throughout each activity day. We use discourse analysis informed by sociocultural and sociolinguistic commitments (e.g., Anderson, 2009; Bucholtz & Hall, 2005; Mercer, 2004), including the immediate details of talk (pauses, pronoun usage, indexicals, content) as they relate to social positioning as well as categorizations of the group's trajectory of participation across the ten months of the intervention.

## Findings

We present the overall findings in terms of the elements of the CR for each episode. Our analysis includes both verbatim snippets from the group's CR discussion and our commentary on how that aligned with what we saw actually happening in the video recordings of their math discussions preceding the CR discussions. We first present an account of how the students used the conversation rubric and the alignment between their reflections on their participation and our observations of their participation. We then consider the episodes in terms of positioning.

## Day 2

The group's reflections on their activity from the second day in the CR discussion was generally positive; for the most part, the group stated that they had collaborated quite productively as a group, at least with respect to the items to which they responded. Specifically, they claimed that: "we tried to listen to [the explanations]"; "[we] heard what everyone had to say," and "'sort of'" asked questions when we didn't understand each other." Likewise, the group claimed that they had offered productive explanations, stating that they had "half and half tried to describe our way of thinking about the problems." "We said 'I don't think that's right' if we didn't understand each other," and "did not just sit there and nod our head." "We used math reasoning." In contrast however, they noted that they did not robustly challenge one another when working on the problems, stating: "We didn't really voice different reasoning and solutions except at the very end (after Dori)." Although one student claimed that their performance at challenging one another was only mediocre, others argued they did well because "we actually tried and did our best."

These reflections were generally not aligned with our observations of students' actual math discussions on Day 2: although students did at times listen to each other to the extent that they shared answers or procedures, they did not work collaboratively beyond "reporting out." As an example, after the students had finished the first problem on their worksheet, they were asked to share their answers with their group. The following exchange ensued:[1]

**Christy:** Um, I did drawings like 12.5 plus 5, you just add. You just, like, add. So I just added 5 to that one. And then if you do, um, 12.5 times 5, you'd be doubling, the number over and over again. So, like that's why I thought it would be greater. Because with this you only add 5 and you'd be doubled.
**Trey:** I didn't get anything.
**Christy:** Well, how far did you get?
**Trey:** I didn't get any [inaudible] [has covered his face with his paper]
**Christy**: I thought you had something wrote down.
**Trey:** But then I erased it.
**Christy**: [looks at Adam who is concentrating on his paper] Well, what did you think? [looks back at Trey]
**Trey:** [closes the paper closer over his mouth] My mind is blank.
**Mandy:** Wait, what?
**Trey:** [turns head to Mandy] My mind's blank.
**Christy:** OK. Adam, what did you get?

This exchange represents an "explanation relevant" moment; one of the members of the group expressed confusion about the problem but did not receive an explanation or assistance from the rest of the group. In this way, Trey was positioned as both off task and unworthy of assistance, as his confusion did not merit discussion or explanation from any of the other group members.

## Day 4

The group began this day prepared to listen actively to each other, because they decided that "we weren't listening to each other's problems last time; We're gonna try to listen to each other more," in their discussion about what to improve upon this day (based on last months' CR). Importantly, the group left their goal at this relatively unspecified level; they did not detail what listening actively looked like, or what specific steps they would take to ensure that they were realizing their goal. In reflecting on their discussion of the problem set (completed in two pairs this time) using the conversation rubric, the students did not evaluate their listening very positively; Christy said that she and Trey "did really good listening to each other and asked questions and communicating," but Mandy reported that she and Adam were only "sort of" listening to each other at the end a little bit. Interestingly, the students did not refer back to their stated goal for the day. With respect to explaining, Adam said (of he and Mandy), that "we did good because at least we explained. It may have been wrong but at least we challenged with respect and stuff." However, as a whole the group concluded that they could have done more to challenge each other because they didn't talk or listen all the way through.

Again, our observations of the group's work did not conform closely with the students' own characterization of their work. The group broke into pairs (as instructed by the teacher). Christy and Trey worked mostly independently next to each other; they listened to each other's answers and reviewed their procedures, but mostly they did not engage each other beyond stating their answers and reasoning. They did not actually work on the problem together. Mandy and Adam, however, did not even discuss what they

[1] Transcription conventions: [text] = description of non-verbal action; TEXT = stressed speech.

had written with each other and required extensive intervention from one researcher to even comparing their answers.

### Day 10

Adam was absent this day, and although the teacher and research team encouraged the rest to work as a threesome on the problems, Trey resisted (and Mandy immediately said that was fine with her and Christy). This final day of our analysis illustrates the extent to which the group's interaction came to a head; whereas in the previous two episodes, reflection about their work was generally not contentious and only tangentially related to the group's work, in this final episode the CR became an explicit tool for positioning each other in relation to the group's work. Specifically, although Christy and Mandy claimed that they had worked well together, Trey argued vociferously that they had neither listened nor explained *to him*. In our observations of the video data, although Christy and Mandy worked together without conflict, their collaboration was rather one-sided with Christy leading the work and Mandy writing answers and neither asking for, nor receiving, explanations. Trey worked independently, initially by his own desire, and later when the three were meant to discuss what they had written because he could not get the attention of the rest of the group.

In their discussion of their collaborative work, the CR became a mediating tool that Trey leveraged to successfully note his dissatisfaction with the group's discussion (or lack thereof). Although he had previously attempted to get the attention of the two girls, it wasn't until the CR became a topic of discussion that he was able to engage his group mates productively.

**Christy**: Listening? We listened to each other.
**Mandy**: What, where?
**Christy**: We listened to each other [points to CR].
**Trey**: No we're not done yet. We're not done yet [meaning not ready to discuss the CR].
**Christy**: Too bad.
**Trey**: You can't do it [CR], we all have to do this together [discuss their work].
**Christy**: [to Trey] Do you think we listened good?
**Trey**: [pauses] No.
**Mandy**: Yes.
**Trey**: NO, we haven't listened at all to each other.
**Christy**: That's because you didn't want to work with us, so too bad. We listened to each other!
**Trey**: But you cut- we all have to agree!
**Mandy**: But you said you didn't want to work with us.
**Christy**: No, you just don't want to work with us, so it's [inaudible]
**Trey**: No but we all have to agree. She said when you're done after we discuss this [lifts up activity sheet. Christy keeps writing on CR with Mandy looking on. 16 sec pass. Trey picks up their written work and examines it].

As the excerpts and descriptions above illustrate, the group did not really engage the CR in deep and meaningful ways, which was the case across the 10 activity days throughout the school year. For this reason, we argue that although they clearly used the CR for interpersonal positioning, especially on day ten, they did not engage in disciplinary positioning around the CR discussion (one of our hopes in designing it).

## Conclusions and Implications

To revisit our earlier stated aims, in this paper we considered one small student group's discourse across three monthly, collaborative math activities as evidence of the extent to which the *Conversation Rubric* was a mediating tool that supported collaborative engagement in math activities and shaped students' reflection about their understanding and their positions in discussions in ways that might not have occurred without the CR. With respect to these two points, we conclude from our interactional analysis of the three activity days that the CR supported competitive rather than collaborative engagement for this group, and that it failed to shape actual reflection on math understandings. We base this claim on observance that the group tended to focus on procedural display, task completion, and compliance with teacher formulations of the CR discussion as well as arbitrary group-dictated rules rather than considering how they might learn from each other or reflect on changes in understanding about the math from beginning to end of each activity day (or between activity days—another goal of the CR that was not realized for this group.

Clearly the CR had affordances for shaping group discussion, but how these affordances were realized as compared to how they were envisioned by the research team, at least with respect to the evidence supported in this case study, begs the question of whether the CR in fact does not afford reflexivity, or whether its use in this classroom with this particular group simply thwarted these affordances. In terms of design, we feel that if the group had taken up the CR as an actual platform for considering their math discussion, it could have worked. However, this group became fixated on either getting it done quickly and complying as if it were a set of boxes to tick, or using it to enforce compliance with dominant group members' whims (as seemed to be the case on day 10 with Christy and Mandy). As we stated above, activity designs can afford productive tensions between students that lead to positioning of each other. In this case, we observed tensions, but they unfortunately were not productive in terms of pushing understanding and learning from difference. Instances of different mathematical representations for this group were either glossed over as the same representations (so they could move more quickly through the activity) or became arguments about who was "right." As a result, the group never moved beyond initial understandings of the math activities, and they never reflected on these differences in the CR discussions. To further explore the design implications of the CR, we will be analyzing all eight groups' discourse and positioning in a future paper, of which this analysis will serve as a model for the analytic methods. In addition, we will also compare the second year iteration with that of the first year's groups' work on the CR, which was slightly different in form and enactment (see Anderson, 2009 for an in-depth analysis of one group's positioning relative to the CR in the first year).

Our methodological contribution from this analysis includes considering how a mediating tool shaped the texture of learning across small-group discussions, which we examined across time. In this student group's case, the CR-as-artifact shaped math discussions but not in ways we had intended or hoped. The CR-as-methodological lens, however, provides us with useful implications for considering the role of math discourse in supporting opportunities to learn, as we can learn considerably from negative cases. We examined the CR discussions as discrete points along the group's trajectory where values became explicitly associated with participation explicitly in light of intervening math discussions. In this way, the CR foregrounds how participation in small group discussion highlights tensions surrounding accountability—*especially* when such practice is not the norm for a classroom.

This analytic lens on the surfacing and navigation of tensions surrounding group participation is useful for understanding how interpersonal positioning can afford or thwart deep math discussions. For this group, their trajectory across the ten activity days spanning ten months illuminated a practice that did not change—their explicit attention was always focused on listening, but they never really changed how they listened to each other much beyond the second day. In terms of learning, it is unclear whether the math discussions or the CR aided this group's collective or individual understanding. We argue that these lacks stem from a failure on the group's part to get beyond the notion of their math work as their own, in other words something to which they alone were individually accountable. The group treated the math activities as their own work for which they would eventually be evaluated and the CR as a rote activity in which to give the appearance that they were doing things as a group. However, because the CR was not pushed or taken up in this classroom in a meaningful way, it thus failed to be meaningful. From these conclusions we summarize that interpersonal positioning must be navigated so that it does not get in the way of engaging the math, as it did for this group because vulnerability and righteousness clouded their ability to see the math for the spats. Instead, interpersonal positioning must lead into an appreciation for the variety of different ways there are to approach the representation and solving of math problems. In this way, the group we considered here "talked with their mouths full" of the CR, in that they interpreted their participation through its lens. However, that mediating tool only shaped participation after mathematical activity was completed, and thus the CR served more as a snack than a meal.

# Fostering meaningful scientific argumentation practices through ongoing classroom interactions

Xiaowei Tang, Janet Coffey, University of Maryland, College Park, 2226 Benjamin Bldg, UMD, MD20742
Email: kitty@umd.edu, jecoffey@umd.edu

**Abstract:** Specific sets of structural elements are often taken as the criteria for assessing students' argumentative abilities and designing curriculum or teaching strategies that promote classroom argumentations. In this paper, we take issue with such oversimplified, research paradigm, arguing for the necessity of examining students' argumentative practices as rooted in the complex, evolving system of classroom. Employing a sociocultural-historical lens, we illustrated through close discourse analysis how a high school biology class continuously builds up affordances and constraints for their argumentation practices through interactions. Whether argumentative conversations can take place in certain situations and sustain, and how the teacher and students participate in it have much to do with the learning goals, norms, teacher-student relationships and epistemic stances constructed overtime. Based on such findings, we suggested that the field should consider promoting classroom scientific argumentation as a long-term process, requiring supportive resources to be developed through continuous interactions.

## Argumentation: Structure, Skills and Classroom Norm

Over the last half century, scholarly views of science have shifted from a dominant focus on experimental processes to increasing concerns about its socially constructed nature (Driver, Leach, Millar & Scott, 1996). Conceiving science as ongoing human activities, philosophers of science have suggested scientific argumentation as playing a central role in the production of scientific knowledge, constituting a core element of scientists' practices (Latour & Woolgar, 1986; Fuller, 1997). Following in suit, reforms in science education has made efforts to promote scientific argumentation practices (NRC, 1996, 2000; Kelly, Druker, & Chen, 1998; Driver, Newton, & Osborn, 2000).

A framework commonly used by educational researchers to conceptualize argumentation derives from Toulmin's (1958) *Use of Arguments* (Bell & Linn, 2000; Driver, et al, 2000). While the original purpose of Toulmin's work was to challenge the traditional, inference-centered view of argument with practical emphasis on justification, it was reduced to a model consisting of the typical structural elements of argument and their functional relationships. In short, *data* refered to the evidence used to support a *claim*—the point-making statement, and warrants were the logical statements bridging *data* and *claim*. (Other elements of his framework -*qualifier*, *rebuttal* and *backing* –are less frequently employed in educational research).

This general account of formal argument has been modified into important tools for examining and evaluating argumentation practices in classroom (Kelly, et al, 1998; Jime´nez-Aleixandre, Bugallo-Rodrı´guez, & Duschl, 2000; Erduran, Simon, & Osborne, 2004; Dawson & Venville, 2009). Some directly applied a Toulmian model as the coding scheme, analyzing argumentation discourse for how frequently specific structural components got involved (Kelly, et al, 1998; Jime´nez-Aleixandre, et al, 2000); others developed scaling measurements, assessing student arguments based on structural completeness (Erduran, Simon, & Osborne, 2004; Dawson & Venville, 2009). With similar emphasis, early work from Kuhn (1991, 1993), though not employing a Toulmian framework, also linked argument structure with cognitive skills in coordinating theoretical claims and evidence.

Findings from research focusing on argumentation structure point to both the incomplete structure of students' arguments and the weaknesses in students' argumentation skills. For example, many found that students often argued by stating their claims without justification through warrants and data (Jime´nez-Aleixandre, et al, 2000; Dawson & Venville, 2009). Through interview studies, Kuhn (1991, 1993) suggested that adolescents and lay adults lack the skills to distinguish data and theoretical explanation of data. These deficiency explanations motivated the development of specific curriculum and instructional strategies for initiating, supporting and scaffolding students' argumentation practices, such as explicit teaching of general reasoning patterns (Zohar and Nemet, 2002), using open-ended argumentation prompts (Erduran, Simon, & Osborn, 2004), creating opportunities for peer or small group discussions (Erduran, Simon, & Osborn, 2004), and replacing written scaffolds with teacher introduction of an explanation framework (McNeill, Lizotte, Krajcik, & Marx, 2006). Through pre and post assessments designed to measure the structural completeness or the usage frequency of certain components, these interventions showed satisfactory changes in students' argumentation discourses.

While this research proves prevalent, its guiding framework and overarching goal greatly limits the scope of understanding on classroom scientific argumentations. As a structural account of formal arguments, Toulminian scheme provides neither tools nor language for analyzing argumentation as a goal-driven, socially constructed discourse phenomenon, embedded in either classroom discourse or the broader discourse of science (Kelly, et al 1998; Driver, et al, 2000). Judging the quality of a scientific argument according to structural features, in separation from its functional role and the cultural-historical contexts in which it is rooted, can be misleading. First, as Kelly et al (1998) suggested, language can be flexibly used in conversation, and the need for justification is often shaped by the interactive history and shared knowledge. He noted it was difficult to identify components of an argument without considering the related contexts and conversational dynamics, and even more difficult to make fair inference on individuals' abilities or skills in argumentation based on the structure of their arguments in an interactive discourse.

Second, the value of argumentation in science rests in its power to resolve scientific discrepancy (Driver, et al, 2000). If argumentation skills get foregrounded and established as the learning goal, but learners are not pursuing something that would raise the need to argue, we have little to ensure that argumentation gets developed as a useful discourse tool that students can draw on, and risk making parts of an argument another school-defined convention.

With such concerns, some scholars suggested that scientific argumentation should be established as a classroom norm (Driver et al, 2000; Engle & Conant, 2002). They called for argumentation to become evident in discourse patterns that permeate a variety of classroom activities, emerging naturally as part of students' regular sense-making interactions. In alignment, recent research has begun to investigate the complexity of classroom argumentation phenomena, taking into account multiple, interdependent factors of the learning environments. Studies on how learning contexts motivate engagement in argumentation suggested the important roles of factors such as social norms of classroom interactions (Berland & Reiser, 2009) and epistemological resources (Louca, Elby, & Hammer, 2004). In a case study of an emergent and lasting classroom argumentation, Engle and Conant (2002) demonstrated how a class' disciplinary engagement was constructed through continuous effort in fostering a learning community that encompassed such features as attitude and values towards controversial ideas, positions and roles of students, accountability for disciplinary norms, and supportive classroom resources. This line of research conveys a resounding message: to understand classroom affordance of meaningful argumentation practices, we need to look into the non-linear, multifaceted development of classroom learning environments.

Following this train of thought, our study explores how classroom norms conducive to scientific argumentation take shape and give rise to students' sense making interactions in a high school science classroom. From a sociocultural-historical perspective (Vygotsky, 1978; Engestrom, 1987), we view learning as continuously occurring in interactions between the social and individual planes, mediated by artifacts and sociocultural contexts and developed through the interactive history of the specific group and broader communities. From there we ask these questions:

*What affords or constrains the use of scientific argumentation in science classrooms?*
*How do classroom affordances and constraints of argumentation get constructed over time through classroom interactions?*

## The lens of localized activity theory

The dynamic and evolving view of classroom activities came from the theoretical lens of Activity Theory (Engestrom, 1987, 1999). According to this model, in a continuously changing activity system, collected subjects conduct object-driven activities that provide the momentum for its changes. Their actions and interactions towards the object are mediated by material and symbolic artifacts as well as factors from the broader contexts such as rules, community and labor division. Localizing this framework to fit the specific features of my subject, we consider a classroom as an activity system in which teacher and students carry out activities driven by overarching and specific learning objects, or other classroom/school related objects (such getting familiar with each other, setting dates for exam). These activities are conducted employing material tools (such as textbooks) and communicative tools (such as language). Contextually, activities are also shaped by norms and routines of a classroom (rules), values and norms held by the educational system (community), as well as the roles of and the relationship between teacher and students (labor division). I referred to all these factors as *classroom mediational resources*.

The term "resource" has already gained various meanings within the field: Hammer (2000) employed it to describe the conceptual and epistemological "knowledge in pieces" (diSessa, 1988) brought to learning by individual students. Crawford, Kelly, and Brown(2000) used it to refer both to individual knowledge of science practice and the artifacts affording science practice; Engle and Conant (2002) broadly defined "resources" as supporting settings ranging from available space of class time to classroom constructed artifacts and norms to modes of discussion. In this study, the meaning of *resource* is closer to Engle and Conant's (2002) use, but broader (e.g.: to include epistemological resources), and focuses on a functional common ground, that is, when functioning together, they afford certain interactions and constrain others.

Mediational resources get constructed in interaction, both explicitly and implicitly. Explicit construction occurs through actions/interaction with clear goals of setting up resources for current and/or future learning activities. Such situations, do not appear as common as implicit constructions, in which the interactions are not focusing on setting up resources, but as certain discourse and participation patterns, compatible values, norms and relationship that emerge and hold potential to mediate current and future interactions.

Within this framework, scientific argumentation is a general form of interaction serving the objects of different classroom activities. For such interactions to emerge, the class needs to develop shared understandings of when argumentation is allowed, what type of language to use and how to participate. The norm of argumentation also needs to be compatible with other classroom norms, both content wise and context wise. To illustrate the establishment of such argumentation "norm," we have to explore the complexity of an evolving classroom system. The influence of mediational resources for argumentation extends beyond structural concerns to content, purpose, values and participation patterns of specific argumentation interactions.

## Data Source and Methodology

To investigate classroom affordances and constraints on scientific argumentation, we videotaped a teacher's (Sarah's) class for a full semester (September 2008- January 2009). The class was an ethnically diverse, honor's level, biology class, comprised of 24 students, with a roughly balanced gender ratio and a mix of 9$^{th}$, 10$^{th}$ and 11$^{th}$ grade students. At the time of this study, Sarah was in her 3rd year teaching biology in a large, suburban-urban fringe public high school. She had participated in a university-based collaborative research project that sought to better understand teachers' curricular modifications. During that project, she was identified by researchers as relatively good at scaffolding student argumentation and as a teacher who strove to facilitate students' participation in other scientific inquiry practices, despite institutional pressures associated with standardized curriculum guides and high-stakes testing that could focus attention elsewhere.

Our analysis of classroom data focused on interactive learning discourses, mainly speech, but including contextualization cues (Gumperz, 1982; Duranti & Goodwin, 1992) such as eye gaze, gesture, writing, and visual representation on the board. Initial analysis entailed cataloging summaries of interaction content of all classroom video, in one to five minute intervals. The thickness of descriptions (Geertz, 1973) was determined by the richness of the discourse data and how closely it related to the interest of this research—thicker where students shared ideas and built arguments.

We began to identify discourse patterns and shifts on different levels: 1) General discourse structure, such as triadic dialogue (Lemke, 1990), reflective toss (van Zee & Minstrell, 1997), and back-and-forth argumentation (Cazden, 1988); 2) Ways in which productive learning interactions were initiated and maintained, which included type and amount of teacher scaffolding; 3) (i.e.: scientific language and everyday language (Lemke, 1990)); and 4) Patterns of expressions (common words or phrases).

Episodes bearing patterns or demonstrating shifts in patterns were transcribed and subjected to closer analysis in order to draw out meanings of discourses and gain insight into the social processes underlying the learning interactions. (Gee, 2000; Erickson, 2004; Kelly, 2005). To do this, we summarized participation and discourse features of each episode. We then worked backwards (and forwards) to try to identify an interactive history through which parallel features emerged. Analyses across episodes helped bring out possible meditational resources, how they were constructed and what work they accomplished for classroom learning.

## Data Analysis

To illustrate how such theoretical and methodological frameworks guide our analysis, we draw on several representative argumentation episodes from the class we studied.

### An Illustration of the Classroom Argumentation "Norm"

The first one took place during a class review of biotic relationships (predation; commensalism; mutualism; parasitism), which is a month into the fall semester and a week after they took notes on that topic. The teacher Sarah asked students to name and explain the meanings of different biotic relationships. After she confirmed that parasites usually do not kill the host, one student threw in a challenging question and a discussion ensued:

Acer: if there is like a parasite or something in the prey or whatever dies, like, because of it, would you call it predator or what or still parasite?"
Charles: like you could die from mosquitoes… like the disease they carried...
Sarah: so the disease they carried like kills them, not the mosquito.
Charles: well, the mosquito bit the person.
Students: Yeah…
Christine: Yeah, but it wasn't/
Sarah: but the bite didn't kill the person.
Christine: It is the disease…
Acer: Um, What, wha…isn't a virus like a parasite?
Charles: but they inject the virus that caused the disease.
Sarah: So, here is, if I were gonna argue back with Acer. He just said isn't a virus like a parasite. If I'm gonna argue back…Does anybody else wanna argue back?
Students: No.
Sarah: I'm gonna argue that/
Charles: Because virus isn't an organism.
Sarah: some people would not consi…virus is kind of falling in this iffy place where we are not sure we should call them alive or not alive. So I would argue that is not a relationship between two living organisms. I would say that there are always exceptions to the rule, like, Tim said, "That's rare." There are exceptions though. So usually parasites don't kill their host. If they did kill them, I don't know, maybe you would want to call it a predator 'cause it hunts it and kills it.
Tim: but usually it just doesn't happen
Tim: like it would be predator and prey if that in that form. [inaudible]
Sarah: what did you say?
happens a lot, but it can happen sometimes but usually the other animal doesn't die, so it is just parasitism.
Charles: Oh, my gosh, he sounds so smart. [class laughter]

This collaboratively constructed scientific argumentation flew through shorthanded and co-constructed arguments, demonstrating the students' ability to engage in scientific argumentation and also reflecting their conceptual understanding of the subject. As Acer problematized the demarcation between parasitism and predation with a particular situation—a parasite in a prey that dies from it, he made an argument based on a hypothetical overlap between the two categories. This required certain conceptual understanding of both types of relationships. . The exchanges between the teacher (and Christine) and Charles showed that they both have certain understanding of the pathological mechanism behind mosquito-borne, transmissible disease, but have different interpretation of the case in terms of what is the killer: while the teacher identified the disease rather than the mosquito as the direct cause of death, Charles defended his argument by emphasizing the mosquito's initiator position in the causal chain—it "bit the person" and "injects the virus." The argumentation shifted when Acer brought up virus as an example for the situation he described. Charles and the teacher both argued through denying virus' status of living organism and excluding it from the category of parasite, which is the precondition for it to be considering as a candidate for the situation they talked about. By introducing the "iffy place" about virus' being alive or not, Sarah indicated the debatable nature of her rebuttal, and also took a step back, acknowledging the possibility of a loose boundary—"If they did kill them," "maybe you would want to call it a predator 'cause it hunts it and kills it." Tim then jump in and showed an understanding of the probabilistic meanings behind accident and normality

While this episode shows merits if examined in terms of argument structure or content, its significance extends far beyond that. First, the argumentation is initiated by a student's challenge of the canonical boundary between parasitism and predation, which had been established by the teacher in previous class sessions and confirmed just prior to this episode in a teacher-student interaction. Such moves are rare, in our observations and in the common patterns of classroom argumentation interactions recorded by the literature, as usually argumentations get start with open question and without "correct answer" being given (Engle, 2002). Second, this conversation occurred during a review activity, where checking conceptual understandings and knowledge of terminology is far more typical than engaging in scientific argumentation. Third, the students brought up arguments on their own rather than following specific probes from the teacher. While the teacher's scaffolding moves were very limited (The main move she made is bringing Acer's argument to the class' attention and ask "Does anybody else wanna argue back?" which is followed by the "virus is not alive" argument co-made by Charles and herself.), the students attended to the ideas from each other and from the teacher. Lastly, the nature of the teacher's participation is distinct from more commonly adopted roles: she was an arguer in the field, actively constructing her own argument. Though some might find some authoritative flavor in her arguments, we noticed that the students treated her ideas on par with their peers' arguments rather than as ones to accept. They argued with her without hesitate, clearly demonstrating their understandings and critical thinking.

We argue that understanding the features listed above are important for explaining how argumentation took place at the moment. We would also argue that these are the indicators that certain argumentation "norm" has established in this class, so that argumentation can naturally emerge and contribute to the class' sense-making process. The immediate contexts of this episode, however, does not explain what gave rise to these features. When examining this episode as embedded in the interactive history of classroom, we have identified previous episodes that share or contrast this episode in certain discourse features. Through comparing multiple episodes, we analyze how mediational resources conducive to scientific argumentation get constructed, and contribute to the features and participation patterns seen here. The following section demonstrated the construction of one piece of such resources.

## "Because You Keep on Asking"

While the students attend to the substance of each other's and the teacher's ideas in the parasitism-predation argumentation, this was not always the way they interacted in this class. On the third day of class, in a discussion on "why do we brew tea in hot water?" after the students came to agreement that hot water works faster than cold water since molecules move faster in it, Sarah posed the question: "At the end of all, are we going to get the same product using hot water and cold water?" At first, the class together made the "yeah" sound in a low-pitch, elongated tone, as if that answer was so self-evident. After this question being pushed back twice, only several students still remained in responding, and their answers provided a simple causal explanation for their previous judgment —"it (the tea) would eventually go into water." As Sarah, again, pushed it back to students by explicitly asking for "anybody thinks no?" the following exchanges took place:

Sarah: Does anybody think no, we are not gonna get the same thing?
Dani: (raises up hand)
Sarah: Yeah? How come?
Dani: Because I think that's the right answer.
Sarah: And … why?
Dani: Because you keep on like, asking that.
Sarah: I'm just trying to get you guys disagree about stuff! One person said something and you were all like, yeah— (she mimicked their lazy tone. The whole class laughed and Tristan put his hand up).

In response to Sarah's push, Dani raised his hand and voted for the "not gonna get the same thing" claim. When Sarah probed for his reason by asking "how come?" he gave no scientific explanation but stated that he thought "that's the right answer." It was after another push from Sarah he shared his interpretation that the teacher's keeping asking when everybody said "yes" must suggest the opposite to be correct. Danny did not receive any counterargument, laughter, or other looks from his classmates; instead, the class remained silent with their eyes fixing on Sarah, implying that they were also waiting for an answer. Sarah did not show much surprise either. Claiming the purpose of "get you guys disagree about stuff," she then imitated and made fun of the way students casually threw away their agreements, indicating that she would interpret such answers as not resulting from critical thinking.

At this moment of the discussion, students did not generate scientific argument. Even the teacher's move to scaffold was misinterpreted as an indicator of correctness. Sarah did not play the arguer role here. Since the students would accept what they thought she indicated, it is reasonable to guess that they were concentrating on getting the correct answer and probably would not stand on equal foot and argue with her.

This conversation did not end there. Students offered an alternative answer, and one student provided a piece of reasoning that would support the claim: there would be less water in tea made with hot water due to evaporation, so there would be a higher concentration of tea. This argument was not taken seriously and respectfully, as the class immediately exploded in laughter and made funny "ohhh" soundand one student even sarcastically stated, "what an awesome answer" with rolling eyes. Sarah, however, ignored the sarcasm and grabbed the idea. She offered the student a chance to repeat his idea to the class and then encouraged him to further his chain of reasoning.

This discussion ended up with several students claiming that hot tea resulted in a higher tea concentration. Other classes of Sarah's ended up with the opposite conclusions. As Sarah told us in the interview, there was "not an exact right answer such discussion tried to reach." Reasoning-based arguments on either side would count towards fulfilling the object of the activity.

In contrast to the student-initiated predation and parasitism-predation argumentation, although this tea brewery discussion was planned to be an open-ended one, the way the students participated indicated their expectation of a correct answer from the teacher. Instead of thinking critically about the phenomenon or reasoning through ideas, the students pursued the teacher's confirmation. Sarah made much effort scaffolding: first she encouraged argumentation by pushing back reasoning-lacking agreement; she probed students for reasoning, and communicated the purpose of her discursive move; finally, by requesting students to articulate a chain of reasoning, she claimed value for this spark of scientific thinking, and set an example for the class on how to focus on the scientific substance of ideas.

When contextualized in the larger picture of school education and the settings of this classroom, what gets communicated here is much more than what has been explicitly said. By explicitly associating her discursive move with promoting disagreement, and by attending to the scientific substance of an idea the class laughed at, Sarah also negotiated with the class a shift in the general goal and values of science learning. This shift, we would argue, is a piece of resource that could contribute to the ways in which students attended to ideas in later argumentation (such as in the parasitism-predation discussion).

We have identified other resources through comparative analysis of episodes of classroom interactions. Due to the page limit, we summarize them in the findings but would not go into details here.

### Constraints on Classroom Argumentation

While Sarah's class has constructed significant affordances for student participation in scientific argumentation, it is not the case that scientific argumentations can be developed towards any direction at any time. We saw constraints on argumentation in that class. For example, the parasitism-predation argumentation lasted for a few minutes and did not develop to its fullest. The conversation was called to an end when students started to challenge the "iffy status" of virus. Sarah's decision to "get back on topic" highlights that not all tangents are fair game, and not all argumentation are permitted. The predation-paratism exchange showed how the class was afforded to go on tangents, initiating and sustaining argumentation in an activity not particularly framed for scientific debate or open-ended scientific discussion. In that part, the arguments focused on demarcating the concepts of parasitism and predation. However, with tighter objectives of a review activity's object on understanding biotic relationships, redirecting the conversation was not an option. In previous classes, we have observed situations when similar tangential argument got accepted and followed in activity with looser and multifaceted objects (not shown here): for one thing, the activity was set up as a chance for everyone to participate, attending to, challenging and building on each other's ideas; for another, they were trying to make sense of a truly unsolved scenario, which even the teacher was not sure what was going on. This allowed (and actually required) in depth explorations into the details of ideas. In contrast, the unit review activity has a much more specific goal and therefore clearer boundary for tangent, since there was a more to-the-purpose topic to "get back on".

How, then, should we understand such constraints? What contribute to where and when they present? What determine the strength of their effects on ongoing conversations? When tracing back the class' interactive history, we identified mediational resources constructed by the class that would contribute to such constraints.

## Research Findings

The major finding of this research, as partially depicted in the analysis above, is a more contextualized account of classroom scientific argumentation. We go beyond evaluating and boosting certain argumentation structures, moving into the construction and functioning of argumentation-related classroom mediational resources. Our analysis demonstrates how classroom norms, rules, teacher-student relationship and discourse patterns formed through interactions, some of which even seem unrelated to argumentation, can later mediate students' participation in argumentation.

Through analysis, we have identified resources that could organize and mediate the class' participation in scientific argumentation in activities not framed as ones for practicing argumentation. These include: A comfortable-to-share and whole-person-respected classroom relationship; general goal and values assigned to the substance of ideas; the participating norm of "talk about shared ideas;" and repeatedly conveyed epistemic messages that biology concepts "always have exceptions."

We have also noted the tenuous nature of the classroom argumentation "norm" in the face of system-wide presses, like common curricula and high-stakes testing. We identified interactive history the discourse constructs of "fun" and "serious/boring," which set different participation norms for activities focusing on substance of scientific ideas and activities focusing on test preparation. As unit exams and the final state assessment became more impending, we saw significant changes in the teacher and students' participation patterns, including a drop in the frequency and length of student-initiated argumentations. Some other constraining resources included the different values and different nature of knowing attached to different biological subdomains and the classroom norm for resolving goal conflicts.

## Research Significance and Implications

We chose to write about this classroom, not just for the distinct argumentations it affords, but also for the weight of realness it bears. The word "realness" here has two folds of meanings. One points to the systemic pressure this classroom has to deal with—since classrooms cannot always be experimental sites in vacuums. In order for the goal of scientific argumentation to organize classroom learning in a meaningful way, it has to coordinate with many other objects that orient classroom activities. The other points to the goal of promoting argumentation in science education: to construct a useful way that affords students' sense making process, rather than as a performance to satisfy researchers' criteria, then researchers, need to better situate the practices of argumentation in the broader fabric of schooling and science.

This study aims to capture how classroom argumentation "norm" grows out of (or fades away through) sequential classroom interactions. As the story of Sarah's classroom unfolds and as our analysis goes deeper and more thorough, we identified mediational resources that contribute to the affordance and the constraints of argumentation practices in this classroom. This provides a reference of things to account for in establishing the classroom argumentation "norm". For teacher educators, this study suggested the necessity of attending to continuous classroom discourse and the long term consequence of interactions. Considering classroom interactions as the process of constructing learning related, shared mediated resources may help teachers and teacher educators to reflect on teaching practices and understand teaching effectiveness from a more constructive, long-term perspective. While activity theory has established theoretical account of how activity system can evolve locally on itself, little work has been done to illustrate such process with data. Through thick description on the construction and functioning of shared mediational resources in science classroom, this study also provided a concrete account corresponding with such theoretical processes.

# Knowledge Transmission and Engineering Teaching

Amy Zhang and Monica Cardella, Purdue University, 701 West Stadium Avenue, West Lafayette, IN, 47906, USA
Email: zhang212@purdue.edu, cardella@purdue.edu

**Abstract:** This paper explores the concept of knowledge as well as the process of knowledge transmission, both in general and specifically regarding engineering knowledge. This study focuses on twenty-four parents who discussed the activities that they engage in to help their children learn about engineering during hour-long interviews. The intergenerational transmission of knowledge that is described in the interviews is analyzed through 1) social structural and cultural analysis, and 2) a case study. We find that parents teach children what they perceived as engineering knowledge, which is not necessarily true but rather subjective, and believed to be a fact based on the parent's other forms of knowledge learned in the past. Understanding this will help us look at engineering education from a new perspective, and the application of this understanding could be used to help provide non-engineering parents alternative ways to support their wish to explore engineering knowledge with their children.

## Introduction

This paper deals with pre-college students' engineering education within the backdrop of the current state of pre-college engineering education in the United States: while engineering has traditionally not be explicitly taught in the K-12 schools as a subject, there is growing interest in incorporating engineering in K-12 schools (e.g. NAE and NRC 2009). A small number of states have even begun adopting engineering curriculum standards. However, as this is a recent change to K-12 education, there is little research on engineering pedagogical content knowledge or the impact of engineering instruction on students' understanding of engineering. As such, rather than focus on expert teaching practices exhibited by K-12 teachers, this study focuses on the teaching practices of engineering parents. While this expertise may not always translate to practices that classroom teachers can adopt, we believe that some of the parents' practices can inform classroom instruction as well as the development of resources for non-engineer parents. Additional motivation for the study is based in a desire to increase diversity in engineering at the college-level and beyond (i.e. post baccalaureate studies and industry practice).

In order to investigate the practices that parents with engineering backgrounds employ to help their children learn about engineering, we interviewed 24 parents who self-identified as parents of children aged 2-18 who "help their children learn about engineering." As we selected our study participants, we were careful to include parents from different engineering backgrounds in addition to academic vs. industry vs. mix-of-industry-and-academic backgrounds, as well as parents of children of difference ages and sexes. Each parent participated in a semi-structured interview that last approximately 60 minutes. We began by asking about their children; their children's schools; their academic background. Then we asked them about how they helped their children to learn about engineering, and asked follow-up questions based on their responses.

The interviews were conducted among 24 participants, among whom there are 12 males, and 12 females. 14 parents out of 24 are faculty members, 2 are PhD students, and 8 are in industry. Both of the parents who are PhD students have had respectively 9 to 30 years working experience in industry prior to the PhD program. The parents' work and educational backgrounds touch on 20 specific engineering fields, such as civil engineering, biomedical engineering, aerospace, electrical engineering, and industrial engineering. Out of their 50 children, 26 are girls and 24 are boys. Their ages range from 17 months to 29 years old. Besides 11 outliers, there are 39 children who age from 2 to 18. The interview questions have covered parents' background, interactions with children (content they teach their children, teaching strategies, and children's reactions), parenting ideology, and parents' own understandings of engineering.

In this paper, we use these interviews to explore parents' roles as teachers; how knowledge is transmitted intergenerationally; and interplays of socio-cultural factors and parents' own history of learning that impacted parents' activities. We do this by focusing on four participants: Laura, an Asian mother of one son and one daughter and is pursuing a PhD in software engineering; Liz, a Professor teaching biomedical engineering who has a four year old son; Tom, a father working in the industry with an engineering background covering several fields (metallurgical engineering, material engineering, and process engineering) and who has a 2.5-year-old daughter and a 5.5-year-old son; and Aaron who is a father of a 4.5-year-old son and is a professor with an electrical engineering background.

We begin this paper by discussing the concept of knowledge. By dividing knowledge into specific knowledge and common sense knowledge, we are able to analyze interplays of the two during the process of the intergenerational knowledge transmission– how the former is based on and restrained by the latter which is deeply embedded in and in turn reinforces the former. The process of intergenerational knowledge transmission is analyzed on two levels – social structural and cultural analysis and processual analysis. In order to understand the meaning of parents' teaching activities, we have to look at the social structure and cultural environments in which these practices are performed. Structural analysis as a methodology thus helps us understand 1) that parents' educational practices are shaped by the basic principles of their common sense knowledge, 2) their ideology of education functions as to ensure the common sense knowledge to be put in their daily practices and obeyed, 3) how different social systems such as families, engineers, and different ethnic groups are integrated, 4) how individual parents justify their practices through scrutiny, and 5) how through the interaction between individual parents and the society, both the parents' goals and the social expectations become realized.

## Knowledge transmission through teaching and learning

In a footnote of Foucult's Archaeology of Knowledge (Foucult, 2002:16), his translator A. M. Sheridan Smith wrote:

> "The English word 'knowledge' translates the French 'connaissance' and 'savoir'. 'Connaissance' refers to a particular corpus of knowledge, a particular discipline – biology or economics, for example. 'savoir' which is usually defined as knowledge in general, the totality of connaissance is used by Foucult in an underlying, rather than an overall, way. He has himself offered the following comment on his usage of the terms:
>
> > 'By connaissance I mean the relation of the subject to the object and the formal rules that govern it. Savior refers to the conditions that are necessary in a particular period for this or that type of object to be given to connaissance and for this and that enunciation to be formulated'
>
> Throughout this translation I have used the English word, flowed, where the meaning required it, the the appropriate French word in parentheses."

There are two types of knowledge implied in the above message which are not mutually exclusive. One is expertise or skills gained in a specific field through education or learning; the other is implied above by Foucult, that is – different epistemologies we believe in and practice every day to know and make sense of the world (i.e, common sense knowledge). However scientific the former might be, it is always limited by the latter which we practice almost unconsciously in everyday life. However encompassing our common sense knowledge might seem to be, our specific knowledge gained from systematic learning in turn reconstructs our common sense knowledge by a series of rejections, confirmations, and readjustments. Therefore, as Hansen states, "the transmission of knowledge is subject both to conservative forces and to tendencies toward continual redefinition" (Hansen, 1982:26).

In our case, the specific knowledge being transmitted from parents to children is more transparent. The knowledge is everything that parents think is engineering related – fixing a household item, building an electric circuit, practicing mathematics skills, understanding how things work, etc. The common sense knowledge, however, is more complicated, pervasive, and taken for granted during most of our waking hours.

According to Hansen (1982), common sense knowledge – which he calls cultural knowledge – is a set of maxim, ideas about human nature, aesthetic preferences, values, affective patterns, beliefs, etc. (Hansen, 1982:25). According to Leiter (1980) and Schutz, common sense knowledge does not only include the "rules of thumbs that are vague, contradictory, and self serving", but it can be studied from three dimensions – the stock of knowledge, the natural attitude of everyday life, and the practices of common sense reasoning (Leiter, 1980). Much of these dimensions hinges upon the various assumptions people make about each other and each other's reasoning. In this study of parents' teaching experiences, we examine the process of knowledge transmission by looking at the interactions of these two types of knowledge and how parents reorganize these types of contradictory as well as mutually sustaining knowledge to selectively teach it to the next generation.

## Structural & Cultural Analysis

Knowledge transmission reflects social structure. Social structure is viewed by Sewell (1992) as "dual", as "both the medium and the outcome of the practices which constitute social systems". Social structure also "differs in 'depth' (how pervasive, invisible, and taken-for-granted their schemas are), and 'power' (how great the resources they generate from)" (Sewell, 1992:22-6). Practices are therefore enabled as well as constrained by social structure, and these practices in turn make the transformation as well as the continuity of social structure possible. Parents' everyday teaching practices such as the types of knowledge selected by parents, their children's expected responsibilities and privileges, and the descriptions of children's "good" and "dissatisfying" performances (which reflects their core values) are enabled and constrained by what facilities are around the parents, what methods are favored by the mainstream culture (e.g., what they see from the mass media), what parents can afford to do, what parents' peer groups are doing, and how parents cope with their children's school curriculum.

In our 24 interviews, there are two channels through which parents teach their children engineering related knowledge: material resources and daily interactions. These two channels are not necessarily mutually exclusive. The most commonly used material resources are manipulative toys, computer programs, websites, books (either literature or science oriented), TV programs and DVDs, and trips to museums or exhibitions. The use of these resources is largely determined by the manufacturing and consumption preferences of the society, distribution of knowledge and skills, relationship between specific knowledge and its financial reward as well as its social reward, access to the resources due to the parents' social class, parents' financial ability, household locality, and the children's age, gender, birth order, and their assumed personality.

For example, the parents' financial ability decides what types of toys are on the top of their hierarchy and for what purpose the parents are buying the toys. Laura (1), one of our parents who participated in the study, mentioned that she used Barbie dolls as tools to help her daughter practice counting when she was 2 years old. In contrast, imagine a low-income family with many children. Here, the parents might use objects that are more practical and affordable or objects that they already have in their possession. The purpose of buying a Barbie doll is different, too. For a low-income family, parents may buy their children a Barbie doll based on their wish to provide their children a toy that other children possess. In contrast, Laura might have multiple different considerations. For example, a different Barbie doll would increase the variety of toys for her children, and the toy itself can be used as a teaching mechanism (and Barbie's latest career as software engineer, though announced after our study concluded, may provide yet another opportunity for parents to teach their children engineering concepts) .

Another channel through which parents teach their children engineering concepts is daily interactions. Some parents take 10 to 20 minutes every night to answer some questions before their child goes to bed, usually curious questions about nature. In doing so, they claim to encourage their children's curiosity, a characteristic which is highly valued in a middle class American family with both parents systematically and well educated. Some parents invented a mini project such as building an electric circuit or fixing an old computer to engage their children in the problem solving process in a "natural" environment. Most parents have taken their children to work, and some of them have exposed their children to specific objects they use at work. According to the Neo-Marxist conflict theory (Collins, 1985), such a way to organize interactions reflects the social status group of the parents. Additionally, through associations with members in the same group, the parents share common status cultures such as language styles, parenting styles, requirements for education, interpersonal dynamics, values, topics, etc (Collins, 1985). Such ways in which educational interactions take place make it possible for the children to become technologically capable, curious, creative, and able to fix problems. These are expectations that overlap in both the macro American culture and the engineering culture specifically and are constructed under these certain social structures. In meeting the expectations, the social structure in turn is reinforced.

The above analysis is not to imply that these parents – who share a similar social class status, academic backgrounds, parenting styles, and expectations for children – as a group are homogenous. The knowledge these parents choose to pass on to their children through selected strategies reflect the integrated core values of 1) the mainstream Anglo-American culture, 2) the microscopic engineering culture, 3) various subcultures (race, gender, nationality, etc.), and 4) the parents' historical experiences. For example, students in American culture are encouraged to take initiative and be motivated to learn. "Students are expected actively ask questions and participate in class discussions and other activities; they are frequently rewarded for contributing to the class and giving critical and constructive ideas" (Pai & Adler, 2001:221). Self-motivation, independence, curiosity, and creativeness are considered as desirable qualities (Pai & Adler, 2001). Children are expected to reflect such qualities as well. Liz, who is a professor teaching biomedical engineering, complained that her son doesn't have initiative to learn. When we asked her to describe her son, she carefully said that her son is "different" from other kids in the sense that he doesn't seem to have a lot curiosity, and he doesn't ask a lot questions. Liz's worry came from the awareness that her son doesn't have some of those core values that are preferred by this society: curiosity and initiative. While every other kid is praised for being curious, Liz is concerned that her sons' passive learning characteristic will not help him succeed.

As Swidler (2001) postulated, social structure depends on the mutual reproduction of schemas and resources. Schemas are the semiotic codes shared by a group of people and used by them to make sense of the world. A schema is what makes a resource meaningful as a resource (2001: 78). Take our parent study as an example. These parents with engineering backgrounds are well educated by formal institutions with at least a Masters degree while some have a Ph.D. The engineering schemas – such as solving an engineering problem –

that are deeply embedded in heavily scripted engineering classroom interactions are internalized. Thus when parents who share the same engineering schemas see a child taking a toy apart, they think of the action as initiating a problem which leads to the next step – putting the toy back together. However, parents who don't share the same schemas are more likely to blame their children for breaking the toy and possibly causing unnecessary financial repercussion. The schemas parents internalized during their own learning process became their own rationale they use to interpret resources and interact with their children who in turn learn to interpret things by using the same schemas. With the ongoing mutual reproduction of resources and schemas the social structure is sustained.

Different parenting styles may also be attributed to different sub-cultural backgrounds. Aaron, who is a professor described how he took his son down to their basement and explained to him the structure and functions of the water pipes. Laura, who is a Chinese woman pursuing her Ph.D. in America says that she is not very satisfied with the mathematics education here. "There's too much play-work here in American elementary schools", she said, "I still think the Chinese way is better". She gave her children math practices to do and graded them like a teacher. Our interviews suggest that parents within engineering fields but with different specializations have different understandings of what engineering is and therefore have different focuses on teaching what they think is engineering related. Parents who see engineering as problem solving are more inclined to initiate a small project to get their children involved, and the focus is on how things work. One parent who calls herself a "soft engineer" (which is generally associated with problem solving, design, communication skills, and teamwork) focuses more on the basic scientific and numeral skills which she thinks are fundamental and crucial to engineering. Tom, who has worked in industry for a long period of time (as opposed to other parents who are in academia) sees that engineering is not always problem solving but most of the times is just maintaining, to "keep the machine running" as he said. However, his teaching strategies don't seem to be too different.

According to Durkheim's social order theory, the study of social structure focuses on the moral order, the central value system that though created by people, has an independent and external existence and acts as a constraining and conditioning force upon individual people (Meighan and Sirah-Blatchford's, 2003: 252). Parsons, like Durkheim, saw social order achieved through the operation of an integrating system common to all members of society; yet he also emphasizes how individuals constantly adjust themselves through scrutinizing the process of socialization (2003:256). Structural analysis as a methodology thus helps us understand 1) that parents' educational practices are shaped by the basic principles of their common sense knowledge, 2) their ideology of education functions as to ensure the common sense knowledge to be put in their daily practices and obeyed, 3) how different social systems such as families, engineers, and different ethnic groups are integrated, 4) how individual parents justify their practices through scrutiny, and 5) how through the interaction between individual parents and the society, both the parents' goals and the social expectations become realized. Further, the integration of structural analysis, cultural analysis, and Swindler's understanding of structure as the mutual reproduction of schemas and resources provides us a different perspective that gives meaning to parents' teaching activities. Therefore, we not only focus on the relationship between individuals and society, but also the meaning of individual practices under certain schemas constructed by the members of the society (e.g. a child taking a toy apart is perceived by engineering parents as an aspect of curiosity and an initiative step to problem fixing). However, the study of social structure and culture focuses on the relatively stable features of behavior and context and the patterned arrangement of relationships among individuals and groups while leaving the problem of process untouched. We are also interested in the process of how these schemas came into being and how parents reorganize the messy and conflicting knowledge from different levels of social systems and transmit the knowledge to the next generation. In the following case study, we delve into these processes by analyzing a specific interview with a female engineer who we think is particular in representing both conflicts and integration of all kinds of knowledge she is trying to pass to her children.

## Case Study

Our case study will center on an interview with a female engineer and parent. In order to better reveal the process of intergenerational knowledge transmission, in which the parent tried to put different pieces of knowledge (engineering knowledge, the parent's own cultural background, and the mainstream American culture perceived to be true by her) together, we follow Hansen's suggestion (Hansen, 1982, 1990) by dividing the following analysis into several steps. These steps will allow us to see how the social structures are created, maintained, challenged, and modified over time as well as process an individual's adaptation necessary to his/her changing environment (Hansen, 1990: 192). The steps are: 1) the definition of the situation; 2) the cultural significance associated with communication channels used to encode and decode communications; 3) the interplay among channels of transmission; 4) the communicative-interpretive repertoires of participants, including communicative competence in the codes being used, 5) the communicative strategies participants used to realize their respective interests and purpose, and 6) the role and identity attributions.

Laura is a Chinese woman pursuing her Ph.D. degree in engineering, specialized in software programming, computer networks, and information security. Her husband is also an engineer and currently working in industry. Prior to pursuing her Ph.D., Laura had eight years of industry experience. Laura has two children, a son and a daughter. In the following conversation, you will see Laura trying to tell the interviewer what kind of engineering related knowledge she taught her children. She also stated that she was a "soft engineer" and that many things she had to do at work are math related. Therefore, she viewed math as fundamental for engineering.

> Interviewer: so you started doing that after they have learned some math at school?
>
> Laura: yes . but actually , their math, uh-mostly, I uh taught them math because their math is more advanced than what they are learning at school?[ Interviewer: uh-hmm] so I uh, the-they learned their math at home, basically. ((chuckle))
>
> Interviewer: Oh, OK. So-
>
> Laura: [Schools, especially middle schools here are not too demanding here in America? I would say American education here, eh- even in the best middle schools, in west Lafayette, I know a lot of parents, the way they teach math, I think it's not demanding enough, so that if I don't teach them at home, I feel like their talent will get wasted. So ((chuckle)), that's how I feel.
>
> Interviewer: So are there other ways in which you tried to explain math to them?
>
> Laura: um, see, uh-here in America, we like to say let's play games and do math. [Interviewer: uh-hmm]And we don't do it that way. I do it in the Chinese way. I came from china, and I, and I-learned my way there. Ah-I teach them Chinese way((laugh))
>
> Interviewer: [OK. So it's kinda like complementary-
>
> Laura: [yeah I thought it was very important. ((laugh)) [A: OK. That's interesting.] I actually think the Chinese way of teaching math is better? ((laugh))

According to her description, her definition of the current situation was that she is not satisfied with both the depth of the math education in America in general and the play-work teaching strategies she has observed from other parents and schools. The school was wasting her children's talent. She expected that teaching her children math the Chinese way would stop her children from falling behind where they were supposed to be, were they raised in China.

Apparently there are two conflicting communicative channels that are associated with two different cultures. One channel is associated with mainstream American culture and stresses the importance of autonomous study, independence, initiative, and having fun, especially at the level of elementary school. The other channel through which the knowledge is transmitted is associated with Chinese culture which values cooperative study, passiveness (e.g. students are expected to follow the guidance and authority, and learn through watching, listening and emulating), memorizing the knowledge, and heavy practices. In general, American school personnel see schooling as a process of developing the whole person (Pai &Adler, 2001:220-223). Thus non-academic activities are considered an important part of schooling. Playing, for example, is perceived as a strategy to initiate children's curiosity to learn as well as a way to develop the children's social skills. As Spindler and Spindler (1990:37) generalized, one of the core values of the Anglo-American society is a sociable, get-along-well orientation. The ideology of early children's education is also to explore and support their own interests instead of pushing them to any one direction (which is almost a taboo in the interviews with parents). However, in a Chinese mom's eyes, playing at school – where only academic related activities are supposed to take place – can be a distraction to the child's intellectual training and cause anxiety for the mother. Being a Chinese mom, Laura also expects her children to be among the top students in their classes. Even though she claimed that she didn't intend to push her children, she was very proud when she told me that her son had won several math competitions and her daughter – who didn't show very much enthusiasm in math – was a year ahead of her classmates. Facing this anxiety, Laura felt the impulse to change the situation. She then went on to tell me how she achieved this change.

Another channel through which Laura teaches her children engineering related knowledge is associated with the history of her engineering learning process. Most of Laura's education was done in China where she also had 8 years of experience working in engineering industrial practice. She is also currently studying for her Ph.D. in engineering in an American institution from which she has internalized the core engineering values in the U.S. through her learning practices. Her perspective of what engineering is can be very different from the mainstream perspectives as we shall see below:

> :: (My daughter)-she's very self sufficient,? She, she, she cooks her own pancakes,?((chuckle)) [A:oh] so we think that would related to engineering. you wouldn't think cooking and engineering (*are related*), but engineering, uh, you follow a direction, mix the eggs and flour together, ((laugh))[A: right]. I think that'll will be good-]
>
> Interviewer:
> [It's a, i-it's a process of production?
>
> Laura: Right. Production. And also you know the modern grinder, the mixer. So 'cause grandma has to do it by hands, she does it by hand. And with the mixer, they know this is the-because there is engineer.(ing).

The above conversation shows that engineering is perceived by Laura as a symbol with two meanings: 1) engineering is to "follow a direction" or follow instructions, and 2) engineering is to design innovations which improve our lives. The second meaning is a commonly shared meaning within the American engineering culture, whereas the first one is gained from Laura's history of learning and working in China. While the second meaning is articulated frequently and almost throughout the entire interview, it is the first meaning of engineering – follow the instruction that Laura uses to construct her real parenting practices. For example, feeling the anxiety that the school is not demanding enough at math teaching, Laura brought home many math practice sheets for her children to work on, and "I grade them like a teacher", she said. If the children did the problems wrong, she would circle the wrong answers and ask them to redo the questions. Laura also bought her children the Stanford EPGY (Educational Program for Gifted Youth), a computer based program for math, and asked them to practice by following the program's instructions at least half an hour each day. Both solutions consist of two types of instruction following: one is to follow Laura's own instruction to finish the work she gave to her children, the other one is to study math by following the instruction of the program.

When asked about what she usually taught to her children, just like all of the other parents we have interviewed, Laura felt the necessity to immediately claim that she didn't really teach her children anything specific because she wanted her children to be free to choose what they like to do. However, in the later description of how her daughter learned math, she first showed some dissatisfaction since her daughter wasn't as motivated to learn math as her son; she then said she felt lucky because her daughter doesn't really hate math even though she didn't show much enthusiasm; at last, she was proud to say that her daughter, although not as successful as her son, was still doing very good at math and her level was one year more advanced than her peers. Therefore, by articulating what is expected by mainstream society and then actually practicing under completely opposite schemas, the social values are sustained and Laura's personal purpose is realized. Laura also did not have to be fully conscious during the process of readjustment.

As we have shown above, the interview with Laura was full of contradictories. As a self-selected participant, she was attracted by our flyer looking for parents who transmit engineering knowledge to their next generation and told us that this project was interesting. She might have been interested in our project for two possible reasons: 1) our requirement of participants confirmed her self-presentation with multiple identities – a mom, an engineer, and a responsible mom (for she gives "good" education to her children), and 2) she hopes our research will provide more learning opportunities. Either reason implies her will to expose her children to engineering knowledge. However, she came to us and claimed that she had never intentionally taught her children anything specifically about engineering like almost every other participant does. She tried very hard to leave us an impression that she is a good mom, and therefore will give her children enough freedom to explore what their interests are and be supportive. However, this concept of a good mom is challenged when she saw her children doing activities that are non-academic and thought such activities might hinder her children's potential to become successful, for being a good mom also means having successful children. It is possible that she did not teach her children engineering knowledge specifically as she stated, yet the fact that she was attracted to our research was a self-presentation as an engineer who is self reflexive and aware of the many benefits our society has credited to the engineering field.

As shown above, when unfolding the process of knowledge transmission it is important to understand the definition of the situation (what is happening, who is present, and what is expected to happen next), the interactions among different channels through which the knowledge is transmitted, how individuals either consciously or sub-consciously manipulate the meanings associated with different social groups, and the process of role making within such situations. It is in people's interactions that we find things meaningful.

## Summary

In our 24 interviews, parents discussed teaching their children engineering related knowledge: through two primary channels: material resources and daily interactions. The most commonly used material resources are manipulative toys, computer programs, websites, books (either literature or science oriented), TV programs and DVDs, and trips to museums or exhibitions. The use of these resources is largely determined by the manufacturing and consumption preferences of the society, distribution of knowledge and skills, relationship between specific knowledge and its financial reward as well as its social reward, access to the resources due to the parents' social class, parents' financial ability, household locality, and the children's age, gender, birth order, and their assumed personality. The daily interactions through which parents claimed to teach their children engineering knowledge have revealed different forms of knowledge that have been transmitted along with engineering knowledge. During the analysis of the process of knowledge transmission, we were able to see both conflicts and integrations of different forms of knowledge, and how parents tried to put the pieces together in order to achieve their goals of education. Both channels showed that knowledge is messy and exists in many different forms, and that when engineering is taught by parents to their children as one type of knowledge, other forms of knowledge are also inevitably active in this process. These forms of knowledge (culture, specific knowledge, schema, practice, and etc) help in shaping and in turn reinforcing each other.

Understanding the concept of knowledge and the process of knowledge transmission allows us to come out of our own bubble and look at engineering education from a different perspective. During the learning process in general, we draw the information from our stock of knowledge, assume the existence of order and pattern, and seek to organize our perceptions in such way to discern it (Hansen, 1990:4). We categorize the information by using our internalized hypotheses learned from the past and orient our ways to export the knowledge by reference to these hypotheses. During the engineering education process within the household in particular, parents teach children what they perceived as engineering knowledge, which is not necessarily true but rather subjective, and believed to be a fact based on the parent's other forms of knowledge learned in the past. In the future study, we intend to apply our understanding of knowledge transmission to k-12, and pre-school engineering education. We intend to build on the study presented in this paper through further interviews with parents as well as observations of parents and children at play. We also plan to extend the work by providing resources for non-engineer parents to use as well as using our research findings to develop activities to use in formal (i.e. classroom) settings. The study described in this paper also shows us that increasing access to engineering education for children who might not traditionally be exposed to engineering is not as simple as providing ideas for activities that parents or teachers can engage in with children; instead the parents' and teachers' prior engineering experiences and cultural experiences can deeply impact the way that they approach engineering education. Thus these engineering and cultural beliefs must be understood in order to impact pre-college engineering education.

# Listen to each other: How the building of norms in an elementary science classroom fosters participation and argumentation

Suna Ryu, William A. Sandoval
University of California, Los Angeles, Los Angeles, CA 90095
Email: sunaryu@ucla.edu, sandoval@gseis.ucla.edu

**Abstract:** The present study explores and documents the process of building social and argumentation norms in a combined third- and fourth-grade science classroom and examines how the processes regulate students' participation patterns, including the students' roles. This study also investigates the positive potential of negotiating norms and taking on intellectual participatory roles for fostering scientific argumentation. The analysis focuses on how one norm, *listening to each other*, contributes to distributing participation rates and forces students to take more critical audience and intellectual roles. Students also show improvement in argumentation in terms of frequency and epistemic quality.

## Introduction and Background

Argumentation is one of the central discursive practices of science, and has been highlighted as an essential part of science instruction (Driver, Newton, & Osborne, 2000; NRC, 2007). This emphasis stems from recently articulated views of science that underscore the deeply social aspects of knowledge construction in science. Due to this growing importance, a body of research has developed about student argumentation and how to support it(see Eduran & Jimenez-Alexaindre, 2008). In this research, scholars do not always make clear what they mean by argument or argumentation. We use the argument here to refer to any "text" (written or oral) that involves one or more claims and justifications for those claims. Argumentation is thus the process by which such texts get produced. We also view learning to argue as an important goal in itself for science education, as Driver et al. argue, as opposed to arguing as a particular method of learning concepts (Andreissen, 2006).

From this body of research scholars agree that learning to argue well requires more than just acquiring cognitive skills. Argumentation, by definition, is a social practice (van Eemeren et al.,1996). Consequently, student argumentation has a complex relationship with other social aspects of the classroom culture. Hence, learning to argue well involves the mastery of a complex discursive practice governed by a set of norms that has been refined over a long period of time. Fostering argumentation in the classroom community requires a fundamental shift in classroom culture, in particular, an innovative change in discourse use (Duschl, 2008).

Among the issues in the typical classroom culture, teacher-dominated IRE types of discourse and the vertical relationships between teachers and students have a long history of being nominated as fundamental issues that hinder students from engaging in active dialogical argumentation (Driver et al, 2000; Dushl, 2008) Recent research also reports that such discourse patterns and vertical power relationships are often mirrored when students interact with each other. That is, academically high-achieving students tend to take on the teacher's role as the evaluator/answerer/clarifier in small groups and reproduce IRE types of discourse (Webb et al, 2006). For instance, when a group member asks for help, smart students simply give the answers to the student. Hence, the reproduced discourse among students may prevent students from voicing different opinions or arguments. Research also indicates that vertical power relationships among students result in unequally distributed participation rates. A stratified pattern of participation tends to be found: some students often dominate the classroom conversation (Cornelius, 2008).

To overcome the problems of traditional classroom discourse, some researchers point out that a teacher's adoption of a new discourse can be the key to improving classroom discourse (Driver et al., 1994, 2000; Erduran, Simon, & Osborne, 2004; Osborne, Erduran, & Simon, 2004). In addition, many studies across disciplinary areas have explored participant structures in which teacher and students re-define their roles to improve their discourse. For example, studies have documented how teachers can newly position themselves as a facilitator, and/or negotiator, rather than as an evaluator, or answer the student so that students take the main role as knowledge co-constructors. Brown and her colleagues (Brown & Campione, 1990; Brown, 1992; Brown et al., 1993) facilitated the engagement of students by encouraging them to take specific roles in a jigsaw, and the students generated, manipulated, and discussed their ideas in a public forum. Herrenkohl and Guerra (1998) highlighted three practices, including monitoring one's own comprehension of another's ideas, coordinating theories with existing evidence, and challenging the claims put forth by others. They found that students were more likely to coordinate claims and evidence by taking an audience role that encouraged the students to provide clarifying and monitoring comments associating with taking intellectual roles. The researchers argued that students can participate in a social practice common to scientists by having students engage in episodes that request coordination between theories and evidence. In the study, an important aspect of dialogical argumentation—ideas and perspectives are exchanged, refined, and evolved—was highlighted by asking students to take the role of an audience that is actively involved in initiating engagement rather than simply taking on the role of passive intellectuals. Van Zee and Minstrell (1997) found that the teacher's use of the "reflective toss," pushed students to elaborate on each others' and their own ideas, and become more active participants in whole-class discussion. These studies illustrate the kind of classroom community and culture may promote students' argumentation. As Roseberry et al. (1992) argued, students not only take on new roles and more actively participate in classroom discussion, but they also are more likely to provide better scientific explanations that relate evidence to claims.

However, many issues about how a teacher's discursive practice with students (the establishment of specific discourse norms that can help students to reorganize and regulate their roles, and how these things may work together) can foster students’ argumentation remain unexplored. We don’t really know how teachers create these classroom communities. In addition, rarely studied is how the established norms and roles, guided by the teacher may influence students' power dynamics. In this context, I address the following three questions.

1) When a teacher initiates social norms in the context of the elementary science classroom, what participation and argumentation norms seem to emerge and become negotiated?
2) How does the process of initiation and negotiating norms help students to reorganize/regulate their roles in small group discussion?
3) How do the negotiation of norms and the taking on of participatory roles foster scientific argumentation?

### Setting and Participants

This study took place in a combined third- and fourth-grade classroom in a laboratory elementary school at a large public university in the western United States. The population of the school approximately mirrors its state's population in ethnicity and socioeconomic class. The class included 21students: 12 third-graders (6 boys and 6 girls) and 9 fourth-graders (5 boys and 4 girls). Ethnically, there are 18 Latino students, 2 Caucasian students, and 1African-American student because this class is part of a dual-language (English and Spanish) immersion program at the school. There were three one hour periods of science each week. For a unit consisting of four or five weeks, students began by creating big ideas and questions. In this science class, students were asked to research science topics, often by reading books and websites. The students also conducted investigations and collected data. For example, students investigated the characteristics of magnetic force by putting magnets into the sand box on the playground of the school, by observing the number of washers required to break two magnets, and by drawing graphs and comics about the magnets. The students were then asked to represent their findings and present them to other students. As they worked, students were encouraged to participate in discussions by presenting one another’s opinions and by resolving disagreements.

Students spent 65% of their time, on average, in small groups, rather than together as an entire class. In a small group, students are assigned to one of various roles, such as a starter (who explains the group’s goal and plan), recorder (who records the data and presents them to the class), helper (who asks for helps from the teacher if the students have questions or need other help), or a gatherer (who prepares the materials for the experiments). Once a week, the teacher assigns students new roles. The teacher, Ms. Green, had been teaching 38 years at the time of the study. Ms. Green originally majored in English, but she had more than 20 years of experience teaching science at the elementary school level.

## Data Sources and Methods

A qualitative case study design was used in this study. A case study design was employed because it provides an in-depth description of a particular activity and situation (Creswell, 2003; Meriam, 1994; Miller & Salkind, 2002) that verifies how the norm is developed in a classroom (natural context) and examines students’ roles and power dynamics.

I used a combination of classroom observation (field notes and video data), teacher interviews, and student interviews to answer my research questions. Videotaping and taking field notes were essential because this study requires fine-grained analyses of student discourse use and interaction. The video record enabled in-depth micro-analysis of interaction (Erickson, 1992). Brief field notes were also recorded in order to capture classroom contexts that might occur outside the camera’s range. The video data for this paper include 18 science lessons (approximately 20 hours) from the first six weeks of the school year. The video data were first logged, and episodes determined to be of analytic interest were fully transcribed. The transcription included partcipants' speech, gestures, facial expressions, and behaviors. To analyze the data, a text management program, Atlasti, was used to investigate the frequency of incidents and to categorize similar incidents together.

The purpose of the interviews was to address the teacher and students’ recognition of norms, and their position (alignment) with the norms. The teacher interviews consisted of one semi-structured interview, conducted during the second week of the school year, and multiple informal interviews. The interviews included questions such as which norms are important and why, how the teacher wanted to initiate and operationalize the norms, and which norms the teacher thought were sustained and appropriated. The students' interviews consisted of a semi-structured small group interview, conducted during the sixth week of the school year, and informal individual interviews. The interview supposed a situation in which the group was asked to help a new student, named Jenny. Questions included "Jenny wants to know some of the rules of your science class so that she can actively contribute to discussion. What are three rules? About the norm that you guys just mentioned, do you think that you are doing well or not?," and "Why do you think that the norm you've just introduced to Jenny is important to make discussion better in your science classroom?" The interview data were fully transcribed.

## Findings

### Classroom norms: participation and argumentation norms

Classroom norms were identified inductively first, and then categorized by referring to Cobb et al.'s work (1996, 2001) on classroom norms and participant structure. For example, a candidate norm was labeled a norm when the candidate norm appeared more than three times. In addition, I looked for instances indicating violation of norms as evidence of established norms for the classroom (Cobb et al., 2001). The classroom norms are basically divided into two categories: participation norms and argumentation norms (Table 1).

Table 1: Emerged participation and argumentation norms

| Category | Norm | Description | Example (T: teacher, S: student) |
|---|---|---|---|
| Participation norms (PA) | Listen to each other | Ask students to listen to what other people are saying | T: We need to be able to listen. It is very important. When you work in groups, you also need to listen very carefully so that you can really understand what your friends are trying to say.<br>S: Listen. We are supposed to listen in science class.<br>S: Tell me what I just said.<br>S: You've got to listen. |
| | Talk aloud | Ask students to state their opinions aloud | T: Not everybody may hear important questions and answers if you talk like this. Imagine when you are yelling at your dog. How would you call the dog? Really project your voice so that others can hear. |
| | Attention behaviors | There are short phrases used to turn the class's attention to the teacher. | T: Raise your hands to hear my voice. One, two, three, eyes on me. |
| | Hold for a minute | Often the teacher blocked a few, more available students' answers right after the questions or comments in order to give others opportunities to talk. | T: Now let's just hold for a minute so that others have a chance to think. |
| | Call on others to help you | When someone wants to continue, or dominate the discussion, the teacher asks her/him to call for others (from the class) to add comments. | T: Why don't you ask for help from your group? Are there any comments from Group 2 about Maximo's comments? |
| | Talk to your group/ class, not me (Talk to us, not just one member) | Some students tend to talk to the teacher, not to the class. Then the teacher asked the students to talk and explain their opinions to the class. | T: You talk to me; that is not good. You should talk to the class. |
| Argumentati on norms (AR) | Think, talk, and act like scientists | The teacher highlights that 'we are scientists.' She frequently used this phrase, especially when students conducted experiments. | T: As scientists do, we fill out sheets to record our data. Scientists like measuring.<br>S: We did that three times because if we just did once, we wouldn't know whether it was accurate. So we did it three times like scientists. |
| | No right or wrong answer | The teacher also highlighted that there is no right answer in science. | T: I heard something interesting because we did not hear that before. I'd like to you to continue. There is no right or wrong answer. We want to hear what you think and believe. |
| | Feel free to have other opinions (what do you think) | Encourage students to disagree with others and provide alternative ideas | T: Isn't this an issue if there is just one person for one opinion? Do we have to be embarrassed if we make a different choice from the others? No, we don't have to. |
| | Back up your claim with evidence (why do you think what you think) | Encourage students to explicitly explain how evidence is related to claims | T: Don't forget. You also need to think about how you convince the rest of your group, so you need to give them some evidence about why your idea is a good idea. |
| | Convince others of your opinions | The teacher explained several ways of convincing others and then encouraged students to convince others | T: We'd like to let others know what we know. How do we convince others? |

Because the teacher has a proactive role that introduces and initiates norms in the classroom, I interviewed Ms. Green, and asked her which norms she thought were important for fostering argumentation and how she planned to initiate and operationalize the norms. She reported her aim was to emphasize norms to evoke broad participation, especially for the first two months. The reason for this was her acknowledgment of the existence of unequal participation and power dynamics among students. As a mixed-grade class, five or six of the fourth-grade "oldtimers" dominated classroom talk and work in their groups. She expected that the stressing of participation norms might contribute to encouraging other members, especially those who were new to the class, to talk and participate more. For example, when she was asked to introduce the most important classroom norm, she chose “listen to each other.” According to her, the norm not only focuses on the importance of listening to others' opinions but also helps students to ensure understanding of others' opinions and equal distribution of opportunities among students by encouraging them to ask for others' opinions. She felt this enabled the broadest student participation.

In addition to directly asking students to listen to what others are saying, she also encouraged this listening norm by having students rephrase, interpret, or summarize what another student had just said. Interestingly, she also emphasized that some participation norms could provide a basis for fostering argumentation. She said that if students are not willing to listen to others' opinions, then there is no reason to argue something because they are just satisfied with their own opinions.

Regarding the argumentation norms, the norms she answered seem to be derived from her beliefs about science. She projected an image of scientific knowledge as changeable, depending on what evidence is used. She stressed that scientists explore and work hard to better understand the world. There is no such thing as a right or wrong answer; it depends on how you convince others, by using evidence. Hence, the frequently used phrase, *we think, talk, and act like scientists*, implies argumentation norms, because she thinks that the central part of scientists’ work is to make a theory (claim) and back it up with evidence to convince others. Because there is no right or wrong answer, feeling free to have opinions and making an effort to convince others with your evidence was also stressed.

## Negotiation of norms

Students come to understand and share a norm through ongoing negotiation, not simply by having a norm presented to them (Yackel et al., 2000). In Ms. Green's classroom, this negotiation process included clarifying the classroom's understanding of the norm, generating new related norms, and extending the meaning of the norm. In the following example, Ms. Green and students began their discussion about a norm, *listen to each other*, and continued to discuss why *what do you think?* is a good question. Then the discussion was extended, and they agreed to include “*why do you think*” questions as a new norm. Ms. Green said, “Remember how important it is that the groups listen to each other. I heard somebody say, ‘What do you think?’ I think that this is a really good question to encourage listening to each other.” She asked the students why they thought this is an important question. Marisa answered, “In this way, we can gather what other people think. Maximo said, “It can get others involved in the discussion.” He also pointed out that this question was good for opening up a discussion, so that group members can focus. Oscar added the point that scientists are really curious, so this question encourages a scientific mindset. Then Josue pointed out that this question was nicer than other questions:

| | |
|---|---|
| Josue: | Because it is nicer, instead of screaming like “c'mon” because you don’t really have a chance to talk because it is difficult to say you should participate. |
| Ms.Green: | It’s better than an invitation. So, you think *what do you think* is better than *why don’t you work*? Or *why don’t you do something*? Or *you should participate*. Why do you guys think it is better? |
| Maximo: | I agree with Josue. Because it also very hard to make them into something by saying to them. You can also say *why do you think*, and then they would also go along with the evidence. |
| Ms.Green | Good. Excellent comments. That goes along with evidence and backing up claims. So we will ask, what do you think and why do you think? |

As seen from this example, the importance of listening norms was related to asking the question, *what do you think?* The *what do you think?* question was related to the ‘think, talk, and act,’ like scientists norm according to Oscar’s comments, and it seemed to enable the class to address an important argumentation norm (‘go along with evidence’) by including the ‘why do you think’ question, as addressed by Maximo and Ms.Green.

After this discussion, when Ms.Green visited a small group, she often checked whether the group members conformed to or violated this norm. She asked, “So, did you ask Camila a question, a ‘what do you think and why do you think’ question?” Then Josue asked a question about whether all members should ask this question of each other. She answered, “Yes, I’m strongly encouraging you guys to do that. Scientists like asking about their opinions, and they really like asking question ‘why do you think that?’”

## Change of participation and power dynamics, argumentation within groups

In the whole-classroom-level interaction, the distribution of the students' participation seemed to expand over the six weeks of observation. Ms. Green said in the fourth week, "It is true that there are some boys and girls who used to dominate the class, but now some other people are ready to join. Teena will pitch in. Marisa is another one. Sofia is a really good thinker." As shown below, students' participation seemed to be more evenly distributed by the sixth week, and there were some students who participated significantly more in the whole classroom discussions (Figure 1).

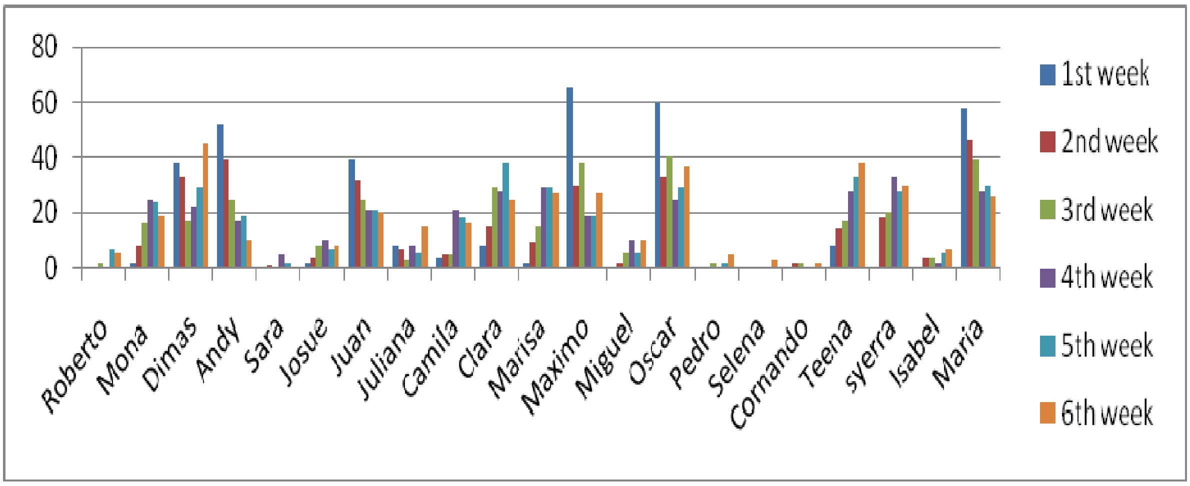

Figure 1. Distribution of individual students' participation through the first 6 weeks of class.

It must be noted that Ms. Green has distributed opportunities to participate on purpose, and often blocked the dominating students and had others talk. In other words, the improved distribution could be a result of the teacher's explicit manipulation of participation. Note that some of the frequently addressed norms, such as 'hold for a minute,' 'call others to help you,' and 'talk to your group/the class, not the teacher,' discourage students from dominating class discussions. For example, when Dimas said in the first week, "Ms. Green, I think…" in a little voice, the teacher asked him to turn around to the class and talk to the class, not the teacher only. She said, "Dimas, I know what you mean, but you should talk to your friends, not me. Turn around, stand up, and really project your voice to the class." Therefore, in order to see whether the establishment of norms enabled students to participate more, and encourage them to reorganize their norms, it was necessary to trace back to the changes in participation to small groups. The groups, organized by the teacher, are heterogeneous in terms of sex, grade, and academic achievement.

In order to see the changes in participation at the small-group level, I selected two groups for analysis. Each group included a member who showed significant improvements in participation at the whole-classroom level to see if the members who improved in whole class discussion also showed improvement in small groups. The analytical points of the group discussions included the participation frequency of each member, identifying the norms addressed during the discussion, recognition of students' roles (Herrenkohl & Guerra, 1998) and power dynamic, and counting and characterizing argumentation (Ryu & Sandoval, 2008) (Table 2).

Table 2: Analysis of small group discussion

| | Group 1 (Oscar, Clara, Pedro, Camila) | | Group 2 (Andy, Marisa, Teena, Juan) | |
|---|---|---|---|---|
| | First week | Sixth week | First week | Sixth week |
| Taken assigned roles (S: starter, R: recorder, H: helper, G: gatherer) | Oscar: S, Clara: R<br>Pedro: H, Camila: G | Oscar: R, Clara: S<br>Pedro: G, Camila: H | Andy: S, Marisa: R<br>Teena: H, Juan: G | Andy: R, Marisa: S<br>Teena: G, Juan: H |
| Taken audience/ intellectual roles (C: challenger, CL: clarifier, F: facilitator H: hypothesizer N: negotiator, S: summarizer) | Oscar: CL, H, S<br>Clara: H<br>Pedro: none<br>Camila: none | Oscar: CL, H, N, S<br>Clara: C, F, H, N<br>Pedro: CL, S<br>Camila: F, S | Andy: C, CL, H, S<br>Marisa: F, S<br>Teena: C, CL<br>Juan: C, H | Andy: C, CL, F, H, S<br>Marisa: C, CL, F, H, S<br>Teena: CL, N, S<br>Juan: H, S |
| Addressed participation norms (frequency) | Talk aloud (2) | Listen to each other (2)<br>Talk aloud (1)<br>Call others to help you (1) | Talk aloud (1) | Listen to each other (4)<br>Talk aloud (2)<br>Call others to help you (1)<br>Hold for a minute (1)<br>Talk to us, not just one member (1) |

| | | | | |
|---|---|---|---|---|
| Addressed argumentation norms (frequency) | Like scientists (1) | Like scientists (1)<br>Feel free to have other opinions (1)<br>Back up your claim with evidence (2) | Like scientists (1) | Like scientists (2)<br>Back up your claim with evidence (1)<br>Convince others of your opinions (1) |
| # of arguments | 0 | 2 | 0 | 3 |
| # of arguments with warrants | 0 | 1 | 0 | 1 |
| # of arguments with rebuttals | 0 | 2 | 0 | 2 |
| Power dynamic | Oscar is a dominant member, a main decision maker, and a task performer. | Clara increased her power as a challenger and facilitator. | Andy and Juan are main decision makers and performers. | Marisa and Teena's power increased a lot. With equal power, this group seems to have more arguments. |

Let us look at the following example. Ms. Green asked the following question, and had the group members discuss it: what will happen to two magnets if the space between the two magnets is increased?

The second week 10/06/09
Oscar : (He is counting the numbers of washers on the table, and is looking at the group's worksheet.)
Clara: Camila, do you know what will happen? (She asked the question of Camila, and looked at Oscar.)
Camila: (She does not say anything back to Clara, and turns to Pedro.)
Pedro: Think, think, think!
Ms.Green: Has any group come up with an idea about what will happen? Oscar?
Oscar: It gets weaker.
Teacher: What gets weaker? Clara, can you add some comments to Oscar's?
Clara: (She looks at Oscar. But Oscar does not say anything and looks atMs.Green.)
Ms.Green: Oscar, did your group discuss this?
Oscar (He does not answer the question, and he continues what he just mentioned.) If I put one, it is still strong. But if I put two, it gets weaker. The magnetic force is then weaker.

As seen above, Oscar, a fourth-grade male student, seemed to know or had an idea about the teacher's question, but he did not discuss it with the others. Even when Ms. Green asked Clara to add some comments, and she seemed to want to ask for help from Oscar (although she did not explicitly ask for help), he did not respond to Clara, and answered the question by himself.

In this group (Group 1), there was no significant discussion among the group members for the first three weeks. When there was a question or mission given to the group, Oscar made most of the decisions by himself, and conducted most experiments, even though there were roles assigned by the teacher, such as starter, gather, helper, and recorder. While he was not very talkative, he seemed to hold a dominant position in this group because he took on the roles of the sole decision maker and the main task performer. Oscar usually provided a claim but often without backing it up. Of the other members, Clara, a fourth-grade student who made improvements in participation, did not contribute to the discussion that occurred during this time. Pedro, and Camila, both third-graders, did not make additional contributions after Oscar's claim.

The other group (Group 2) consisted of Juan, a fourth-grade male student, Teena, a fourth-grade female student new to the class, Andy, a third-grade male student, and Marisa, a third-grade female student also new to the class. The girls are newcomers in this school. Juan and Andy talked to each other, answered questions together, and did experiments. While Marisa often provided her ideas, especially when she was assigned as a starter (who is supposed to explain the goal for the experiment), the two boys did not really respond to her ideas.

The second week 10/07/09
Marisa: How thick is different. Magnetic force is different because how thick the desk is and twenty pieces of paper are different.
Andy: Doesn't really matter. Go get the compass.
Marisa: Doesn't it matter how thick it is?
Andy: It doesn't matter.
Marisa: Fine. It doesn't matter.

Now look at the following two examples of the groups that occurred in the sixth week. The following discussion happened in Group 1 after the students generated their graphs based on their T charts: Oscar and Clara talked about whether they wanted to finish the graphs so that they could present them or just show the class the T chart showing the number of washers used to separate two magnets.

The sixth week 10/28/09
Oscar: So, you said that graphs are better. *Why do you think* that a graph is better?
Clara: Graphs told us information.
Oscar: But it is the same info.
Clara: No. It's not. This one (T chart) tells like numbers, how much it is, and the graph shows, the graph shows

| | |
|---|---|
| | shapes, and lines like. |
| Camila: | So we just want to show two lines? |
| Ms.Green: | (Ms.Green was listening to Oscar and Clara talking.) Can you see a pattern from here? (Pointing to the T chart) |
| Oscar and Clara: | No. |
| Ms.Green: | Can you see a pattern from here? |
| Oscar and Clara: | Yes. |
| Oscar: | I see. We cannot remember information from the T chart, but we can see and remember from the graphs. I like your idea. Let's just finish the graphs. I'll get stickers so we can finish. |

In this dialogue above, Oscar conformed to the norm, asking a 'why do you think' question. When Clara claimed that graphs told us information, Oscar disagreed and provided a rebuttal that it is the same information. Clara disagreed with his claim again, and provided a further explanation of her claim, why she thought that T charts and graphs are different. Although Clara did not fully support her ideas, both Oscar and Clara understood the difference between the two when the teacher provided a hint, and Oscar accepted Clara's opinion at this time. In addition, a noticeable difference found is Oscar's use of 'we' as the subject. In the first weeks' example, Oscar tended to use "I" whenever he talked. The use of 'we' seems to reflect Oscar's newly established group membership.

Let us look at the example of Group 2. This group conducted an experiment regarding how many washers are necessary to separate two magnets. The group's members talked about whether they needed to apply one washer at a time or more than one. Marisa argued that putting one at a time was a more accurate method, and Andy argued against her, because he thought that it could waste time. While he argued that they might need to put one at a time at the last measurements, Marisa disagreed with him because it could be difficult to figure out which would be the last measurement if they applied multiple washers.

| | |
|---|---|
| The sixth week | 10/26/09 |
| Marisa: | If somebody put five at a time, maybe the balance is five, but maybe the balance is two and if you put five, then maybe you need to pick some out, more in to see find balance, then it takes much longer than putting in one at a time. |
| Andy: | I disagree. Because when you put it in there, it doesn't matter how many you put in as long as you are going to put. Whether you put two or one, it doesn't matter until last time you put. So you put five at a time. |
| Marisa: | I don't understand. See we are doing like, by two, and then broke. And it can be seventeen or eighteen. It was seventeen? Or eighteen? Then you didn't quite know which one was. |
| Andy: | Look. If it breaks, then just go back to the last one. Then you need to put one at a time. Just do last time, and add one at a time. |
| Marisa: | One more what? |
| Andy: | Because it has to be one for the last time. But not for other times. It wastes time. |
| Marisa: | What if we broke the seventeen, but you put two? So it can't to make it, actually it wasn't seventeen, you don't know. |
| Andy: | But you know that it's not sixteen if you put two at a time. It is seventeen or eighteen. Right? |
| Marisa: | Yeah, I understand what you mean. But it is harder than putting just one at a time, then you may get the block. You know it just not accurate. |

A clear difference between the first week discussion and this week's is Andy's way of talking. While he did not explain why thickness did not matter in the example from the first week, now he explained in much more detail. Marisa's behavior also differs from that of previous weeks. In the first week, she said, "Fine." In the sixth week, she said, "I don't understand," and elaborated her claim. Although these two students did not reach a consensus, the way that they talked to each other has improved.

## Concluding Remarks

From the findings above, while the establishing of norms seems to work to some extent to encourage students' participation and argumentation, it is difficult to make a generalization that norm establishment can make every single student in the classroom participate more, and argue more. There are still silent students. However, for those who made improvements in whole classroom discussion such as Clara and Marisa (showed great improvement in their small group discussion), their participation seemed to enable the group to have more discussions. This indicates that the establishment of norms, guided by the teacher's discursive practice, improved the distribution of participation.

The teacher, Ms. Green, highlighted the norm "listen to each other" as a way to come up with new related norms, to interpret or extend the meaning of the norm through the negotiation process. Using this norm, students became more likely to monitor each other's thinking and ask about their reasoning to back up their claims. In other words, the students actively took audience roles. Taking these audience roles, in turn, seemed to help the students to take more intellectual roles because asking questions such as what do you think or why do think often became the same returning questions, what do YOU think and why do YOU think.

Hence, the findings suggest that paying more attention to participatory norms and roles may help students to appropriate argumentation norms and intellectual norms, and thus encourage students to have more scientific argumentation. While we often think that different opinions or disagreements are generated only from cognitive conflicts, which lead to scientific discussion, they could be triggered by social ones linked to cognitive ones. From this perspective, dynamic power relationships caused by social and cognitive conflicts may be encouraged by asking students to take on audience and intellectual roles.

# Interactional Arrangements for Learning about Science in Early Childhood: A Case Study Across Preschool and Home Contexts

Siri Mehus, University of Washington, smehus@u.washington.edu
Reed Stevens, Northwestern University, reed.stevens@northwestern.edu
Linda Grigholm, University of Washington, lgrigholm@gmail.com

**Abstract:** In this case study, we compare activities experienced by one 5-year old child in her home and her preschool in terms of how they afford scientific exploration and inquiry. We focus specifically on two types of interactional configuration: the first is an adult-guided mode of interaction in which a parent closely monitors the child's attention and action and accordingly orchestrates the emergence of opportunities for scientific observation, exploration and knowledge construction; the other is a type of peer play that occurs frequently at preschool, in which children collaboratively explore the physical properties of the world around them. Through close microanalysis we compare these activities as *learning arrangements* (Stevens, Satwicz & McCarthy, 2008), considering how they allow for or constrain children's entry into scientific activities, as well as the particular opportunities for learning they may afford.

## Introduction

In this paper, we compare aspects of the home and preschool contexts in terms of how they afford particular types of scientific exploration and inquiry in early childhood. Rather than surveying the entire range of activities in which children may engage in each of these environments, we focus on two types of interactional configuration which map onto these contexts—by this we mean not just that we have found them occurring in one of these settings, but rather that there are particular aspects of the environments that make them more likely to occur in one than the other. The first is an adult-guided mode of interaction in which the adult closely monitors the child's attention and action and accordingly orchestrates the emergence of opportunities for scientific observation, exploration and knowledge construction. Like others (e.g., Goodwin, 2007; Crowley & Jacobs, 2002), we have observed this occurring in family interactions. The other configuration is a type of peer interaction that occurs frequently within "free-play" periods at preschool. Often in the service of other goals, which may be fluid and loosely defined, children collaboratively explore the physical properties of the world around them—making observations, developing hypotheses, and even conducting informal experiments in short-lived social groupings of varying sizes. In both contexts, the type of science learning we focus on in this paper might be termed emergent or serendipitous (e.g., Stevens, 2000; Bell, et al., 2009) in that it occurs in the process of everyday living and playing with others, rather than within events that are explicitly designed for science learning.

In the pages that follow we analyze several interactions engaged in by one 5-year-old girl in our study. These include home interactions in which the child and her parents discuss the plants growing in their garden and the child's techniques for watering them, as well as preschool-based peer interactions such as one in which the child and her peers use a tape-measure to calculate the length of various objects in their classroom and then discover how to use it as a projectile. Through close microanalysis we compare these activities as *learning arrangements* (Stevens, Satwicz & McCarthy, 2008), considering how they allow for or constrain children's entry into scientific activities, as well as the particular opportunities for learning they may afford.

## Background

This study responds to previous calls for research investigating learning across school and out-of-school experiences (Stevens et al, 2005). While much educational research has focused on children's school experience at the expense of what happens in the home, research on informal science learning in early childhood has focused primarily on the family. Such research has shown that children have opportunities to learn scientific concepts in everyday life, and that adults in their lives have practices for supporting them in this process (e.g., Tizard & Hughes, 1984; Callanan & Oakes, 1992). Other researchers have pointed to the value of learning from peers in early childhood (Rogoff, 1990; Williams, 2001). Our observations suggest that informal play activities create a rich interactional environment for such peer learning. Interestingly, a primary site for such informal peer interactions seems to be the quasi-formal context of the preschool.

While educational research on school-age children may tend to focus on the classroom more than the home, research on learning and development in early childhood has tended to focus on the home, and particularly the dyadic interactions between parents and children that occur there. This tendency may be partly due to dominant cultural notions about child-rearing in the American middle class, but has been compounded through the research methods usually employed to study interaction and development in early childhood (Ochs

& Schieffelin, 1984). Our ethnographic approach, on the other hand, allows us to examine both home and preschool settings in their own right to identify and examine the ways in which learning is occurring, which can then be compared with the other contexts of children's lives.

## Study Description

This paper reports on one piece of a larger study examining young children's learning (2-5 years old) as it occurs in the multiple environments of their everyday lives, environments which may differ markedly in the opportunities for participation and resources for learning they offer. By observing and recording young children's interactions in multiple contexts (such as preschool, home, and playgroups) and among different configurations of co-interactants (including peers, older and younger children, teachers and caregivers), we seek to capture the complexity and variety of the social environments in and through which young children learn.

The first phase of this study involved weekly video-recording in a childcare classroom for approximately five months. In addition, two of the children in the classroom were also observed and recorded in their home environments. All in all, approximately 98 hours of video were collected, digitized and logged. In a second phase of this study, we are video-recording in four rooms at two preschools for a total of nine months. In addition, out-of-school activities of eight children are being recorded.

In this paper we report on the first phase of the study, in which we observed and recorded activities in "Rocket Room," a kindergarten-readiness classroom (4-5 years old) in a nonprofit NAEYC-accredited childcare center. The center was located in a middle class neighborhood of a mid-sized Western city. There were 20 children in the Rocket Room, supervised by a lead teacher and an assistant teacher. Our observations took place in the mornings, during which time the children participated in free-play, breakfast, art activities, and circle time. We describe learning interactions experienced by Darcy, one of the focal children in the study, both in the preschool and her home environment. Darcy was 5 years old at the time of the study and had an 18-month old sister. Both Darcy and her sister attended the childcare center full time. Darcy's parents both worked in high-tech occupations.

We employ the method of video-based microanalysis of interaction (Stevens & Hall, 1998; see also Jordan & Henderson, 1995; Streeck & Mehus, 2005). Our moment-by-moment analysis allows us to demonstrate possibilities for learning and requirements for interaction in the activities in which children participate. This form of qualitative inquiry allows us to cautiously generalize our findings not to populations but rather to practices and activities based on principles derived from analyzing structures of social action.

## Analysis

### Parent-Guided Learning Interactions at Home

When video-recording children in home environments, we frequently captured interactions that were intensely mediated by parents. In the section that follows, we describe some such interactions that arguably could have relevance for the development of scientific skills and interest, and analyze the particular opportunities for learning they afford.

#### Key Characteristics of the Learning Arrangement

What do we mean by "parent-guided learning interactions"? These are events that may be planned in advance, but even if not they are organized for children's learning as they proceed. Within these activities, children's talk and actions are closely monitored by adults and frequently commented upon, usually praised. Children's actions and other aspects of the environment are frequently used as a starting point for elaboration and exploration, within which there are clear (and often explicit) attempts to guide children's perception toward particular aspects of the scene and to provide labels for what children are experiencing (Stevens & Hall, 1998). The segment below exemplifies several of these features. This occurs in the back yard of Darcy's home. Darcy is splashing in an inflatable swimming pool while her mother and father watch. Her mother gets up to take a look at their garden, and calls Darcy's attention to what she sees.

Table 1: Data Excerpt

| | | |
|---|---|---|
| 1 | Mom: | Here you know what (.) Darce? It looks like the (.) the: uh sweet peas (over here) |
| 2 | | need water. (That soil still) looks dry: doesn't it. |
| 3 | | *((Darcy starts watering where her mom pointed))* |
| 4 | Mom: | Do you need some help with that? *((gets up))* |
| 5 | | It's probably on the far side so it's kinda (.) kinda rough huh. |
| 6 | Mom: | You want me [to |
| 7 | Darcy: | [I can smell the sweet peas. |
| 8 | Mom: | You can smell the sweet peas? What do they smell like. |
| 9 | | Do they smell (.) sweet? |
| 10 | Darcy: | *((grunts))* |
| 11 | Mom: | Woah. (.) |
| | | *((Darcy is rocking watering can back and forth))* |

| | | |
|---|---|---|
| 12 | | That's kinda clever. |
| | | *((Darcy steps up onto side of bed))* |
| 13 | Mom: | You're like (.) rocket-shipping. |
| | | *((Darcy reaches out with watering can over bed, wobbles))* |
| 14 | | Oh there you go. |
| 15 | | Here I'll hang on to you: *((Mom holds Darcy around torso. Darcy holds watering can))* |
| 16 | Mom: | Hang on to you: (.) |
| 17 | | That's kinda heavy huh. *((takes watering can))* |
| 18 | | °Here you go. ° |
| 19 | | (can I) do these? |
| 20 | Darcy: | Mm hm. *((turns away from garden, towards pool))* |
| 21 | | *((Darcy gets into pool, Mom continues watering))* |
| | | … [01:10 exchange between parents and researcher not transcribed] |
| 22 | Mom: | Darcy! (.) Did you no:tice? |
| 23 | Dad: | Oh there's some sprouts coming up? |
| 24 | Mom: | Check it ou::t! |
| 25 | | Holy cow that's fa:st. We just put this in last week. |
| 26 | | Look! |
| 27 | | What are tho::se? |
| 28 | Darcy: | Sprouts. |
| 29 | Mom: | What kinda sprouts. |
| 30 | Darcy: | Sunflower sprouts |
| 31 | Mom: | =sunflower sprouts. [Holy cow::! |
| 32 | Dad: | [°Sunflower sprou::ts.° |
| 33 | Darcy: | I've done (.) some (.) very good watering |
| 34 | Mom: | =You've done some very good watering. |
| 35 | | That is instant gratification. (.) [Right there. |
| 36 | Dad: | [Oh. Educational moment. |
| 37 | Researcher: | Yeah. |

This segment exemplifies several of the features that characterize adult-child learning interactions in the homes that we studied. First, these *events are managed for children's learning*. In some cases, they are pre-planned, involving the preparation of materials and the use of predesignated roles and actions. Even when they are not, the activities are organized by adults in the moment, with slots for children's participation being provided by the parents. While the particular event above was not planned at the level of a classroom lesson, it was purposefully brought into being for educational purposes by the parents. Darcy's mother told us that they decided to plant a garden (their first) specifically for Darcy's benefit (as a means to "inspire little Darcy about growing things," as well as potentially get her more interested in eating vegetables). Within the moment, Darcy's mother enlists her participation in a familiar interactional routine. For examples, in lines 27-31, Darcy's mother engages her in a school-like initiation-response sequence in which the mother is asking Darcy "known-answer" questions (cf. Mehan, 1979; Cazden, 1988).

Within these events, *children's actions and talk are closely monitored*, explicitly commented on, often praised, and elaborated upon. For instance, in line 12 Darcy's mother verbally calls attention to Darcy's action and labels it as "kinda clever," further describing it in line 13 as being "like rocket-shipping". *Physical phenomena in the environment are also noted and commented upon*, even used as opportunities for "occasioned knowledge exploration" (Goodwin, 2007). We see this in lines 1-3 above, when Darcy's mother first calls her attention to the garden's need for water, as well as in lines 22-34, when she discovers new growth and subsequently guides Darcy in specifying what they are seeing. Parents orient to these as potentially educational moments (though not usually as explicitly as does Darcy's father in line 36 above).

## Opportunities for Learning in Parent-Guided Interactions

There are several types of learning opportunities that children encounter in these types of interaction. Many of them are provided by parents through talk. For instance, a prominent source of potential learning in the interaction above comes from the mothers' directing of her daughter's attention and guiding or disciplining of her perception (e.g., Stevens & Hall, 1998). We see this in lines 1-2, in which Darcy's mother not only calls her attention to a specific aspect of the environment, but guides her in how to *see* it—i.e., to recognize the dirt as soil that "looks dry."

We can also see this in the way Darcy's mother calls attention to Darcy's actions. For example, in this exchange Darcy's mother verbally takes notice of an action being performed by the child and frames this action as being both purposeful and ingenious. In Line 12 an explicit positive assessment is made, linked to the child's action with the deictic pronoun "that's." This assessment is followed by elaboration of *why* the child's action seems like a good idea, in the form of a description of what the child is achieving through her action (line 13). At that moment Darcy is standing on the edge of the garden bed and rocking the watering can back and forth, which causes the water to slosh out, reaching further into the bed than it would if she were simply pouring it out. Darcy's mother's "rocket-ship" analogy conveys the notion that through her action, Darcy is causing something to be propelled through the air, "cleverly" solving the problem of how to water the far side of the garden. This represents a compelling example of the ways in which adults can frame aspects of the world for children, in this case quite possibly shaping a child's retrospective understanding of her own action.

Darcy's mother also engages Darcy's participation in these labeling activities. For instance, in line 27 Darcy's mother elicits a label from Darcy by asking "What are those?", and then requests specification in line 29 with "what kinda sprouts?". As Darcy participates in these activities, she potentially learns ways of seeing, categorizing and labeling the world around her—as well as ways of thinking about and valuing her own actions.

Finally, it should be noted that Darcy takes advantage of this interactional arrangement to initiate and further her own learning experiences. Twice she issues declarative statements that draw responses from her mother. For instance, in line 7, Darcy asserts that she can smell the sweet peas. Her mother responds with the question "what do they smell like?" then proposes a candidate answer: "Do they smell sweet?" In line 33, in response to her mother's enthusiastic pointing out of the new sprouts, Darcy comments that she (Darcy) has "done some very good watering." The timing of Darcy's assertion suggests that she is making a connection between the sprouting of the sunflower seeds and her previous watering actions—an idea that may have been planted (so to speak) in previous interactions with adults. By making this claim in the context of an interaction with her mother, Darcy makes it available for confirmation, which her mother provides unambiguously in the next line.

### Discussion: Adult-Child Interaction in the Home as Learning Arrangement

The participation framework of adult-child talk in the home makes for excellent learning opportunities for children: parents guide children's attention, deliver comments and questions that are tightly coupled with children's activities, and design and orchestrate interactions with children's learning in mind. Children's initiations of learning opportunities are taken up readily and enthusiastically. The interactional demands on children are low: adults do much work to invite children's participation and ensure that these activities work as learning arrangements. These do not represent the totality of children's interactions at home; there are times when the children do not have their parents' full attention. Even when they do, parents are not always able to take advantage of every learning opportunity. It should also be noted that other types of interaction that occur in this home (and other homes) may offer different types of learning opportunities (such as guided participation in adult activity, intent observation of adult or peer activity, peer learning in sibling play, to name only a few). We focus on this type both because we observed it frequently, and because particular features of the interaction format make it rich with learning opportunities, as described above.

We propose that structural and cultural aspects of the home setting make these types of interaction more likely to occur there than in preschool, most simply the numbers of adults and children. In preschool, the ratio of children to adults means that teachers must frequently shift attention in order to monitor and care for everyone. While adults in the home may also have other demands on their attention, they are much more likely to be able to carry out extended interactions in which they maintain focus on the talk and action of an individual child. This does not mean that similar interactions cannot occur in preschool settings, and in fact they do. It does suggest, however, that the unique features of the preschool environment may give rise to *other* interaction patterns, which can in turn be analyzed for the ways in which they allow science learning to occur.

## Learning through Peer Interaction in the Preschool Classroom

In this section, by way of comparison, we analyze the learning opportunities inherent in an interactional arrangement that we found in our preschool observations and did not find to occur in home—these are small group activities, organized and guided by children. Though we do not preclude the possibility that this type of activity might occur in other contexts, there are certain features of this environment that make it possible. For instance, during free-play periods at school, teachers rarely spend long periods of time with a single child or group of children. This means that while they do set up activities for children and step in to mediate children's interactions, teachers infrequently engage in the intense moment-to-moment guidance typical of the homes we observed. Rather than having interaction initiated and maintained for them, children engage one another.

### Key Characteristics of the Learning Arrangement

The type of activity analyzed in this section is characterized by (1) including 3 or more children (more children may come in and out of the activity), (2) being initiated, guided and maintained by the children, rather than by adults, (3) enduring over a relatively long stretch of time (for example, the measuring activity analyzed in this paper endured for nearly 45 minutes in total), (4) being organized towards some purpose (although individual goals may not be shared by all participants and may shift during the activity). For the purposes of this paper, we analyze one extended activity in which all four characteristics are present, as representative of this type of interaction format. Though the activity we describe is not explicitly undertaken as a "science" or "math" activity, there are opportunities for scientific and mathematical exploration and discovery available within it.

## Measuring Tape

The activity we analyze in this section occurs over an extended period of time during which a core group of three children, joined occasionally by other children in the room, play with a tape measure that one of the children has brought from home. It is free-play time in the preschool classroom. One of the children, Anna, gets up from a table and shows a drawing to one of the teachers (Nancy). She then brings it over to her cubbie, puts it in, and pulls out a tape measure. "I brought this from home:::!" she says enthusiastically to an entering parent. Anna then brings the tape measure over to Nancy who compliments her on the idea to bring a tape measure from home and asks her what she wants to measure. Anna begins to measure a bookshelf. Though Nancy soon becomes occupied with other children, Anna is able to regain her attention long enough to get some help with the measuring task she has begun. Specifically, Nancy provides instruction in reading numbers from the tape ("A three and a seven is thirty-seven.") and with the unit of measurement ("An inch is about that long," gesturing with thumb and forefinger). She also provides a different type of guidance: in the form of a question, she suggests to Anna ways of linking her current measuring activity with adult professional practices ("Are you a carpenter? A mathematician? A scientist?"). After this point, the children's measuring activity proceeds with no significant input from any of the adults in the room.

Perhaps taking her cue from Nancy's question, Anna then initiates a game with some other children, in which Anna plays the role of carpenter. That game is short-lived, and when it ends Anna and one of the children (Mira) begin stretching out the measuring tape and letting it go so it retracts into the case. They are then joined by one of the girls who will make up the core group: Susan. Susan suggests that they measure people, and though Anna initially resists this idea, when we find them again (after a one minute gap in which they are out of camera range) Susan is measuring Anna's height, while Mira watches. Susan struggles with the challenge of holding the tape at the floor with one hand and extending the to Anna's head with the other, and then being able to see the numbers at the top.

It is at this point that Darcy (one of our focal children and the third girl forming the core group) joins them. She approaches the two girls, takes the end of the measuring tape, stretches it to the top of Anna's head, and holds it there. This allows the girls to move to the next step of the measuring task, which is to read the number. Anna and Susan then measure Darcy, and the three then move on to measuring a large cardboard tree. The three girls continue to work together as a team, measuring objects all over the preschool classroom.

For most of this period, they measure pre-existing objects, such as tables, the refrigerator, chairs, bookshelves, the elevated stage, room dividers, and a large block. During this time, they negotiate a set of roles and a turn-taking system. The set of roles evolves and shifts over the course of the activity, however, some core "jobs" emerge, such as holding (and hooking) the tab end of the tape measure; extending the tape measure case; looking at, reading, and shouting out the measurements (numbers); and being the one to yell "Let go!"; and releasing the tape measure case (so that it springs back to the hooked tab end as the tape retracts into the case).

In the last minutes of the activity, the girls begin to put blocks together to construct a low wall to measure. Though it may not be appropriate to attribute an overall purpose to the activity – as purposes surely shift locally and vary between individuals – a concern expressed explicitly and manifested in the girls' actions is to add a block between each measuring without reaching the point where the tape measure will no longer extend to the end of the block line. When the block line gets all the way to a low stage on one side of the room, they discover that when they let the tape case go it will slide along the top of the block line and then jump up onto the stage. This effect is greeted with celebratory whoops and jumps and repeated several times.

There is then an interruption of the dominant activity while the girls join some of their classmates in a different activity with one of the teachers. When the girls leave the line of blocks, other children immediately approach it and begin to appropriate the blocks for their own purposes. The girls enlist the help of a teacher (Nancy) in re-establishing the exclusive use of the block line for measuring activities. One of the children, Nathaniel, sticks around and gains access to the group by assigning himself a role ("I'm the guy who watches") in the activity. It is at this point that our focal child, Darcy, exits the group to engage in another activity.

## Learning Opportunities

Over the course of the period the three girls play with the measuring tape, there are multiple opportunities for them to learn from (and teach) each other. We focus here on the experience of our focal child, Darcy, and find types of learning afforded by the activity can be analytically separated into two rough categories. The first is more directly related to the activity of measuring as ordinarily carried out and relates to a set of concepts that include number identification, dimension (height vs. length), and quantitative comparison (testing whether one thing is longer or shorter than another thing). The other category is not directly tied to the activity of measuring, but rather to the physical affordances and constraints of the tape measure as an object. This set includes learning about the limitations of the material – both in terms of its length (the tape can only be stretched a certain distance) and in terms of its strength (the tape will collapse if it is stretched too far without any external support). Particularly interesting for Darcy and the other girls is a particular affordance of the tape measure tool: that the tape automatically retracts into the case when released, and that this mechanism will also cause the case end to spring toward the tape end when that end is held (or hooked on something). While the learning in the first category can be related by a knowledgeable observer to mathematics (including geometry), the second can be related primarily to physics and engineering.

Over the course of the activity we do not necessarily see a clear progression towards mastery of particular concepts or skills. However, we do see the children engaging in negotiation and discussion about how to do things, trying out terminology with one another, making discoveries, issuing predictions about the behavior of physical objects (informal hypotheses), and watching to see if their predictions are borne out.

*Learning about measuring*: One of the basic sub-tasks involved in measuring is *identifying and reading the numeral*s printed on the tape. Anna receives direct instruction in this from the teacher (as described above). After Darcy joins the group, the girls continue to negotiate how do to this. In the excerpt below, the girls are measuring their sixth object together, and still working out how to read numbers from the tape. Also under discussion and available for learning are issues of *dimension*; i.e., that there are different terms to describe measurements made in different directions (lines 13 and 15), and that this is a distinction worth noting.

Table 2: Data Excerpt

| | | |
|---|---|---|
| 1 | Susan: | *((jumps off stage and bounces over to Anna))* How about the ta::ble. |
| 2 | Anna: | (oew:::) |
| 3 | | *((girls run off-screen))* |
| 4 | Anna: | I know. |
| 5 | | How about we measure this table. |
| 6 | Susan: | Okay. |
| 7 | Anna: | Okay. so. |
| 8 | | Um Susan [we're measuring to thi::s |
| 9 | (Darcy:) | [(we're measuring the table) |
| 10 | Susan: | Okay. |
| 11 | Anna: | You know::? |
| 12 | | Okay um |
| 13 | Susan: | You mean you're measuring how long it is. |
| 14 | Anna: | Yes. |
| 15 | Susan: | Not how tall it is. |
| 16 | Anna: | Yeah. |
| 17 | Susan: | Hey. When it (springs) back it might (.) pinch your fingers. |
| 18 | Darcy: | Yeah. I know that. |
| 19 | Anna: | =How many [is it? |
| 20 | (Susan:) | [(so if it falls (.) back it might) |
| 21 | Darcy: | It's seventy-five feet. |
| 22 | Susan: | Lemme see! Actually (.) it's (.) fifty-seven feet. |
| 23 | Anna: | OKAY:: [(         ) |
| 24 | Susan: | [Actually actually it's (.) seventy-five feet. |
| 25 | Anna: | Okay. STA:ND BACK EVERYONE: |
| 26 | | *((sound of tape measure case scooting over table and dropping to floor))* |
| 27 | Girl: | YES! |
| 28 | Anna: | How about the fridge? |
| 29 | Susan: | Yeah we'll mea:sure the fri::dge! |

*Learning about the constraints and affordances of the object*: Over the course of their play activity, the girls encounter and explore various properties of the tape measure itself. For instance, they (particularly Anna) display awareness that the tape is limited in length, and concern themselves with limiting the length of their block wall accordingly. Earlier on, they discover that the strength, or the ability of the tape measure to support its own weight when extended, is also limited – e.g., when measuring a tall cardboard tree, the measuring tape bends over on itself and Anna yells, "It's too high!"). However, it is a curious affordance of the tool that captures their interest the most. That is the self-propelling action of the tape measure – that the tape end automatically retracts into the case, but also the case end can spring back to the tabbed end if the tabbed end is held in place (see lines 17-18 and 25-27 above).

That this is a learning experience for Darcy is evidenced at a later moment. The girls are measuring a bookcase by placing the tape measure case on the floor and extending the tape towards the top of the bookcase. When Anna lets go of the case, which is resting on the floor, Darcy abruptly pulls her hand back and jumps away from the tabbed end. Evidently, she expects the case to spring up towards the tabbed end (though it does not because it is too heavy). Darcy's reaction represents learning in progress. Her earlier experiences with the tape measure have led her to form the expectation that the case will always spring towards the tabbed end when released. It is fairly certain that she would not have expected a metal case to rise into the air if she had not had this experience with the tape measure. That the tape measure does not do what she expects provides an opportunity for Darcy to revise her conceptualization of the properties of this object, potentially gaining a more complex (though unarticulated) understanding of the interaction between gravity and the pull of the spring retracting the tape measure into the case.

Much later, after the girls have created a wall of blocks for measuring, the girls discover that when the tape measure is released so that it runs along the block wall, it will act as a projectile and pop up onto the stage (beyond the spot at which the end was hooked). The first time this happens, the girls react with excitement and try it again. The second try is less successful and meets with less enthusiasm. The third try is presented below.

Table 3: Data Excerpt

| | | |
|---|---|---|
| 1 | Anna: | OKAY. Now:::: *((nasal))* I wanna do (.) as many ( ) *((picks up blue block and puts at end of wall, looks back to Darcy* |
| 2 | | *and Susan))* |
| 3 | | *((Darcy stretches measuring tape along the length of the wall))* |
| 4 | Anna: | *((nods)) ((puts hands on hips))* I think (it'll) stop soon. Because it does stop. |
| 5 | | *((Darcy gets to end of block wall--back end of tape measure is lined up with end of wall))* |
| 6 | Anna: | Okay. *((looks at end of tape measure, looks at Darcy))* |
| 7 | (Darcy:) | Okay? |
| 8 | Susan: | Okay. |
| 9 | | *((Both girls look at Susan, holding tab end))* |
| 10 | Girl: | (All right. Let's go. Looks goo::d.) |
| 11 | | *((Susan lets go of hooked end and moves away from block wall.))* |
| 12 | Anna: | Okay [( ) |
| 13 | | [*((Darcy lets go of tape measure))* |
| 14 | | *((tape measure pops up onto stage))* |
| 15 | Anna: | Waaa[::oh *((runs toward tape measure))* |
| 16 | Susan: | [Wu Hoo::= |
| 17 | Darcy: | =Wuhoh *((jumps, walks to end of wall))* |
| 18 | | *((Susan jumps, walks toward group at table.))* |
| 19 | Anna: | Okay 'm gonna I'm gonna |
| 20 | | *((Susan moves chair))* |
| 21 | Anna: | *((calling out))* Okay. Put ano- another block the::re. |

Four times in all the girls let go of tape measure and it pops onto the stage. The girls display excitement about this when it happens (in the form of whoops, jumps, and screams). They do not make verbal reference to it. This activity is in some ways like an experiment. For instance, as she lets go of the case on the last try, Anna says, "let's see:::," which suggests that she is orienting to this as trying something out. It is also experiment-like in that it consists of multiple repetitions of a procedure with slight modifications each time. These multiple repetitions, in which the girls take different roles, allow them to see the phenomenon from different perspectives and observe which aspects remain stable and which aspects change. However, there is no evidence that the modifications undertaken are designed to produce an effect, especially not of making the tape measure jump when released. To the extent that there is a particular purpose indicated, it is to add blocks of the right number and length such that the tape measure will still extend to the end of the block wall (lines 1, 4, 19-21). Otherwise, the majority of the talk surrounding this activity is about the turn-taking process itself (e.g., "It's my turn.") and the appropriate performance of roles (e.g., "No. You have to say 'let go'!").

## Discussion: Peer-regulated Group Activity as Learning Arrangement

We can recognize several advantages of this form of interaction as a learning arrangement for young children. First, there appears to be strong social motivation for participating in these activities. Even when their participation is not solicited nor reliably rewarded by other children—as it tends to be by parents in the home environment—children actively seek out and work hard to gain entrance into these activities. We might say that the activities exhibit something like a gravitational pull on children. Furthermore, these activities afford different types of learning opportunities. Children negotiate with each other in guiding and regulating the activity themselves—as such they have increased opportunity to both exercise agency and to develop skills at collaborating with others. Children can position themselves as both learners and teachers in such interaction. The lack of stable and explicit goal orientation gives children a great deal of freedom to explore the aspects of a phenomenon that most interest them (Rogoff, 1990). These peer-organized learning arrangements also seem to offer enhanced opportunities for embodied participation and experiential learning, as children move about the rooms with little constraint, drawing into their activity a variety of different types of artifacts and structures.

There also are disadvantages when compared with adult-mediated interaction. These have to do with the interactional challenges of the activity and the lack of adult support in developing an activity in the direction of disciplinary knowledge. In child-regulated peer group activity the interactional demands fall squarely on the shoulders of the children themselves. Our analysis of this activity shows that gaining entrance is itself a difficult maneuver—while one our focal children succeeds, the other attempts to participate but is unsuccessful (even reprimanded for her attempt by the core trio of girls). Similarly, it is the children who must maintain the activity and direct it in fruitful and enjoyable directions. Young children may not always be able to do this effectively, which may be why such activities rarely last as long as the one we analyze in this paper.

Children also do not experience the same level of interactional support for learning in peer activities as they do in parent-guided activities. Unlike parents, peers may not monitor for opportunities for teaching and learning. To the extent that children's activities are monitored, peers are more likely to see shortcomings and provide correction than recognize innovation or respond with elaboration. These qualities of peer play do offer opportunities to develop skills at argumentation and negotiation--part of the collaborative practice of science.

Another possibility is that rich opportunities for learning may occur but not get developed in the direction of disciplinary knowledge. For instance, in the block-measuring activities described above there is no movement toward investigation of why the tape measure flies. Over the course of the repeated tries girls encounter 'information' about the physical workings of the tool; however, they do not seem to engage in purposeful or principled experimentation in order to find out more. Without the involvement of knowledgeable adults or peers there is little opportunity to link this activity to disciplinary principles or practices.

## Conclusion

The distinction between formal and informal learning takes on a peculiar status when applied to the lives of very young children. Though formal education reaches into the mostly informal lives of young children in many ways, "school" does not neatly map onto "formal" and "home" does not neatly map onto "informal". In fact, due to the particular social configurations of preschools (versus middle class homes), they seem to offer *more* opportunity for the highly informal learning arrangement of uninterrupted, child-organized group play.

In light of the affordances and limitations of informal peer-group interaction for science learning discussed above, it remains to be determined exactly what role participation in this type of activity might play in a trajectory of 'becoming a scientist' or even in building the disciplinary knowledge needed to succeed in science learning later in school. Our analysis supports pedagogical practices that take advantage of the opportunities for peer learning afforded by the preschool classroom setting by allowing children the freedom to self-organize into groups and pursue activities of their choice. On the other hand, our analysis also suggests that strategic adult support, provided at key moments in children's peer play, could provide disciplinary connections and promote deeper learning of a kind that may not happen when children play together without intervention.

**Abstract:** Designing effective technology-based learning environments is challenging. Designing effective technology-based learning environments to facilitate learning about complex knowledge domains is more challenging. To a large extent, the key to the puzzle lies in identifying which scaffolding strategies are more effective; and under which conditions. In a simulation-based inquiry-learning environment, this controlled study investigated the effect of two promising scaffolding strategies; *question prompts* and *system dynamics model progressions*, on ninth-grade biology students' cognitive regulation and complex problem-solving skills. For simpler complex problems, findings suggested that both scaffolding strategies were equally effective. However, as the problems increased in complexity, system dynamics model progressions were significantly more effective for facilitating both cognitive regulation and complex problem-solving skills.

## Introduction

How can we effectively facilitate learning in complex knowledge domains such as science, technology, engineering, and mathematics (STEM)? This question led us to the study presented in this paper. Recent research on problem solving in complex knowledge domains illuminates a number of learning challenges due to the nature and structure of the real-life problems in these domains. For instance, ecology is a difficult subject matter for many students. Learning ecology calls for learning about the complex ecology systems. In other words, students should understand the dynamic interdependencies among different organisms and their environment. As such, a complex system involves a large number of interdependent variables and they are all connected with one another dynamically (Dörner, 1996). Prior research suggests that humans have significant difficulties in understanding complex systems, due to the challenges involved in building a mental representation of complex systems, predicting dynamics outcomes, monitoring the cause and effects of complex systems, and monitoring their own strategies of information processing. (Dörner, 1996; Dörner & Wearing, 1995; Funke, 1991).

Mental model theory provides a framework to understand the learning processes of complex systems, in which learners take the input from their learning environments and simulate the events in their mind to accommodate revised mental models (Rumel, Smolensky, McClelland & Hinton, 1986; Seel, 2001). While learning about complex systems, learners are required to construct and reconstruct their mental models, which (1) guide learners' comprehension of the systems, (2) allow them to explain the system states, and (3) allow them to predict the system behaviors (Greeno, 1989; Seel, 2006; Young, 1983).

Therefore, it is argued that simulation-based inquiry learning environments would help students in the inquiry processes, because they allow learners to visualize and investigate complex systems (de Jong & van Joolingen, 1998; Linn, Davis & Bell, 2004). In a simulated-based inquiry-learning environment, students are expected to discover dynamic relationships underlying a complex system through an iterative process of hypothesis generation, data collection, and data analysis. Indeed, simulation-based inquiry learning is gaining visibility, especially in the area of science education, as a way to address the challenges of complex learning (The National Research Council, 2000). Education researchers advocate simulation-based learning environments to foster scientific inquiry skills (Wilensky & Reisman, 2006). However, studies showed that many students have difficulties with simulation-based inquiry learning (Hogan & Thomas, 2001). In addition, the effectiveness of inquiry-based learning is debatable (de Jong & van Joolingen, 1998; Linn et al., 2004). Recent research suggests that low-level cognitive regulation skills are a major cause of failure in simulation-based inquiry learning (Lavioe & Good, 1998; Simmons & Lunetta, 1993; Schauble et al., 1991; Shute & Glaser, 1990).

Cognitive regulation, which refers to how individuals engage in a recursive process utilizing feedback mechanisms to direct and adjust their learning and problem-solving processes, is crucial for constructing mental model of the complex system to be learned (Azevedo, Guthrie & Seibert, 2004; Manlove, Lazonder & de Jong, 2006), especially when learners are lacking required domain knowledge (Pintrich, 2000). Thus, it is argued that simulation-based inquiry learning environments should include scaffolds to support students' cognitive regulation. This, in turn, would positively support students' inquiry processes starting from hypothesis generation to their interpretation of the findings.

A review of the literature reveals two quite different scaffolding strategies for cognitive regulation that can be ubiquitously embedded into simulation-based inquiry learning environments: (1) question prompts (Ge & Land, 2004); and (2) model progressions (White & Frederiksen, 1990). Providing question prompts to students yielded promising results in some studies (see Ge & Land, 2003); however, others did not yield such positive results (see Greene & Land, 2000; King, 1992). Similarly, model progression did not yield consistent effects on learning performance (Alessi, 1995; Quinn and Alessi, 1994; Rieber and Parmley, 1995). We argue that questions prompts and model progressions may enhance students' cognitive regulation skills, which, in turn, foster their learning of complex system; however, the complexity of the learning domain is a main factor determining the effectiveness of question prompts and model progressions as cognitive regulation scaffolds.

Despite its importance, however, there have been very few systematic studies on which of these strategies are more effective, under which conditions, in scaffolding students' cognitive regulation and learning about complex systems in a simulation-based inquiry-learning environment (Kirschner, Sweller, & Clark, 2006). Moreover, limited number of studies investigated the relationships between cognitive regulation and learning performance in complex systems while existing studies on other technology-based learning environments point out to mixed results.

The purpose of this study is to examine the effect of two promising technology mediated scaffolding strategies, *question prompts* and *model progression*, on ninth-grade students' cognitive regulation skill acquisition and learning about complex ecology systems. We hypothesize that task complexity is an important determinant for whether or not certain cognitive regulation scaffolding strategies are effective. This study seeks to replicate past findings and eliminate some confounding factors.

The reminder of our paper is organized as follows. The next section presents the details of the research study, the research questions, the design of the experiment and the data analysis methods. Then, results are presented. Finally, we conclude with a discussion of the implications of our study and provide suggestions for future research.

## The Present Study

The purpose of this study was to investigate the effects of (1) *question prompts (QP),*and (2) *system dynamics model progressions (MP)*, in scaffolding ninth-grade students' learning of a complex ecology system in a simulation-based inquiry-learning environment. In addition, this study aimed at examining the relationships between cognitive regulation, learning about complex systems, and task complexity. Thus, the following research questions were posed:

1. Does scaffolding with question prompts and system dynamics model progressions affect students' cognitive regulation in the process of developing solutions to problem scenarios ranging in their level of complexity?
2. How do task complexity influence the effectiveness of question prompts and system dynamic model progressions as cognitive regulation scaffolds to support students' learning about complex ecology system?

### Participants and Design

A rural high school in the Midwest of the United States was used as a testbed for this study. 251 ninth-grade biology students were randomly assigned to one of the ten classes. Out of these ten classes, five were randomly assigned to experimental (system dynamics model progression group) condition and five were randomly assigned to control (question prompts group) condition. Of the 219 students, from whom we received both consent and parental assent forms, 113 were in the experimental group and 106 were in the control group. There were 50.6% males and 49.4% females.

### Materials

*Food Chain* is a simulation-based inquiry-learning environment designed to support students while they carry out a sequence of activities that correspond to the steps in the scientific method. *Food Chain* incorporated always-available domain-specific knowledge, scaffolded activities, and analytic tools to help students learn about the processes of experimental design and data analysis, the nature of scientific argument and proof. Scaffolding strategies incorporated in *Food Chain* are aimed at supporting cognitive regulation, metacognitive, and inquiry skills required for implementing scientific methods and effective complex problem-solving. *Food Chain* was originally developed by isee Systems and modified for the purposes of this study.

### Procedure

Participants in both study conditions interacted with the *Food Chain* simulation-based inquiry-learning environment for three weeks. In the first week, participants were introduced to the *Food Chain* simulation-based inquiry-learning system. They were asked to design their own experiments and test their hypotheses to answer a relatively simple complex problem (challenge# 1): which two species (out of eight) can survive in Lake

Mirabile by themselves for 90 days? This first week was intended to familiarize students with the simulation environment and to teach about scientific reasoning processes of hypothesis generation and testing. During this initial run, students in both conditions had access to domain-specific knowledge related to the species in Lake Mirabile, but they did not receive any scaffolding from the system. At the end of each inquiry-cycle, they only received a text-based verification feedback of whether or not their hypotheses were correct.

In the second week, participants tackled a problem scenario with medium complexity (challenge# 2), in which they were asked to identify the smallest number of species that will enable Sunfish, one specie out of the eight species in the simulated environment, to survive for 90 days in Lake Mirabile. Their entire hypotheses, experimental designs, and elaborated reports of the findings were collected.

During the third week, participants tackled a very complex and ill-structured problem scenario (challenge# 3), which called for environmental policy-making. In this problem scenario, students were asked to play the role of an environmental scientist and evaluate the proposal to build 100 new houses on the shoreline at Lake Mirabile from an environmental impact standpoint. All of their hypothesis, results of their experiments, and their elaborated report of recommendations and assessment were collected.

During the second and third weeks, the only difference between the two study conditions was the type of scaffolding strategy provided by *Food Chain* at the end of each inquiry cycle. Following their experiment, participants in the experimental (MP) condition were only provided with a text-based verification feedback (e.g., Nice try…but the species you chose didn't survive! View logic model and try again) and they were given access to the system dynamic model progression, which included an annotated system dynamics model progression (see Figure 1). On the other hand, participants in the control (QP) condition were only provided with a text-based verification feedback and related question-prompts (see Figure 2) to scaffold their new hypothesis generation.

## Measures and Data Analysis

In *Food Chain*, students were required to go through inquiry processes to solve three ecology problems in increasing complexity. For each problem, they were asked to go through the inquiry process at least four times. Each inquiry cycle in *Food Chain* simulation involved the following steps. First, students individually developed a hypothesis using their prior knowledge and information given by the software. Then, they observed the results and analyzed the charts generated by the simulation environment for each variable. Finally, they explained the results. A computer-generated question prompt or an annotated dynamic model progression was provided to the students to interpret their findings. Students were expected to develop their subsequent hypotheses using these scaffolds. Scoring rubrics were used to rate participants' *cognitive regulation* and *complex learning* based on their protocols, which included, for each challenge (complex problem) in the *Food Chain* simulation, four sets of hypotheses, hypotheses justification, results, and explanation of the results.

Cognitive regulation refers to how individuals engage in a recursive process utilizing feedback mechanisms to direct and adjust their learning and problem-solving activities. Therefore, *cognitive regulation* was measured by rating how well the previous inquiry cycle informed the consecutive inquiry cycle, and whether or not the participant responded the cognitive regulation scaffold (question prompt or system model) in generating and justifying the subsequent hypothesis (see Table 1).

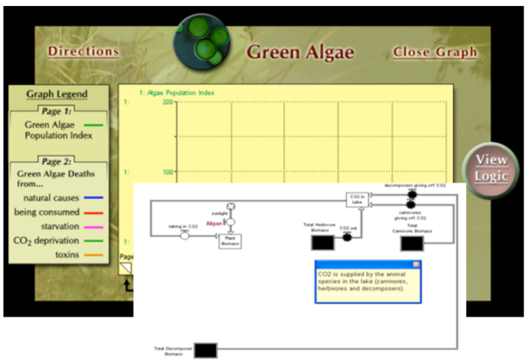

Figure 1. Model progression scaffold received by participants in experiment condition

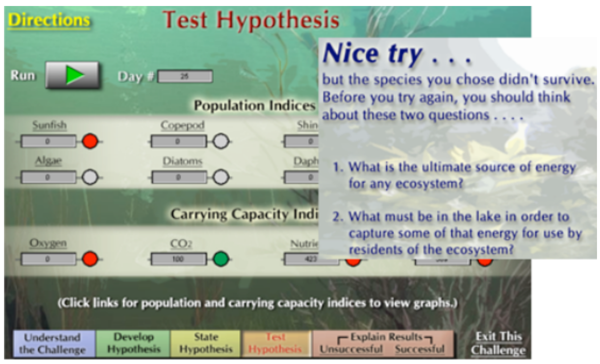

Figure 2. Model progression scaffold received by participants in experiment condition

Table 1: Overview of the scoring rubric for *cognitive regulation* measure

| Coding Category | Number of points given |
|---|---|
| Quality of the hypothesis | 2 points: strong evidences of *using system feedback* to develop the subsequent hypothesis; 1 point: some evidences of *using system feedback* to develop the subsequent hypothesis; 0 point otherwise |
| Quality of justification of the hypothesis | 8 points total: There are two questions per question prompt. 2 points for a clear and correct answer to each question, and 2 points for strong logical justification responding to each question. Deduct 1 point per question if the response is not elaborated clearly. |

In addition, *complex learning* was measured by rating participants' hypothesis, hypothesis justification, and explanation of the results in the inquiry cycles to see if a participant is developing a comprehensive understanding of the lake ecology system and the dynamic interrelationships among its variables. In other words, whether students are able to (1) identify various variables affecting the lake ecosystem (for example, fungi, bacteria, green algae, diatoms, sun energy, $CO_2$, $O_2$, nutrients, etc.), and (2) identify the interrelationships among these variables (for example, diatoms produce the oxygen that fuels bacterial respiratory processes, while bacteria generates the $C0_2$ and nutrients that diatoms require for driving their photosynthetic processes. Both diatoms and bacteria die, of natural causes, feeding the stock of detritus. That stock, in turn, nourishes bacteria that then decompose detritus to create the nutrients that diatoms require for nourishment.) The scoring rubric of the complex learning measured is shown in Table 2.

Two raters coded all protocols based on the analytical rubric system developed by the research team. The interrater reliability was 95% for cognitive regulation measure and 90% for complex learning measure. Any discrepancies of assigned scores were discussed among the raters and the adjudicated score was used. Consequently, a high consensus was reached. Repeated measures ANOVA analysis was conducted to examine change on *cognitive regulation* and *complex learning* measures both after challenge 1, after challenge 2, and after challenge 3 in the *Food Chain* simulation.

## Results

Table 3 summarizes the descriptive statistics for the two dependent variables (cognitive regulation and complex learning) for both control (QP) and experimental (MP) groups along the three challenges: (T1) simpler complex problem where no scaffolding was provided from the system; (T2) more complex problem scaffolded with either QP or MP; and (T3) very complex, environmental policy analysis problem scaffolded with either QP or MP. Below is the statistical analysis report in response to each of the hypotheses tested.

Table 2: Overview of the scoring rubric for *complex learning* measure

| Coding Category | Number of points given |
|---|---|
| Correct variables | 2 points: all correct variables are identified; 1 point: some correct variables are identified; 0 otherwise. |
| Energy cycle | 1 point: evidences of understanding that plants harness energy from the sun; 0 point otherwise |
| $CO_2/O_2$ cycle | 4 points: evidences of understanding that some species are providing $CO_2$ and consuming $O_2$ in the ecosystem and other species are providing $O_2$ and consuming $CO_2$ in the ecosystem; deduct one point each if the students could not identify $CO_2$ , $O_2$, consumption or production cycle. |
| Nutrient cycle | 3 points: evidences of understanding that species are providing for other species for nutritional needs; deduct one point each if (1) the student identify do not have the complete food cycle, (2) cannot identify decomposer role in the system, and (3) do not give a clear explanation. |

Table 3. Descriptive statistics for cognitive regulation and complex learning measures

| *Measures* | Control (QP) Group | | | | | | Experimental (MP) Group | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Mean | | | Std. Dev. | | | Mean | | | Std. Dev. | | |
| | T1 | T2 | T3 | T1 | T2 | T3 | T1 | T2 | T3 | T1 | T2 | T3 |
| Cognitive Regulation | 2.01 | 4.21 | 5.72 | 1.03 | 1.13 | 1.95 | 1.97 | 4.15 | 6.20 | 0.96 | 1.70 | 2.16 |
| Complex Learning | 1.84 | 3.45 | 4.33 | 0.89 | 0.49 | 1.16 | 1.64 | 3.75 | 6.92 | 1.04 | 0.89 | 1.30 |

## Effects on Cognitive Regulation

The first research question asked whether scaffolding with question prompts and system dynamics model progressions affect student cognitive regulation in the process of developing solutions to complex problem scenarios.

As evident in the descriptive statistics shown in Table 2, participants in the MP condition had lower mean scores than the participants in the QP condition in *cognitive regulation* after the first challenge in the *Food Chain*, during which no cognitive regulation scaffolding was provided by the system. However, the repeated measures ANOVA analyses did not indicate significant differences between the two groups in these two dependent variables $F$ (2, 209) = 0.47, $p$ > .05, $\eta^2$ = .025. The results indicated that the participants in both conditions were comparably on equal basis after they completed the first challenge.

However, the repeated measures ANOVA analyses revealed a significant main effect in participants' cognitive regulation of inquiry learning in both QP and MP conditions between the first challenge, where no scaffolding were provided by the system, and the second challenge, where participants received either scaffold $F$ (2, 209) = 0.47, $p$ > .05, $\eta^2$ = .025, which supported the hypothesis that students, when received either cognitive regulation scaffold, would perform significantly better than when cognitive regulation was not scaffolded during inquiry learning. Nevertheless, after completing the second challenge in the *Food Chain* simulation-based inquiry-learning environment, the repeated measures ANOVA analyses did not indicate significant differences between the two groups with respect to their cognitive regulation skills.

After the third challenge, which included a very complex environmental policy making problem, the repeated measures ANOVA analyses revealed a significant main effect in favor of the MP group, $F$ (2, 209) = 0.47, $p$ > .05, $\eta^2$ = .025, which supported the hypothesis that, in highly complex learning tasks, providing students with annotated system dynamic model progression was more effective than question prompting as a cognitive regulation scaffold in simulation-based inquiry learning.

## Effects on Complex Learning

The second research question asked whether scaffolding with question prompts and system dynamics model progressions affect students' learning about complex systems, hence, complex problem-solving skill acquisition.

As seen in Table 2, participants in the MP condition had lower mean scores than the participants in the QP condition in *complex learning* after the first challenge in the *Food Chain* simulation-based inquiry-learning environment, during which no cognitive regulation scaffolding was provided by the system. However, the repeated measures ANOVA analyses did not indicate significant differences between the two groups in these two dependent variables $F$ (2, 209) = 0.47, $p$ > .05, $\eta^2$ = .025. The results indicated that the participants in both conditions were comparably on equal basis when they completed the first challenge.

However, the repeated measures ANOVA analyses revealed a significant main effect in participants' cognitive regulation of inquiry learning in both QP and MP conditions between the first challenge, where no scaffolding were provided by the system, and the second challenge, where participants received either scaffold F (2, 209) = 42.66, p < .01, $\eta^2$ = .53, which supported the hypothesis that students, when received either cognitive regulation scaffold, would learn about complex systems better than when cognitive regulation was not scaffolded during inquiry learning. Nevertheless, after completing the second challenge in the *Food Chain* simulation-based inquiry-learning environment, the repeated measures ANOVA analyses did not indicate significant differences between the two groups with respect to complex learning.

For the third challenge, which included a very complex environmental policy making problem, the repeated measures ANOVA analyses revealed a significant main effect in favor of the MP group, F (2, 209) = 49.86, p < .01, $\eta^2$ = .57, which supported the hypothesis that, in highly complex learning tasks, providing students with annotated system dynamic model progression was more effective than question prompting to support students' learning of complex ecology systems during simulation-based inquiry learning.

## Discussion

The purpose of this study was to investigate the effects of two promising cognitive-regulation scaffolding strategies, *question prompts* and *model progression*, on ninth-grade biology students' (1) cognitive regulation of inquiry learning; and (2) learning of a complex system (lake ecosystem) in a simulation-based inquiry-learning environment. This study also addressed the effect of task complexity on the effectiveness of students' cognitive regulation and their successful learning in complex systems.

The results of this study pointed out to a number of important issues. First, the results showed that both scaffolding strategies were effective in providing the cognitive regulation support for students using a simulation-based inquiry-learning system. However, as the complexity of the problem increased, model progression was significantly more effective than question-prompts. This is consistent with earlier studies, which suggested the ineffectiveness of question prompting as a self-regulation scaffold in situations where students have insufficient prior knowledge, which plays an important role in elaborated learning (Ge & Land, 2003; Greene & Land, 2000; King, 1992).

This finding also explains some of the mixed results in earlier studies regarding the effect of model progression on self-regulation. For instance, Quinn and Alessi (1994) performed a study, in which students has access to a simulation of a spread of a disease within a simulation. Students had to manipulate two to four input variables to minimize the value of one of the output variables. Their data revealed that model progression had no overall positive effect on performance. It should be noted, however, that the domain that was used by Quinn and Alessi (1994) was quite simple: the variables in the model did not interact. In another study with simulation of a more complex system (multimeter) Alessi (1995) found that model progression was beneficial for initial learning and for transfer. Similar positive results were observed in Rieber and Parmley's (1995) study in the area of Newtonian motion.

Secondly, the results of this study confirmed the findings from the earlier studies, which suggested using question-prompts as a self-regulation support early in the simulation. For instance, Showalter (1970) recommended using question-prompts early in the simulation to focus learner attention to specific aspects of the simulation. Similar studies by Zietsman and Hewson (1986), Tabak, Smith, Sandoval, and Reiser (1996), White (1984; 1993) also pointed out to the effectiveness of such strategy in different domains for providing self-regulation (especially for planning) support during simulation-based inquiry learning.

Finally, this study provided empirical evidence for the link between cognitive-regulation skills and learning in complex systems (i.e., complex problem-solving), which was suggested in earlier studies (see Butler & Winne, 1995; Davis, 2000; Lin & Lehman, 1999; Schraw, 1998). In this regard, there was no significant difference between the impact of question-prompts or model progression when the problem was a simpler complex problem. However, as the complexity of the problem increased, cognitive scaffolding by model progression had significantly higher impact on learning than cognitive scaffolding by question-prompts.

In future studies, it would be beneficial to investigate the effectiveness of both scaffolding strategies on far-transfer complex problem-solving tasks. These studies should also factor in individual student differences and investigate whether there are differences among low-achieving and high-achieving students. Students who participated in our study had not received any prior instruction on lake ecosystems; the domain-specific knowledge required for inquiry learning was constantly accessible, on demand, in the *Food Chain* simulation environment. Directions included in the system encouraged students to read the domain-specific information prior to generating hypothesis. Therefore, in this study, an attempt was made to bring individual differences to a minimum possible level in order to rule out confounding factors that might have affected the results of this investigation.

Overall, this study provided empirical evidence to the critical importance of embedding appropriate feedback strategies in technology-based learning environments (see Cohen, 1985). This corresponds with the current discussion about the failure of the popular movements of constructivist learning environments adopting discovery, problem-based, experiential, and inquiry-based teaching approaches and provide support to the arguments by Kirschner et al. (2006) and Mayer (2004). We hope to see more studies investigating the effectiveness of technology-mediated scaffolding strategies so that an appropriate design theory for instructional simulations may arise. Current attempts, though interesting, are necessarily fragmentary and incomplete (Thurman, 1993; de Jong & van Joolingen, 1998). Coupled with such a theory, inquiry learning with simulations can fulfill its promise in learning and instruction.

# Made by Hand: Gestural Practices for the Building of Complex Concepts in Face-to-Face, One-on-One Learning Arrangements

Stephanie Scopelitis, University of Washington, scope@u.washington.edu
Siri Mehus, University of Washington, smehus@u.washington.edu
Reed Stevens, Northwestern University, reed-stevens@northwestern.edu

**Abstract:** Our study investigates how the hands and body can serve as communicative, cognitive and interactional resources when they are employed in the teaching and learning of complex science and math concepts. We consider how speakers and hearers produce, take up, and re-use gestures to support explanation and conceptual formation in expert-to-non-expert conversation. The study suggests that in face-to-face, one-on-one interaction gesturing plays an important role in facilitating the joint achievement of new conceptual understanding for novice learners. We believe that the gestural practices used to explain complex concepts in informal interactions can be profitably extended to the teaching and learning of STEM (science, technology, engineering and mathematics) subjects in other learning arrangements such as the classroom.

## Introduction

Language is an important resource for teaching and learning, but it is not the only one. The intent of this study is to closely examine how both non-verbal and verbal modalities are employed together in face-to-face, one-on-one interactions in which experts in the fields of math and science explain complex concepts to non-experts. Paying attention to how multiple modalities are employed in informal face-to-face, one-on-one explanations of complex concepts can offer valuable insight into how we design practices for teaching and learning in other learning arrangements such as the classroom.

Our study particularly investigates the coordination of gestures and body movement as we as speakers and hearers jointly produce, take up, and re-use gestures to support explanation and concept formation in the context of conversation. We consider gestures and body posturing as participating elements in communication (Becvar, Holland & Hutchins, 2005; Goodwin, 2000; Hutchins, 1996; Kendon, 2001, 2004; Stevens & Hall, 1998; Streeck, 1994, 1996) as we also examine the hands and body as explicit, tangible teaching tools.

The study illustrates how gesture facilitates the joint achievement of new conceptual understanding for novice learners in face-to-face interaction. We believe that the gestural practices used to explain and understand complex concepts in informal interactions can be profitably extended to the teaching and learning of STEM subjects across learning sites. Our study concludes with the suggestion that as we create ever more sophisticated educational designs, we may need to pay more attention to the potential of the most readily available resources – the hands and the body.

## Theoretical Background and Perspective

Our overarching interest is in how knowledge is produced in interaction. We see learning as an interactional process that is dynamically constructed through actions and inter-relationships among resources (Hutchins, 1995; Stevens & Hall, 1998). These resources include participants, settings, multiple modalities, objects and sequences of activities. In our analysis, we employ the concept of *learning arrangements*, which refers to social and material configurations that people arrange for learning, with the question of whether learning is actually achieved being an empirical one for investigation (Stevens, Satwicz & McCarthy, 2007). This concept allows us to examine the resources made available in face-to-face, one-on-one learning arrangements and compare them with other learning arrangements. We are therefore able to treat gesture as both a technical resource and an interactional resource in the active and collaborative enterprise of teaching and learning. We consider how the hands act as media for representations and how the hands and body participate in coordinating available, external representations in interaction to achieve the end task of understanding.

Our study concentrates on teaching and learning in STEM fields (science, technology, engineering and mathematics) and provides perspective on the view that teaching and learning in the STEM fields involves the use of multiple representations such as graphs, models, and charts (Kress, 2001;

Stevens & Hall, 1998). We consider how the hands act as flexible, manipulable, and literally "ready-to-hand" embodied resources for representation. We also respond to recent literature that looks at how professionals in science fields build theory in collaboration. Studies suggest that idea construction and knowledge communication in professional settings happen through an interactional exchange that employs multiple resources that include gestures (Becvar et al, 2005; Hall, Stevens & Torralba, 2003; Ochs, Gonzales & Jacoby, 1996; Stevens & Hall, 1998).

Much of the recent work on the use of gestures in teaching and learning takes a psychological orientation. Such research has suggested that gestures in the classroom can be used to reinforce and extend meaning provided in speech, can aid the gesturer in thought production, and can reveal cognitive processes as a means for evaluating understanding and guiding instruction (McNeill, 1992, 2005; Singer & Goldin-Meadow, 2005; Wagner, Alibali, Flevares & Goldin-Meadow, 1997; Ozyurek, 2002). We expand upon this psychological orientation as we consider not just the relationship between gesture use and cognitive processes, but also the role that gestures play in communication. Attending to both aspects simultaneously provides a more complete and realistic view of how gestures participate in teaching and learning.

## Methods

The study employs the methodology of microanalysis of videotaped interaction, which involves fine-grained, qualitative analysis of sequences of talk and action. This process of analysis allows for the close investigation of moment-to-moment, turn-by-turn, interactional exchanges giving detailed information about what is happening in a particular instance.

The database consists of video-recorded conversations in which experts in STEM fields explained complex concepts to non-experts. Participants came from a pool of volunteers who responded to requests for participation that were distributed via e-mail to STEM departments of a large university. Conversations were held primarily in the offices and labs of the experts and lasted between 30 and 60 minutes. Participants discussed topics of their choosing which they deemed as relevant concepts to their defined discipline and/or research. The recorded interactions were logged and transcribed and the verbal and gestural techniques used to explain concepts were identified and analyzed.

## Data Sources and Evidence

In this paper we analyze segments from three interactions in which experts (two professors and one graduate student) explain concepts in microbiology, mathematics and animal biology in one-on-one conversations with a non-expert. These segments exemplify moments in our data in which the interactions take a conversational format for exchange of knowledge, as opposed to a lecture-like format in which the expert delivers information and the learner is relatively passive. Close examination of the use of gesture in these exchanges shows that the gestures are not merely the outward manifestation of the speaker's cognition, but rather can be co-constructed with a recipient in the service of building conceptual understanding.

## Results

Through our analysis we demonstrate that gestures and posturing are not just the unconscious by-product of a speaker's cognitive processes, but rather often are tactically employed for communicative purposes that respond to particular contingencies of the situation and perceived learning needs of a recipient. As evidence for this perspective we outline examples showing how gestures are (1) built step-by-step for and with the recipient, (2) positioned and adjusted for the recipient, (3) used to correct the learner's misunderstanding (in response to the learner's gesture), (4) used by both the speaker and the hearer to drive the interaction toward the shared goal of achieving understanding, (5) treated as a communicative artifact by speaker and hearer. Finally, we show how, in a single segment, gestures can be seen to support both cognitive and communicative processes.

### Example 1: Constructing a Gestured Object for the Learner

The first segment shows how an expert engages in the process of building, step by step, a gestured object. Sakina is a graduate student in molecular biology. She is explaining the replication of DNA. She first explains the basic architecture of DNA. To do so, she constructs a model layer by layer, enlisting her hands as the material for construction. Sakina begins the construction for the learner/hearer by saying, "Then there are two strands," as she simultaneously lifts her two index fingers, positioned side-by-side, and lowers them--drawing two lines in space (see Figure 1).

Figure 1. "Then there are two strands"

Sakina then raises her left index finger, pointing up, establishing it as a model of the DNA strand. As she says, "One strand we call it the five prime end and the three prime end?" she lifts her right hand and points to a spot toward the tip of her finger and then another spot towards the base of her finger. The right hand thus takes on an indexical role as the left hand models the DNA strand (see Figure 2).

Figure 2. "Five prime end and the three prime end"

Once this basic structure has been established, Sakina alters it to show the learner that the strands go in opposite directions. She does this by straightening her right index finger and then flipping the hand so that the finger is now parallel to the left index finger, but pointing downward. She completes this movement as she utters "anti-parallel" (see Figure 3).

Figure 3. "Anti-parallel"

The gestured object is sequentially constructed for the benefit of the hearer. This is evidenced by 1) the gaze direction of the participants, 2) the speaker's positioning of the gestured-object and 3) the speaker's adjustment of the gesture.

As she begins to set up the model, Sakina shifts her gaze to her hands. The hearer tilts her head to see Sakina's hands (see figure 4). This move by the hearer displays her recognition that the built gestured-object is for her, and that this information is consequential for her understanding.

Figure 4. The hearer tilts her head to see S's gesture; S repositions the gesture.

Sakina immediately responds to the hearer's head tilt by repositioning the gestured-object so the hearer can see it. Sakina's adjustment is a marker that the gestured-object is intentionally constructed and placed for the learner. The speaker's repositioning also works to outline the interactional field. The speaker's body acts as frame, defining a field of action. The speaker and hearer conjointly establish this workspace: first the hearer tilts her head and then the speaker adjusts.

### Example 2: Repairing Understanding through Gesture

In the following example, gestures participate in the repair of a misconception. After Sakina reaches a completion point in her explanation, the learner initiates a turn by putting up two fingers, thus taking up the previously constructed gesture-object. As she does this she says, "Okay so you have the two strands." The gestured-object she displays, however, shows the parallelism of the strands but fails to show the opposing directionality (see Figure 5).

Figure 5. "Okay, so you have the two strands."

Sakina moves to repair the misunderstanding, not through speech but through action. Sakina demonstrates the anti-parallelism with her hand. As she does this, she repeats the learner's previous phrase, "so you have the two strands." The language is the same; it is the gesture that provides the correction. In response, the learner flips her hand to mirror Sakina's and repeats "two strands" (see Figures 6 and 7).

Figure 6. "So you have two strands."

Figure 7. "Two strands."

## Example 3: Assuming the Perspective of the Learner

Another indicator that gestures can be intentional teaching tools is when a speaker shifts position to assume the hearer's perspective on an already built gestured-object.

Max, a professor of geometry, explains the concept of four-dimensionality. First, he explains a more basic concept: three-dimensionality. Max creates the object using the fingers to represent three dimensions (see Figure 8). Once he settles on this construction, he then pauses in the process of explanation. He holds the gesture in its established space and, as though detaching himself from his role of maker of the gestured-object, he steps out of conversational space, crosses the interaction field and observes the built object from the learner/hearer's visual perspective (see figure 9).

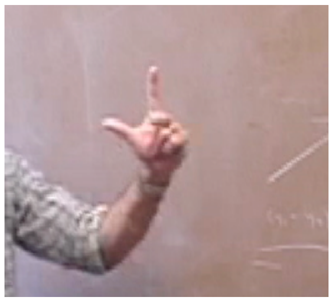

Figure 8. Three dimensions

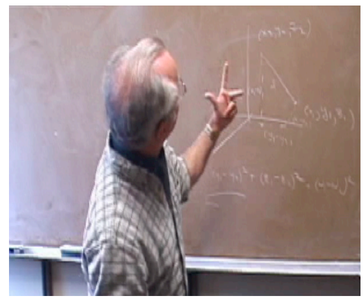

Figure 9. Takes learner/hearer's perspective

Here is a clear embodied representation of recipient design (Sacks, Schegloff & Jefferson, 1974), as the speaker not only constructs and displays the gesture, but steps into the physical position of the learner/hearer in order to "check out" how the gesture looks from that perspective.

## Example 4: Thinking through Gesture Together

A fourth segment shows gesture playing a major role in an extended process in which the expert and learner work toward a shared understanding of a scientific concept. In this case, the expert, Mara, (a biologist) is explaining how fish gills function. Mara, in response to the learner's question about the shape of a fish's gills, moves the discussion away from the process of oxygenation and on to the relationship of surface area to oxygen consumption. In this sequence we see several of the phenomena discussed so far. For instance:

- gestured-objects are constructed for the benefit of the learner;
- gestures are used to repair and clarify the learner's misconceptions; and,
- gestures participate in the moment-to-moment assessment of where the learner is in the process of understanding.

In addition, this segment also shows how the function of the gestured-object may shift as it is passed back and forth by the expert and learner as it also reveals how the body organizes this exchange.

There is a dynamic development of a single gesture that happens as the gesture is passed between the interacting participants. The specific gesture that is the focus of this discussion is made up of an open hand with the thumb pulled to the palm and four fingers loosely separated (see Figure 10). The gesture refers to the gills of a fish. Mara introduces the gestured-object by placing it in the center of the interactional space in the learner's sight line and asking, "But what does this give you when you are like that?" The central placement of the gesture and the use of deictic pronouns "this" and "that" direct the learner's attention to Mara's gesturing hand. The learner, in the turn to follow, takes up the gesture and reproduces it with her own hands (see Figure 10).

Figure 10. "But what does this give you when its like that?"
Speaker displays and hearer mimics "gill" gesture.

The learner's taking up of the gestured-object acts as a demonstration for the participants that the "hand-as-gill" gesture has now been established as a shared object central to the explanation.

When Mara presents the hand-as-gill gesture it is acting as a representational model. When picked up by the learner the gesture shifts to become a manipulable model used to work out an idea, i.e., a thinking tool. This shift of function is evident from the learner's treatment of the gestured-object. She pulls the gesture from the center of the interactional space and to its periphery. She draws it closer to her own body and performs actions on the gestured-object in an abbreviated manner. The gesture, now a thinking tool in the hands of the learner, is used by the learner to explore various relationships between a gill and water. As the learner's left hand maintains the hand-as-gill gesture, the right hand is used to simulate various aspects of the movement of water over the gill such as pressure, impact and flow (see Figure 11). For example, in one simulation the learner moves the fingers of her right hand (the right hand representing water) between the fingers of the left hand (the left hand acting as gill) and utters "it [water] can get through."

Figure 11. Learner uses gestured-object as a thinking tool.

Other uses of the hand-as-gill gestured-object spin out of this interactional activity. In addition to acting as an evaluative tool and a thinking tool, the gesturing also becomes an interactional tool used specifically to organize and *co-coordinate* the teaching and learning. Mara and the learner use their hands and body as mechanisms to steer the direction of the conversation toward the achievement of the shared goal of understanding the concept in play. Mara uses the body positioning to direct the learning toward the kind of investigation that will get to conceptual understanding, and the learner making use of the evaluative benefits of making her thinking visible, uses the hands and body to *check in* and assure that her exploration is on the right track.

As Mara presents the hand-as-gill gestured-object, her body remains on the very outside edge of the interactional space (see figure 10) while the gestured object takes a central position. By remaining on the periphery and foregrounding the built gestured-object, Mara's body positioning further signals for the learner that she is now to step in and take over the learning. The learner responds by doing just that – picking up the gesture-object and exploring it. As she begins to act upon the gestured-object now in her possession, Mara drops her gesturing hand out of the center of the field. The pass has thus been completed. Mara steps out of explanation mode and allows the learner to slip into exploration mode.

The learner's introspective focus, demonstrated not only by the abbreviated manner of her action on the gesturing hand, but also suggested by the slight pulling inward of her body to create her own frame around the gesturing, marks the current function of the gesture as a thinking tool. But it is not just a cognitive tool in use for the learner. It is part of a documentation that is meant to be seen by Mara. The learner's choice to reveal her thinking to Mara through the visibility of the gestures and the audible "figuring out" talk suggests that the learner is seeking on-going guidance from the expert. The learner's vacillating gaze from an inward focus on her hands to outward focus toward Mara also functions to keep the expert "on deck" as a resource while the learner works through learner's questioning. Mara picks up the learner's bid for approbation and/or clarification and shows this as she shifts her body back into the space (see Figure 11) when the learner verbalizes an idea that may move her toward an understanding of the concept. In just a few turns, we witness the intricate, multimodal work participants perform in this interactional process of explaining and understanding.

This final segment shows the importance of adopting both cognitive and interactionist perspectives on the use of gesture. We see that gesture may be employed by the learner and the expert as a (1) communicative tool, (2) a thinking tool to work out and organize knowledge, and (3) an interactional tool to organize the trajectory for learning. The various functions the hands and body can assume are determined and negotiated through a complex interactive exchange between speaker and hearer, learner and expert.

## Conclusion

Our analysis shows that the hands and body do something important in the teaching and learning of complex concepts in face-to-face, one-on-one learning arrangements made up of experts and novices. The gesturing hands can be employed as tools to build a representational object that both the speaker and the hearer act upon in order to achieve a shared understanding of a complex concept. The examples we describe show that gestured-objects are constructed for the benefit of the learner, that gestures participate in moment-to-moment ("formative") assessment in face-to-face, on-on-one interaction, and that gestures are used to repair and clarify misunderstandings. Gestures can be used by both the speaker and the hearer as proposals, cues, and requests that steer the interaction toward the shared goal of achieving understanding. These multiple roles that gestures take in interaction demonstrate that the hands and body are prominent resources for learning in these types of learning arrangements.

Our study also provides evidence that gestures in face-to-face, one-on-one interaction can have both cognitive and communicative functions. Seeing gesture as both cognitive and communicative is an improvement on the dominant cognitive view in that it (1) reveals an important way in which people routinely accomplish teaching and learning in informal talk, and (2) clarifies how both the artful production and the perceptive recognition of gesture is a critical interactional activity achieved and negotiated by all participants.

We believe that by examining the interactional activity that happens in face-to-face, one-on-one learning arrangements between experts and novices we can come to better understand the material and social resources used in the explanation of complex concepts. In all three examples from our study, representations made by the hands and negotiated in interaction become vital aspects of the process of explanation. We invite research that explores ways to extend the benefits of gesture activity for concept learning from face-to-face, one-on-one interaction into the classroom. Certainly, by the very nature of the classroom arrangement, the available uses and functions of gestures are different compared to those present in face-to-face, one-on-one arrangements. Particular gesture activities in co-present interaction may be endogenous to that specific learning arrangement. If so, what certain aspects of gesture use in interaction can be organically and effectively performed within current arrangements for classroom learning? It is, for instance, certainly not possible for teachers to have their gestures respond to each and every learner's displayed understanding but it does seem possible, and worthwhile, for at least some of this to happen.

Our study encourages further research into the profitability and possibilities of extending effective gesture practices that happen in face-to-face, one-on-one interaction into the classroom. We also suggest that investigating gesture use in a variety of learning arrangements will offer more insight into how gestures are shaped by and function within social and material configurations and thus further inform educational design and practices.

# *Micros and Me*: Leveraging home and community practices in formal science instruction

Carrie Tzou, University of Washington Bothell, 18115 Campus Way NE,
Bothell, WA 98011-8246, tzouct@u.washington.edu
Philip Bell, University of Washington, 312 Miller Hall, Box 353600
Seattle, Washington 98195, pbell@u.washington.edu

**Abstract:** Critiques of school science from sociocultural perspectives focus on the narrow scope of the science that is presented to students in school, which in turn constrains how children should engage in scientific sense-making in classrooms. We have designed a seven-week instructional intervention, *Micros and Me*, which attempts to (a) make science more personally consequential to students' lives and cultural memberships, and (b) connect authentic scientific practices deeply with students' repertoires of practice. We report on two iterations of *Micros and Me*, focusing our analysis on two design issues: (1) how we attempted to broaden the definition of what counts as school science through a self-documentation task, and (2) how the self-documentation task problematized the conception of "culture" in each of the classrooms. We end with design implications for the design of science learning environments that take as their starting point deep knowledge of students' repertoires of practice.

## Introduction

Research suggests that wanting to participate in science is influenced partly by whether students identify themselves as people who can or cannot do science (Brickhouse, Lowery, & Shultz, 2000), yet unfortunately science as it is traditionally taught in schools has little to do with the science done by scientists or science as it is practiced in children's everyday lives. In traditional school science, there is usually one "right" answer, and one "right" process to find that answer. Uncertainty and controversy are not part of the discourse of school science textbooks, and laboratory exercises in which students attempt to approximate the "right" answer leave little room for discussion and debate (Bell, 2004a, 2004b).

Critiques of school science from sociocultural perspectives focus on the narrow scope of the science that is presented to students (Warren, Ogonowski, & Pothier, 2003; Eisenhart, Finkel, & Marion, 1996), which constrains how children should engage in scientific sense-making in classrooms (Ballenger & Carpenter, 2004). School science is overwhelmingly Western science (Harding, 1998), with a narrow range of norms of practice (Aikenhead, 1996; McIntyre, Rosebery, & Gonzalez, 2001). Furthermore, these norms of practice may not necessarily be consistent with students' cultural ways of knowing. The literature from sociocultural perspectives tells us that there are problematic ways in which science instruction (and school instruction in general) has attempted to leverage students' repertoires of practice. One way is essentializing students according to their presumed membership to certain cultural groups (Nasir, Rosebery, Warren, & Lee, 2007). Cultural essentialization leads to "treating cultural differences as traits" (Gutierrez & Rogoff, 2003, p.19), unchanging over historical time and belonging to every member of a cultural group. One danger in seeing cultural differences as traits instead of dynamic processes that vary between individuals is the tendency to see these traits as explanations for underachievement, behavior, or other academic problems that apply to all members of a cultural group—the deficit model of cultural differences. Instead, Gutierrez & Rogoff argue that we need to see individual students as having their own experiences and histories that are influenced rather than dictated by their membership in certain cultural groups.

Another, related way in which culture is treated problematically in classrooms is making superficial connections between specific cultural practices (often assumed to be practiced by *all* members of a particular cultural group) and classroom learning. Warren, Ogonowski, and Pothier (2003) cite the example of cooking rice and beans as a way of demonstrating phase transitions. While it is fine to bring such examples in the classroom, we need ways to connect students' culturally-based ways of knowing deeply to scientific meaning making in classrooms. Cultural practices need to be constructed as rich sites of complex reasoning that can be applied to discipline-specific reasoning practices in classrooms.

These critiques underlie the importance of expanding what normally "counts" as science to include children's everyday expertise, or what Gutierrez and Rogoff (2003) call "repertoires of practice". Repertoires of practice refer to the dynamic ways in which people engage in activities based on their background experiences, interests, and cultural memberships. Rather than assuming that certain instructional contexts will connect with students' lives and therefore be motivating contexts for learning, we take the perspective that others (Lee, 2007; Warren, et al, 2001; Moll, 2004) have taken that the design of instruction should begin with deep knowledge of students' repertoires of practice and their corresponding areas of expertise and connecting that in meaningful ways to authentic scientific practices. To this end, we have designed a seven-week instructional intervention, *Micros and Me* (Tzou, Bricker, & Bell, 2007), that attempts to (a) make science more personally consequential to students' lives and cultural memberships, and (b) connect authentic scientific practices deeply with students' repertoires of practice. In this unit, we attempted to elicit and leverage students' repertoires of practice around health in order to motivate the study of microbiology and the connection between microbiology and health. We assume that part of what goes in to building a student's repertoires of practice around health is their membership in certain cultural, family, community, or peer groups.

In this paper, we will describe the context for the science instruction at the study site, briefly describe the design of *Micros and Me*, and present findings from analysis of two iterations of the curriculum, specifically around a self-documentation task (Clark-Ibañez, 2004) in which students were asked to document their health practices and connect those practices to a scientific research project. We end with dilemmas and design implications for applying leveraging students' repertoires of practice in the design of discipline-specific science learning.

### Research Questions

In this design, we asked three questions: (1) how can we *elicit and make visible* students' everyday expertise around health in science instruction? (2) how can we *deeply connect* this expertise to disciplinary practices in science? (3) what are implications for design of science learning environments that start with deep knowledge of students' repertoires of practice and connect disciplinary practices to that knowledge?

## Context for science instruction at Granite Elementary

We conducted this design work in collaboration with three fifth-grade teachers at Granite Elementary, a school located in the southern part of a large, urban city in the Pacific Northwest. The school is marked with significant ethnic and linguistic diversity, with a significant percentage of students on free and reduced lunch, and high achievement on the state standardized tests. This design collaboration is part of an ongoing (5+ year) partnership with the fifth grade teachers at Granite Elementary.

### Design of Micros and Me: an overview

This work is tightly connected to a cross-setting team ethnography of thirteen children's activities in and out of school in order to analyze several conceptual themes: personally consequential biology, argumentation, images of science, diversity (cultural, gender, economic) and uses of technology (cf, Bricker & Bell, 2008). The team has followed the children and their families in school, at their homes, and to a wide range of settings in order to understand the everyday sensemaking practices of children across the settings of their lives. Of the thirteen focal participants in the ethnography, four children were in the fifth grade classes in which the designed curriculum was first enacted. The major goal in the design was to understand how to better architect learning pathways between home and school through:

1. meaningfully incorporating ethnographic findings and protocols into the design of the unit, and
2. eliciting and deeply incorporating students' areas of everyday expertise into the science instruction using ethnographic methods.

*Micros and Me* is a re-design of an existing commercially-available kit called *Microworlds* (NSRC, 2002). The elementary science program in the school district to which Granite belongs is composed entirely of commercially-based kits. Every year, three such kits are taught, and *Microworlds* is one of the three kits taught in fifth grade in the district. The decision to re-design *Microworlds* as opposed to one of the other units in the fifth grade science curriculum was the prevalence in the ethnographic data of chronic health problems such as asthma and allergies. Granite Elementary, and many of the students who attend Granite, live in an area of Seattle that has a very high incidence of hospitalization due to asthma—many times higher than the rest of the county. The area of the city in which Granite is located—Granite Hills—is very industrialized, near ports, railroad tracks, and an airport—all of which are major contributors of pollution. Therefore, we chose to re-work *Microworlds* to help students see the connection between consequential health decisions and practices and scientific inquiry.

## Methods and data

We situate this work under the umbrella of *design-based research* (Collins, 1992, Bell, 2004a), in that we are attempting to understand how to design a personally consequential science curriculum that highlights children's everyday cognition at the same time that it engages children in systematic, discipline-specific practices. The literature is thin on work that designs for students about whom we have thick descriptions from their everyday lives. Seldom do designers have firsthand insight into lives of the children for whom they are designing.

*Micros and Me* was enacted for the first time in the spring of 2007 and every year since in all three fifth grade classrooms at Granite Elementary. A variety of data sources were collected during this effort: daily, videotaped observations of every day of the enactment, artifacts the students produced (including science notebooks, final reports and projects, pre/post assessments, and surveys of their everyday activities), and interviews with focus groups of students after the enactment. For the purposes of this paper, we draw on videotaped observations of students and teachers during the self-documentation lessons and the pictures and journals from 34 students across the three fifth grade classrooms. Videotaped observations were content logged and key episodes were transcribed in more detail.

Journals and classroom talk were analyzed for evidence of repeated activity systems that pertained to health and explanations for those activity systems that were rooted in family or cultural belief systems. We were especially interested in understanding whether the self-documentation technique would give us enough insight into students' everyday expertise around health that we could connect that expertise to the classroom scientific inquiry. Therefore, the following analysis is not so much concerned with the particulars of what students took pictures of, but of the potential for eliciting and making visible students' health practices in the context of classroom instruction. We use as a theoretical basis for this analysis the Everyday Expertise framework (Bell, et al, 2006), that highlights three dimensions of analysis: individual, social, and cultural, as well as the accompanying learning phenomena for each. *Cognitive ecology* refers to the diverse terrain of influences on the way an individual cognitively makes sense of, or assigns meaning to, the world. For example, an individual may have certain ideas about herself as a learner (epistemological knowledge) based on cultural, gender, age, and class identities, and these ideas influence the way she acts upon the world (diSessa [2002] for his notion of conceptual ecology). Although these histories and experiences are socially situated, they are considered here in relation to how they influence the perceptions and actions of individuals as they engage in social activity.

*Situated activity systems* refer to activity that takes place within the boundaries of a (socially constructed) place (Goffman, 1961). Individuals can "boundary cross" (Phelan, Davidson, & Cao, 1991, p. 227) as they move between activity systems, each of which contains culturally-based narratives. The social plane is the space where individuals enact their personal epistemologies in social interactions and in situated activity systems. As individuals enter places, they interact not only with each other but also with the cultural narratives and resources available in those places. Cultural toolkits (Swidler, 1986) refer to the ideologies, technologies, and narratives that are uniquely present at a given historical moment. We consider cultural activities and toolkits broadly, to include resources from environmental education, environmentalism, school, ethnic group memberships, and religious participation. These toolkits then shape activities and interact with an individual's own cognitive ecology.

Taken together, these dimensions help us see the practices that students self-document and discuss in class as situated within activity systems in specific socio-historical contexts. For example, when students self-documented a narrow range of health practices relative to the variation that we knew existed based on our ethnographic work, this framework allows us to interpret those findings in light of norms within the situated activity system of "doing school science" that typically allow for only Western science practices to count as school science (Harding, 1998).

## Findings and design implications

In this section we present findings from an initial analysis of the self-documentation task and design implications from those findings for the next design iteration of *Micros and Me*. We present our findings by telling the design story of the curriculum over the first two iterations, which occurred in the spring of 2007 and the spring of 2008.

### Iteration 1: Making visible students' everyday expertise around health through self-documentation

We knew, from our ethnographic findings, that students in this school population engaged in rich and varied repertoires of practice around health. Reeve (in preparation), using Chrisman & Kleinman's (1983) framework of multiple domains of health care, reported that families in the ethnographic study utilized multiple domains (what Chrisman & Kleinman call professional, popular, and folk) to manage their health care. This means that they went outside of established Western medicine in the maintenance and treatment of health-related issues. In this population of students, therefore, we were expecting to see similar varieties of health-related practices. Our first attempt to elicit and make visible students' everyday expertise around health was through student self-documentation. This was a photo-elicitation activity (Clark-Ibañez, 2004) in which students took pictures of practices they engaged in around health and explained how those pictures related to health. We loaned each student a digital camera for one night and asked them to take pictures of activities that that they engaged in around health. We also gave students a worksheet to document and explain the pictures they took. The intention was to gain a deeper understanding of students' repertoires of practice around health in order to connect those practices with the scientific inquiry in the classroom. We hoped that one of the activities documented during the task would be used as the basis for students' research projects at the end of the unit.

After we collected their pictures and their worksheets, we constructed what we called "maps" of their everyday health expertise using a commercially-available comic-strip making software program. These maps showed a subset of the pictures each student took (chosen by the researchers as the practices that had the most potential to be research topics) and the explanations of those practices in the students' own words.

### Construction of self-documentation activity as "school science" activity

In the first iteration of *Micros and Me*, there was wide variation in what the students documented as related to staying healthy and preventing illness. However, most of these fell squarely into what we would categorize as "mainstream" practices, well-documented in Western science as linked to health maintenance (drinking water, handwashing, eating vitamins, etc). We were at first disappointed in these results, since from the ethnographic data we had conjectured that this population of youth would engage in more varied practices around health. However, we soon realized that the self-documentation task was capturing only a partial list of health practices in which students engaged. When teachers conducted discussions with students about their self-documented pictures, we found that the classroom discussions showed potential to be rich sites for further exploring students' repertoires of practice around health. Consider the following brief discussion in one teacher's classroom:

1 Ms. E: One thing I'm always wondering about I think would be my topic is in my culture, in my family, everybody says I'll make you chicken soup, it'll make you feel good. And I always wonder is that just something to make people feel good because it's nice and warm and shows that people care about them, or is there something in the chicken soup that helps you get healthy. So that's a cultural thing that I always wonder about that has to do with being healthy. I want you also to think about tonight is there anything in your culture that has to do with um staying healthy or that people say. Some cultures have special things they wear, or put on their bodies to prevent them from getting sick or help them get healthy. Robbie
2 Robbie: You get a coin, and get this white or green ointment and put it on your back.
3 Ms. E: but is to help you get better or prevent you from getting sick?
4 Robbie: better
5 Ms. E: Ok so that's another cultural thing. Danielle
6 Danielle: there's this dance that you do
7 Ms. E: Ok so a dance. And is it supposed to help you get well?
8 Danielle: Yeah
9 Ms. E: Ok. So there's lots of things that we do in our culture, ethnicities that have to do with getting well. And I still have to find out if they always say I'll make you chicken soup is it going to help you feel better or is there something inside. So tonight as you're thinking about this, I want you to start thinking is there something in your pictures that you would like to research about staying healthy. *(Transcript of Classroom observation, 2007-05-29)*

In the above example, Ms. E was able to elicit culturally-based health practices that had not been documented in Robbie or Danielle's self-documentation tasks. By modeling the cultural practice of making chicken soup, she helps students understand what "cultural practice" means in this context. This is evidenced by Robbie's and Danielle's responses. However, she also says, "I always wonder is that just something to make people feel good because it's nice and warm and shows that people care about them, or is there something in the chicken soup that helps you get healthy", thus indicating a way in which a cultural practice could be leveraged in the context of a scientific research project. She not only asks questions that would allow her to examine that cultural practice scientifically, but also indicates ways in which it could be connected specifically to microbiology and health.

The contrast between the practices documented in the self-documentation activity and the practices students shared during the class discussion are evidence that the students were constructing this activity as a "school science" activity—where a narrow range of practices usually "counts" as science. When the teachers explicitly inquired into practices that were *cultural*, a different range of practices emerged. In the second iteration, we decided to more explicitly address "cultural practices" in the self-documentation task, building in more formal structures to do so.

## Iteration 2--Explicit conversations around cultural practices: problematizing "culture" and the Costco incident

In the next iteration of *Micros and Me*, we had the teachers make two substantial changes to the self-documentation task. First, they presented their *own* self-documentation maps when they introduced the activity, giving students a chance to see their teachers' repertoires of practice around health. We hoped this would prompt the students to think about the self-documentation task more broadly, outside of the narrow confines of Western school science. The second change was instituting a whole-class discussion in which teachers specifically addressed practices as "cultural", in order to get a better idea of what Gutierrez & Rogoff (2003) call the "historied and varied practices" that students engage in around health. What emerged was both a broadening of "what counts" as science and a problematizing of what it means to talk about practices as "cultural".

The whole-class discussion around cultural practices was preceded by a discussion in which teachers simply prompted students to share some of the practices that they had documented. In this discussion, the practices that students chose to share all fell squarely within the confines of Western science: eating off of clean dishes, using Clorox, drinking milk, washing hands, taking vitamins. In the *next* discussion, however, when the teachers addressed practices explicitly as *cultural,* a very different list of practices emerged (see Table 2). We argue that Discussion 2 was able to somehow elicit a qualitatively different list of practices, most of which were documented on the self-documentation maps, but not shared in Discussion 1. Many school science activities would have stopped at Discussion 1, but would have missed the rich variation in practices that were elicited in Discussion 2. Because the space was opened up in Discussion 2 to accept a broader range of acceptable practices in the context of science class, students re-constructed the task as something different from a school science task (as illustrated in the difference between the two lists).

Table 2: Comparison of elicited practices in Discussions 1 and 2 in the second iteration of *Micros and Me*

| Discussion 1 | Discussion 2 |
|---|---|
| • Eating off of clean dishes<br>• Taking showers<br>• Brushing teeth<br>• Drinking milk<br>• Using a vacuum<br>• Washing hands<br>• Taking vitamins<br>• Drinking water<br>• Exercise<br>• Using Clorox | • Mangosteen for allergies<br>• Pho: prevents illness<br>• Tea (black, cinnamon, brown)<br>• Green oil on back, scratching with a spoon: tells you how sick you are and helps you get better<br>• Ginseng: clear face, helps make you feel better |

In the following example, we show a short excerpt from the beginning of Discussion 2 in Ms. Evans's class to examine the pedagogical moves made during this discussion.

Ms. E: Allison and Kristin, because you both know it. How many others of you know what Mangosteen is?
Student: Can you show us an example?
Ms. E: I don't have one, I've never seen it, I know nothing about it. Can you t--So yes, I can. Ok? (holds up a student's self-doc with it)
Ms. E: This is mangosteen. Tell us what you do with it.
Allison: um, when you buy it I put it in a tablespoon and then I drink it.
Ms. E: and so what does m--what does mangosteen--why do you drink it? Does it taste good?
Alice: It gives you energy and then it keeps you from sneezing and allergies.
Ms. E: And so you just take one spoon and it, and it keeps you...
Alice: from sneezing and allergies.
T: Ok, so it keeps you from sneezing and allergies.
Ms. E: Amy, you say you use it as well? Do you use it for the same thing?
Amy: yeah
T: And do you take it when you're sick or do you take it to prevent sickness?
Amy: Every day
Ms. E: So you think it would prevent this.
Ms. E: Do you use it as well? Do you use it for the same thing?
Ms. E: Anybody else use Mangosteen?
Ms. E: So if you look at the jar, and if we look at the jar (gets a student's self-doc), I look at the jar and I've never had Mangosteen, or used it, um, is this something that you think is part of your culture?

Allison: No, you can just buy it at Costco.
Ms. E: You can buy it at Costco. I'm guessing that it's something that your parents or grandparents knew about because as I look around the room, many of us from your culture don't know about it but all the people that do know about it are of the Asian cultures. Does that make sense? And so will all who use it go home and talk to your parents and find out how they knew to use Mangosteen.

In this example, Ms. E makes some pedagogical moves to scaffold the discussion around cultural practices. The first move is a *positioning* move (Harre, et al, 1999) in which Ms. E positions herself, in lines 4 and 21, as someone who knows nothing about the cultural practice in question, drinking Mangosteen. Simultaneously, she positions the two students who documented this practice, Allison and Amy, as experts in this practice, thereby highlighting the value of varied repertoires of practice and in this discussion. Another move Ms. E makes in this discussion is to not assume that all students who might use this product would use it for the same purpose. She asks, in lines 13 and 20, "do you use it for the same thing?", thereby avoiding essentializing the practice to one purpose or one cultural group. We note that this pedagogical move represents a sharp diversion from the "traits" model of cultural practices (see Introduction) towards a model of *practice*—to "bring the multiple dimensions of students' lived experiences to life in the classroom" (Rosebery, McIntyre, & Gonzalez, 2001).

## Defining "culture"

Across all three classrooms, varied definitions of "culture" emerged through this discussion. In the above example, when Allison says that Mangosteen is *not* part of her culture because "you can just buy it at Costco", it brings up the question for us of what it means to talk about culture with students, how one defines it, and how one leverages "cultural" practices in the context of science instruction. In this section we briefly present the varied definitions of culture that emerged through the discussions around the self-documentation activity. We raise this point not because it is surprising that "culture" was a contested term in all three classrooms, but to raise the question (still unanswered for us) of what are design implications for making cultural practices an explicit object of inquiry in science classrooms.

In the following examples, we show classroom excerpts from all three teachers to illustrate the varied definitions of cultures from each teacher:

1. Ms. Love: culture is something that would be different from what I do: *"I also want to be able to pull out what are some of the things that are cultural to us? Anyone know what I mean by cultural to us? So if I walked into your home, what would be different from what would be in my home? If I walked in there sick, and I'm just like (starts coughing, holding her side, acting sick), what are the kinds of things would your parents do for me if they took me in, those kinds of things? Or if you walked into my home sick, what are the kinds of things I would do for you?"*
2. Ms. Evans: culture is based in your family and your ethnicity: "*I'm guessing that it's something that your parents or grandparents knew about because as I look around the room, many of us from your culture don't know about it but all the people that do know about it are of the Asian cultures. Does that make sense? And so will all who use it go home and talk to your parents and find out how they knew to use Mangosteen."*
3. Ms. Williams: culture is handed down from your families: "*So what we're really interested in here is what your family does based on the culture that you come from. Ok? So this is something that comes down for you from your family, from your culture, that's especially important. So not something that you learned in school, but something that you learned from your family of ways to keep you healthy, ways to keep you from getting sick…So raise your hand if something that is on your self-doc, something that's on your map in front of you right now with the pictures on it, or something that you know of off the top of your head, that's something that you do when you get sick or something that you do everyday that's something that your grandparent does, or that you've learned from your family."*

In Ms. Love's example, her definition of culture seems to assume that there are no *shared* cultural practices—that a person's cultural practices only count as "cultural" if they are different than someone else's. In Ms. Evans's example, culture is handed down through family and membership in an ethnic group. In Ms. Williams's case, culture is only something that is learned from your family, *not* something learned in school. While each of these conceptions of culture may be incomplete in some way (ie, excluding peer groups as a site of cultural membership, thinking about shared cultural practices), they represent a starting point for us to think about how to support conversations around culture in classrooms—especially as they pertain to science. For example, the self-documentation gave teachers a glimpse of sources of certain knowledge systems around health ("my dad says that drinking tea gives you more blood"). With the recognition that students' beliefs around health come from strong family histories of knowledge being passed down from one generation to the next (Ms. Williams's definition of culture), teachers are less likely to see these beliefs as "misconceptions" and more as rational ideas. By recognizing (and celebrating) differences between individuals' cultural practices (Ms. Love's definition of culture), we can begin to broaden our definitions of what counts as school science. Finally, in recognizing that some cultural practices are common among people who share certain ethnicities—and by pointing that out in science class, we begin to position students as both experts *and* members of certain ethnic groups, thereby helping students to "affirm their cultural identities" (Ladson-Billings, 1995, p. 6) at the same time that they participate in meaningful scientific learning.

## Implications

This design effort represents our first attempt to incorporate ethnographic data and methods into the design of formal science instruction. In attempting to surface and leverage students' out of school expertise around health, the self-documentation technique shows promise as a way for teachers to gain some insight into their students' out of school practices. Because of the time-consuming nature of ethnographic work, thick descriptions (Geertz, 1973) are formed about a small number of participants. Self-documentation might be a way to help practitioners, with 20 or more students in their classes, gain some insight into who their students are—the multiple and varied repertoires of practice that they engage in and the corresponding areas of expertise they bring with them to the classroom.

This analysis also raises some dilemmas for us about *how best* to leverage students' culturally-based health practices in the learning of discipline-specific practices. Gutierrez and Rogoff (2003) argue that "An important feature of focusing on repertoires is encouraging people to develop dexterity in determining which approach from their repertoire is appropriate under which circumstances" (p.4). While the self-documentation task itself was successful in eliciting students' repertoires of practice around health, more work needs to be done in the design of science learning environments to leverage those practices (while knowing the histories behind them) and support students in understanding when and how to navigate between their various repertoires of practice and where there is overlap or tension between them.

Another implication we see from this study is the challenge of leveraging culturally-based practices *while at the same time* supporting the learning of disciplinary practices and content. At the same time that the self-documentation activity gave teachers insight into how to connect science to their students' everyday lives, we have more work to do to connect these practices with deep disciplinary content.

**Abstract:** As science educators, we want all learners to see the relevance of science to their lives and the world in which they live. Achieving this goal, however, has proven to be a difficult endeavor. Many learners see science as useful only in school, and they face difficulties connecting science to the real world and to their own interests and goals. In our research project, Kitchen Science Investigators, we aim to start with learners' interests and goals in cooking. We then help them connect cooking to science, using play to help them see food as an object of investigation. We then transition learners into engaging in authentic scientific practices. In this paper we present three cases that highlight scientifically meaningful experiences for KSI learners and the ways play, facilitation, and artifacts bridge the gap between their interests and scientific practices.

## Introduction

As science educators, we want all learners to see the relevance of science to their lives and the world in which they live. Indeed, this is also a goal set forth by science education standards (Rutherford & Ahlgren, 1991). Achieving this goal, however, has proven to be a difficult endeavor. Many learners see science as useful only in school, and they face difficulties connecting science to the real world and to their own interests and goals (Chinn & Malhotra, 2001). Subsequently, many students are turned off by science. We therefore aim to understand how we can help learners see the relevance of science to their lives and enthusiastically engage in scientific practices. Success at answering this question is essential if we want more citizens to engage in public discussions about global climate change, stem cells, and other scientifically-relevant endeavors.

Researchers and designers of informal learning environments have found that starting with learners' own interests and goals presents opportunities for helping learners to engage in and to see the relevance of scientific, mathematical, and professional practices to their lives. Seiler (2001) created a science lunch group for African American boys in an underserved and underperforming high school around drumming and sports. For those interested in drumming, their discussions and investigations focused on topics such as sound frequency. For those interested in sports the conversations focused on laws of motion in physics. Nasir (2002) studied African American males' use of advanced mathematical understanding in the context of playing basketball to calculate their shooting statistics and to compare themselves to professional basketball players. Shaffer & Gee (2007) leveraged children's interest in video games to engage them in epistemic thinking and reasoning particular to a professional practice. They found that after playing one such epistemic game that required learners to act as urban planners, learners began to think of their own worlds in new ways. They also found that these learners thought in more complex ways about city planning. In each of these approaches, learners' interests and hobbies are engaged to help them move toward learning the "rules of the game" in some discipline or field they might join someday (Shaffer & Gee, 2007).

We, too, have created an approach to engaging more learners in science practices. In Kitchen Science Investigators (KSI), participants learn science and engage in scientific practice as they are creating and perfecting recipes (Clegg, Gardner, Williams, & Kolodner, 2006). Our afterschool and summer camp cooking and science program provides opportunities for learners, who may or may not be interested in science, to learn science through cooking. Our goal was to start with learners' interests and goals in cooking, help them to see food as an object of investigation through play, and then transition them into engagement in authentic scientific practices. We have seen this approach lead to scientifically meaningful experiences for our learners.

In this paper, we explore three experiences KSI participants indicated were scientifically meaningful to them. We seek to find out (1) What is a meaningful scientific experience to a middle-schooler who may not be particularly interested in science? (2)What scientific practices and accomplishments are supported by these scientifically meaningful experiences? (3) How can the having of such meaningful scientific experiences be promoted?

Of course, we cannot begin to answer these questions without defining some terms. To us, a *scientifically meaningful experience* is one in which learners derive meaning relevant to their lives from acting and thinking as scientists. In KSI, they do this through answering a question of interest to them, answering a question useful to themselves or to others, and through accomplishing a valued goal. Sometimes, they recognize the meaningfulness of the experience while it is happening; other times they don't recognize the meaningfulness until some time later when they are in a situation where what they have learned is valuable to someone else. We define *play* as voluntary engagement in recreational activities and less formal practices guided by learners' personal interests, curiosity, or amusement. Play is fun for participants, and during play, participants tend to be guided by trial and error. Science is more systematic than play, but play is often a good way to promote noticing and perspective taking. We find that we often encourage participants in KSI to play with their food so that they will notice attributes that they don't normally think about when cooking or eating. Then we help them move from playful participation to more scientific participation; we do that by helping them experience the value of systematically investigating attributes of food that they discovered during playful moments.

## Background

Science education literature stresses the importance of going beyond teaching learners *about* science, but also helping them to see *how* science is done (Osborne, Collins, Ratcliffe, Millar, & Duschl, 2001). In order to do this, we must get learners engaged in scientific inquiry by helping them to carry out scientific practices the way that scientists do. However, learners often do not engage in the scientific practices of professional scientists because classroom science emphasizes simple experimentation (Chinn & Malhotra, 2001). Helping them to engage in authentic scientific practice in the context of their own goals, we believe will lead learners to have scientifically meaningful experiences of their own. A scientifically meaningful experience has two components. First, a scientifically meaningful experience will involve learners engaging in scientific practice. Second, it is an experience that has personal meaning to learners themselves.

Scientific practices are those actions and pursuits relevant to scientific reasoning to test and explain phenomena. Such actions include, but are not limited to generating research questions, designing experiments to answer questions, controlling variables, making hypotheses and predictions, making observations, taking measurements, developing theories, and studying others' research (Chinn & Malhotra, 2001; Osborne et. al, 2001). While these actions may be encouraged in traditional classrooms, they are typically enacted in experimentation that is simple and fixed which is different from the experimentation of scientists. In contrast to simple science typically done in classrooms, *authentic scientific practice* that scientists engage in involves doing science (1) in the context of real-world problems, (2) where the full range of variables can be tested and the full range of outcomes may be unknown, and (3) where procedures for answering questions are chosen at least partially by participants, rather than being rigidly prescribed and ordered (Chinn & Malhotra, 2001; Gleason & Schauble, 1999a, 1999b). Authentic scientific practice thus includes, among other things, designing experiments and investigations to answer societal or real world questions, establishing rigor in these pursuits, and checking for the mistakes and misinterpretations of one's own work and the work of others.

A scientifically meaningful experience will not only involve scientific practice, but it will also be a personally meaningful experience for learners. Learners have much richer learning experiences when they can not only learn from the experience but when it also connects to their own interests, passions, and experiences (Resnick, Bruckman, & Martin, 1996; Shaffer & Resnick, 1999). We recognize personally meaningful experiences when learners use what they learned from the experience later and when they report deriving meaning for their own particular goals or interests from those experiences.

Based on our experiences, personally meaningful experiences for middle-schoolers often involve two forms of play: social play and physical manipulation. Talking, joking, laughing, and physical play that often occurs between friends and reinforces the social bonds between peers characterize social play. Play can also refer to tinkering that learners do with objects in the environment -- physically manipulating objects by touching, feeling, smelling, and/or pressing them. With respect to scientific participation, we have found some learners prefer designing experiments that specify actions to be done to objects in their scientific pursuits prior to beginning experimentation. Others prefer to design complex procedures that address problems that arise along the way by trial-and-error, tinkering with objects (Clegg & Kolodner, 2007). Both types of participation fit within the pursuit of science, but the latter is facilitated by playing with objects and can be harder to distinguish as scientific practice, especially when they are highly engaged in social play.

A scientifically meaningful experience will therefore connect a learners' scientific pursuit to their own interests, goals, and style of participation. Our goal then as designers and educators is to help learners participate in science in a manner that is authentic to the disciplines of science. In addition, we want to help them see scientific practices and their understanding gained as a result of engaging in those practices as relevant to their everyday lives, their interests, and their passions. Constructionist learning environments have been successful at designing tools that enable these types of meaningful experiences. Science and Math education literature has shown that these meaningful experiences can indeed happen in natural settings (Crowley & Jacobs, 2002; Nasir, 2002). Our work seeks to inform how we can design activities and facilitation support that enable these experiences in informal learning environments.

## Design of KSI

Our goal in designing KSI was to engage learners in scientific practices through providing them with hands-on cooking and science experiences in an informal after school setting. KSI is informal, in several ways:

(1) participation in the program is not a requirement, rather, on a weekly basis participants have the choice to decide if they want to participate in the program and (2) there are no formal science or cooking standards we are trying to meet, thus (a) participants are able to choose how they contribute and what they learn, and (b) participants' are given choice in the recipes they prepare and perfect and in the direction of any given activity.

In order to design an environment where participants could learn to use scientific practices and pursue ideas that were personally interesting and motivating for them, we designed two activity sequences. First, KSI participants engage in a semi-structured activity sequence to familiarize and scaffold them in engaging in the scientific practices of asking questions, designing experiments, making observations, measuring, sharing results, and drawing conclusions. Second, participants engage in a flexible exploratory activity sequence where they can take the science they learned during the semi-structured activities to iteratively perfect recipes of their choosing.

The overall goal of the semi-structured activity sequence is to engage participants in conducting cooking and science experiments that are focused on understanding what makes foods rise or thicken. Learners and facilitators design experiments that highlight the effects of varying different amounts or types of ingredients in a recipe. The cooking experiments highlight the effects of ingredients (e.g., increased height, volume, density or thickness) in the context of the recipe they are preparing. During these activities, the facilitator helps participants develop a curiosity about the roles particular ingredients (e.g., leaveners and thickeners) play in their recipes by modeling how to use observations to ask questions and to design experiments to answer the questions raised. For example, participants make pudding with different types of starch thickeners and the facilitator helps them to make observations and compare the different textures and thicknesses of the thickeners. These experiments are designed as a whole group. In small groups, learners carry out each variation and then share their results, taste their dishes, and draw conclusions as a whole group.

Semi-structured activities are then followed by flexible exploratory activities called Choice Days where learners are given the opportunity to use what they have learned about particular ingredients to prepare recipes of their choice and make them come out with their preferred taste, texture, and mouthfeel. During these activities, learners have the opportunity to ask new questions, to practice using results and conclusions drawn from the semi-structured experiments to design experiments that answer their questions.

To help bridge learners' goals and the goals of KSI, we position learners first as chefs who want to understand how to make their recipes come out with the desired taste, texture, and mouthfeel. We then transition them into being investigators, who are curious about the roles that each ingredient plays in making their recipes come out as desired. Last, we help them use scientific practices to find answers to their questions about particular ingredients so that they can make informed decisions about the ingredients they use in preparing their dishes. To help them make these transitions, we encourage learners to play with their food as a means of developing more questions, observing their results, making comparisons across variations, and building understanding of scientific phenomena through engaging in scientific practice.

## Methods

### Data Collection

The cases presented in this paper were taken from data collected in our most recent enactment of the KSI program. The program was implemented as a one day a week after-school program as part of a larger weekly after-school initiative by a local YWCA to engage teen girls in science and technology related activities. The participants in the study were from the same suburban middle school where the population was 99% African American. Thus, all participants were African American girls in 6th – 8th grade. Participation varied over the 9-month period, but we had 15-20 consistent participants (7-9 6th graders, 7-10 8th graders, one 7th grader). The program was led by a team of 3 facilitators: the authors and the school program coordinator. For each session, we collected and transcribed video recordings of each group. In addition, after each session we recorded post-observation field notes that captured the significant learning events that occurred during the session. As a part of Tamara Clegg's (Tammy) dissertation on learning and identity, we also conducted and transcribed interviews with four focal learners, their parents, and their science teachers at multiple points during the implementation and once after the implementation ended.

### Case Selection and Data Analysis

The analysis for this paper emerged from a trend Tammy discovered while analyzing the data for her dissertation in the context of exploring the participation of individuals and roles they took on in the program. In particular, she noticed that the roles individuals took on were impacted by the impromptu side investigations participants engaged in and the physical observations they made during these investigation. After noticing this trend, she intentionally identified all the side investigations and physical observations made by small groups of individuals in her data set. She then selected five particularly salient instances of these practices where scientific practice was enhanced and where learners showed or reported deriving personal meaning from the experience. To establish validity, she then presented these instances to the second author, who reviewed the transcripts and videos to ensure they were representative of scientific practices and personal meaning for learners. From these, three cases were selected based on the range of scientific practices participants engaged in and the strength of evidence from transcripts and interviews that suggested the practices were useful and meaningful to the participants. With the unit of analysis being the small group, we then coded each case for instances when groups engaged in the following scientific practices: asking questions, making observations, making explanations of scientific phenomena, sharing results with others, and drawing conclusions.

## Case Studies

As you read the three cases that follow, notice that Cases 1 and 2 represent the ways in which participants initially engaged in simple scientific practices in KSI on Day 12, while Case 3 characterizes the ways in which they engaged in more complex scientific practices on Day 20, the last day of the thickeners unit. Also notice how the facilitation and artifacts in the environment promoted participants' engagement in the scientific practices modeled.

Cases 1 and 2 occurred on Day 12, two days into the "thickeners" unit. On this day, the main activity was a pudding experiment where each group made pudding with a different type of starch thickener to learn about the variety of textures each thickener created. At the beginning of this session, Tammy, a facilitator, provided an overall framing of the types of scientific practices that the participants would be engaging in: making observations, taking measurements, conducting systematic and precise experiments, and sharing results. Following this framing, she introduced the Food Tasting Activity, an activity we designed to help the learners make objective, descriptive observations about food. This activity was meant to prepare participants to notice the differences in texture and thickness of the puddings they were going to make in the subsequent activity.

### Case 1: Describing, Comparing, and Testing Different Store-bought Puddings

The initial big group activity for Day 12 was the Food Tasting Activity. For this activity, we brought in 15 store-bought desserts and pastries with pudding-based fillings for participants to taste, describe, and compare. We felt this activity was needed to help participants develop imagination about the kinds of complex dishes they wanted to prepare (dishes that combine different ingredients and textures) and to help them develop objective ways of describing and comparing dishes. Our goal here was to move learners from simply sharing their opinions about the tastes and textures of food (e.g., it tastes nasty) to making descriptive observations of particular properties of the taste, texture, and mouth feel of the foods (e.g., it is smooth and thick).

Unfortunately the simple act of tasting the foods was not enough of a catalyst to get participants to make descriptive observations of the food they tasted, even when prompted. For one group of participants, however, a major turning point in the activity occurred when Treeva, bored with tasting the food, and probably satiated, said, "I'm sick of eating this right now." In response, Christina, the facilitator, suggested that they focus on testing and comparing the foods instead of eating them. The girls then began looking at different foods on the table and commenting about their thickness and describing in more detail what they liked and didn't like about the foods they were tasting. After tasting the tapioca, Mercedes said she didn't like the way it felt in her mouth. This prompted Candyce to say that she didn't like the flavor because it was sort of lumpy. Mercedes then agreed that she didn't like the feel of the tapioca balls either.

Not yet satisfied with the level at which the girls were comparing the thickness of the foods, Christina, the facilitator, shifted the activity to helping the girls find ways to describe the texture. She suggested developing a test for thickness. In response, Mercedes, who was dipping her spoon in and out of a cup of pudding and watching how it fell off the spoon, suggested testing the thickness by using a spoon to measure how long a particular food stayed on the spoon when turned over. The test sparked Candyce's interest, and she began suggesting foods to try in this test. The two girls then began playfully placing samples of the puddings and fillings on spoons and turning them over at the same time to see which one fell first. Christina then prompted the girls to use this test to rank the food on the table by thickness. She helped them interpret the meaning of their test with respect to the speed in which it fell and which fell first. The girls concluded that the pudding that fell from the spoon first was thinner than the one that fell last. Observing their tests, the eighth grade participants on the other side of the table began to do the spoon test as well. Intermixed in their testing, Candyce and Mercedes started playful competitions based on their predictions about which foods would stay on the spoon longest and which would be the thickest in the ranking. Included in their predictions were descriptions about how the foods looked and smelled. While they ran the test, Christina helped the girls use the results to rank the foods by thickness by rearranging the food artifacts on the table. Once they completed their rankings, the girls enthusiastically demonstrated their spoon test and shared their results with the rest of the group.

Candyce later remembered and recalled her experience with the store-bought fruit tart during the food tasting activity as not particularly pleasant because of its color. In recalling this experience, Candyce without prompting used a descriptive observation about its color to explain why she did not prefer to make her own fruit tart. During later sessions, these learners also became more consistent in making descriptive observations. For example, on Day 20, as you will see in Case #3, Candyce's described the buttermilk as "creamier and thick," and this descriptive and comparative observation led her to wonder about the difference between buttermilk and milk, which, in turn, initiated a buttermilk vs. milk experiment to figure out the answer.

## Case #1 Discussion

*What made this episode scientifically meaningful to the participants?* Candyce's recollection of the fruit tart indicates that she used her observations about the foods to reflect on the types of foods she would be interested in eating again or preparing herself. We also know that this case was scientifically significant for Candyce because we can see that she learned from it. At the beginning of the Food Tasting Activity on Day 12, she, like the other participants, was having difficulty making descriptive observations and comparisons because they were simply focusing on tasting and eating the foods. However, by the end of the episode the girls were making more descriptive observations as a result of engaging with the food as an object with properties that could be tested and ranked.

*How did the enactment promote this?* First, the facilitator allowed participants to engage in the activity as it felt most natural to them, i.e., through playing with and tasting the foods. Then the facilitator recognized a shift in the participants' interest and participation, from interested to bored, and she used this as an opportunity to refocus the participants' attention onto the scientific practices of testing, making observations, and drawing conclusions. Specifically, the facilitator transformed their play practice of dropping the pudding-based foods from spoons suspended in the air into a more formal test for ranking the thickness of the foods they tasted. The facilitator's ability to create an authentic opportunity for engaging the participants in these scientific practices was also created by the availability and diversity of artifacts, namely the pudding-based foods with varying degrees of thickness for which the crude spoon test would produce noticeable differences in the time it took the pudding to fall. In addition, the facilitator played a major part in structuring the activity by keeping track of results, and using the artifacts themselves to represent the rankings the participants were developing and making the rankings available for participant inspection. This representation of the rankings (the puddings lined up according to how thick they were) allowed the participants to confidently share their results and procedures with other KSI participants.

## Case 2: Viscometer Test

Following the Food Tasting activity, the learners divided into small groups to do a simple cooking experiment. Each group made a simple vanilla pudding recipe but used a different type of starch thickener. The over arching goal of the activity was to understand why foods have a range of textures and thicknesses and the roles starch thickeners play in creating those difference. Thus, we wanted the learners to make objective (descriptive and quantitative) observations of the differences in thickness of puddings with different thickeners, so that they could use what they learned to make more complex dishes similar to the ones that they tried earlier during the Food Tasting activity. To achieve this, we planned to have learners measure their pudding with a tool called a *viscometer* that measures the viscosity or thickness of liquids. Using a viscometer, the girls would be able to measure, in seconds, how long it took for the pudding to flow through the opening in the bottom of the viscometer. While the spoon test they had developed during the food tasting activity allowed learners to rank thicknesses and to characterize the thickness qualitatively; the viscometer allowed them to measure thickness quantitatively.

Measuring the thickness of their pudding was difficult because the girls did not finish making their pudding until near the end of the session. They had to wait for it to cool before putting it through the viscometer, and they were running out of time. However, Tammy saw that some of the group members were not as active as others on this team during the pudding preparation. She therefore encouraged those who were not busy with the pudding to measure the viscosity of milk while their pudding was being prepared. Candyce and Mikayla responded to Tammy's prompting and Tammy showed the two learners how to set up and use the viscometer. When the facilitator asked what they thought would happen, Candyce predicted that the milk would come out more slowly than water because milk is "sort of thick," as compared to water.

As they were waiting for their pudding to cool, Amber asked to take a parfait home. Amber's interest in the pudding made Tammy realize that although they could not measure the viscosity of their pudding right then, they could measure and compare the viscosity of other foods they had tasted and examined earlier. Tammy suggested that they try measuring the parfait with the viscometer to see how its viscosity compared to their pudding. When Tammy brought the parfait for measurement, Candyc, promptly took the parfait and began setting up the measurement with Amber. As they measured, Amber excitedly called Tammy over several times because the parfait was taking much longer to come out of the cup than she expected.

Since the girls were able to stay late, they were able to measure the viscosity of their pudding once it cooled. As they set up the viscometer to measure the pudding, Amber and Candyce made predictions about how long it would take. Amber thought their pudding was thicker than the parfait, so it would take the pudding longer to flow from the hole in the viscometer. As they began the measuring the pudding, they were surprised to see that the pudding was not coming out of the viscometer at all. One group member joked that they could walk up and down the hall for an hour and the pudding would not go anywhere. Mikayla excitedly suggested that they try it. Amber suggested they walk up and down the hall three times. The facilitator permitted Amber, Mikayla, and Precious to carry out their test while Candyce held the viscometer. Upon returning, Amber immediately checked the viscometer and said, "Okay, it's still not done, is it?" When she saw that no pudding had flowed from the viscometer, she exclaimed, "Knew it!"

Later, we learned from Amber that she told her science class about her experience measuring viscosity in KSI when they discussed the topic of viscosity in class. She also talked about the viscometer test, three months later, on Day 20, when the idea of viscosity came up in presentations to their parents. Later, during an interview, she told us that the viscometer measurement was something that she did as a scientist in KSI.

### Case #2 Discussion

*What made this episode scientifically meaningful to the participants?* Participants were able to move from descriptive observations to quantitative representations of thickness when encouraged by the facilitator. In this way, learners were moving from simpler forms of scientific practice (i.e., making observations and predictions) to a more sophisticated form (i.e., using observations to support predictions, initiating their own tests, and designing creative ways to explore their predictions). Amber seemed to be proud of these accomplishments and to see them as scientific, as evidenced by the three different times we recorded her sharing the viscometer experience and its significance to her with others.

*How did the enactment promote this?* Initially, the facilitator recognized the opportunity to engage learners in the scientific practice of taking quantitative measurements to compare thicknesses of the pudding, yogurt, and milk. She saw these opportunities when the participants (1) were bored and (2) were interested in tasting a new dish. Then she introduced learners to quantitatively measuring thickness by showing them how to use the viscometer to take a scientific measurement of thickness. Finally, the facilitator's recognition of the availability of the viscometer, milk, and parfait prompted their impromptu comparison of the thicknesses. It is also important to notice that the parfait was available and accessible from a previous activity (the beginning food tasting discussion) even after its intended purpose was past.

## Case 3: Milk vs. Buttermilk Investigation

Day 20 was the final day of the program, in which we invited the learners' parents and family members to come for an open house during the second half of the session. On this day, we wanted participants to use their knowledge of leaveners and thickeners to revise a recipe of their choosing to achieve their personal goals for the dish. Candyce, Treeva, and Rachael decided to make chocolate cake. Prior to cooking, they thought a little about the leaveners and thickeners they would use in their recipe, but it was not until they were baking and wondered about the difference between buttermilk and whole milk that they really began to think about leaveners in their cake.

As Candyce and Rachael measured buttermilk for their cake batter, Candyce, noticed that buttermilk was "creamier" and "thicker" than milk. She asked about the difference between buttermilk and whole milk. Tammy told her how buttermilk is made and that when buttermilk and baking soda are mixed, a foaming reaction happens. Then, when she realized that we had milk, buttermilk, and baking soda available to help her demonstrate the reaction, she began to set up what she was describing. As Tammy measured the baking soda and whole milk, she asked Candyce and Rachael what they thought would happen. Rachael predicted that the mixture would not bubble up. After adding the milk to the baking soda, they saw that nothing happened.

Switching to the next variation, Tammy asked what they thought would happen when they added buttermilk. Rachael thought it would bubble. Tammy reminded the girls about the baking soda and baking powder experiments they did several months before, and she asked them what type of ingredient they needed to mix with the baking soda in order for it to begin producing air. Treeva remembered it needed an acid. When Tammy poured the buttermilk in the glass, they were surprised to see that nothing happened to the mixture at first. Tammy then noticed something at the bottom of the buttermilk glass and they saw the mixture start to bubble up. Amazed at the size and look of the bubbles, all the girls leaned in over the table to see what was happening in the glass. Treeva picked up the buttermilk glass and asked, "What is it doing?" Candyce made the observation that there were bubbles at the top and that it was foaming. Based on their curiosity about the reaction, Tammy explained that the mixture was producing air, meaning $CO_2$, because buttermilk is an acid. Treeva, became excited by the smell of the mixture; she and Candyce agreed it smelled like baby milk.

As the group continued making the cake, they periodically noticed changes in the smell and look of the buttermilk glass, playfully making observations about it. At one point, Candyce noticed the glass sitting on the table and excitedly said that it looked strange, noticing that the baking soda seemed to settle on the top of the buttermilk. She dipped her fingers into the cup and walked over to Treeva (who was mixing the cake batter), showing her the buttermilk mixture on her finger. Later, when Candyce mentioned throwing the mixture away, because it looked "creepy," Tammy told her she could save it and show their parents in their presentations.

During presentations to their parents, when the facilitator mentioned baking soda and baking powder, Candyce immediately brought up their experiment they had done and walked across the room to get their buttermilk mixture to show the parents. She and Rachel reminded facilitators of the experiment during the presentations when they were about to move on to the next group without allowing them to discuss it. With prompting from Tammy, Candyce explained the concept of leaveners, and Rachael and Candyce described their experiment and results. Afterwards, Candyce moved around the room showing each audience member and fellow KSI members the buttermilk mixture. Later, in a subsequent interview, Candyce used the buttermilk and baking soda experiment as an example of how science has helped her figure out why things happen in recipes:

> Candyce: okay if you have some ingredients, and let's say you mix them together, but something happens and you don't know what it is, then that's where science can help you. You can figure out like why this happened. Like say you mix, baking soda and buttermilk together. You could say like this happened because buttermilk is an acid.

### Case #3 Discussion

*What is scientifically meaningful about this enacted activity?* Learners engaged in the scientific practices of asking questions, making observations, and monitoring results. These experiences also contributed to their understanding of leaveners (as evidenced by their later explanations). We also see that this experiment was meaningful for learners in their continued interest in the artifact even after seeing the initial reaction. For example, they initiated and sustained discussion of the experiment later with their parents. We also see that reflection on the experiment in subsequent interviews helped Candyce see the connection between cooking and science.

*How did the enactment promote this?* First, the facilitator recognized Candyce's curiosity about buttermilk as an ingredient. Then she recognized this curiosity as an opportunity to provide the appropriate prompts, explanations, and experiments to help the group answer their questions. Next, she modeled the practice of using experiments to make explanations by leading an experiment using available materials to show learners the differences between buttermilk and milk. She also gave learners opportunities to participate in the experiment by prompting them to make predictions and discuss what they already knew about the ingredients. Again, the diverse artifacts we had available for this experiment also enabled the experience. Although their recipe did not call for whole milk, it was still available in the environment and the facilitator was aware of that when she initiated the experiment. Furthermore, the unusual reaction of buttermilk with baking soda enhanced leareners' interest in making observations and later sharing their results with the whole group and their parents.

## Discussion

*What is a scientifically meaningful experience for middle-schoolers?* Earlier, we defined scientifically meaningful experiences as ones in which learners make scientific accomplishments that have meaning relevant to their lives. Over the span of the three cases presented here, we see that learners were able to participate more authentically as scientists over time, in that they began to make predictions and descriptive observations, using descriptive observations as evidence for their predictions. Learners also made quantitative measurements of their results (i.e., their dishes). Finally, they were able to make scientific explanations, sharing their results with others. Chinn & Malhotra (2001) suggest that these practices are authentic to the practice of scientists and should be promoted in school science. Here we illustrate how an informal environment supports middle school learners in engaging in these practices. Relating these accomplishments to learners' lives, we see that learners were able to share their accomplishments with their peers and parents. In subsequent interviews, we see that these accomplishments contributed to learners' reflections on their participation in science and on the relevance of science to cooking. Thus, the scientific accomplishments learners made in the context of their everyday lives helped them to think about their role in science and the relevance of science in their lives.

*When does our design promote the having of meaningful scientific experiences*? We can see from our results that it is hard to predict when learners will begin to ask questions and make connections from explanations. Intended goals were not always realized when we expected them to be (if at all), but many were realized over time. Even as they were, they did not happen in the way we expected, nor the timeframe, as we might expect based on Crowley & Jacob's (2002) work. In KSI, the design of earlier experiments and activities was intended to provide common experiences to refer back to over time to help learners perfect their recipes. Facilitators were able to guide participants back to thinking about these experiences later because all activities were designed to contribute to participants' achieving a larger goal that learners had and because learners were aware of what each activity could contribute to achieving that goal. For these reasons, it was natural for facilitators to bring learners back to those experiences at relevant moments, just as Crowley & Jacobs (2002) advise. But, while Crowley and Jacobs help us understand how to use timely opportunities to provide children with explanations and to help them connect across experiences, our work uses the same ideas to suggest ways of finding timely opportunities for learners to explore answers to their own questions and use those experiences to help them connect their experiences.

*How can we promote the having of those experiences?* This work offers a glimpse into the underlying mechanisms of facilitator support and artifacts in an informal learning environment where facilitators may be less aware of participants' attention, interests, and curiosities than a parent might be with their child while visiting a museum (Crowley, 2002). Yet, in the cases we presented, facilitators were able to recognize times when learners' interests and attentions were piqued and when they were dwindling. They were then able to capitalize on these moments, using them as opportunities to engage learners in unplanned scientific activities by selecting the appropriate scientific practices for the given moment. Keeping track of learners' interests and attentions and the learning opportunities available may seem like an impossible feat. However, when working with small groups of learners, facilitators can often build off of the interest of one participants to help others become interested and engaged.

To promote such unplanned scientifically meaningful experiences, facilitators must also be equipped with the necessary artifacts to help the learners increase their understanding, familiarity, and experience with the scientific practices (e.g., the puddings with a range of textures). And they must take advantage of the opportunities for piquing interest when the opportunities arise rather than waiting for lulls in activity. Our work shows that, unlike museum visits or home explanations, artifacts do not only trigger the explanations; they can also be used to engage learners in building, interpreting, and applying explanations.

## Conclusions

We presented an approach to helping participants learn and practice science in the context of their own interests and goals. The approach led to scientifically meaningful to experiences for learners. We found that helping learners to play with artifacts promotes learners' engagement in authentic scientific practices and meaningful experiences. But these experiences must be grounded in the context of a larger goal that learners have, and facilitation is needed to orient learners' practice with the objects, helping them to explore and investigate in meaningful ways. More work is needed to understand the complexity of these learning environments and to understand the impact these meaningful experiences have on learners' identities and views of science.

# Science Learning as the Objectification of Discourse

**Abstract:** The study presented here seeks to contribute to the dialog of how students come to learn disciplinary knowledge. Students in a highly-interactive physics course were studied as they constructed a model of magnetism. Two focus students were video taped throughout the 7-hour unit. They transitioned through 7 different representations of their models and their discourse and model-building practices evolved. The findings of this study are framed in terms of Sfard and Laive's (2005) ideas about the objectification of discourse as a definition of learning. The findings from this study are used to demonstrate the power of this perspective and to illustrate that the learning of disciplinary knowledge resulted from the students objectifying their discourse away from the self and its communication with other people and toward the self in relation to the human-independent world of magnetic phenomena.

## Background and Theory

Language is often treated as a communication medium rather than as a legitimate part of cognition in research on the learning of disciplinary knowledge. Many researchers have studied the role of language in the development of scientific knowledge (Lemke, 1990; Moje, Collazo, Carrillo, & Marx, 2001; Kelly, Crawford, & Green, 2001; Lee & Fradd, 1998) and in other types of disciplinary knowledge (Gutiérrez, Lopéz, Alverez, & Chiu, 1999; Gutiérrez, Lopéz & Turner, 1997; Gee, Allen, & Clinton, 2001; Gee, 1990). It is ever clear in this body of research that both language and concepts are involved in the learning process but they are very difficult (if not impossible) to analytically distinguish from one another. Roth and Duit (2003) refer to this phenomenon as the "structural coupling" of language and concepts, a phenomenon that remains a largely unexamined field of inquiry and is the subject of the research reported in this paper.

Gee uses the term "Discourse" not to refer to the exchange of words in general, but to refer to the language and practices of a particular community. In science, Discourse includes the formal terms and how terms are put together in sentences (e.g. an object does not *have* a force, an object *exerts* a force), symbols and their uses (e.g. an arrow on top of an the letter *a* means something different from arrows extending from a dot), what is deemed salient in a given situation (e.g. differentiating "noise" and signal on a graphical representation), the practice of making evidence-based claims, mechanistic reasoning, and the practice of creating and using models of phenomena. The preceding list of scientific practices constitutes much of what is meant by *scientific literacy,* or being literate in science. Like any literacy, it consists of a set of obligations, expectations, practices, values, meanings, and ways of using language that make up participation within the community thus defined. Within the scientific community this includes the learning of scientific terms and how to use them, the symbols and their contextual applications, how to read out the appropriate features of a given situation, and how to argue mechanistically in support or rejection of a model of an observable phenomenon.

Although models of phenomena are central to all scientific discourse, research on students' understanding of models in science has only begun to blossom in the recent decade. Work on meta-modeling competence (Schwarz & White, 2005), students' understanding of the nature of models and modeling (Harrison & Treagust, 2000; Harrison & Treagust, 1998; Gilbert & Butler, 1998; Windschitl, 2004; Windschitl & Thompson, 2006; Snir, Smith, & Raz, 2003; Bhushan & Rosenfeld,1995; Harrison & Treagust,1998; and Coll, France & Taylor, 2005), and students' development of mechanistic reasoning strategies (Russ, Scherr, Hammer & Mikesha, 2008) are increasingly becoming part of the mainstream of science education research. Overall, these studies continue to show that by in large, science classes fail to explicitly teach, and students fail to learn skills for developing, revising, and utilizing scientific models to explain observable phenomena. This finding is critical because models and modeling are the crux of the Discourse of science.

The practice of reasoning with models and mechanism involves testing for a hypothesized process involving underlying *mechanisms* that could drive observable phenomena (Machamer, 2004). In a study, Windschitl (2004) demonstrated that science majors revealed a common "folk theory" of scientific inquiry that did not involve model-based or mechanistic reasoning. The secondary science teacher certification students in his study, "did not make the methodological connection that investigations should be based on some explanatory premise nor was there evidence that they understood that the goal of inquiry is to support, revise, or refute various aspects of scientific models" (p. 491). Instead, they engaged in "relation-based reasoning" where empirically testing relationships between variables was viewed as an epistemological end in itself. Windschitl argued that these students viewed models and theories as optional tools that could be used to help explain results after a scientific study is complete. In contrast, much of science *is* the practice of building models and experiments serve the purpose of demonstrating that a model is adequate for explaining phenomena. High school and college students have difficulty developing skills associated with model-based reasoning (Windschitl, 2001; Abd-El-Khalick, 2001) and often fail to learn the Discourse of science.

In a provocative publication, Sfard and Lavie (2005) argue that learning within a discipline (in their case mathematics) involves the *objectification of discourse*—the use of words as if these words signify *discourse-independent entities* out there in the mind-independent world (Sfard & Lavie, 2005). Sfard and Lavie paraphrase Vygotsky and go on to indirectly define learning as a process that "begins as an interpersonal affair (and) turns in the growing mind, into a matter of one's relation with human-independent world." They also claim that, "…this kind of development is a 1-way process, and the change from the interpersonal to between-person-and-the-world outlook, once accomplished, can hardly be reversed," (p. 238-239). This is Vygotsky's theory of concept formation (Vygotsky, 1986), and in line with Vygotsky's theory, Sfard and Lavie (2005) define learning as an irreversible change in outlook that requires the "ability to see as 'the same' things that, so far, could only be seen as different," (p. 238). I will elaborate on this idea throughout this paper, but first a note on the notion of *disciplinary knowledge.*

Human beings tend to talk about disciplinary knowledge as if it is a thing that a person can possess rather than as a narrowly defined set of obligations and expectations that form the basis for communication (synchronous and asynchronous) with individuals who are familiar with, identify with, participate in, and continue to define these obligations and expectations. In the 1930's Ludwik Fleck developed the idea of *Denkkollektiv* (or *thought collectives*) and in 1935 he carefully elaborated this idea in his book, Genesis and Development of a Scientific Fact (Fleck, 1975). Fleck used the term thought collective to describe a system of (ever evolving) knowing that participants draw from and contribute to, a system that exerts a compulsive force on the thinking of an individual and thus constrains the set of possible thoughts of individuals within a community, but not on the community itself. Similarly, Sfard and Lavie (2005) describe disciplinary knowledge in terms of "endorsed narratives," which are defined as "sets of propositions that are accepted and labeled as *true* by the given community," (p. 246). The work of Sfard and Lavie (2005) synthesizes nicely with Fleck's work in attempts of answering the shockingly complex question: *what is disciplinary learning*. Sfard and Lavie argue that because human language is ontologically and epistemologically laden, it has up to now been difficult to understand the learning process due to the fact that disciplinary terminology is often (if not always) a result of the irreversible *objectification* that they claim defines learning. In other words, since language lives in the space of "the learned" it is very difficult to apply to the space of the "unlearned" or the space of the "learning," because each space is replete with its own (somewhat distinct) set of obligations, expectations, and practices that do not necessarily lie along a continuum. In fact, an entire literature on misconceptions in science has been established that merges these two spaces (for a discussion see Otero & Nathan, 2008). Indeed, Vygotsky's theory of concept formation mostly applies to the space of "learning," and throughout his influential work he struggles with language in efforts of bridging the space of the "unlearned" and the space of the "learned." The work of Sfard and Lavie brings the field of the learning sciences closer to bridging this gap.

Sfard and Lavie differentiate between disciplinary words and routines. Disciplinary words such as *force* in physics or *smaller* in mathematics have specialized meanings within the respective Discourse. Routines are ways of approaching tasks and come in the form of *deeds*, *exploration*, and *rituals*. *Deeds* are actions actually taken by the individual that produce a change in the environment. For example, if a teacher asks a child to pick the box that is biggest, the child reaches out and moves the larger box closer. *Explorations* have the aim understanding the world. Explorations often consist of extradiscursive entities that are the subject of discourse (as is the case in reasoning with mechanism about an invisible entity such as a charge). Exploration is what science education researchers would refer to as model-based, mechanistic reasoning. Rituals on the other hand, are socially oriented, with the aim of fostering solidarity with whom they are performed. Rituals have the sole aim of communication with the other. These distinctions become important as we attempt to understand science learning through the lens of the objectification of discourse. In observing students as they learn the practice of model-building and reasoning with mechanism, we are looking for transitions from discourse that is solely ritual to discourse that involves exploration and discussion about extradisursive entities.

In the remainder of this paper, I use empirical data from a physics course for adult learners to illustrate how the perspective articulated by Vygotsky (1986) and extended by Sfard and Lavie (2005) can begin to answer the question, "what is science learning?" My perspective differs from that of Sfard and Lavie only in that when they speak of the objectification of discourse, they apply it only to learning that differentiates children from grown-ups. I use this notion more broadly, to apply to all humans engaged in the process of learning disciplinary knowledge. In the research that follows, the modest question, "what does learning look like?" is mapped out through the exploration of three specific questions: (1) How do students' representations of models of magnetism evolve over the unit? (2) How do students' model-building practices evolve over the unit? (3) How do students' language practices evolve over the unit on magnetism?

## Study Context and Participants

Physics and Everyday Thinking (PET) is an introductory college level inquiry-based physics course designed to meet the needs of adult learners, non-physics majors, especially elementary and middle school teachers. This study focuses on the Models of Magnetism unit, throughout which students have several opportunities to develop and revise explanatory models of magnetism with the expectation that through guided experimentation, negotiation, and model revision, they will arrive at an expert-like model of magnetism.

Each activity in the curriculum consists of three parts: initial ideas, collecting and interpreting evidence, and summarizing questions. In the initial ideas section, students are asked to express their prior ideas and thoughts about the phenomenon that will be explored in a particular activity. Throughout the *collecting and interpreting evidence* parts of activities, students do experiments such as rubbing iron nails with magnets and investigating phenomena with laboratory apparatus and computer simulations. Questions in the curriculum frequently ask students to explain how their conceptual models account for their observations or how they might need to revise their models on the basis of observations. In some parts of the unit, *summarizing questions* explicitly guide students through the process of mechanistic reasoning, for example, one summarizing question asks, "Based on the results of the experiment, how would you describe each of the individual entities inside the magnet-rubbed nail?" Intentionally or not, this question asks students to begin to objectify the discourse by introducing the notion that there must be something (entities) inside the nail that is worth discussing. The curriculum is built on research on how students learn, so it is not surprising that by this time in the curriculum, most students have already introduced some type of entity within their drawings. However, the former question and several that follow it explicitly direct students to consider the term "entities" as a pointer to *discourse-independent entities* out there in the mind-independent world. Questions that follow within the curriculum begin to help students to use these entities as the agents that ultimately are responsible for the outcome or observation. Whether the curriculum developers intended it or not, the questioning sequence helps students to objectify their discourse.

A classroom that uses the PET curriculum is an appropriate context for a study of this type because it relies on students' making sense of scientific phenomena by constructing models that can be supported by evidence. There is no textbook used for the course, students are expected to construct their own understandings through small group work and discussion and larger whole-class discussions. The role of the teacher is mostly to lead discussions, making sure that students support claims with evidence, consider all of the evidence when making a claim, and ultimately come to consensus as a class on the ideas that will be used to explain the data.

## Study Design and Method of Data Analysis

This study focuses on a group of two students who were representative of the class, Brie (an experienced elementary teacher) and Mona (a pre-service elementary teacher), who were video taped throughout the course. Both Brie and Mona are white, middle class adults, both with families of their own and neither identified herself as a "science person" at the beginning of the course. The Models of Magnetism unit was approximately 7 hours, all of which was videotaped, transcribed and analyzed. A constant comparative method was used to generate and revise initial codes to characterize the nature of all of the discourse. On the basis of analysis and lengthy discussion by three different researchers, the following codes emerged: metacognitive discourse, explicit discussions about the nature of science and the nature of models, analogical reasoning, evidence-based reasoning, experience-based reasoning, model-based reasoning, conducting experiments, logistics, and off task discussions. All of the data were coded independently by the three researchers who met weekly over the course of one year to compare the coding of each transcript. Only those codes for which a full consensus could be established were kept and analyzed further. Of the consensus codes, all but the last three, "conducting experiments, logistics, and off task" were considered "sense-making" behaviors and were further investigated in order to understand how students' learned the disciplinary knowledge associated with a model of magnetism. Sense-making data constituted 165 minutes, approximately 40% of class time. Many episodes of what we referred to as "finding terms" were identified by all researchers, where the students struggled with terminology and seemed to be looking for the appropriate scientific terms to express their ideas. We therefore re-examined all of the sense-making data for the frequency of use of scientific terms such as force, charge, positive, and energy. The frequency measurements, the characteristics of the discourse, and the models of magnetism were then compared for the purpose of understanding how the students revised their models and how the nature of their scientific discourse changed in the process. Finally, these data were analyzed in terms of the routines used by the students, whether they were deeds, explorations, or rituals. Inferences about objectification of discourse were then made, and supported by changes in the nature of the students' talk as they moved closer and closer to the type of model associated with the endorsed narrative of magnetism in science.

## Findings and Analysis

A summary of the findings of this study is organized in four sections. The first section presents the students' representations as they changed over the unit. The next three sections are organized according to three theory-laden claims that outline how discourse was objectified throughout the student's learning process and illustrate that disciplinary learning begins "as an interpersonal affair (and) turns in the growing mind, into a matter of one's relation with human-independent world."

## Evolution of Students' Model Representations

The six models of magnetism that Brie and Mona wrote, discussed, and shared are described in Table 1 in the order that they occurred. Model is defined here as a representation constructed by the students along with the actual statements that they made when drawing or discussing the representation. The drawings in figure 1 were photocopied from the written work of the students. The text used to describe the group's models including the model names, were developed by the researchers but checked with the students after the course was completed. The models described below are not intended to serve as a one-to-one mapping of what was going on inside the students' heads. Instead, they illustrate the models that a group of students co-constructed and presented to each other and to the class.

In the three units that preceded the magnetism unit, the students investigated forces, different forms of energy, and energy transfers. The Energy model was Brie and Mona's initial model of magnetism (model 1), containing much of the same language that was used in the previous units of the curriculum. By the end of the magnetism unit, Brie and Mona developed a tiny-magnet (domain-like) model (model 7), which was the target model of the curriculum and aligned with the scientifically accepted (domain) model of magnetism.

Table 1: Brie and Mona's Models of Magnetism in the order that they occurred throughout the unit

| Model Description | Actual Group Drawing |
| --- | --- |
| **Model 1: Energy Model.** An unmagnetized nail has no energy but it has the potential to have energy, and a magnetized nail has stored energy (usable energy), which becomes magnetic energy during interactions. |   |
| **Model 2: Energy/Charge Separation Hybrid.** An adaptation to the Energy Model, where collections of positive and negative charges now appear at either end of the rubbed nail. |   |
| **Model 3a:** Worm Regeneration Model. A magnet is like a worm insomuch as its properties are replicated on both pieces when it is cut in half. The properties that are replicated are that one end is positive and the other is negative. |   |
| **Model 3b: Charge Separation Model**. Positive and negative charges exist randomly within unmagnetized nails. During rubbing, the charges become separated at the two ends of the nail. |  |
| **Model 4: Fractal Model:** Entities exist in the nail and they are tiny versions of the nail, like an iron filing is to a large piece of iron (nail). The nail takes on the properties of the tiny iron filings. | *The students provided no illustration of this idea.* |
| **Model 5: Activation Model**. Entities exist in the unrubbed nail and are activated when the nail is rubbed with a magnet. The activated entities are represented the same way a magnetized nail is represented, by a plus or minus symbol on either end. |   |
| **Model 6: Plus/Minus Entity Alignment Model**. The positive and negative charges within a magnet are coupled and inseparable. They are randomly arranged in an unmagnetized nail and by rubbing the nail with a magnet, the entities are aligned. |   |
| **Model 7: North/South Entity Alignment Model.** This is similar to the plus/minus alignment model except the entities in the nail are tiny magnets. This is the target model of the unit and consistent with the domain model. |   |

The nuanced discussion of each of the seven models shown in Table 1 is too lengthy to include here. Instead, I present a discussion of the claims that can be made from these models and the associated discourse.

## Claim 1: Models 1, 2, and 3a are illustrative of ritual routines

Brie and Mona's early models *describe* their observations. The energy model (model 1), the energy-charge hybrid model (model 2), and the worm regeneration model (model 3a) all ascribe *conditions* that can *account* for the observed phenomena (attraction, repulsion, and the dipole behavior of both ends of a cut nail). None of these three models provide a mechanism for how these macroscopic observations could come to be nor do they provide discussion about the properties of the entities (the little plus and minus symbols that appear in model 2 and 3a) beyond that they represent opposite things.

I argue that, for Brie and Mona, the purpose of the first three models was to mediate a discursive procedure (ritual routine) rather than to understand the world (exploration routine). This is not to say that Brie and Mona's discourse does not represent their thinking about the phenomenon. On the contrary, they clearly have ideas about energy and are trying to describe the behavior of the magnetized and unmagnetized nail. The transcript and the group's representations suggest that the visual mediator of the discourse around models 1, 2, and 3a is the nail itself. The pronoun "it" is used by the students to refer to the nail (later "it" will be used to refer to the entities within the nail.) Also, a majority of the discourse was an attempt to determine the appropriate words to use. This was partially constrained by the situation; the students were expected to express their ideas first in their workbooks and then on a 3'X4' dry erase board and present it to the class. But in both cases it seems that they were preparing their ideas for others (the teacher or the other rest of the class) to describe *that* a nail becomes magnetized rather than seeking to understand *how* a nail becomes magnetized. The excerpt below demonstrates that Brie and Mona searched for the correct terminology. Some transcript has been removed for brevity, represented by ellipses.

| | | |
|---|---|---|
| 500 | M | What do we:: agree on? Yeah negative and positive. So we agree that |
| 501 | B | Something's flowing in it |
| 502 | M | And that it's become magnetized. Or, has magnetic energy, right? |
| … | | |
| 506 | M | Um:: I like the idea that it has two opposing ends, or forces, or whatever you want to call it |
| 507 | B | So south and north? |
| … | | |
| 508 | M | Yeah, or just somehow maybe indicating that this one is neutral, it doesn't have, you know what I mean? Does that seem right? |
| 509 | B | Yeah, what is neutral? What's the sign for neutral? S? |
| 510 | M | Mmm, or a positive N? |
| … | | |
| 518 | B | Well, yeah. Neutral means nothing. And that's like, don't do anything, |
| 519 | M | No magnetic energy |
| 520 | B | Does not do anything. You know? |
| 521 | M | Doesn't have any energy? |
| 522 | B | ((makes a circle with her hands)) No smoking |
| 523 | M | Has energy potential but it doesn't have any energy. |
| 524 | B | Let me write that on my thing, I kinda like that |
| … | | |
| 536 | B | You're right. You said a word, now what is it, what was it? |
| 537 | M | I just said that energy was present, but energy is *infused*, I don't know. |
| 538 | B | Potent... oh no, not potential. |
| 539 | M | Stored! |
| 540 | B | ((waves her arms and legs around excitedly)) |

In lines 500-507 the students are looking for a way to represent that the nail that has been rubbed with a magnet is magnetized and the unrubbed nail is not. They use terms such as negative and positive, magnetic energy, south and north, and neutral. In lines 518-522 they search for the term that would be necessary to describe the concept of *nothing* and conclude using the terms *neutral, no magnetic energy, potential energy,* and a circle with a line through it. In lines 536-540 the purpose of the discourse appears to be to negotiate which words would most appropriately describe an agreed upon condition of magnetized versus unmagnetized. These terms are also present on their representation of Model 1 in Table 1. Brie and Mona revised their model to include some of the symbols used by the other students (pluses and minuses) for model 2 and developed a worm regeneration analogy for model 3a when they were asked what would happen when they cut the magnetized nail in half. In all three models, Brie and Mona discussed only the nail in a broad sense and not what was happening within the nail. I argue that this represents a ritual routine because the discussion centers on how to *describe* the macroscopic properties of the observation—while privileging scientific words, rather than on *explaining* the observations themselves. The rest of the models were, however, mechanistic.

## Claim 2: Models 3b, 4, 5, 6, &7 illustrate the exploration routine

I argue that models 3b-7 represent exploration routines (model-based, mechanistic reasoning), although the students were still learning how to engage in exploration as they were doing it. Brie and Mona's discussion about each of these 5 models had the visual mediator of the entities inside the nail, rather than the nail itself. The words "it" and "they" no longer referred to the nail; they now referred to the entities inside the nail. These entities were "extradiscursive" in the sense that they were treated as if they existed independent of the discussion or the classroom activity, in the human-independent world. These entities were not intended for the purpose of communication. In these cases, the purpose of the discourse was to negotiate an understanding of *why* the nail behaved the way it did. The discourse was used to discuss the properties, activities, and organization of the entities and ultimately how these things impacted the behavior of the observable nail. As is evident in Table 1, all of the energy terms have vanished by model 3b, and instead plus and minus symbols are used throughout the remainder of the discussion until model 7, where Brie and Mona explicitly switched to "Ns" and "Ss" due to an activity that drew a distinction between electrostatic and magnetic phenomena. Brie and Mona were aware that they did not know what plus and minus really meant except that they were opposites and therefore could be used to signify attractive and repulsive behavior. When the students decided to switch from singular plus and minus entities (models 3b) to dipole entities (models 5-7), Brie and Mona decide to try out the term "electron" to stand in for the objectified entity that was the subject of their discourse. The point is that in later discourse (presented below), Brie and Mona were no longer negotiating which term to use, they were negotiating the behavior of the thing that they used the term to describe.

| | | |
|---|---|---|
| 2268 | B | Let's call them electrons just for kicks and see if we're right. |
| 2269 | M | Ok. |
| 2270 | B | So each electron in the nail behaves the same |
| 2271 | M | I don't know my electron. I wish I had a defin... I should have looked up electron, you know to define it. I wonder what that word means. |
| … | | |
| 2279 | M | Ok, so |
| 2280 | B | It takes on the same... |
| 2281 | M | Right, same properties. Right. |
| 2282 | B | The nail |
| 2283 | M | The nail |
| 2284 | B | ((writes)) takes on the same properties |
| 2285 | B | and...there's something else, and behaves |
| 2286 | M | and the same, um |
| 2287 | B | and behaves in the same way, 'cause don't they behave in the same exact way? |
| 2288 | M | mmhmm yeah. Each one of those behaves in the same way as the nails does, and the same way as a piece of the nail did. |
| … | | |
| 2293 | B | because it takes on the properties and it behaves the same way, you have to say both. |

The discourse above took place as the students were developing model 4, the Fractal Model. As soon as they began to discuss the actual behavior and properties of the entities they moved back to plus and minus symbols and terminology. The difference between the discourse in lines 500-540 and that in 2268-2293 is that the purpose of the former was to put words onto already agreed upon experiences—to communicate with one another, the teacher, and the other students—that the rubbed nail was magnetized and the unrubbed nail was not. In the latter (2268-2293), the purpose was to negotiate the properties and behaviors of invisible entities that might exist within the nail and help to explain the nail's behavior. Later transcript reveals how Brie and Mona chain back and forth between the microscopic entities and the macroscopic behavior of the nail.

## Claim 3: The curriculum shaped the students' discourse and hence, their reasoning

The data suggest that transitions between Brie and Mona's models were facilitated by specific constraints provided by the curricular materials both in the language that was used in the workbook and in the experiments that were prescribed. An experiment that led to the generation of Model 4, provided an analogy to the nail. A closed test-tube was about ¾ filled with iron filings and students rubbed it with the magnet just as they did the nail. They observed similar macroscopic effects. They could also see the effect of rubbing the test tube (analogical nail) on the little iron filings inside the nail. This helped to shift students' attention from the nail as a macroscopic object to the entities within the nail. Further, a summarizing question asked, "Based on the results from the experiment magnetizing the test tube filled with iron filings, how would you describe each of the individual entities inside the nail." Although Brie and Mona had already been talking about entities in the form if plus and minus charges for a while, they now began to focus on the properties and behaviors of these entities. In doing so, the language that they used to describe their model shifted from discussing the magnetized nail as an "it" that behaved differently as a result of being rubbed by the magnet, to discussing the magnetized nail in terms of "they," the little things inside the nail and what they were doing as a result of the nail being rubbed by the magnet. This shift in attention refocused the discourse from the aim of communication to the aim of understanding the behavior of the entities. This

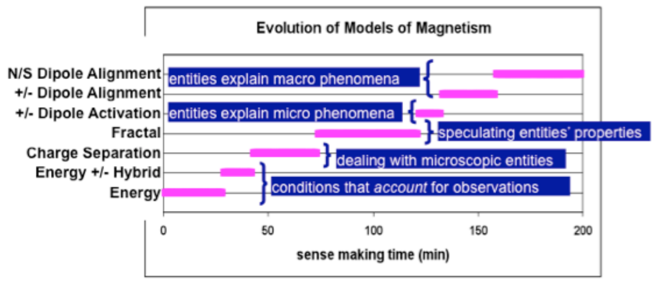

Figure 1: Students models (along y-axis) over time (x-axis) and their mechanistic reasoning.

led to discussions about the how the behavior of the entities could account for their macroscopic observations, which often led them back to change the behavior and properties of the entities until the Brie and Mona arrived at a fully mechanistic model that could account for the observed phenomenon. This backward and forward chaining between mechanistic model and observable phenomenon has been observed by other researchers who study mechanistic reasoning (Russ et al., 2008). Figure 1 summarizes how the students' models evolved along with their attention to different aspects of the entities.

Figure 2 provides another representation of the changes in Brie and Mona's discourse patterns throughout the unit. In figure 2, two 13-minute episodes are presented according to two different coding schemes. The first coding scheme (top two graphs) was used to count the frequency of scientific term use and the second coding scheme identified reasoning strategies employed by Brie and Mona (bottom two graphs). The two graphs shown in set (a) are from early in the unit where I claim that Brie and Mona were engaged in communication-oriented ritual routines. Set (b) illustrates discourse that took place approximately 160 minutes later (not the same day).

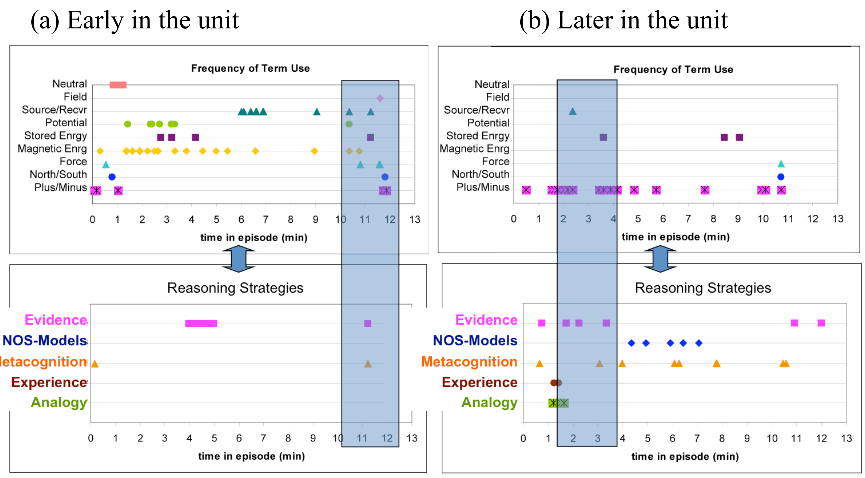

Figure 2. Comparison of students' use of scientific terms (top) and reasoning strategies (bottom). Set (a) is early in the unit and (b) is later in the unit.

As is evident from the graphs, the discourse that took place early in the unit—set (a) was dense with scientific terms such as charge, negative, positive, neutral, force, source, receiver, stored energy, potential energy and the same transcript is sparsely coded with reasoning strategies. Set (b) on the other hand, has fewer terms identified on the top graph and is rich with reasoning strategies as shown on the bottom graph. This suggests that the nature of the discourse was different in these two clips and supports the claim that focus on verbal, term-based communication was more the focus of early discourse and reasoning was more the focus of later discourse.

## Discussion

Like the early math learners in Sfard and Lavie's (2005) study, Brie and Mona practiced model-building in science initially in a largely communicative style, looking for appropriate terminology with which to communicate what everyone already knew. As the unit went on, Brie and Mona increasingly focused on the mechanism that could drive observable phenomena and less on communication for its own sake.

This seeks to demonstrate how discourse becomes objectified as a result of being practiced, and this is what defines the development of disciplinary knowledge. A reasonable question to ask is, "Why do students even have to go through the interpersonal discourse? Couldn't the teacher have just started with the iron filing experiment, telling students to focus on the entities inside the nail from the get go?" The point is not that the curriculum was explicitly set up to allow the students time to engage in interpersonal discourse. Instead, this was direction taken by the students' interaction with it. The unit on magnetism was particularly suited for this type of study because it consisted of a practice that Brie and Mona had little experience with—model building. Therefore, we were able to catch a glimpse at what it looked like as they embarked on early participation in this practice. The data demonstrate that the students' models of magnetism evolved toward the scientific model, their reasoning became increasingly mechanistic, and their discourse about the magnetic phenomena moved from the interpersonal domain into the domain of invisible entities that serve as a mechanism for observable behavior. As hypothesized by Vygotsky and further elaborated by Sfard and Lavie (2005) and countless others, learning involves participation. Participation involves the self and in order for the self to engage with the endorsed narrative of a discipline, she must access any available routine that is handy. In most of our cases, this is the routine of communicative ritual. We play this routine over and over as a means by which to catch on to the rules of play within that community. This is exactly what Brie and Mona did. They played communication as they investigated the problem space. In doing so, they caught on to subtle but critical practices that define success in mechanistic reasoning.

In this study, the task of creating a model of magnetism can be thought of as existing in two stages: (1) the task of creating product that was perceived as acceptable for the purpose of communicating with other individuals (term-dense sentences that could only account for the final conditions of the phenomenon) and (3) the task of objectifying the discourse so that the students' relationship with the objectified world of magnetic phenomena, and therefore the community of scientists, was able to flourish. The students began their model-building experience in discourse that centered on constructing term-dense sentences that could be presented to the others. Brie and Mona said things such as, "You used a word, what was it, Poten- Potential! Yea, I like that," indicating that they were looking for "good words" to use. They ended their model-building experience with a solid model of magnetic phenomena that could account for all of their observations. The entire class ended the unit with a discussion about the nature of models and their role within the scientists' activities. There is ample evidence from this study that the learning of disciplinary knowledge resulted from the students objectifying their discourse away from the self and its communication with other people and toward the self in relation to the human-independent world of magnetic phenomena.

## Acknowledgements

I am grateful to Ian HerManyHorses and Stephanie Jalovec who spent a year analyzing data with me in the beginning stages of this work.

# "Getting Others' Perspectives": A Case Study of Creative Writing Environments and Mentorship

Alecia Marie Magnifico, University of Wisconsin-Madison, 1025 W. Johnson St. Madison, WI, 53706
ammagnifico@wisc.edu

**Abstract:** Giving students opportunities to interact with real readers of their work may not only motivate them to write, but also to take on new literacies and see themselves as writers in new ways. I detail two case studies of successful writing communities—a high school classroom and an extracurricular arts program—and describe adolescent writing practices in the active (and often interactive) presence of the two different collaborative audiences. I discuss structural implications for the structure of authentic writing and writing workshop environments, the role of mentors in such instructional spaces, and the importance of teaching students how to be effective, collaborative audience members and readers of each others' writing.

## Introduction and Significance

In recent years, writing has become the new "basic literacy skill," as central as reading both in the workplace and in education (Brandt, 2001, 2009). Students write in many genres, both for school and for personal exploration and communication (Lenhart, Arafeh, Smith, & Macgill, 2008; Lunsford, et al., 2008). In schools, many states have mandated writing assessments, pushing teachers to emphasize writing throughout the curriculum (e.g. United States Department of Education, 2007). Only 25% of 12th grade students in United States schools were graded as "proficient" writers on the 2007 NAEP writing assessment (NAEP, 2008), however, suggesting a disconnect among the skill of writing, its real-world importance, and the teaching of writing in secondary schools. Part of this shortfall may be a result of the typical presentation of writing in secondary schools: a way to evaluate student knowledge, rather than a useful skill or a communicative tool (Applebee, 1996; Boscolo & Hidi, 2007; Nystrand, 1997).

While creative writing, the major form of in-school communicative and expressive writing, appears often in elementary schools, it drops out of most curricula by high school (Boscolo & Hidi, 2007). I argue in this study that mentors and teachers can encourage more authentic, communicative writing practice through design: Creative, expressive writing communities can motivate students to practice their own writing, to read others' writing, and to improve their broader literacies—all skills that prepare them to be writers and communicators in school and beyond.

This study explores relationships among instructional practices, instructional spaces, authentic writing, and adolescents' engagement in and understanding of creative writing. I take up two specific research questions: (1) At a design level, how are creative writing communities structured? What are the salient participant structures in which students and mentors participate? (2) What are the roles that students and mentors play? How do the structures affect these roles, and, more importantly, students' experiences and engagement with creative writing?

## Theory

In traditional classrooms, influenced by the belief that writing is more a tool for evaluation than an independent content area, most writing activity involves answering questions with a "correct" answer known by a teacher (Applebee, 1996; Nystrand, 1997). As a result, most classroom writing at the secondary level assesses content knowledge rather than students' ability to make an original argument, write cohesive narrative, or impact an authentic audience (Boscolo & Hidi, 2007; Cohen & Riel, 1989; Flower & Hayes, 1980). This particular focus, reinforced by state-level assessments as well as the number of subjects taught in schools, leads to a narrow view of writing instruction: content knowledge, structure, and Standard English conventions (Hillocks, 2002).

In contrast, students' writing in various authentic "communities of practice" (Lave & Wenger, 1991; Wenger, 1998), or "affinity spaces" (Gee, 2004; Lankshear & Knobel, 2007) is a tool for communication, creativity, and expression. These communities are found informally in places like online blogs and formally in publications such as literary magazines or club newsletters (Brandt, 2001). Differently from classrooms, the writing practice and instruction in these spaces tends to be "integrated" with preparing writing for an audience (Langer, 2001). Instead of completing a school assignment for a teacher, writers here must consider the communicative context of their work (Cohen & Riel, 1989; Fishman, Lunsford, McGregor, & Otuteye, 2005; Lunsford, et al., 2008).

Recent research into programs that bring authentic writing into classroom contexts has reported positive results, showing strong student engagement in the learning necessary to complete writing (Heath, 1983; Purcell-Gates, Duke, & Martineau, 2007), as well as critical thought about the audience and presentation of specific pieces of writing (Cohen & Riel, 1989; Dyson, 1997; Purcell-Gates, et al, 2007). In addition, work from writing and media studies suggests that young writers take on challenging topics and engage in key identity development when they have the opportunity to write for audiences in these ways (Dyson, 1997; Heath, 1983; Halverson, 2005; Hull, 2005).

Literacies research in secondary schools has established the writing workshop model—one that brings many features of authentic writing and affinity spaces into the classroom—as an effective practice for teachers (Alvermann, 2001; Atwell, 1998). Different from evaluative writing, workshop writing encourages students to think through ideas using writing as a tool, to read critically, and to understand classroom writing as preparation for advanced literacies (Alvermann, 2001). At the same time, both students and teachers need extensive practice with workshop techniques to be "effective responders" to each others' work (Simmons, 2003).

## Methods

I collected multiple forms of data from two creative writing environments in order to build distinct *instrumental case studies* (Stake, 1995) of successful environments in which the creative process, writing process, teaching and learning methods, and available audiences for the writing are different. These case studies exemplify two settings in which young people learn to write and practice writing: a school classroom and an extracurricular arts program.

### Participants, Settings, and Data Collection

The first case, a *school environment*, follows nine students (six female, three male) through a creative writing unit in an 11th grade English classroom at a K-12 suburban school. Two of the students identified as Asian exchange students, one as African-American, and six as White/Caucasian. The classroom teacher aimed for students to understand the genres of fiction and poetry better by working in small groups to write, revise, and analyze their own poems and short stories. These observations totaled approximately 15 hours over ten weeks.

The second case, an *extracurricular environment*, follows seven participants (five female, two male) at an urban creative writing camp for 9th-12th graders. Organized and staffed by local professional writers ("writing coaches"), the camp helps young people to hone their writing craft. Activities focused on daily writing, reviewing writing in small groups, and revising prose and poetry pieces for a final public reading. These observations totaled approximately 25 hours over one week.

I collected data from a variety of sources in both cases described above. In each setting, I observed and participated in one full *production cycle's* worth of work, which included the duration of creative writing instruction planned by the mentor(s). Despite the differences in each setting, the activities in which the participants engaged (e.g. writing, feedback, and revision) were comparable. Observations were captured in field notes and audio recordings. In addition, I conducted semi-structured interviews. I interviewed students twice, using pre- and post-interviews that were largely reflective, allowing them to speak in depth about their own writing processes, the pieces of writing that they worked on, and their experiences of class or camp. I interviewed mentors once, at the end of the writing instruction, about design choices that they made and their evaluation of the program.

### Data Analysis

Especially when considering a less-researched context such as secondary-level creative writing, qualitative methodologies such as open coding (drawn from grounded theory, e.g. Charmaz, 2000) and thematic analysis (e.g. Aronson, 1994; Braun & Clarke, 2006) are particularly important. While I have entered the analysis with specific hypotheses, these open-ended techniques allow me to identify, describe, and understand broad patterns in adolescents' perceptions of their online writing and the effects of these experiences on their learning.

This paper presents a preliminary thematic analysis (Aronson, 1994; Braun & Clarke, 2006) of these data. To conduct this analysis, I broke student interviews and classroom conversations into excerpts by question (for the interviews) or episode (for the field notes and classroom conversations). I began with open coding and refined my coding scheme in subsequent rounds of coding, highlighting central themes inductively from the data (e.g. "mentorship," "useful feedback") and deductively from the theoretical framework, (e.g. "affinity space structure," "authentic audience," and "evaluation").

### Pseudonyms — Student and Mentor Numbers

In order to track students and mentors across two cases, I have devised the following numbering scheme: All students in the *school case* are labeled with an "S#": In other words, they are identified as S1, S2, etc. All students in the *extracurricular case* are labeled with an "E#": E1, E2, etc. Since there was only one *teacher* in the school case, he is labeled "T1." The four *writing coaches* in the extracurricular case are labeled with a "C#": C1, C2, etc.

## Results: Major Findings

I present three themes drawn from observational data and student interviews, each examining an element of the design of the two instructional spaces and the effects of these design choices on the students. These themes are: (1) feedback structure, (2) role of mentors and teachers, and (3) how students interact with audience.

## Theme 1a: Feedback Structure — School

In the school case, observations demonstrated that class members (students and teacher working together) established a loose workshop structure among themselves. Students completed a short story and a small poetry collection (the teacher suggested 4-5 poems) during the ten weeks, but were able to choose which genre to take up first. Students were expected to bring writing to class on each workshop day, although not all students did so.

Students who had prepared work formed small groups during each class, read each other's work silently, made notes, and discussed their feedback with little intervention from their teacher, who provided assistance if requested. Students who were not prepared to share written work wrote silently during the class time. As a result of this structure, students received written and verbal feedback from their peers, usually the partners with whom they worked each day. Sometimes these groups remained consistent throughout the duration of one piece—for example, one pair of students worked together six times, repeatedly reviewing one poem and one story (field notes: 3/9/09, 3/20/09, 3/27/09, 4/1/09, 4/3/09, 4/14/09)—but often, students chose different partners during each workshop.

Students could (and a few did) consult with the classroom teacher directly for additional formative feedback. For example, S2 commented on his teacher's ability to help him focus on sensory details in his poetry: "I really like to focus on the big things and... it gets harder and harder for me to focus on actually expressing those thoughts in the poem, so he really pushed me to get those, the specifics." More formal written teacher feedback came in the form of a grade and comments after students had turned in an assignment.

## Theme 1b: Feedback Structure — Extracurricular

In the extracurricular case, observations demonstrated that each writing coach led a "writers' circle" of 6 students, which provided the central mechanism for students' sharing and getting feedback on their writing. The writers' circles met twice a day with consistent membership—each student received daily formative feedback from the same peers and writing coach. Some students worked on the same piece of writing throughout the week, bringing revisions or new sections to each writers' circle, while others brought several different pieces during the week.

The structure of writers' circle was proscribed and consistent throughout the week. Approximately 3 students shared their work in each writing circle. With two circles each day, each student was expected, though not forced, to share writing at least once a day. During each circle, one student read her work aloud while the others listened and made notes. After this reading, each member (including the coach), shared her feedback and passed her notes to the initial reader/writer. A short discussion occasionally followed, usually if many students gave feedback on the same aspect of a piece. For example, when two writers were struggling to resolve stories of loss and guilt., C1 began a conversation encouraging students to describe how they felt in these situations to help the writers capture these feelings realistically in their characterizations and descriptions (field notes, 8/5/09).

In the writers' circles, coaches listened and gave feedback, and students were often impressed by the details that coaches noticed: "[Coaches] have schooling and stuff on this topic... There's some things [my coach] noticed... [she saw] I was using adjective noun a lot, like that pattern. That was really good" (E6). If a student needed additional feedback, writing coaches also encouraged conferences during silent writing time (field notes, 8/5/09).

## Theme 1c: Feedback Structure — Looking Across Cases

The structure of these two learning environments may be represented in the following way:

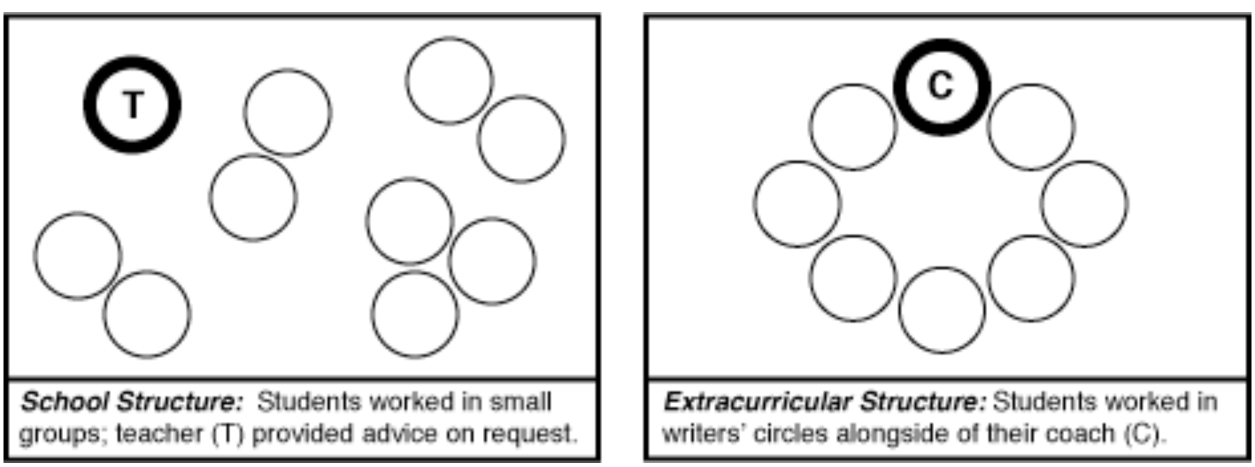

Figure 1: Structure of Learning Environments

All of the students in both cases (9/9 school, 7/7 extracurricular) recognized at least some value in getting feedback from readers (peers, mentors, or both) during the process of writing and editing, from "motivation... because I'm going to have to be sharing this" (E6), to "support... when I was scared to write poetry" (S4), to "other people's perspectives" (E5). In their interviews, students reported using the edits from the workshop groups and writers' circles—their peers and mentors—to improve their poems and short stories:

> It was helpful to see what other people understood... [One person] read this and said 'well, I'm not sure what you mean...' And then listed out potential ideas that they had... I saw what they took from it and could see... I need[ed] to emphasize these parts better (S6).

> Well, you don't have to follow [the feedback] but it's always good to know what other people thought... because if this part's not clear, or you can't see what this [character's] thinking, or it's not realistic that [a character would] feel this way after this happened, then it just opens your eyes. And then you work on it. And you get better by working (E3).

When audience members became collaborative editors, students in both of the case studies became invested in receiving criticism about the quality of and meanings behind their writings, and in working to revise with that feedback in mind.

## Theme 2a: Role of Mentors — School

In the school case, likely as a result of the design of the instructional space, observations and interviews revealed that the teacher did not have a clear role in mentoring the day-to-day happenings of the creative writing workshop sessions. He gave advice to individuals or small groups and kept time (and, occasionally, order) as students workshopped their writing, but he was not directly involved in the feedback structures of his classroom's workshops. He sometimes seemed unsure of his role in the new space that he and his students had built, although he was certain that he "d[id]n't want to grade them on their creativity" (T1), and spoke in class about not interfering with their ideas or process, "as long as [they were] writing" (T1). On the first day of workshop writing, just as students had begun reading each others' work, he came over to ask me "what do I do now?" (field notes 3/9/09).

In their post-interviews, a third of the students (3/9) expressed frustration with their teacher's role, specifically because it did not allow them access to his expertise unless they sought out his advice. Students appreciated that their teacher was trying not to apply "pressure... [like] whether or not you're [writing] what the teacher wants you to get" (S8) but at the same time, noted that his "adult opinion" (S8) was valuable to them. Many were eager to hear what he had to say about their writing: "[I wanted] to hear more of what he had to say a lot of the time... I think he [didn't give more feedback] maybe for the purpose of not having any influence" (S6).

## Theme 2b: Role of Mentors — Extracurricular

In the extracurricular case, the writing coaches were all familiar with the writers' circle feedback structure because they had used this design in prior writing camps (field notes, 8/3/09). Observations of and interviews with writing coaches demonstrated that all of the coaches (4/4) believed their central role to be supporting the students' writing by giving them "sacred writing time" to write and "good feedback on their work," through writers' circles. Almost all (6/7) of the students, too, connected the feedback from their coaches with improvement in their writing skills:

> [My coach gives] professional feedback. I mean, it's good across the board, the feedback [from my coach] that comes from experience, and then, from my fellow young writers, you get that feedback that just comes from the gut. [They tell me] I read this, and it kinda tripped me up. And that's kinda my audience... they will tell [me] what's right, what's good and what's not good (E7).

Students saw this feedback as vital to their development because they saw their coaches as an audience: experienced writers who knew about such difficulties as continuity, structure, and revising stories and poems for publication.

## Theme 3a: Writing for an Audience — School

While all of the students in the school case recognized the *value* of getting feedback from readers (peers, mentors, or both) during the process of writing and editing, they did not necessarily enjoy sharing their writing. The workshop process was new for almost all of them; 7/9 reported never having workshopped creative writing before. In their post-interviews, only one student in the class, S1, believed that getting feedback from her peers and teacher was always welcome and always useful, because it "can help you figure out if you got your meaning [across]." 4/9 students, however, noted that while they thought that getting feedback was helpful and led to improvements in their writing, they did not enjoy it because the process was often "uncomfortable" (S4, S6) or "too emotional" (S5):

> [In the workshop sessions] I guess I was thinking, oh they're not gonna understand what I'm trying to say here... I wanted them to get the meaning I got from [the poem], but sometimes I didn't want to share that emotion so... it was kind of like I [didn't] know what to do (S5).

One student in this group, S4 only showed her writing to the teacher for the entire 10 weeks. An additional 4/9 students noted that while they generally enjoyed getting and giving feedback, it was acknowledged that this process sometimes made them feel "worried" (S3) or "sensitive" (S8), especially when sharing a new piece for the first time:

> Yes [I liked getting feedback] for certain poems... I'd have to actually really feel good about them myself. I guess it goes with just about anything, you have to feel comfortable yourself with your creation before you show it to other people (S2).

While all of the students felt as if writing for an active, communicative audience of their peers was helpful in some ways, the process of doing so was very difficult for many of them. Particularly students who chose to write about personal, emotional topics felt as if their writing could expose "too much" of themselves (S9), and potentially parts of their lives that they did not know if they wanted to share with their classmates and teacher.

### Theme 3b: Writing for an Audience — Extracurricular

In the extracurricular case, students reported more positive reviews of the process of giving and receiving feedback , particularly in the context of writers' circles. This finding is unsurprising in many ways, since all of the students in this case (7/7) had been to this creative writing camp in prior years, and were therefore familiar with the process of sharing their writing with their peers and writing coach. In their post-interviews, all of the students (7/7) reported valuing the feedback that they got, while 6/7 students noted that they enjoyed sharing their writings:

> I really liked sharing in the writer's circle. I think that we had a really good group too, because they, they evaluated a lot... I dunno, they helped. They didn't just say I liked it, they were good critiquers. [T]hey gave a lotta criticism, but also praise, and... they almost talked about the idea that you had, and what they thought it was. It helped me [to see] other people's perspectives (E5).

A few (3/7) students noted some apprehension, reporting that they felt "kind of anxious" (E1), or "nervous" when sharing a new story (E2), but all of the extracurricular students tempered these feelings with stories of how peers and coaches helped them to improve their writing, or inspired them to keep going with a difficult piece of writing.

One unexpected finding was that many students (4/7) in the extracurricular case did not only talk about why they enjoyed camp, but about why they did not like sharing their writing at school. Their main complaint was the lack of constructive criticism, or, as E1 stated, "they just are like ohmigod, this is really good... how am I going to improve off of that?" The biggest condemnation of sharing outside of camp, however, came from S6, who argued that English teachers should "never" force students to read creative work aloud in school:

> [F]or school, I hate it when they have us read stuff out loud... [B]ecause all of the ideas I had that would've been perfectly fine at camp... they wouldn't be the same if they were told to all of my classmates. They would just think of the idea as really weird, instead of just appreciating it, and so then I couldn't think of anything [to write]... I knew that they were all gonna be reading me and judging me on it because you know, it's sort of a school environment where everyone judges you on what they hear...it wasn't like that at all at [camp] (S6).

Whereas sharing her writing with camp students—other writers who appreciate unusual ideas—is easy, sharing her writing at school is difficult. While the collaborative audience of her writers circle at camp would help her improve a "really weird" idea for a story, the evaluative audience of her classmates would judge her for her creativity.

## Discussion and Implications

In both of these cases, the mentors made efforts to reduce the differences between themselves and their students by avoiding many evaluation structures that are typical to schools and working to create a space in which students felt free to pursue creative, productive writing. Instead of commenting summatively on students' work, mentors in both cases made themselves available to give formative feedback and allowed students to choose topics freely. While students in the school case had some limits—the necessity of exploring both prose and poetic genres, an analysis of their own work—students in the extracurricular case students explored writing as they wished. Largely, these design elements helped both of these spaces to cohere as successful writing environments. In the school case and in the extracurricular case, students wrote several creative pieces, successfully solicited and received feedback from their peers, mentors, or both, and revised their writing to the specifications of that feedback. (All students in both cases revised at least one piece of writing: Reports on revision data are forthcoming.)

It is worthwhile to note, however, that the purpose of writing in each of these environments is quite distinct, and affords feedback and collaboration differently: As many sociocultural theorists note, context matters (e.g. Black, 2008; Dyson, 1997; Heath, 1983). Students who engage in creative writing as part of a school program are forced to do so, at least at some level. While many students did explore themselves, their emotions, and their histories as topics for their poems and prose, it was difficult for some to engage in this important identity work at school. This kind of writing exposed sensitive feelings in front of classmates and for a grade—a situation where risk-taking is understandably dangerous (Dyson, 1997; Halverson, 2005). In contrast, the students in the extracurricular case had much more freedom to explore "weird" writing at camp (as S6 noted), partly because other creative writers are tolerant of offbeat ideas, but perhaps also partly because camp is necessarily separate from everyday communities.

Combining the ideas of purpose and mentor roles in these two case studies sheds light on the importance and the difficulty of establishing *truly* collaborative audiences in a writing workshop environment. Not only must writing instructors design a space that supports purposeful, expressive writing and establishes a structure for students' collaborative interactions, but a structure for mentors' participation as well.

In the school case, the teacher required that his students write and he stood outside of the collaborative feedback structure. While the intention of this design choice was to allow greater expression within a required assignment—he spoke often of "not grading students' creativity"—this move backfired. Because he was outside of the collaboration, teacher feedback came only when students sought out his advice or had turned in an assignment, and thus was seen as summative. Despite the workshop-oriented structure of the classroom, and the students' collaborations, it was difficult for the teacher to avoid the norms that are inherent to classroom communication and evaluation (Applebee, 1996; Nystrand, 1997). In the end, it seems that the power structure of school cast him as an evaluator, although another result may have been possible if he had participated more fully in the workshop.

In contrast, writing coaches were integral to the feedback structure in the extracurricular case, acting as expert writers and representatives of a community of practice that the participating students sought to join (Lave & Wenger, 1991; Wenger, 1998). Students chose to attend writing camp, many of them for several years running, because they appreciated this kind of expert instruction. Coaches modeled listening and feedback in writers' circles, and often drew connections across young writers' experiences, pointing out broad patterns in students' writing and offering ideas for how they might achieve an attempted technique. Instead of their role as leaders forcing them into evaluation, the writing coaches used their place inside of the writers' circles to encourage debate, frame students' comments, provide additional insights, and offer questions or future directions for students' writing. This was, however, no doubt easier for coaches who did not have to evaluate students in the end—this structure likely made it much easier for students to see their feedback as collaborative and formative.

One interesting reading of this difference is in the separation between the goals of the school environment and that of the extracurricular environment. In the extracurricular case, the coaches saw their role quite literally as coaches: Their job, in the week-long camp, was to help young, inexperienced writers improve as much as possible, which requires intensive modeling and guidance from listeners with writing experience (Simmons, 2003). In contrast, the teacher in the school case was not invested in modeling writing, but in his students' learning of literary devices through experimentation. He wanted his class to learn how to think about why writers make certain choices, connecting their own struggles with figures of speech (for example) with the analysis of stories and poetry written by more famous authors—common practices in secondary English classrooms (Applebee, 1996).

While the creation of workshop groups with collaborative, authentic audiences was similar across both cases, the purposes of writing and the overarching instructional structures were very different—and this difference had a profound effect on the mentors' roles and the students' experiences. Can students and mentors participating in instructional spaces serve as authentic readers and audience members for each others' writing? This preliminary analysis suggests that these kinds of interactions are possible, particularly with practice and a carefully designed structure. At the same time, the transformation from traditional classroom to authentic writing workshop is not a straightforward one for teachers or students, and should be approached with deliberation and attention.

# Cross-disciplinary practice in engineering contexts – a developmental phenomenographical perspective

Robin Adams, Tiago Forin, Saranya Srinivasan, Purdue University, West Lafayette IN
Email: rsadams@purdue.edu, tforin@purdue.edu, sap@purdue.edu
Llewellyn Mann, Swinburne University of Technology, Melbourne AU, suneagle@hotmail.com

**Abstract**: This paper presents an overview of results from a phenomenographic study that investigates critical differences and similarities in the ways people experience cross-disciplinary practice in engineering contexts. Study implications are discussed regarding developmental perspectives on cross-disciplinary ways of thinking, acting, and being.

## Introduction

Many complex engineering problems facing society such as climate change, healthcare and international security require cross-disciplinary approaches that integrate diverse perspectives into a collective whole. Here, "cross-disciplinary" refers to practices associated with thinking and working across different perspectives such as multidisciplinary, interdisciplinary, and transdisciplinary. Reports on the future of engineering education stress preparing engineers to become "emerging professionals" who can deal with complexity, innovate, flexibly adapt to new situations, and bridge disciplinary boundaries to produce deeper insights (NAE, 2004). There has been substantial investment and interest in cross-disciplinary practice; however, the level of empirical attention is considerably less (Bromme, 2000). Studies focus on humanities and social sciences (e.g., Klein, 1996; Lattuca, 2001), although there are some studies on the physical and natural sciences (Galison, 1997; Nerssessian, 2006; Newstetter et al, 2004) and engineering design (Adams et al, 2009a).

While understanding how groups work together and create new knowledge is an important research focus, this study moves the lens from groups to individuals to make visible the development of cross-disciplinary practices. Phenomenographical methods were used to investigate critical similarities and differences in how individuals experience and comprehend cross-disciplinary practice in engineering contexts. Using experience as a lens for investigation acknowledges the relationship between experience and learning (Tuan, 2007, p. 16): "the modes through which a person knows and constructs a reality…and learn from what one has undergone." Phenomenography also provides unique understandings of practice that can readily contribute to course and program renewal and redevelopment (Daly et al, 2008). In this paper we present an overview of study results and discuss some implications for research and education.

## Theoretical Frameworks

Three frameworks guided this study. The first framework involved a synthesis of cross-disciplinarity at the group level of analysis (Adams et al, 2009a) that revealed important variations regarding: problem orientation (from thematic oriented projects to systems oriented participatory projects), mode of knowledge production (from juxtaposition of perspectives to an overarching and transformative synthesis), outcome (from no change in knowledge to knowledge fusion through critical reflection), interaction structures (from collaborating as disciplinarians to transcending disciplines), discourse practices (from common interests to creation of new language and logic), and impacts on participants (from retaining a disciplinary identity to critical reflection on pluralistic identities). While the synthesis illustrates how multidisciplinarity, interdisciplinarity, and transdisciplinarity differ in significant ways, they all presuppose that cross-disciplinary practice is driven by problems beyond the confines of any single discipline and involves transgressing disciplines. Disciplinary practices are systems of inquiry characterized by theories and concepts, and modes of observation, interpretation, and arguing claims regarding truth and validity (Klein, 2004). Cross-disciplinary practice at the individual level is likely to involve confronting, recognizing, and respecting different epistemological views (Lattuca, 2001; Klein, 1996) in which deep learning interacts with identity development (Sfard & Prusak, 2005). This synthesis aided this study by (1) highlighting important variations in cross-disciplinary practice to guide participant recruitment, (2) revealing the need for empirical research at the individual, not group, level unit of analysis, (3) indicating theories of epistemological and identity development that may emerge from this study, and (4) characterizing cross-disciplinary practice as a situated practice.

The second framework is based on Dall'Alba's (2009) model of professional development. Dall'Alba and Sandberg (2006) describe understanding as embedded in dynamic, intersubjective practice – a notion that integrates thinking, acting, and being into an unfolding "professional-way-of-being" that makes visible the situated nature of professional development, variations in skill development, and characteristics of skillful performance. This connects to theories of situated learning, reflective practice, and communities of practice. For this model, skill progression represents how individuals might become increasingly adept at tasks that they routinely practice. Skillful performance (an embodied understanding of practice) represents a limited number of qualitatively different ways a practice is understood. Advancement along this dimension is marked by increasingly comprehensive ways of understanding – an "unfolding circularity" of ongoing inquiry to achieve more complex and comprehensive understandings of the central ideas of their practice. This framework aided this study by (1) identifying ways to characterize an embodied understanding of cross-disciplinary practice, (2) further locating this study in theories of situated cognition, and (3) informing the choice of phenomenography as a research framework.

Phenomenography is a qualitative method to investigate different ways of experiencing and understanding aspects of practice (Bowden & Green, 2005; Marton & Booth, 1997). It is used to reveal surface and deep approaches to learning and has been used to investigate the experience of learning, teaching, concepts such as programming and velocity, and more recently professional practice. In phenomenography the "phenomenon" is a person's experience in relation to an aspect of the world and the outcome of phenomenographic study is the researcher's interpretation of that phenomenon (Mann et al, 2007). It is an empirically derived method where a theory of variations is emerging as a way to explain the existence of categories and how they are related. In phenomenography, the goal is to identify categories of description comprising distinct groupings of qualitatively different ways of experiencing a phenomenon and internal relationships among groupings as increasingly complex ways of experiencing the phenomenon and a growing awareness and comprehension of practice (Bowden & Green, 2005). In this way phenomenography creates a link between experience and awareness where variations in experiences may reveal characteristics of an embodied understanding of practice.

## Research Design

Twenty-two (22) engineers and non-engineers who work in engineering contexts were strategically recruited to maximize diversity and establish an inclusive "outcome space". This sample size and strategy is consistent with typical phenomenographic studies. Variations in the sample were identified through a literature review and include: context of work (academia, private industry, and community service), years of cross-disciplinary experience, gender, nature of experience in terms of project scale (i.e., size of teams) and complexity (i.e., number of disciplines involved), and epistemological distance (i.e., scale of disciplinary similarity or difference). Epistemological distance is the extent to which an individual interacts with those with similar ways of knowing such as an engineer working with other kinds of engineers or substantially different such as an engineer working with a social scientist or artist. Figure 1 shows key sample variations: years of experience, project scale, and epistemological distance.

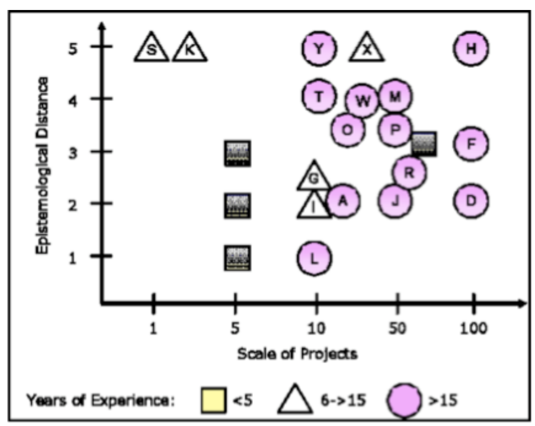

*Figure 1. Sample distribution among key characteristics. Letters represent participant identifier code (e.g., G = Grace, I = Isabella)*

Data was collected using a semi-structured interview protocol in which participants were asked to bring to mind concrete experiences of cross-disciplinary practice (see Mann et al, 2007). Follow up questions ask interviewees to elaborate on their experiences and what they mean by certain concepts. Probes may include information about the situation or characteristics of that situation that represent their ideas of cross-disciplinary practice. All probes were based upon what the participant expressed so far in the interview, and not formed through predetermined ideas and questions from the interviewer. Interviews lasted 30 minutes and were audio recorded then transcribed.

Analysis began with reading and re-reading transcripts as a collection and identifying what was significant within a whole transcript and in relation to other transcripts. Transcripts were sorted into piles of similarities and differences and assessed by identifying substantive excerpts from the transcripts that supported patterns in each pile. Over time the number and description of the different piles settled and became the categories of description. Subsequent passes through the data focused on articulating and substantiating the relationships among these categories, drawing from the data as well as theoretical frameworks. Relationships among categories were examined in terms of how categories related to a set of common ideas and to differences in breadth and depth of understanding. In this study, the relationship among categories mapped out increasingly more comprehensive understandings of cross-disciplinary practice. Overall, the analysis was a rigorously iterative process of being disciplined by the data, looking for empirical evidence of patterns, and seeking logical arguments in how patterns mapped to theoretical frameworks. In this way findings emerged through a co-evolutionary process of discovery of categories and construction of structural relationships between categories.

## Results

Below we summarize key findings: the four categories of description that emerged, critical variations across categories, and relationships among categories that reveal increasingly advanced ways of experiencing and comprehending cross-disciplinary practice in engineering contexts. Progression from Category 1 to Category 4 represents increasingly complex ways of experiencing and understanding cross-disciplinary practice in engineering contexts. In this paper we provide illustrative examples of the categories of description and present new findings on the hierarchical relationships among categories. An in-depth analysis of the categories is provided elsewhere (Adams et al, 2009b).

### Category 1: Working together – Emily, Grace, and Isabella

The experiences in Category 1 illustrate *cross-disciplinary practice as working together with people who have different training to effectively find a better solution*. The following excerpts highlight some of the key attributes of this category: (1) an iterative process of asking questions, challenging assumptions, and listening for understanding, (2) being comfortable with asking for information that might seem obvious, (3) knowing what you and others contribute, and (4) recognizing differences in what people know and how they communicate, (5) and the need to take personal responsibility to be an effective collaborator.

> "For me cross-disciplinary practice is probably working with someone of another discipline in a rather intricate way. In a way that's as brief as possible so that each party can continue their own work, but as thorough as possible when you get together so that you have very good information for each other…what needs to be improved, what details need to be in there." [Emily]

> "I mean it's very much learning how to talk to people that don't come from the same background that you do, academically. Being able to communicate what you want to do in a language that is accessible to an average level PhD scientist but not someone inside your own discipline necessarily….Just don't jump right in to the gritty details of it." [Isabella]

> "…probably the biggest challenge is getting the two to communicate…to listen and be very clear as to what you're trying to say and to make sure that the people listening to you are understanding that so, listening, asking questions to follow up is the biggest thing." [Grace]

> "I think it's vital. I think that's the only way to do it. If you don't have value for the other discipline, what are you even doing working with them? If you don't value what they are doing, you are not going to care how they do it, why they do it. You're not going to ask enough questions, and the questions are going to be important for the way you design what ever you're designing." [Emily]

> "Give people more respect as far as what they can contribute….I found that there were lots of good ideas that came from the engineers when they spoke up and there were lots of really important things that the nursing staff could contribute that I didn't think they could. Engineering people look at nursing people and think they're smart but in a whole different way that's not really that smart. They don't think of it as being difficult knowledge because it's all really, it seems like common knowledge like take chicken soup for a cold or something….really have their own special way of knowledge and I've come to appreciate that a lot." [Emily]

### Category 2: Intentional learning – Uri, Olivia, Pablo, Brianna, Ryan, Nadia

Where the experiences in Category 1 focus on the dynamics between people, the experiences that represent Category 2 focus on individuals' intentional learning. For Category 2, *cross-disciplinary practice is intentional learning so that everyone gains (me, my team, and my stakeholders).* The following excerpts highlight some attributes of this category: (1) creating opportunities to learn new perspectives or ways of knowing, (2) purposefully educating each other to collectively enable a systems perspective, (3) learning *through* experience and failure, (4) learning *how* to negotiate meanings across perspectives and formulate or investigate problems through multiple lenses, and (5) a passion and appreciate for continual learning.

> "…and every time I work with one of these people you have to understand something about what they do and you always, when you first start and everybody I've ever talked to seems to have this same perspective; you underestimate how hard the other person's field is. You've spent all this time and effort developing your capability; and oh, by the way you'll pick that up too and you learn pretty quickly if/that if you're not just going to do this superficially; that you know they've traveled their long road too. And so you have to meet as equals but you have to, and respect each other, but you have to learn about they're problem if you're really going to be successful in at least some amount and commit to that. But that's fun so…" [Olivia]

> "…a you help me/I help you kind of thing but and I would come back and I would never know enough so you'd have to read more and the best way of doing it was in an immersion kind of mode..." [Olivia]

> "I think I've become more convinced that the people need, it's like you go along in you need your immunizations, you need to have these points in life of injection of something and I think that it's important to plant those seeds along the way and I haven't really thought about that…" [Olivia]

> "I want to say I just became more open minded towards other disciplines. I used to think, we're engineering, it's much more difficult than everything else and although we can't communicate as well as the business people, but we're more technical, but when you start working with them, everyone sort of has their own set of abilities and weaknesses that they have to work together. I think by working cross-disciplinary, it sort of strengthens everybody." [Uri]

**Category 3: Strategic leadership – Jacob, Michael, Fergus, Tyler, Daniel, Yvonne**

Where the experiences of Category 2 focus on learning, the experiences that represent Category 3 focus on applying learning to actively enable cross-disciplinary work and outcomes. In other words, *cross-disciplinary practice is strategic leadership to enable cross-disciplinary work and synergy for the best outcome*. Leadership is central in that it involves being the "interface", "connector", or "communication specialist" to enable innovation or proactively transform a negative working environment into a positive one. The following excerpts highlight some attributes of this category: (1) make or enable conceptual connections, (2) build allegiances and trust, and (3) facilitate systems-oriented strategies or frameworks that leverage diverse perspectives. Some strategies involve actively transforming a negative working environment into a positive one.

> "…cross-disciplinary engineering is creating or innovating across multiple disciplines, so that's just saying it differently. But the strongest thing that does come for me is across markets or educational pillars. The other one which doesn't fit real nicely, but these days a lot of people do, is across different cultures." [Daniel]

> "I've got components, now I've got to think about, based on this organization, who are the right people that I need to speak with and get on a team so that we can ensure that we drive this thing forward." [Fergus]

> "I'm a communications specialist…I get a sense for people so I also get a sense of what they mean when they're telling me something. And so I would use that capability to get minds met. I would use a lot of other techniques, but I was a bridge." [Jacob]

> "…I believe, because there is a possibility that people who come in late don't get the same deal, don't get treated the same way. You've missed a lot of the discussions, you don't understand. In addition, if you're really adding a valuable team member, the discussions probably weren't as productive and fruitful as they could have been without his missing voice. So if you believe in a balanced approach to the problem-solving which I happen to believe, statistically you're more likely to have a better solution if you have more voices that are reasonable and respected sitting in the room….So balance, to me, says that you, you and I and three or four other people, whatever the size of the team is, are sitting around and we respect each other, ok, and we're willing to listen to each other and consider that these things, these issues that are raised or solutions that are raised are real and should be considered. That's what I mean by balanced problem solving….So everybody's in on the ground floor. It's important because you get a better solution in my opinion. You also have owners of the solution." [Jacob]

> "We're so busy trying to be sure that we're understood by others, that we don't seek to understand….So that is absolutely critical in order to be trusted, to trust people, you have to be trustworthy yourself. So it really starts with you and then you model behavior you want. It's also important in this team. And then probably the one that (captures) it best is believing in the value of synergy." [Jacob]

**Category 4: Challenging and transforming practice to integrate systems – Anthony, Xavier, Hannah, Logan, Samantha, Wendy, Kelvin**

Where the experiences of Category 3 focus on enabling cross-disciplinary work, the experiences of Category 4 represent transformative reflective practice that challenges prior training and ways of thinking.

For this category, *cross-disciplinary practice is challenging and transforming practice to integrate systems and produce an outcome greater than the sum of its parts*. The following excerpts highlight some attributes of this category: (1) critically challenging disciplinary practice and the ways conflict can be transformative, (2) integrating stakeholders as collaborators, (3) attuning to the human aspect of complex systems, (4) advocating perspectives by taking into account the broader context, and (5) embracing cross-disciplinarity as everyday practice.

> "Perspective really comes from the experiences that one has had and not one person has had the same experiences....that gives me a different perspective because I've seen different things, I've been exposed to different things. Maybe I've traveled all over the world, or no, I've only lived in Indianapolis all my life. You know those kinds of things; it gives you, that brings perspective…" [Hannah].

> "For better or worse I am who I am and some people appreciate that….I don't do anything different here than I do at home as I'm looking through something. So this is not my 'day' personality." [Logan]

> "I've always thought that it's always a good interaction from the standpoint of a multi-disciplinary scientist, that when you go in you work with the stakeholders you're at, you're on equal ground, you're on equal footing. There is an exchange of information. They're kind of framing the problem in a much different way than what you see it. You tend to be more isolated as a scientist, as someone who is at a university. They're dealing with this on a day-to-day basis, they have the muddy-boots kind of experiences. So the way in which they articulate the problem, they way in which they see it, the way in which they, the constraints that they have, is very, very valuable to listen to that….So, working with stakeholders is not just, you know, something we take lightly. It's actually part of the science. It's incorporated into the whole methodology." [Xavier]

> "…there are a whole bunch of metaphors, like the idea of poaching or borrowing or, I can't think of any more now, ok there really are a whole bunch of metaphors, that I don't see as transformative enough. That's great; you went out and borrowed an idea from somewhere else, and you're like so how can I use that tool in my stuff? But does that transform your stuff? Does that transform your discipline? I don't think so." [Samantha]

> "Well, you know, we did it collaborating with social scientists, right, in some respects. I mean, I've invested a tremendous amount of my own time trying to learn what these methods are. You know, I'm reading, you know, qualitative methods. I've got the books around here too that my colleagues read and so I'm making the personal investment to sit down and learn what I can about their practice of science and how it integrates with my traditional practice of science. How do you structure mine and how do you structure theirs to come and do, you know, make the interface work." [Xavier]

> "…if either of the two disciplinary scientists aren't willing to give up some turf, it's never going to happen, you know, it's never going to happen productively." [Xavier]

> "does the home need to have institutionalization or institutional markers or some kind of outward existence or can it be a group of people who identify in certain ways are, that don't find their cognitive home somewhere else? I don't know. But it's a more dynamic place. It is a more revolutionary place." [Samantha]

### Relationship Among Categories

The categories of description that emerged from the analysis are *distinct* – each captures a qualitatively different facet of cross-disciplinary practice in engineering contexts. These map to the framework for an embodied understanding of professional practice in terms of thinking (awareness of "difference", situation complexity, and goal direction), acting (engaging with "difference" and situation complexity), and being (self-perceived role or identity). Relationships among these categories are also *hierarchical* (see Figure 2). While attributes of each higher category encompass attributes of prior categories, critical variations of the more comprehensive categories are not evident in less comprehensive categories (see Table 1). This hierarchical progression is both data-driven (emerged from the analysis) and logical (attributes of higher categories move from surface to deep and narrow to broad comprehensions).

*Figure 2. Relationship among categories of variation*

Category 1 (Working Together) is distinct because of a focus on the experience of collaborating and communicating with people who have different perspectives, language, interaction styles, and ways of thinking. This appears to be a foundational category since the other categories build off of these ideas in increasingly complex ways. As shown in Table 1, critical attributes of Category 1 involve an awareness of differences in disciplinary training and how these differences complicate the process of working together towards an effective outcome. This awareness often triggers an iterative communication process of asking

TABLE 1. CRITICAL VARIATIONS IN CROSS-DISCIPLINARY PRACTICE

| | Category 1: Working together | Category 2: Intentional learning | Category 3: Strategic leadership | Category 4: Challenge & transform practice |
|---|---|---|---|---|
| AWARENESS OF COLLABORATION DIFFERENCES | • Difference = disciplinary training<br>• "Difference" makes collaboration complicated<br>• Everyone "smart" in own way<br>• Respect as "value-added" | • Difference = disciplinary perspective<br>• "Difference" as opportunity<br>• Respect for difficulty of disciplinary training | • Difference = disciplinary, organizational, cultural<br>• "Differences" clash; need strategies and new paradigms to enable collaboration and innovation<br>• Aware of need for common ground, trust, shared ownership<br>• Respect for the interfaces | • Difference = lived experiences; transcends disciplinary boundaries<br>• "Differences" enable transformation<br>• Honor other ways of knowing; no way is better than another |
| AWARENESS OF SITUATION COMPLEXITY | • Complexity as function of client and technological needs<br>• Aware of limits regarding technological feasibility<br>• Problems as client-driven, theme-driven | • Complexity as function of societal and global dimensions<br>• Aware of limits of own knowledge<br>• Problems as emergent | • Complexity drives need new paradigm of societal, global, economic views<br>• Aware of limits of disciplinary approaches and frameworks<br>• Problems require organizational thinking | • Complexity requires attuning to human context<br>• Aware of stakeholder risks and consequences<br>• Aware of system boundaries (disciplinary, organizational, cultural)<br>• Problems require integrated technological – social – human systems thinking |
| AWARENESS OF GOAL | • Meet needs, expand application, identify what is feasible from another disciplinary perspective | • Learning as its own goal – self, team, stakeholders<br>• Interaction yields new insights<br>• New partnerships | • Worthwhile outcome for all<br>• Successful launch<br>• Common ground as an outcome | • System level and participatory outcome greater than sum of parts<br>• Shape decisions<br>• Give up disciplinary turf<br>• Integrative synthesis that transcends disciplines<br>• Transform views on good practice, good science |
| ENGAGEMENT WITH SITUATION | • Iterative communication process | • Self-directed intentional learning process<br>• Create opportunities to learn - immersion and failure<br>• Build partnerships | • Change the parameters to discovery and cross-disciplinary paradigms<br>• Focus on problem formulation through multiple perspectives (not "jump too quick to implementation")<br>• Create collaboration networks | • Work at the interface; work at mile high system view<br>• Complex systems thinking<br>• Bring all aspects of lived experiences together<br>• Passion to improve system performance |
| ENGAGEMENT WITH DIFFERENCES | • Client / partner as information source<br>• Take responsibility for being effective communicator | • Meet as learners, educators<br>• Learn how to think between disciplines, synthesize<br>• Learn how to collaborate | • Proactively manage and leverage differences<br>• Orchestrate discovery and innovation<br>• Bring people together around shared goal; build expert network<br>• Build trust, shared ownership, allegiance, common ground | • Engage stakeholders as partners<br>• Advocate different perspectives; be altruistic<br>• Diversity and conflict as transformative |
| IDENTITY | • Responsible for contributing training as disciplinary team member<br>• Team member | • Passion for learning, dealing with complexity<br>• Learner and educator | • "Let up on the ego" – enable team<br>• Take the risk and lead<br>• Facilitate synergy at interface, synergy angels<br>• Interface, bridge, translator, etc. | • Live at interface as transformational learning site<br>• Revolutionary new "home"; perceived loss of disciplinary home<br>• Cross-disciplinarity as everyday practice – integrates work and life |

From Category 2 to 1: Improving the conditions needed to work together with people with different training to address complex problems of social and global significance

From Category 3 to 2: Applying prior learning on the challenges and affordances of cross-disciplinary practice to proactively enable successful cross-disciplinary discovery and innovation

From Category 4 to 3: Critical reflective practice to enable transformative learning and outcomes (for self, teams, stakeholders, and disciplinary practices) questions and listening for understanding with those who are perceived as a relevant for determining what is desired or feasible within a bounded application space such as meeting a specific client's needs. This also often involves taking individual responsibility for being an effective communicator and collaborator. Different perspectives are seen as a "value-added" but not understood in a deep way.

Category 2 (Intentional Learning) distinctly focuses on the process and outcomes of collaborative and situational learning. This category builds off of Category 1 (Working Together) because it represents a process of *improving the conditions needed to work together with people with different training to address complex problems of social and global significance*. As shown in Table 1, a focus on cooperation and collaboration expands to include social learning, a focus on complex problems expands to include social and global elements, and a role evolves from being a collaborator to being a self-directed learner. Awareness of differences changes from recognizing disciplinary differences to respecting the difficulty of disciplinary training and learning at the intersection of differences. Creating opportunities to address complex challenges emerge from intentional learning experiences that involve seeing failure through an opportunistic mindset and having a passion for self-directed learning. Here, personal learning occurs in parallel with efforts to be an educator so that collaborators can co-create a shared understanding.

Category 3 (Strategic Leadership) distinctly focuses on proactively enabling successful cross-disciplinary discovery and innovation through managing and leveraging differences. "Orchestrating" is emphasized explicitly through a self-identified role of being a facilitator at the cross-disciplinary interface and taking the risk of leading projects towards successful outcomes. As shown in Table 1, this is a leadership role that is about enabling the team rather than promoting individual egos. Like Category 1 (Working Together) elements of collaboration and successful outcomes are evident in Category 3; however, an awareness and understanding of what enables success expands to include issues of trust, respect, shared ownership, and inclusivity such that disciplinary, organizational, and cultural perspectives can be synergistic and open up new ways of thinking. Category 3 builds off of Category 2 (Working Together) by *applying prior learning on the challenges and affordances of cross-disciplinary practice to proactively enable successful cross-disciplinary discovery and innovation*. As shown in Table 1, prior experiences have established an awareness of how cross-disciplinary work can break down: differences in perspectives across disciplinary, organizational, and cultural perspectives; poor problem formulation that leads to ineffective and inappropriate solutions; an inability of disciplinary paradigms to meet the needs of complex situations that involve economic and political dimensions; a need to engage a social network of expertise; and the importance of building allegiance, a common vision, and collaborative decision making.

Category 4 (Challenge and Transform Practice) distinctly focuses on questioning practices and boundaries. Where Category 3 (Strategic Leadership) involves leading teams in creating common ground and new ways of thinking, a leadership role for Category 4 expands to include *being a transformative agent as well as being transformed*; where Category 3 focuses on enabling cross-disciplinary discovery and innovation, Category 4 is about *critical reflective practice to enable transformative learning and outcomes (for individuals, teams, stakeholders, and disciplinary practices).* As shown in Table 1, Category 4 involves expanding the idea of "difference" to include lived experiences and recognizing how boundaries between differences are socially constructed. This awareness facilitates critical analysis of the idea of "difference" and a critical exploration into similarities across different perspectives, which leads to new inclusive practices, theories, and identities. The essence of Category 4 is challenging epistemic frames comprised of skills, knowledge, values, identity, and theories of knowledge, as well as honoring differences and how diversity enables transformative thinking and transcending boundaries. Part of this is attuning to the human and contextual aspects of complex problems. This focus on human issues is evident in participatory strategies that engage diverse stakeholders as partners, not just information resources. When human and contextual factors are integrated into the system, the limits of prior views of "good practice" or "good science" are revealed and enable new ways of thinking about system performance. For Category 4 there is a unique and explicit identity of "being cross-disciplinary". This new identity may involve disrespect within and exclusion from prior disciplinary communities as well as seeking out new revolutionary "homes".

## Implications and Future Work

While there are a number of theoretical implications of this study, a central contribution is a developmental framework of cross-disciplinary thinking, acting, and being at the individual level. Overall, the analysis revealed four hierarchically related categories of variation that emphasize (1) the ways "difference", complexity, and goal motivations are experienced and (2) how these experience shape actions and self-perceived identities. Across these variations are themes of epistemological development, respect for “difference”, social networking and participatory acts to create common ground, and identity development (for self and in relation to others). F or example, an expanding awareness of “difference” is associated with epistemological reflection and an evolving respect for different perspectives. This is evident in the ways “difference” is described (from disciplines to organizational structures to cultures to lived experiences), the actions associated with an awareness of difference (as something to be overcome, explored, leveraged and managed, and critically reflected upon and transformative), and how it is characterized in reference to other perspectives (as a relevant “value-added”, as respected as difficult, as respected in decision making, and as honored as a way of knowing). In this way, studies of cross-disciplinary practice may help understand how disciplinary and cross-disciplinary learning interact.

This study also suggests practical implications. In phenomenography, the link between practice and preparation for practice is that the way learners experience a phenomenon *in the past* will form *how they act in the future*. Some of the themes in the results have direct implications for structuring and sequencing learning opportunities. For example, a theme of learning to collaborate as well as learning through collaboration suggests the potential impact of engaging learners early and often in cross-disciplinary collaborations – regardless of their level of disciplinary grounding. Similarly, a theme of intentional learning suggests the potential for connecting self-directed and self-regulated learning strategies or mindsets to a broader agenda of cross-disciplinary learning. At a minimum, the role of variation in developing an awareness of cross-disciplinary practice suggests a critical need to provide learners with diverse experiences to enable an embodied understanding of practice.

## Acknowledgments

The authors would like to thank Shanna Daly, Denny Davis, and David Radcliffe for their insightful contributions, and the National Science Foundation for funding this work (EEP-0748005).
